The present study utilizes a mechanical crusher to extract Karanja oil, which functions as a feedstock. Prior to the addition of the methoxide solution, 500 cc of Karanja oil is heated to 105 °C. The catalyst in a 150 ml methoxide solution comprises 1.5 wt% potassium hydroxide (KOH). The solution mixture is constantly stirred at 700 rpm using a mechanical stirrer, and the reaction temperature is kept at 60 °C. Subsequent to transferring the liquid to the conical beaker, allow it to settle for a duration of 15 to 24 hours. Subsequently, biodiesel will be observed floating atop, while glycerol will settle at the bottom. The resulting solution is rinsed to remove any excess water, alcohol, or catalyst. Table 3 presents the fuel characteristics of the B100 and B15 Karanja biodiesel blends. The B15 mix resembles diesel fuel more closely and has superior performance compared to the B100 blend.

II.2 PILOT FUEL PREPARATION

Table 2: Properties of hydrogen and diesel.

Parameter	Hydrogen	Diesel
Formula	H_2	$C_n\ h_{1.8*n-c8-c20}$
Heating value (MJ/kg)	141.9	44.8
Self-ignition temperature (K)	773–858	483–573
Viscosity at 300 K (mm^2/s)	95–120	0.4–1.0
Cetane number	-	45–52
Specific Gravity	0.069–0.073	0.82–0.86
Flame Velocity (cm/s)	250–330	25–40

Source: Authors, (2026).

Table 2 enumerates the attributes of diesel and hydrogen. The data in the table indicates that hydrogen possesses a higher self-ignition temperature compared to diesel. This indicates that for optimal combustion, hydrogen fuel ought to be combined with diesel, biodiesel, or ethanol, all of which possess lower ignition temperatures. Using 99.9 % pure hydrogen, experiments are carried out using a modified CI engine that has a flame arrester and other devices. The section on experiments delineates the specific steps.

II.3 ANTIOXIDANT ADDITIVE PREPARATION

The foliage of Azadirachta indica (neem), a tree typically reaching 20–30 m in height (occasionally up to 40 m) was selected for antioxidant extraction owing to its high carotenoid and chlorophyll content, proven radical-scavenging properties, low cost, and wide availability. Neem leaves are pinnate (20–40 cm long) with serrated leaflets, exhibiting lighter green on the lower leaflets and deeper green on the upper ones; the tree produces oval drupes that ripen to a yellowish-green color. Freshly harvested leaves were shade-dried for 10 days to minimize photooxidative degradation, followed by oven-drying at 50–70 °C for 10–15 min to remove residual moisture. To inactivate oxidative enzymes such as polyphenol oxidase, the dried leaves were immersed in water at 50 °C for 10 min. The material was then cut into 1–2 mm fragments to increase surface area and pulverized into a fine powder using a mechanical crusher. For solvent extraction, 100 g of powder was combined with 20 mL of an acetone–ethanol mixture (v/v) and agitated at ambient temperature for 1 h, producing a pale green opalescent suspension. The mixture was allowed to rest for 1 h to facilitate sedimentation, and the supernatant was collected and concentrated under reduced pressure using a rotary evaporator at 40 °C. The concentrate was dried at the same temperature for 72 h to obtain the crude antioxidant extract. This extract was incorporated into a B15 Karanja biodiesel blend at a concentration of 1000 ppm for subsequent oxidative stability and performance evaluations.

II.4 EXPERIMENTATION

This research utilizes a water-cooled, single-cylinder direct injection engine together with all necessary loading and measuring apparatus. Operating conditions can be regulated by sustaining specific ranges for exhaust gas temperature, cylinder pressure, air flow, and fuel flow,. A piezoelectric transducer is utilized to monitor the engine cylinder pressure. The engine possesses a rated power of 3.7 kW, a compression ratio of 16.5:1, and operates at a speed of 1500 rpm. All potential loads, ranging from 0% to 100%, including 25%, 50%, 75%, and full load, are evaluated during the trials. An eddy current dynamometer is employed to modify the load during experiments. A gas analyzer, an AVL smoke meter, and thermocouples are employed to measure emissions including hydrocarbons, smoke, and nitrogen oxides, in addition to the exhaust temperature and fuel flow rate. A flow meter and flame arrester are used to feed more hydrogen into the CI engine's air and hydrogen intake systems. Flame arrestors are a group of devices used in hydrogen systems that are intended to stop explosions. Flame traps have proven effective in lowering backfire and other unfavorable combustion events in a hydrogen engine system.

A non-return valve (NRV) in the fuel line prevents gases from returning to the cylinder. Hydrogen is supplied by a 140-bar high-pressure cylinder with an outlet pressure of 2 bar. Upon traversing the flame arrester and trapper, the hydrogen proceeds to the non-return control valve. The digital flow meter quantifies the flow rate. As additional hydrogen gas reaches the non-return valve, it inhibits reverse flow, directing the gas to the engine. The flame arrestor is then filled with hydrogen. A flame arrestor can prevent an explosion in the fuel encasing system. The fundamental concept of the flame arrestor is that the gas must provide sufficient heat to sustain the flame. The enrichment of hydrogen transpires when air and hydrogen are amalgamated post-collection at the flame trap unit and subsequently discharged into the input manifold. A variety of hydrogen flow rates—8 lpm, 10 lpm, 12 lpm, 15 lpm, and 18 lpm—were supplied into the input manifold. The findings make it possible to compare the performance and emission characteristics of the CSI engine using a hydrogen and B15 combination with and without the antioxidant AI. Figure 2 illustrates the configuration of the CI engine employed in the trials.

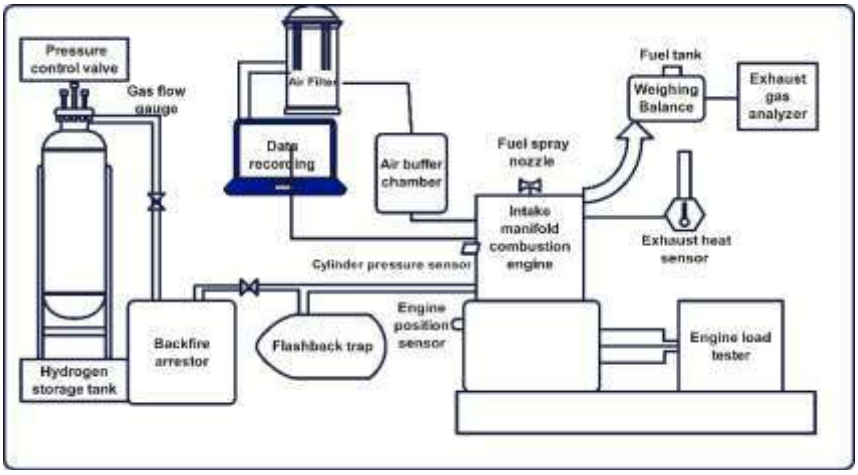

Figure 2: Configuration of CI engine test setup.
Source: Authors, (2026).

The Kirloskar AV-1 is a water-cooled, four-stroke, single-cylinder diesel engine operating continuously at 1500 rpm in the experimental configuration. The engine parameters comprise a 560-cc displacement, 80 mm bore, 110 mm stroke, and a compression ratio of 16.5:1. The injection pressure is maintained at 20 Pa, with the injection duration for both diesel and biodiesel set at 23° CA before top dead center (bTDC). The engine, connected to an eddy current dynamometer for load assessment, can deliver a maximum power output of 3.7 kW.

II.5 UNCERTAINTY ANALYSIS.

The standard deviations and uncertainties of the experimental measurements were subjected to statistical analysis. The fuel volume flow rate, defined as the duration required to consume 10 cc of gasoline, exhibited an absolute error of ±0.1 s and a relative uncertainty of ±0.5%, with a standard deviation of 0.18 s. The overall fuel consumption exhibited a relative uncertainty of ±0.5% and an absolute error of ±0.005 kg/h, with a standard deviation of 0.01 kg/h. The peak pressure exhibited a relative error of ±1%, an absolute uncertainty of ±1 bar, and a standard deviation of 1.58 bar. The exhaust gas temperature fluctuated by 7.97 °C, with absolute uncertainties of ±3.6 °C and relative uncertainties of ±1.1%. The standard deviation for nitrogen oxides (NOx) was 8.72 ppm, accompanied by a relative uncertainty of ±0.5% and an absolute inaccuracy of ±4 ppm. The hydrocarbon emissions exhibited a relative uncertainty of ±1.5%, an absolute error of ±2.5 ppm, and a standard deviation of 5.4 ppm. The carbon monoxide values exhibit a relative inaccuracy of ±5%, an absolute uncertainty of ±0.008%, and a standard deviation of 0.02%.

II.6 ERROR ANALYSIS

It is infeasible to entirely eradicate the potential for errors or unforeseen circumstances during testing procedures. The selection of equipment, environmental conditions, calibration, observation, evaluation, analytical methods, testing protocols, and preparation can all mitigate these errors and uncertainties. It is essential to verify the dependability, probability and accuracy, of the experimental results. Consequently, an unforeseen analysis is conducted using the methodology outlined by Holman. The overall percentage of the experiment's uncertainty is calculated by taking the square root of the sum of the squares of the uncertainties for, HC, EGT BTE, CO, BSFC, NOx, BP and Pressure. Total experiment uncertainty = $\sqrt{}$ ((pressure transducer uncertainty)^2 + (angle encoder uncertainty)^2 + (NOx uncertainty)^2 + (HC uncertainty)^2 + (CO uncertainty)^2 + (EGT uncertainty)^2 + (stop watch uncertainty)^2 + (manometer uncertainty)^2.

$$\text{Total percentage of uncertainties} = \sqrt{}\{(0.1)^2 + (0.2)^2 + (0.1)^2 + (1)^2 + (0.2)^2 + (1.0)^2 + (0.15)^2 + (1.0)^2\} = \pm 2.3\%$$

III. RESULT AND DISCUSSION

III.1 COMPARISON OF VARIOUS HYDROGEN FLOW RATES WITH BIODIESEL

This text discusses the performance and emission characteristics of B15 Karanja biodiesel, which was initially utilized as fuel in CI engines with hydrogen flow rates of 6, 9, 12, 15, and 18 lpm. Graphs of emissions for HC, CO, and NOx are plotted versus load, while efficiency and BSFC are utilized to create performance graphs.

III.2 EFFECT ON BRAKE THERMAL EFFICIENCY (BTE)

Figure 3 illustrates the correlation between BP and BTE for B15 as a function of hydrogen flow rate. The optimal brake thermal efficiency, in comparison to diesel fuel, is attained with hydrogen flow rates of 15 lpm and 18 lpm combined with B15. Consequently, it may be inferred that hydrogen actively participates in combustion and is responsible for enhancing thermal efficiency. The enhancement of brake thermal efficiency results from hydrogen's numerous advantageous properties, such as its elevated calorific value, swift combustion characteristics, and its ease of amalgamation with air. Blends of B15 with 15 lpm and 18 lpm exhibited improved brake thermal efficiency compared to diesel, at 28.60% and 27.62%, respectively.

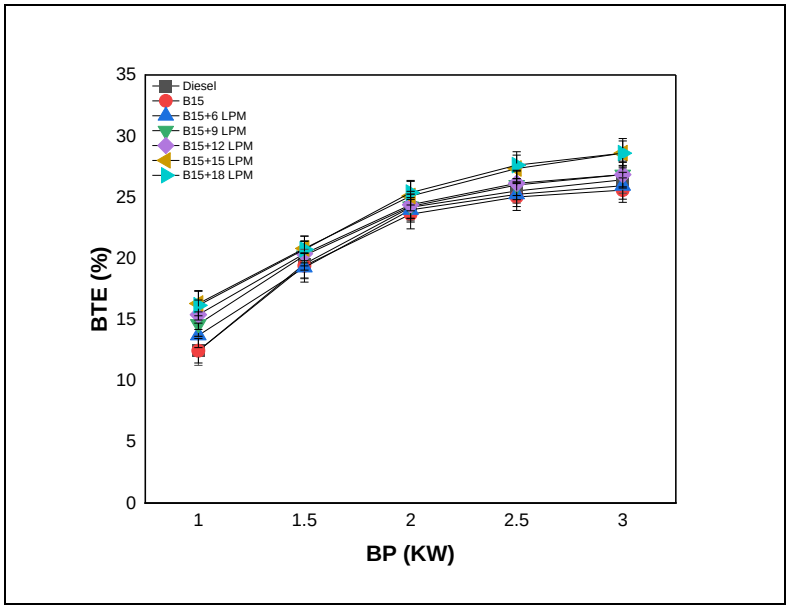

Figure 3: The B15 blend's BP and BTE at varying hydrogen mass flow rates.
Source: Authors, (2026).

In another study, A preheater was fabricated to raise intake air temperatures (30–60°C) for B20 Pongamia biodiesel. Higher intake air temperature improved BTE by 1% and reduced BSFC by 9%, while lowering HC by 36% and smoke by 16%. However, NOx emissions increased by 10.1%. [24].

III.3 EFFECT ON BSFC

Figure 4 depicts the correlation between BP and BSFC for the B15 blend at varying H2 flow rates. For B15 + 15 lpm and B15 + 18 lpm blends, it is seen that brake specific fuel consumption decreases with an increase in hydrogen flow rate. The minimum BSFC for B15 at 15 lpm is 0.23 kg/kW-hr, and for B15 at 18 lpm, it is also 0.20 kg/kW-hr. B15 BSFC demonstrates superior performance under maximum load circumstances compared to traditional fuel, with varying hydrogen flow rates. When hydrogen and air are properly combined, the flame velocity can be enhanced, resulting in more efficient combustion. The B15 blend surpasses other blends with a BSFC of 15 lpm and 18 lpm. The optimal mixture for all loads is B15, containing a hydrogen concentration of 15 liters per minute.

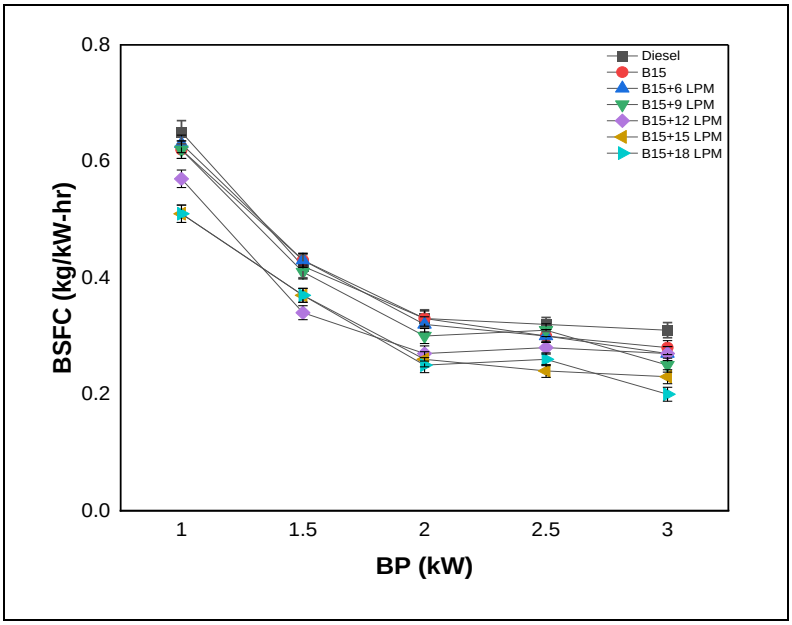

Figure 4: Comparison of BP and BSFC for the B15 blend at various hydrogen mass flow rates.
Source: Authors, (2026).

III.4 EFFECT ON HC

Figure 5 illustrates the hydrocarbon (HC) levels in relation to boiling point (BP) for B15 at various H2 flow rates. HC emissions were reduced in the B15 + 15 lpm and B15 + 18 lpm blends relative to standard diesel. The cylinder holds a blend of hydrogen and Karanja biodiesel oil, ensuring adequate mixing in the engine, elevating temperature, and facilitating the post-flame oxidation process. The hydrocarbon emission levels for diesel are 115 ppm, 75 ppm, and 80 ppm for B15 + 15 lpm and B15 + 18 lpm, respectively. B15 combined with 15 lpm decreases HC by 32.17%, whereas B15 combined with 18 lpm reduces it by 26.96%, respectively. In another study, Pongamia Pinnata methyl ester B20 was enhanced with 40–100 mg/L graphene oxide (GO) nanoparticles and 3% diethyl ether. At 100 mg/L GO + 5% ether, BTE rise by 19.7% and BSFC fell by 10.71% at maximum load. CO, HC, and smoke dropped by up to 70%, while combustion improved with higher peak pressure and shorter ignition delay [25].

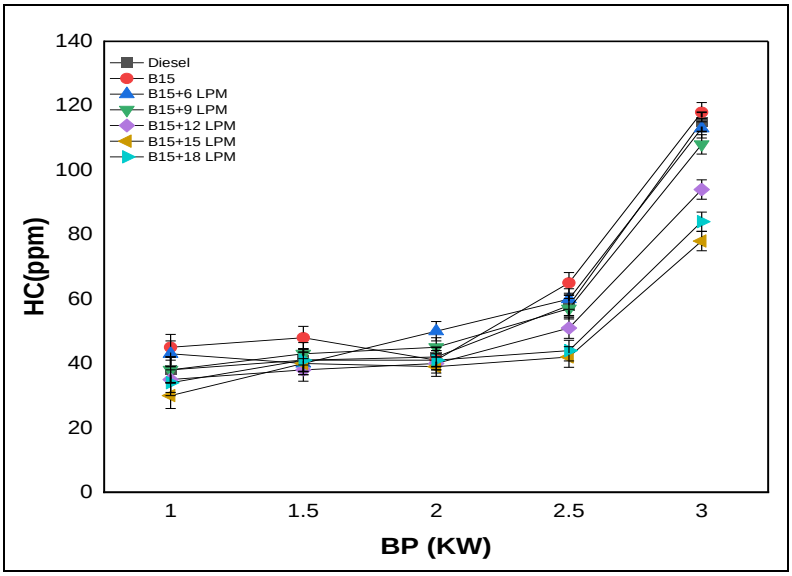

Figure 5: Variation of HC emissions with BP for the B15 blend at various hydrogen mass flow rates.
Source: Authors, (2026).

III.5 EFFECT ON CO

Variations in the H2 flow rate result in alterations to the CO/BP deviation for the B15 blend (refer to Figure. 6). Karanja biodiesel B15 lowers CO emissions with an increase in hydrogen flow rate. Reduced CO emissions were seen with the B15 + 15lpm and B15 + 18lpm blends in comparison to the others. This decreases CO emissions as the B15 + H2 mixture contains no carbon molecules. As a result, a substantial decrease in CO emissions is attained at all H2 flow rates. Diesel, B15 + 15 lpm, and B15 + 18 lpm exhibited CO emissions of 0.18%, 0.06%, and 0.17%, respectively. B15 combined with 15 lpm decreases CO emissions by 30% relative to diesel, while B15 with 18 lpm results in a 39% reduction. Prolonging combustion beyond the combustion stroke and subsequent extended injection results in a significant rise in CO levels at maximum load. As a result, when the exhaust valve was opened, the carbon monoxide emissions from the intermittent combustion products would solidify.

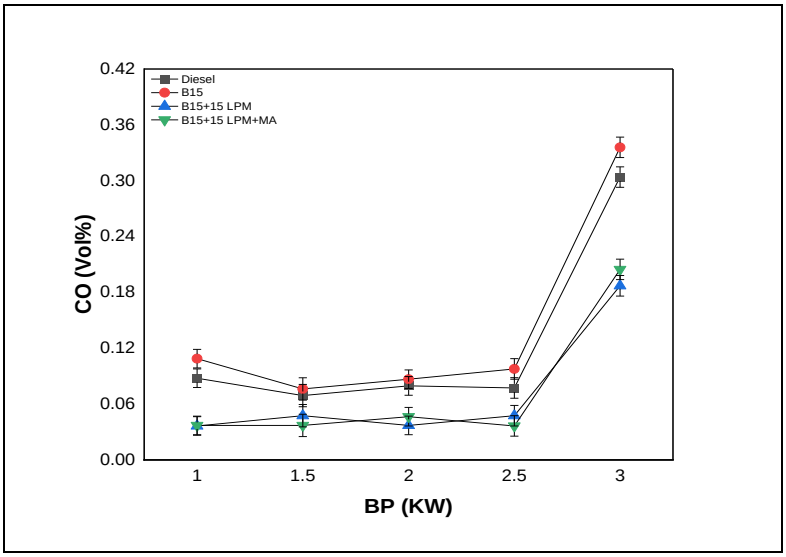

Figure 6: Variation of BSFC with BP the B15 blend at different hydrogen mass flow rates.
Source: Authors, (2026).

III.6 EFFECT ON NOX

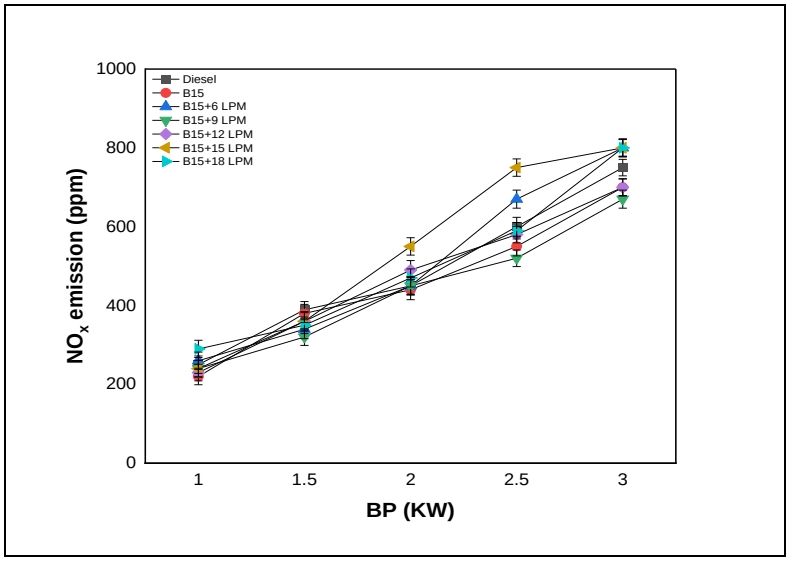

Figure 7: Emission of B15 blend with varying H2 flow rates as a function of BP and NOX.
Source: Authors, (2026).

Figure 7 illustrates the NOx levels in relation to BP for various H2 flow rates in the B15 mix. The complete response of an alternate fuel in the engine is governed by NOx, the most pivotal factor among these elements. As hydrogen flow rates increase, NOx levels also escalate. The production of nitrogen oxides (NOx) is primarily influenced by the temperature of the combustion chamber and the internal oxygen composition. Moreover, the presence of additional oxygen in the B15 blend exacerbates the production of NOx emissions. The combustion residence time is reduced due to the diesel engine's exceptionally narrow flame response zone. Diesel with B15 at 15 lpm exhibits NOx levels of 967.26 ppm, whereas B15 at 18 lpm shows values of 1307.72 ppm and 1340.58 ppm, respectively. The blends B15 + 15 lpm and B15 + 18 lpm exhibit increases of 25.2% and 27.6%, respectively, in comparison to diesel fuel. In earlier study, the use of TiO_2 nanoparticles (25–100 mg/L) in a B30 blend of Pongamia Pinnata biodiesel was studied. The B30T75 sample delivered the best performance. NOx emissions increased slightly (2.91%), and HRR rise by 5.4% compared to B30, indicating improved combustion efficiency [26].

III.7 INVESTIGATION ON NATURAL ANTIOXIDANT ADDITIVE

The optimal test fuel was identified as B15 + 15 lpm in the previous investigation. Nonetheless, irrespective of the load, this fuel generates a higher volume of NOx. Consequently, diesel, B15, and B15 + 15 lpm are evaluated using an antioxidant component inherently found in the B15 mixture. After using a natural additive, we can notice changes in performance and emissions. Following the same procedure as before, graphs of performance and emissions are produced.

III.8 EFFECT ON BTE

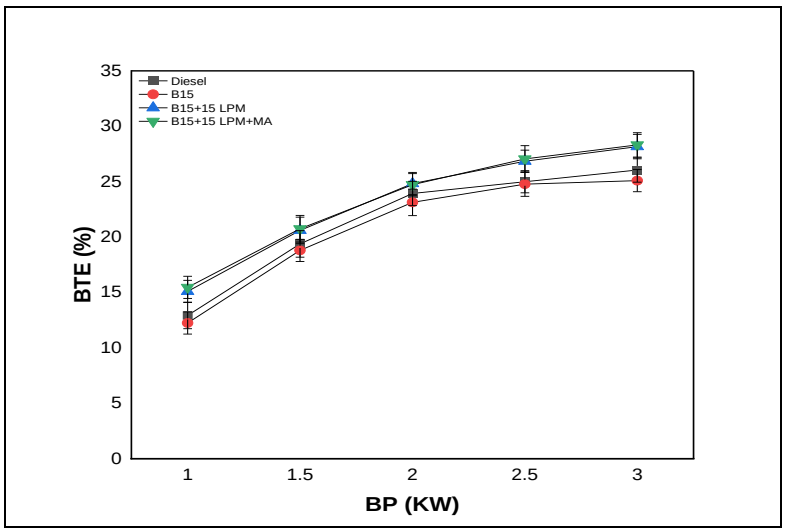

Figure 8: Comparison of B15 + 15 lpm BP against BTE with and without MA.
Source: Authors, (2026).

Both with and without the inclusion of a natural antioxidant component, Figure 8 shows BP with BTE for B15 and H2. The B15 + 15 lpm combination exhibits a Brake Thermal Efficiency (BTE) of 28.96%, which increases to 29.58% when an antioxidant ingredient (AI) is used. When operating at full load, the BTE efficiency of B15+ hydrogen with AI surpasses that of diesel by 5.2%. In previous study, Jojoba (JME), polanga (PME), and mixed methyl ester (MME) biodiesels tested enhanced with diglyme (cetane improver) and cumene (antioxidant) in a single-cylinder DI diesel engine at 1500 rpm. MME15+DG5 achieved the highest BTE improvement of 15.78%. Cumene also improved efficiency, with MME15+CU5 showing an 8.77% BTE increase and reduced exhaust gas temperature [27].

III.9 EFFECT ON BSFC

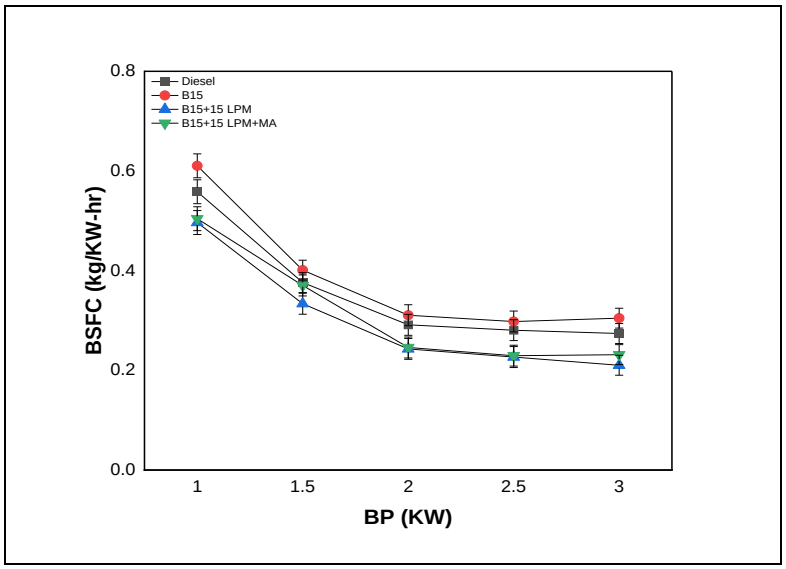

Figure 9 Comparison of BP and BSFC for B15 + 15 lpm with and without MA.
Source: Authors, (2026).

Both with and without the addition of the natural antioxidant MA, Figure 9 shows BP with BSFC for B15 and H2. Incorporating a natural antioxidant into a B15 blend with hydrogen in dual fuel mode in compression ignition engines enhances the brake specific fuel consumption (BSFC). The brake specific fuel consumption (BSFC) for B15 at 15 liters per minute with AI is 0.23152 kg/kW-hr, but without AI it is 0.21023 kg/kW-hr. The presence of chlorophyll and carotenoids results in a greater BSFC for B15 + 15 lpm compared to the additive blend.

In another study, Diphenylamine (DPA) antioxidant with ceria nanoparticles in a B30 Jatropha blend to address biodiesel's NOx emissions. Using hybrid RSM–MCDM (entropy, TOPSIS, VIKOR), the optimal B30+DPA50+$CeO_2$50 blend improved BTE by 1.01%, lowered BSFC by 5.67%, and reduced NOx by 18.87% [28].

III.10 EFFECT ON CO

Figure 10 illustrates the impact of CO on BP and B15 with H2, both with and without the inclusion of MA, a natural antioxidant. The addition of an antioxidant slightly increases CO levels. Incorporating 1000 ppm of additive into B15 + 15 lpm increases CO emissions from 0.187 08% to 0.43%. This happens because the natural antioxidant component takes too long to convert carbon monoxide to carbon dioxide and the combustion process is inadequate. The reduction in CO emissions can be attributed to the absence of carbon molecules in H2.

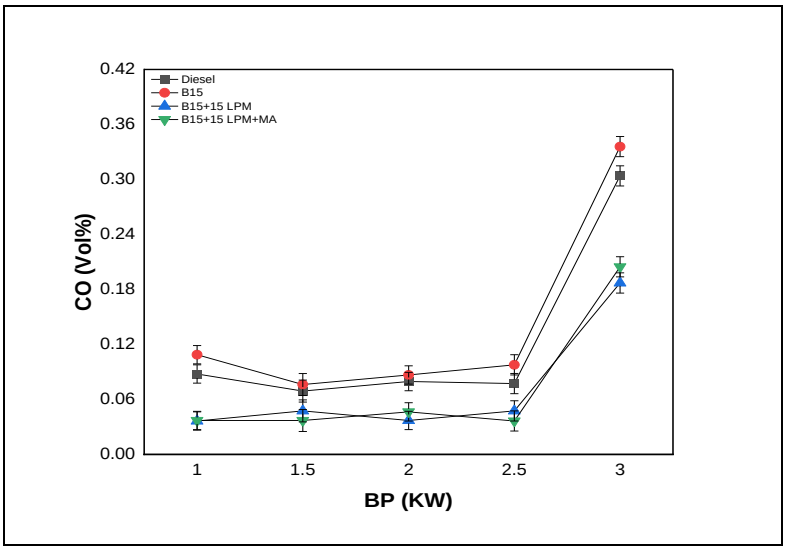

Figure 10: Comparison of B15 + 15 lpm's BP and CO with and without MA.
Source: Authors, (2026).

III.11 EFFECT ON HC

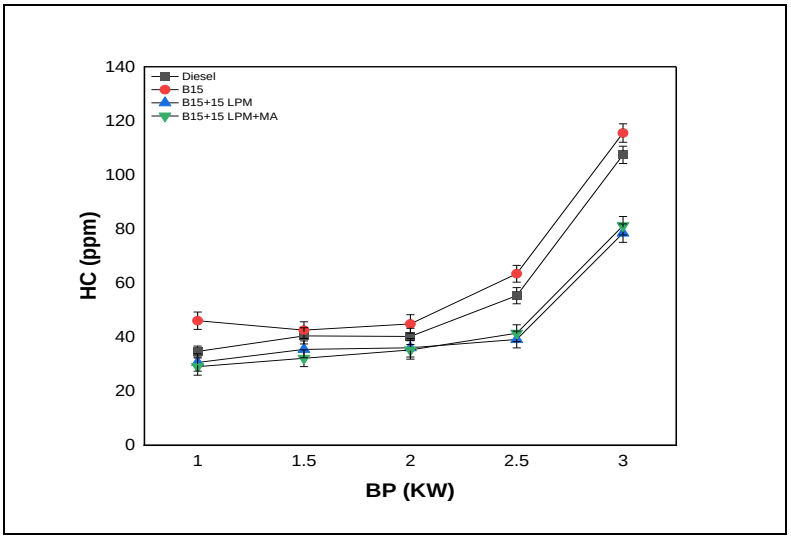

Figure 11: Comparison of B15 + 15 lpm BP and HC with and without MA.
Source: Authors, (2026).

Figure 11 illustrates the comparative effects of BP and HC on B15 and H2, both with and without the incorporation of MA, a natural antioxidant. A reduction in combustion chamber temperature is attributed to inadequate mixture formation, which leads to elevated HC emissions for B15 with 1000 ppm and 15 lpm of hydrogen. In comparing B15 + 15 lpm with and without the AI additive, the rise in HC for the former is 2.36 %. Furthermore, HC is measured at 79 ppm for the B15 + 15 lpm blend and 82 ppm for the B15 + 15 lpm blend with MA. In previous study, Albizia lebbeck leaf-derived natural antioxidant (NA) was incorporated into SBME20 (soybean methyl ester) biodiesel for low heat rejection (LHR) engines at 500–2000 ppm concentrations. The 1000 ppm blend delivered the best results, reducing BSFC to 0.38 kg/kWh and increasing BTE to 32%, alongside decreases in CO (−15%), HC (−10%), NOx (−12%), and smoke opacity (−20%) [29].

III.12 EFFECT ON NOX

Figure 12 illustrates both the NOx B15 and H2 BP samples, with and without the incorporation of the natural antioxidant agent MA. The NOx emissions from a B15 + 15 lpm blend are 24.14 % greater than those from conventional diesel, which is already significantly elevated. To reduce NOx emissions, add 1000 ppm of a natural ingredient to the B15 mixture. To reduce NOx emissions, the temperature and oxygen concentrations in the combustion chamber are diminished. The nitrogen oxides (NOx) for B15 + 15 lpm blends at 1000 ppm, with no load, are 1371.27 ppm and 1074.0 ppm, respectively. B15 combined with 15 lpm of additive decreases NOx emissions by 21.7 % relative to B15 with 15 lpm without the addition.

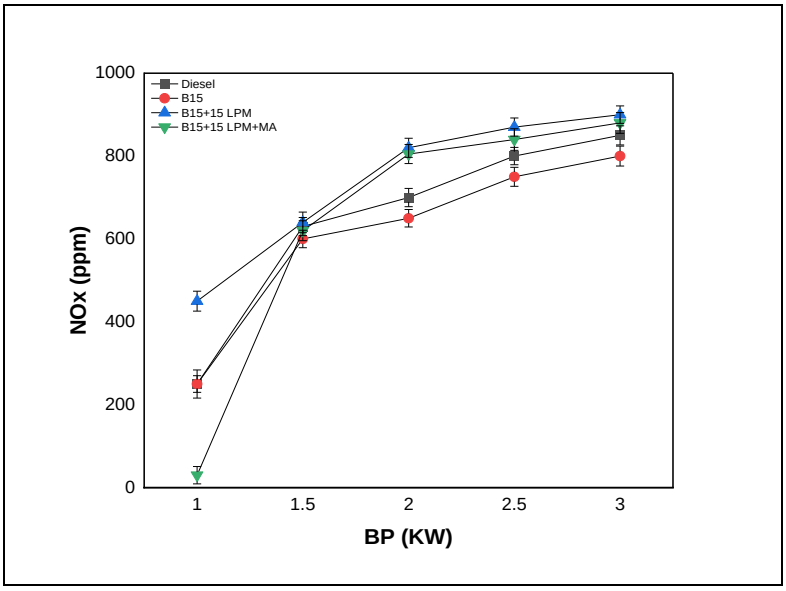

Figure 12: B15 + 15 lpm BP against NOx with and without MA.
Source: Authors, (2026).

IV. CONCLUSION

The subsequent results were obtained from tests performed on hydrogen and B15 in a CI engine, both with and without the use of 1000 ppm of AI additive.

- The B15 with 15 lpm and 18 lpm hydrogen shown an enhancement in brake thermal efficiency (BTE) and a reduction in brake specific fuel consumption (BSFC) compared to diesel. The BTE for B15 + 16 lpm, B15 + 18 lpm blends is 28.96 % and 29.58 %, respectively.
- In comparison to the B15 blend, the Brake Specific Fuel Consumption (BSFC) for the B15 + 15 lpm and B15 + 18 lpm mixtures is reduced to 0.23 kg/kW-hr and 0.20 kg/kW-hr, respectively.
- At maximum capacity, the CO emissions for the B15 + 15 lpm blends are diminished by 26.98%.
- HC emissions are diminished by 32% when B15 is amalgamated with 15 lpm of H2.
- As the flow rate of H2 increases, NOx emissions also rise.
- The outcomes for B15 at 15 lpm under maximum load are 1307 ppm, but the outcomes for B15 at 18 lpm are 1340 ppm. All measures enhanced when B15 and 15 lpm H2 with 1000 ppm MA were utilized.
- When B15 + 15 lpm with additive is compared to B15 + 15 lpm without additive, the BTE is elevated by 2.62 %. Both combinations exceed diesel in terms of brake thermal efficiency (BTE).
- Radioactive symbol B15 + 15 lpm without additive exhibits a BSFC of 0.2315 kg/Kw-hr, which is 8.8% higher than B15 + 15 lpm with additive.
- The B15 + H2 + MA blend exhibits a little increase in HC and CO emissions.
- The incorporation of antioxidant compounds leads to a substantial reduction in NOx emissions. In comparison to B15 + 15 lpm without additive, the mixture B15 + 15 lpm + AI decreases NOx emissions by up to 21.7%.

Piezoelectric actuators and sensors,
Active Vibration Control (AVC),
Linear Quadratic Regulator (LQR).

ABSTRACT

In this paper, a comprehensive finite element (FE) formulation is developed for the dynamic analysis and active control of classical laminated composite plates with embedded piezoelectric layers. The model, based on the First-Order Shear Deformation Theory (FSDT) and Hamilton's principle, accurately captures transverse shear effects and electromechanical coupling. Stiffness, mass, and piezoelectric contributions of actuator and sensor layers are explicitly included, providing a fully consistent multi-field representation of the intelligent structure. To enhance vibration performance, piezoelectric actuators are employed within an active vibration control (AVC) framework. A Linear Quadratic Regulator (LQR) controller is designed using the independent mode space approach, enabling efficient computation of optimal feedback gains for dominant vibration modes while keeping the control model reduced-order and computationally tractable. Numerical simulations on various laminated configurations show excellent agreement with ANSYS benchmark results in terms of natural frequencies and mode shapes. The LQR-based AVC strategy is shown to significantly reduce vibration amplitudes, with peak responses decreased by up to 92% within a few seconds and the damping ratio increased more than fivefold. Frequency-response analysis reveals up to 50% attenuation of resonance peaks, highlighting the synergistic effect of state-feedback control and piezoelectric coupling in increasing effective damping. These results confirm the effectiveness of the proposed FE-LQR approach in suppressing vibrations, accelerating structural stabilization, and enhancing the dynamic resilience of smart composite plates.

I. INTRODUCTION

The increasing demand for lightweight, high-strength composite materials with integrated sensing and actuation capabilities has significantly expanded their applications in aerospace, automotive, and civil engineering [1], [2]. Laminated and sandwich composite plates embedded with piezoelectric layers have attracted substantial attention due to their ability to suppress vibrations and reduce noise [3], [4], [5]. However, the inherent anisotropy and high flexibility of such structures make them prone to excessive vibrations, necessitating the development of advanced control strategies to ensure structural stability [6], [7]. Active vibration control (AVC) techniques employing piezoelectric materials as sensors and actuators provide rapid response and efficient electromechanical coupling [8], [9].

Among these techniques, the Linear Quadratic Regulator (LQR) has emerged as a widely used method due to its ability to optimize control effort while maintaining system stability, effectively balancing vibration suppression with energy consumption [10], [11], [12]. Recent studies have demonstrated the effectiveness of LQR control in reducing peak vibration amplitudes by over 90% and enhancing damping ratios by several times compared to uncontrolled systems [13], [14]. A robust numerical modeling framework is crucial for designing an effective controller that accurately captures material anisotropy, layer interactions, and complex laminated geometries. The finite element method (FEM) provides a versatile tool for such purposes, allowing incorporation of both mechanical and electromechanical contributions of piezoelectric layers [15], [16], [17]. Recent works have extended FEM formulations to account for viscoelastic damping, functionally graded material (FGM) cores, and optimal placement of piezoelectric patches for enhanced vibration control [18], [19], [20]. Comparisons between FEM-based simulations and commercial software (e.g., ANSYS) have consistently confirmed the high accuracy of these models in predicting natural frequencies, mode shapes, and time responses of smart composite plates [15], [17], [18]. In this study, a finite element-based modeling framework is combined with an LQR-based active vibration control strategy for laminated composite plates embedded with piezoelectric patches. Numerical simulations demonstrate substantial reduction in vibration amplitudes, attenuation of resonance peaks, and accelerated structural stabilization. These results confirm the effectiveness of the proposed approach and contribute to the ongoing development of smart composite structures with enhanced dynamic performance and reliable active control capabilities.

II. FINITE ELEMENT FORMULATION

In this section, a finite element (FE) formulation is developed to model the mechanical and electromechanical behavior of laminated composite plates with embedded piezoelectric layers. The formulation combines the First-Order Shear Deformation Theory (FSDT) for accurate kinematics with piezoelectric constitutive equations, allowing the evaluation of mechanical displacements, strains, and electromechanical coupling. The FE discretization procedure is then presented to assemble the global system matrices for numerical analysis.

II.1 MECHANICAL DISPLACEMENTS AND STRAINS

The First-Order Shear Deformation Theory (FSDT) accounts for transverse shear deformation, which is ignored in Classical Plate Theory, to describe mechanical displacements and strains. By including the transverse shear effect, FSDT provides more accurate predictions for moderately thick laminated composite plates, compared to the classical theory which assumes that normals to the mid-plane remain perpendicular after deformation [21], [22]. This theory is widely used in the analysis of composite and smart structures due to its balance between accuracy and computational efficiency [23]–[25].

II.2 PIEZOELECTRIC CONSTITUTIVE EQUATIONS

The piezoelectric effect can be expressed by four pairs of equations linking the mechanical tensors of deformation $\{\mathcal{E}\}$ and stress $[\sigma]$ to the vectors of the electric field $[\mathrm{E}]$ and the induction (the electric displacement) $\{\mathrm{D}\}$. It is common to present these equations in the following form[26]–[29]:

$$\begin{cases} \{\sigma\} = [\mathrm{Q}]\{\varepsilon\} - [\mathrm{e}]^{\mathrm{T}}\{\mathrm{E}\} \\ \{\mathrm{D}\} = [\mathrm{e}]\{\varepsilon\} - [\epsilon]\{\mathrm{E}\} \end{cases} \tag{1}$$

$[Q]$and $[e]$ are respectively called the elastic constants measured with constant electric field $\{E\}$, the piezoelectric constants and the measured dielectric constants with constant strain.

II.3 FINITE ELEMENT DISCRETIZATION

The shapes and structures of these matrices can be expressed in a standard coupled form, which is widely adopted for finite element modeling of piezoelectric laminated plates and smart structures [30] :

Matrix of masses

$$\begin{aligned} [\mathrm{M_e}] &= \int [\mathrm{N}]^{\mathrm{T}}[\bar{\mathrm{m}}][\mathrm{N}]\mathrm{dv} = [\mathrm{M_{ep}}, \mathrm{M_{ap}}, \mathrm{M_{sp}}] \\ &= \int_{-1}^{1} \int_{-1}^{1} [\mathrm{N}]^{\mathrm{T}}[\bar{\mathrm{m}}][\mathrm{N}]|J|\mathrm{d}\xi\mathrm{d}\eta \\ &= \sum_{\mathrm{i}=1}^{\mathrm{n_g}} \sum_{\mathrm{j}=1}^{\mathrm{n_g}} [\mathrm{N}]^{\mathrm{T}}([\bar{\mathrm{m}}_{\mathrm{p}}, \bar{\mathrm{m}}_{\mathrm{ap}}, \bar{\mathrm{m}}_{\mathrm{sp}}])[\mathrm{N}]|J|\mathrm{d}\xi\mathrm{d}\eta \\ [\bar{\mathrm{m}}] &= \sum_{\mathrm{k}=1}^{\mathrm{n}} \int_{\mathrm{z_k}}^{\mathrm{z_{k+1}}} \begin{bmatrix} \mathrm{I_1} & 0 & 0 & \mathrm{I_2} & 0 \\ 0 & \mathrm{I_1} & 0 & 0 & \mathrm{I_2} \\ 0 & 0 & \mathrm{I_1} & 0 & 0 \\ \mathrm{I_2} & 0 & 0 & \mathrm{I_3} & 0 \\ 0 & \mathrm{I_2} & 0 & 0 & \mathrm{I_3} \end{bmatrix} \mathrm{dz}, (\mathrm{I_1}, \mathrm{I_2}, \mathrm{I_3}) \\ &= \sum_{\mathrm{k}=1}^{\mathrm{n}} \int_{\mathrm{z_{k+1}}}^{\mathrm{z_k}} \rho(1, \mathrm{z}, \mathrm{z}^2)\mathrm{dz} \end{aligned} \tag{2}$$

Rigidity matrix

$$\begin{aligned} [K] &= \int_{v} [B]^{T}[\overline{D}][B]dv = [K_{ep}, K_{ap}, K_{sp}] \\ &= \int_{-1}^{1} \int_{-1}^{1} [B]^{T}[D][B]|J|d\xi d\eta \\ &= \sum_{i=1}^{n_g} \sum_{j=1}^{n_g} [B]^{T}([\overline{D}_p, \overline{D}_{ap}, \overline{D}_{sp}])[B]|J|d\xi d\eta \end{aligned} \tag{3}$$

Damping Matrix

$$[\mathrm{C}] = \alpha[\mathrm{M}] + \beta[\mathrm{K}] \tag{04}$$

Electrical stiffness matrix

$$\begin{aligned}[\mathrm{K_{me}}] &= \int_{\mathrm{A}} [\mathrm{B}]^{\mathrm{T}}[\mathrm{e}]\left[\mathrm{B}_{\varphi}\right]\mathrm{dA} \\ &= \int_{-1}^{1}\int_{-1}^{1} [\mathrm{B}]^{\mathrm{T}}[\mathrm{e}]\left[\mathrm{B}_{\varphi}\right] \\ &= \sum_{\mathrm{i}=1}^{\mathrm{ng}}\sum_{\mathrm{j}=1}^{\mathrm{ng}} [\mathrm{B}]^{\mathrm{T}}[\mathrm{e}][\mathrm{B}_{\varphi}]|J|\mathrm{d}\xi\mathrm{d}\eta\end{aligned} \tag{05}$$

Coupling matrix

$$\begin{aligned}[K_{ea}, K_{es}] &= \int_{A} [B_{\varphi}]^{T}[\epsilon_{a,s}][B_{\varphi} \\ &= \int_{-1}^{1}\int_{-1}^{1} [B]^{T}[e_{a,s}][B_{\varphi}]|J|d\xi d \\ &= \sum_{i=1}^{n_g}\sum_{j=1}^{n_g} [B]^{T}[e][B_{\varphi}]|J|d\xi d\eta\end{aligned} \tag{06}$$

Mechanical forces

$$\begin{aligned}[\mathrm{F_m}] &= \int_{\mathrm{A}} [\mathrm{N}]^{\mathrm{T}}[\mathrm{d}]\mathrm{dA} = \int_{-1}^{1}\int_{-1}^{1} [\mathrm{N}]^{\mathrm{T}}[\mathrm{d}]|J|\mathrm{d}\xi\mathrm{d}\eta \\ &= \sum_{\mathrm{i}=1}^{\mathrm{ng}}\sum_{\mathrm{j}=1}^{\mathrm{ng}} [\mathrm{N}]^{\mathrm{T}}[\mathrm{d}]|J|\mathrm{d}\xi\mathrm{d}\eta\end{aligned} \tag{07}$$

III. ACTIVE VIBRATION CONTROL (AVC)

Active vibration control aims to suppress the dynamic response of flexible structures by using real-time feedback from sensors and applying appropriate control forces through actuators [31], [32] . In smart composite plates with integrated piezoelectric layers, this process requires an accurate state-space representation of the system to design an efficient controller such as the Linear Quadratic Regulator (LQR) [33], [34]. In this framework, the matrices [A], [B], and [C] correspond respectively to the system matrix, the control input matrix, and the output matrix. These matrices describe the structural dynamics, the influence of the actuator inputs, and the measured outputs used for feedback. They are derived by assembling the finite element mass, stiffness, and electromechanical coupling matrices into the standard state-space form [35], [36]:

The system matrix

$$\mathrm{A} = \begin{bmatrix} 0 & \mathrm{I} \\ -\mathrm{diag}(\omega_{\mathrm{k}}^2) & -2\xi_{\mathrm{k}}\omega_{\mathrm{k}} \end{bmatrix} \tag{08}$$

The control input matrix

$$\mathrm{B} = \begin{bmatrix} 0 \\ \mu\Omega^{\mathrm{T}}\mathrm{K}^{(\mathrm{ac})}{}_{\mathrm{me}} \end{bmatrix} \tag{09}$$

The output matrix

$$\mathrm{C} = [\mathrm{K}^{(\mathrm{i})}{}_{\mathrm{me}}{}^{\mathrm{T}}\Omega \quad 0] \tag{10}$$

This state-space formulation provides the basis for implementing the LQR controller and achieving effective vibration suppression in intelligent composite structures.

III.1 OBJECTIVE FUNCTION

To design the Linear Quadratic Regulator (LQR) compensator, the control problem is formulated as the minimization of a quadratic performance index [37],[38]. This objective function represents a trade-off between the vibration energy of the structure and the control effort required by the actuators. The quadratic cost function is classically defined as:

The quadratic cost function

$$\mathrm{J} = \int_{0}^{\infty}(\{\mathrm{X}\}^{\mathrm{T}}[\mathrm{Q}]\{\mathrm{X}\} + \{\varphi\}^{\mathrm{T}}[\mathrm{R}]\{\varphi\})\,\mathrm{dt} = min \tag{11}$$

Where: Q is a positive semidefinite matrix and R is a positive matrix.
The optimal solution is:

The optimal solution

$$[\mathrm{G}] = [\mathrm{R}]^{\mathrm{T}}[\mathrm{B}]^{\mathrm{T}}[\mathrm{K}] \tag{12}$$

Where [K] satisfies the Riccati equation:

The Riccati equation

$$[\mathrm{A}]^{\mathrm{T}}[\mathrm{K}] + [\mathrm{K}][\mathrm{A}] - [\mathrm{K}][\mathrm{B}][\mathrm{R}]^{-1}[\mathrm{B}]^{\mathrm{T}}[\mathrm{K}] + [\mathrm{Q}] = 0 \tag{13}$$

III.2 LOAD LINEAR QUADRATIC REGULATOR (LQR) PROBLEM

The Linear Quadratic Regulator (LQR) is a classical optimal control method used to compute a state-feedback control law that minimizes a quadratic cost function while ensuring system stability. In MATLAB, the command lqr is used to calculate the optimal gain matrix G.

The optimal gain matrix G

$$\text{Syntaxe} : [G, K, e] = Lqr(A, B, Q, R) \tag{14}$$

Where e is the closed-loop eigenvalues.

IV. NUMERICAL ANALYSIS AND DISCUSSIONS

In this section, some numerical results are presented for symmetrically laminated square plate [45, - 45, 45, - 45], with embedded four identical piezoelectric actuators. The geometrical size of the intelligent composite plate is L*L*H=1*1*0.002(m), for the piezoelectric patches are lp*lp*hp= 0.1*0.1*0.0001(m) (Fig.1). The localizations for the piezoelectric actuators are (X1, Y1) = (0.2, 0.4), (X2, Y2) = (0.4, 06), (X3, Y3) = (0.8, 0.7), (X4, Y4) = (0.4, 0.9) (Figure.1).

Source: Authors, (2026).

The simulation featured in this paper assume α=0 and β=0.0015 damping constants. The time step Δt for Transient analysis is taken as $1 / (20 f_h)$, where f_h is the higher frequency. Consider an initial displacement field applied to the plate equal to 0.1 m. Table 1 contains the material properties data for the plate, piezoelectric actuators.

A finite element (FE) model, created using Matlab, facilitates the dynamic modeling of a system. Numerical results are verified using ANSYS, where an FE model of an intelligent composite plate is developed. The solid layers and PZT materials are modeled with SOLID45 and SOLID5 elements, featuring 8 nodes. A coupling electromechanical system is established using the CP command, and a suitable voltage potential is assigned (Figure 2).

In this study, a linear quadratic optimal controller is considered to control the first three modes of the flexible plate. The weighting matrices chosen are: Q= $5e^{-8}$ and R=$0.5e^{+10}$. Here, the control is started after an elapse of 0.5 s in order to compare the controlled and uncontrolled responses. Figure 04 shows the displacement responses of the uncontrolled and controlled intelligent composite plate.

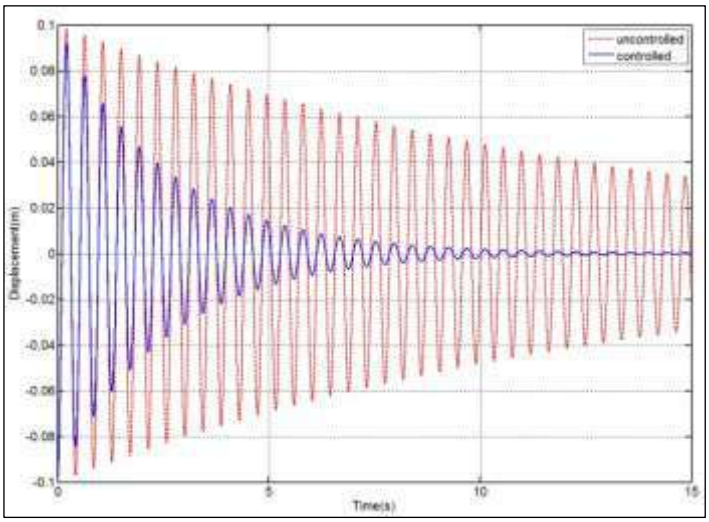

Figure 04: Comparison of uncontrolled and controlled displacement response of an intelligent composite plate with LQR controller.
Source: Authors, (2026).

The quantitative analysis of the responses shows that the introduction of LQR active control significantly improves the dynamic behavior of the composite plate. The maximum amplitude is reduced by approximately 36% from the initial instant, and by nearly 92% after 5 seconds, compared to the uncontrolled case. The calculation of the logarithmic decrement indicates that the damping ratio increases from about 0.61% (uncontrolled structure) to 3.3% under control, corresponding to an increase by a factor of ≈ 5.4. Moreover, the controlled system reaches a quasi-steady state in less than 4 seconds, whereas the uncontrolled system continues to vibrate with high amplitudes throughout the simulation window. These results clearly demonstrate the effectiveness of the LQR controller in enhancing effective damping, reducing vibrational energy, and accelerating the stabilization of the structure. The frequency response graph in Figure 5 compares the uncontrolled and controlled vibration amplitudes of the intelligent composite structure over the frequency range of 10–100 rad/s.

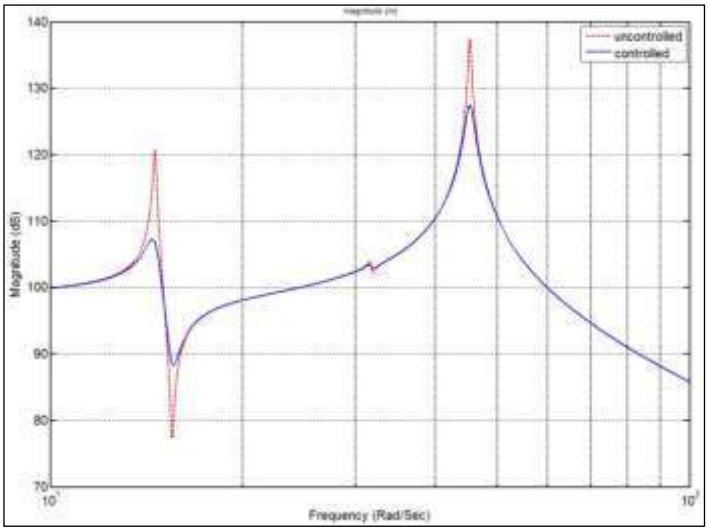

Figure 5: Comparison of the uncontrolled and controlled frequency response of an intelligent composite plate with LQR controller.
Source: Authors, (2026).

The controlled frequency-response curve exhibits a marked reduction in resonance amplification, with the main peak decreasing from approximately 133 dB (uncontrolled) to about 125 dB (controlled), corresponding to nearly a 6–8 dB attenuation which represents a reduction of about 40–50% in vibration energy; this flattening of the frequency response is consistent with the expected behavior of optimal state-feedback controllers, and is further enhanced by the piezoelectric coupling mechanism through which part of the induced strain energy is transformed into electrical energy, thereby increasing the effective damping of the structure.

V. CONCLUSIONS

In conclusion, the results demonstrate that the combined finite element modeling and LQR control strategy effectively reduces vibrations in smart composite plates with piezoelectric layers. Comparison of simulations in MATLAB and ANSYS confirms the accuracy of the model, as the natural frequencies match closely with minimal error. The numerical analyses further show that the LQR controller significantly enhances the dynamic performance of the plate, reducing peak vibration amplitudes by up to 92% within a few seconds and increasing the damping ratio more than fivefold. Frequency-response analysis highlights a substantial attenuation of resonance peaks, with up to 50% reduction in vibration energy, reflecting the synergistic effect of state-feedback control and piezoelectric coupling in increasing effective damping. Overall, these findings validate the LQR controller's effectiveness in suppressing vibrations, accelerating structural stabilization, and improving the dynamic resilience of smart composite structures.

ABSTRACT

Blockchain operates in a decentralized manner that provides the potential data available to the public. Privacy protection is an open challenge for data transparency. Applying Blockchain-based cryptographic algorithms in various applications can increase or protect data storage privacy. This paper constructs a lightweight privacy preserving data storage using Modified Ring signature Scheme based on Elliptic Curve Cryptography (MRSS-ECC). This solution built an anonymous user data storage to ensure the user information with highly secure and user identity privacy and validate the signature in the Blockchain network using the smart contract. Therefore, Security analysis of the scheme to verify correctness, unconditional anonymity, and unforgeability. The proposed system incorporates efficient key generation, signature formation, and verification processes to reduce computational overhead. Experimental evaluation demonstrates reduced signature size and improved verification time compared to related approaches. This framework can be adapted for e-governance, healthcare, and financial systems requiring secure, privacy-preserving public ledger integration.

I. INTRODUCTION

In the current blockchain technology, digital services such as electronic voting, electronic lottery, electronic bidding, electronic payment transactions of various virtual cryptocurrencies, and complaint reporting features are achieved by cryptographic construction such as ring signatures to facilitate protecting the anonymity of users. Chaum and van Heyst introduced the concept of group signatures, in which users in a group leak secrets; the signer's anonymity might weaken the anonymity of innocent users. Ring signature was first introduced by Rivest, Shamir, and Tauman [1] in 2001. [2] A ring signature is a specific cryptographic digital signature that simplifies the group signature. In the ring signature scheme, the signer randomly selects a user to conceal multiple numbers of members in the ring and no group managers with a unique key. At the same time, the signer combines the public key and private key to complete the signature without indicating their own identity. Only this signature set can be verified by the verifier, but it is not known who signed the signature. At present, the Blockchain network address of the data sender and receiver is a completely transparent transaction and raises the possibility of data privacy leaks; however, it ensures the authenticity of the on-chain data. Elliptic curve cryptography integrates with ring signature to provide high security and low computational load, plus it endows anonymity of the signers. The ring signature scheme will avoid the data privacy leaks of the data sender as well as the receiver can realize anonymous transactions on the blockchain. The proposed solution offers these security properties correctness, unconditional anonymity, and unforgeability. This paper proposes a lightweight privacy-preserving data storage based on the Ring signature scheme in Blockchain.

The ring signature is operating to secure the information of the transaction initiator and ensure the blockchain's privacy. The rest of the paper is structured as follows. Related works are presented in Section 2. Section 3,4 describes the proposed scheme as Modified Ring Signature Scheme based on Elliptic Curve Cryptography. Section 5 discusses the performance and evaluation metrics.

II. RELATED WORKS

Ring signatures are modern cryptographic primitives from the cryptographic community that are addressed as more significant attention for innovation and manufacturing societies due to the user privacy-preserving authentication feature and protection against malicious user actions. Ring signature also plays a vital role in many applications such as electronic payment, e-voting, and auctions. [3] proposed an e-voting system using a smart contract, threshold encryption, and linkable ring signature with a trusted bulletin board to provide greater privacy.[4]To preserve individual privacy when exchanging data combined with forward security and identity ring signature to increase data security. The regular ring signature remains undetectable double votes in the e-voting and anonymous transactions as they are unlinkable. A linkable ring signature solves this problem and ensures the linkability of two ring signatures signed by the same signer, but the identities of the signers remain anonymous. [5] Two valid signatures on the same message m with private or public key pair linked by the key image. A trusted third party detects the dishonest signer and provides double-spending protection for each transaction or voting. [6] A blockchain-based voting system uses a Paillier system to count the ballots without leaking the candidate's information. Proof of knowledge convinces the voting system that the vote cast by a voter is valid or not without revealing the content of the vote. A linkable ring signature ensures no one can trace the vote's owner and verify the genuine vote.[7] Efficient linkable and/or threshold ring signature without random oracles providing stronger anonymity and accountability. However, the signature size is sublinear with O (d.$\sqrt{n}$) where n is the number of users in the ring and d is the threshold value.

A blind signature is well-suited for creating untraceable systems in blockchain-enabled systems. A blind signature guarantees the anonymity of the user's sensitive information. The blind signature scheme has been in many applications as e-cash and e-voting, and untraceable payment systems, which are more suitable for privacy preservation in blockchain-enabled systems.[8] adopted an anti-quantum blind signature scheme based on the lattice assumption using reject sampling and the bimodal Gaussian distribution to improve security and efficiency and is more secure against quantum attacks.[9] Proposed a privacy-preserving scheme in a smart grid based on group blind signature to meet the requirements of Anonymous authentication and conditional anonymity without revealing the real identity and tracing the malicious users efficiently.[10]The signature size is independent of the ring size using a constant size ring signature scheme with an efficient implementation based on the strong RSA assumption in the random oracle model (ROM) for anonymous identification in ad-hoc groups.[11] Developed a brand-new supply chain traceability system that uses the MLSAG ring signature protocol to protect the privacy of sensitive data and achieves traceability by obscuring participants in publicly available data on previous transactions. The goal of using ring signature in privacy oriented cryptocurrencies is to protect the privacy of a sender of a transaction by making it computationally infeasible to determine the senders address given the signature [12]. The Verge currency employs stealth addressing, which enables a user to construct a one-time address based on a stealth address provided by the recipient to send money.

The address verified its ownership is only visible to the sender and recipient. Only the recipient has access to recover and use the funds at that particular address. [13] Another popular digital cryptocurrency Monero provides un-trackability means all possible signers have the same probability of each transaction. Tracing the sender transaction is protected to provide a higher level of privacy.[14] Dash is a digital cryptocurrency for protecting user privacy. It provides strong anonymity using a chained approach, PrivateSend mixing service reduces the correlation between addresses.[15] zcash anonymous cryptocurrency is needed to provide privacy, untraceability using zk-SNARKs. It provides a shield for the transaction addresses of the sender, receiver, and amount of coins sent. [16] Distributed key generation and elliptic curve cryptography are combined to provide ECC-based signature with stronger security. The use of distributed key agreement avoids to trust third party authorizer to distributed the key. The distributed generation center (KDC) is responsible for generating the system parameter, validate and manage the cluster members and verify the signature and upload them into the blockchain network.[17] A smart contract-based ring signature algorithm employs multiparty secure computation to preserver signer privacy. To prevent forgery "one encryption per signature is used and also address the issue of large signature size, reduced the signature size by two times and signature generation time and verification time by 3 three times compared to ECC ring signature[18]. A secure medical data sharing scheme is proposed that uses certificateless traceable ring signatures, IPFS for data storage, and smart contracts for access control.

Self-Controlling Objects (SCO) enable decryption and controlled data sharing, while distributed key generation ensures data integrity and preserves patient privacy. [19] An ECC-based ring signature is designed for blockchain to protect stored user data without revealing actual identities, only metadata is stored on-chain and smart contract enforces the privacy rules. This scheme is formally proven secure against unforgeability and anonymity under the random oracle model and also resists key expose attacks. This method also reduced signature size and computation time compared to pairing based schemes.[20] Linkable Ring Signature scheme with unconditional anonymity based on the e-NTRU problem under the random oracle model using preimage sampling, trapdoor generation and rejection sampling algorithm to improve the efficiency as well as shorter signature size. An aggregate ring signature is the combination of multiple ring signatures from different message and different rings into a short single signature to maintain the anonymity of each signer. It allows verification of single aggregated signature rather than of each signature of different ring, [21] smart grids face privacy risks from attacker, to address this issue, Certificate aggregate ring signature scheme provides unconditional anonymity, key management and remove key escrow, also ensure message integrity and efficiency with very low verification costs. [22] Two schemes are designed of privacy-focused blockchain transaction, first an aggregated ring signature that reduces signature space complexity with proven security. Second a compact multi message ring signature based on the lock principle to improve the efficiency. Aggregated linkable tags are proposed to detect double-spending in blockchain transactions.

II.1 PRELIMINARIES

Elliptic curve modulo a prime

Let q denote a large prime number, E denote an elliptic curve over an integer finite field F_q,the set of solutions $E_q(a, b) \in F_q$ defined an equation as follows:

$$y^2 = x^3+ax+b \ (mod\ q) \text{ and } 4a^3+27b^2 \# 0 \ (mod\ q) \text{ where a and b are constants } a, b, x, y \in F_q.$$

Suppose $P(x_1, y_1)$ and $Q(x_2, y_2) \in E_q(a,b)$. The point $P(x, y)$ on an elliptic curve that satisfies the $E_q(a, b)$. If $P = -Q$ the point $Q(x, -y)$ is the negative point of $P(x, y)$ The line l_n passes through P, Q and intersect the elliptic curve at a point $R'(x_3, y_3)$symmetrical about x axis then $P+Q = R(x_3, y_3)$ The point O called the point of infinity form an additive cyclic group

$$G=\{(x, y): a, b, x, y \in F_q, E(x, y)=0\} U \{O\}.$$

Definition 1:(Discrete logarithm problem). Let $G = (P) \leq g$. $P \in g$, P is a point with prime order q , Given a point $aP \in G$. Compute $a \in Zq^*$.

Security Model

The security requirements of a ring signature scheme, Consider the attacker **A** has access to the private keys of some users but also has access to all public keys of ring members.

Game1 Unforgeability of ring signature.

For Attacker A, $Succ_{RS,A}$ is defined as its probability of success in the following game between the challenger R and attacker A.

1. **Setup:** Given a security parameter l_n , challenger R runs the setup algorithm to obtain a list of system parameters and then challenger R sends system parameters to the attacker A.
2. **Hash Query:** Attacker A submits any value he chooses and challenger R returns the corresponding hash value to him.
3. **User Public Key Query:** The attacker A requests any user's public key whom he chooses and challenger R returns the corresponding public key pk_i to him.
4. **Private Key Query:** The attacker A requests a user's private key sk_i and the challenger R returns the corresponding private key sk_i .
5. **Ring Signature Query:** The attacker A submits any message he chooses, and challenger R returns the corresponding ring signature to him.
6. **Forge:** Eventually, the attacker outputs the ring signature σ* on a message m* such that

1. σ* is a valid signature
2. m* has never been submitted to the ring signature query

Definition 2:

A Forge $A(t, q_H, q_U, q_P, q_{RS}, \in)$ breaks a ring signature scheme means that if A runs in maximum time, A makes at most q_H hash queries, at most q_U users public key queries, at most q_P private key queries, at most q_{RS} ring signature queries then $Succ_{RS,A}$ is at least €. A ring signature scheme is $A(t, q_H, q_U, q_P, q_{RS}, \in)$ existentially unforgeable under an adaptively chosen message attack if no forger $A(t, q_H, q_U, q_P, q_{RS}, \in)$ breaks it.

Game 2 Anonymity of ring signature.

Let $U=U_1, U_2, \ldots\ldots U_n$ b be n signers. A is an attacker and R is Challenger who all are involved in game 2.

1. The challenger R runs the setup algorithm to obtain a list of system parameters and sends them to the attacker A.
2. The attacker A adaptively makes a polynomially bounded number of ring signature query.
3. In the challenge phase, the attacker outputs a message m, a group of n user's public key and two different public key $pk_1, pk_2 \in R$ to the challenger R. The challenger R randomly chooses a bit $\mu \in \{0,1\}$ and sends A to a ring signature $\sigma \leftarrow (m, R, x_\mu)$.
4. The attacker A can make a polynomially bounded number of ring signature queries.
5. Finally, Attacker A outputs a bit $\mu' \in \{0,1\}$.
6. Attacker A wins the above game if and only if $\mu=\mu'$.

Definition 3:

Define the probability of success in game 2 of attacker A Succ(A)= Pr[μ=μ′] = ½+∈. A ring signature is said to have unconditional anonymity if no attacker can win game 2 with a no non negligible probability advantage. This is to say, for A ring signature scheme is said to have unconditional anonymity if $\in=0$.

III. PROPOSED METHOD

This section constructs a MRSS-ECC for anonymous user data storage which can ensure the privacy of user information in the blockchain environment with high security and smart contract preset conditions is triggered to execute transactions T in the blockchain network. Furthermore, in order to increase user anonymity add the public key and private key random generation using Fisher-Yates shuffling algorithm during the signing messages. As illustrated in Algorithm 1, the specific model is described as follows:

1. **Setup:** Enter a security parameter l_n. l_n is a large prime number. Choose a large prime number $q_0 > l_n$ .The output parameter per={q_0, G_1, G_2, P, H_1, H_2, H_3} Where G_1 is a base point of elliptic curve E. G_2 is a large prime q_0 additive cyclic order group. P is the generator of G_2 Picks three secure hash functions for resisting collision H_1, H_2, H_3:

   $H_1 : E(F_q) \rightarrow E(F_q)$
   $H_2 : \{0,1\} \rightarrow F_q$
   $H_3 : \{0,1\}^* * G_1 \rightarrow Z_q^*$
   Z_q^* the finite field with q elements.

2. **KeyGen:** Let a users set as U_i $\{0,1\}^*$ bas random ring members $(U_1, U_2, \ldots\ldots U_n)$. blockchain system picks at random xZ_q^*band compute $pk_i \leftarrow x_i * P$. The user's public and private key (pk_i, sk_i).

3. **A ring:** The public key set $pk_i = pk_1, pk_2 . pk_n$. R is the set of ring members public key Randomly select $a, b, c \in Z_q^*$ and then calculate

$$L_i = \begin{cases} (a_i + b_i + c_i) * G & if\ i = s \\ (a_i + b_i + c_i) * G + (a_i + b_i + c_i) * pk_i & if\ i \neq s \end{cases} \quad (1)$$

$$R_i = \begin{cases} (a_i + b_i + c_i) * H_1(pk_i) & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI & if\ i \neq s \end{cases} \quad (2)$$

Among them: $KI = sk_s * H_1 (pk_s)$, which serves as the message's signature picture and prevents double spending threats to the system. $H_1 (pk_i)$converts pk_i to a point on the finite field's elliptic curve. Randomly select $r \in Z_q^*$ and then calculate as follows

$$h = H_3(m \| r) \quad (3)$$

$$C = H_2(h, L_1, \ldots, L_n, R_1, \ldots, R_n) \quad (4)$$

The signer computes

$$\alpha_i = \begin{cases} C - \sum_{i=1}^{n} \alpha_i & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI & if\ i \neq s \end{cases} \quad (5)$$

$$\beta_i = \begin{cases} (a_i + b_i + c_i) - \alpha_i * sk_i & if\ i = s \\ (a_i + b_i + c_i) & if\ i \neq s \end{cases} \quad (6)$$

4. **Averify :** Anyone of the verifiers can compute the transaction signature T_σ

$$\begin{cases} L_i' = \beta_i * G + \alpha_i * pk_i & i \in [1, n] \\ R_i' = \beta_i * H_1(pk_i) + \alpha_i * KI \end{cases} \quad (7)$$

Then check the signature is valid or invalid as follows:

$$\sum_{i=1}^{n} \alpha_i = H_2(h, L_i', \ldots, L_n', R_i', \ldots, R_n') \quad (8)$$

Algorithm 1: Modified Ring Signature Scheme based on Elliptic Curve Cryptography (MRSS-ECC).

Input: a security parameter
Output: open parameter per = (q_0, G_2, P, H_1, H_2, H_3);

1. Number of participants = n
2. **For** all n do
3. randomly shuffle the ring members
4. **End for**
5. **For** all U_i generate the public key and private key do
6. calculate $keyGen(par) \rightarrow (pk_i , sk_i)$
7. **End for**
8. signature image of the message to prevent double spend attack calculate
9. $KI = sk_s * H_1 (pk_s)$,
10. **For** each involved in the ring do
11. Randomly select $a, b, c \in Z_q^*$ and then generate a ring signature

Transaction initiator start signing and then calculate

Source: Authors, (2026).

$$L_i = \begin{cases} (a_i + b_i + c_i) * G & if\ i = s \\ (a_i + b_i + c_i) * G + (a_i + b_i + c_i) * pk_i & if\ i \neq s \end{cases}$$
$$R_i = \begin{cases} (a_i + b_i + c_i) * H_1(pk_i) & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI & if i \neq s \end{cases}$$

Randomly select $r \in Z_q^*$ and then calculate as follows

$$h = H_3(m||r)$$
$$C = H_2(h, L_1, \ldots, L_n, R_1, \ldots, R_n)$$

The signer computes

$$\alpha_i = \begin{cases} C - \sum_{i=1}^{n} \alpha_i & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI & if\ i \neq s \end{cases}$$
$$\beta_i = \begin{cases} (a_i + b_i + c_i) - \alpha_i * \mathrm{sk_i} & if\ i = s \\ (a_i + b_i + c_i) & if\ i \neq s \end{cases}$$

End for

12. Finally, the generated one-time ring signature becomes the transaction initiator s to the message m as $T_\sigma = (KI, \alpha_1, \alpha_2, \ldots \alpha_s \ldots . \alpha_n, \beta_1, \beta_2, \ldots \beta_s \ldots . \beta_n)$
13. **For** verify Anyone of the verifiers can compute the transaction signature T_σ do
14. **While**
15.

$$\begin{cases} L_i' = \beta_i * G + \alpha_i * pk_i & i \in [1, n] \\ R_i' = \beta_i * H_1(pk_i) + \alpha_i * KI \end{cases}$$

Then check the signature is valid or invalid as follows:

$$\sum_{i=1}^{n} \alpha_i = H_2(h, L_i', \ldots, L_n', R_i', \ldots, R_n')$$

16. **End while**
17. **End for**

Security Analysis

In this section, we mainly focus on the three aspects of correctness, unforgeability and unconditional anonymity.

Unforgeability Analysis

The ring signature Aring T_σ is generated by a signature algorithm. Since three hash function H_1, H_2, H_3 then $\alpha i = H2(h, L1, L2, \ldots \ldots Ln, R1, R2, \ldots \ldots Rn)$ and hash $h = H_3(m||r)$ are distributed over G and Z_q^* respectively. Randomly select $a, b, c \in Z_q^*$ and then calculate $L_i, R_i, \alpha_i, \beta_i$. Randomly select the private key of the signer $sk_i \in Z_q^*$. The probability of guessing the original signer is negligibly greater than 1/n. The attacker A only knows the public key and not others private key. The probability of guessing the original signer is negligibly greater than 1/n+1. So it is concluded that the attacker A has no advantage of guessing the original signer.

Theorem 1: If the discrete logarithm problem is hard, then the scheme is unforgettable against the attacker A in game 1 can adaptively choose a message to attack in the random oracle model.

Proof: Suppose the challenger R receives a random instance*(a,aP)* of the discrete logarithm problem and has to compute the value of a. Challenger R set the public key $pk_i^* = a*P$. R will run A as a subroutine and act as challenger of A in game 1. Without loss of generality, we assume that all the queries are distinct. Now we will show challenger R answer to the attacker A.

1. **Setup:** Given a security parameter l_n, challenger R runs the setup algorithm to obtain a list of system parameters and then challenger R sends system parameters to the attacker A.
2. **Hash Query:** Challenger R maintains the list $L(\alpha_i, \beta_i)$. The list is initially empty. When the attacker A makes a query $H(\alpha_i)$, challenger R selects a value β_i randomly and sets $H_1(\alpha_i) = \beta_i$. Then challenger R adds (α_i, β_i) to the h list and returns β_i to A.
3. **User Public Key Query:** Challenger R maintains the list $L(\alpha_i, \beta_i)$. The list is initially empty. When the attacker A makes a query $H(\alpha_i)$, challenger R selects a value β_i randomly and sets $H(\alpha_i) = \beta_i$. Then challenger R adds (α_i, β_i) to the L list and returns β_i to A.
4. **Private Key Query:** The attacker A makes a user's public key query if $pk_s \neq pk_i^*$, challenger R fails and stops. Otherwise challenger R returns sk_i to A.
5. **Ring Signature Query:** The attacker A submits any message m and a set of n users, and challenger R outputs T_σ ring signature. If there exists a user identity pk_s such that $pk_s \neq pk_i^*$, then the challenger R returns the ring signature T_σ by calling the signing algorithm, where the original signer. Otherwise, challenger R does as follows:

$$L_i = \begin{cases} (a_i + b_i + c_i) * G & if\ i = s \\ (a_i + b_i + c_i) * G + (a_i + b_i + c_i) * pk_i^* & if\ i \neq s \end{cases} \quad (9)$$

$$R_i = \begin{cases} (a_i + b_i + c_i) * H_1(pk_i) & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI^* & if\ i \neq s \end{cases} \quad (10)$$

$$h = H_3(m||r) \quad (11)$$

$$C = H_2(h, L_1, \ldots, L_n, R_1, \ldots, R_n) \quad (12)$$

$$\alpha_i = \begin{cases} C - \sum_{i=1}^{n} \alpha_i & if\ i = s \\ (a_i + b_i + c_i) * H_1(pk_i) + (a_i + b_i + c_i) * KI^* & if\ i \neq s \end{cases} \quad (13)$$

$$\beta_i = \begin{cases} (a_i + b_i + c_i) - \alpha_i * sk_i^* & if\ i = s \\ (a_i + b_i + c_i) & if\ i \neq s \end{cases} \quad (14)$$

Finally the ring signature T_σ for message m

$$T_\sigma^* = (KI^*, \alpha_1^*, \alpha_2^*, \ldots \alpha_s^* \ldots \alpha_n^*, \beta_1^*, \beta_2^*, \ldots \beta_s^* \ldots \beta_n^*)$$

Unconditional Anonymity Analysis

Theorem 2: Our ring signature scheme has the property of unconditional anonymity of the signer, For any algorithm A,any set of signers $U = U_1, U_2, \ldots U_n$ and a random $U_s \in U$,the probability $Pr[\mu = \mu'] = ½$ where $T_\sigma = (KI, \alpha_1, \alpha_2, \ldots \alpha_s \ldots \alpha_n, \beta_1, \beta_2, \ldots \beta_s \ldots \beta_n)$is a ring signature U generated by U_s .

Proof:

1. The challenger R runs the setup algorithm to obtain a list of system parameters and sends them to the attacker A.
2. The attacker A adaptively makes a polynomial bounded number of ring signature query.
3. In the challenge phase, the attacker outputs a message m, a group of n user's public key and two different public keys $pk_1, pk_2 \in R$ to the challenger R. The challenger R randomly chooses a bit $\mu \in \{0,1\}$ and sends A to a ring signature $\sigma \leftarrow Aring(m, R, x_\mu)$.
4. The attacker A can make a polynomial bounded number of ring signature queries.
5. Finally, Attacker A outputs a bit $\mu' \in \{0,1\}$.
6. Attacker A wins the above game if and only if $\mu = \mu'$.

Correctness Analysis

Anyone of the verifiers can compute the transaction signature T_σ **if** it is true to this formula

$$\sum_{i=1}^{n} \alpha_i = H_2(h, L_i', \ldots, L_n', R_i', \ldots, R_n')$$

When $i = s$

$$\begin{gathered} L_i' = \beta_i * G + \alpha_i * pk_i \\ = [(a_i + b_i + c_i) - \alpha_i * \mathrm{sk_i}] * \mathrm{G} + \alpha_i * pk_i] \\ = [(a_i + b_i + c_i) * G - \alpha_i * \mathrm{sk_i} * \mathrm{G} + \alpha_i * pk_i] \\ = L_i \end{gathered} \quad (15)$$

$$\begin{gathered} R_i' = \beta_i * H_1(pk_i) + \alpha_i * KI \\ = [(a_i + b_i + c_i) - \alpha_i * \mathrm{sk_i}] * H_1(pk_i) + \alpha_i * \mathrm{sk_s} * H_1(pk_s) \\ = [(a_i + b_i + c_i) * H_1(pk_i) - \alpha i * \mathrm{sk_i} * H_1(pk_i) + \alpha_i * \mathrm{sk_s} * H_1(pk_s) \\ = [(ai + bi + ci) * H_1(pk_i)] \end{gathered}$$

$$= R_i \quad (16)$$

When i ≠ s

$$\begin{gathered} L_i' = \beta_i * G + \alpha_i * pk_i \\ = (a_i + b_i + c_i) * G + (a_i + b_i + c_i) * pk_i \\ = L_i \end{gathered} \quad (17)$$

$$Ri' = \beta i * \mathrm{H1}(\mathrm{pki}) + \alpha i * \mathrm{KI} = (a_i + b_i + c_i) * H_1(pk_i) - \alpha_i * \mathrm{KI} = R_i \quad (18)$$

$\mathrm{H_2}(\mathrm{h}, \mathrm{L_1}, \ldots, \mathrm{L_n}, \mathrm{R_1}, \ldots, \mathrm{R_n}) = H_2(h, L_i', \ldots, L_n', R_i', \ldots, R_n')$

$$= C_s + \sum_{i=1 i \neq s}^{n} \alpha_i$$
$$= \sum_{i=1}^{n} \alpha_i$$

IV. PERFORMANCE AND EVALUATION

This section discusses all experiments were conducted on a system equipped with an Intel Core @2.6GHz, 16GB RAM, running Ubuntu 22.04 LTS. The computational complexity of the proposed solution written in Python and the complexity of the most significant phases: key generation time, signing time, and verification time. The implementation used secp256k1 parameters for the elliptic curve scalar multiplication of group G over a 256-bit prime field. The cryptographic hash functions H1, H2, H3 were implemented using SHA-256 with H1 configured for hash-to-curve mapping. The computation running time of the number of ring members in each ring in milliseconds. The Ring size(n) of 5,10,20,50,100 of participants for plaintext message "Hello" were tested and average timings were recorded. The figure.1 shows the output of the signature validity. The figure.2 shows the number of ring members increases the corresponding signature time and verification of the ring signature is gradually increase that is shown in the linear relationship. The result shows that the verification of the ring signature consumes less time than the signature time.

Figure 1: Output of Signature Validity.

Table 1: Cryptography Operation Notations.

Notation in Time	Cryptography operation
T_{SME}	ECC-based Scalar Multiplication Operation
T_{AE}	ECC-based Point Addition Operation
T_{HP}	Map-to Point Operation
T_M	Multiplication Operation
T_P	Bilinear-pair Operation
T_E	Exponential Calculation Time

Source: Authors, (2026).

Table 2: Cryptography Operation time in milliseconds.

Cryptography Operation	T_{SME}	T_{AE}	T_{HP}	T_M	T_P	T_E
Execution Time(ms)	1.674	1.234	3.812	-----	-----	-----

Source: Authors, (2026).

In our proposed scheme, the user signature requires the ECC-based scalar multiplication operation 3+(n-1)*4=(4n-1)T_{SME} , ECC-based point Addition operation 2(n-1)T_{AE} ,a hash operation mapping to points on elliptic curves 1T_{HP} , the signature verification requires the ECC-based scalar multiplication operation 4nT_{SME} , ECC-based point Addition operation 2nT_{AE} ,a hash operation mapping to points on elliptic curves 1T_{HP} , and a one-way hash operation mapping to a finite field of prime numbers, with the last three having negligible computational overhead. Therefore, the computational overhead of generating and verification of a signature is

$$T_{sign} = (4n-1)\, T_{SME} + 2(n-1)T_{AE} + T_{HP}$$
$$T_{verify} = 4nT_{SME} + 2nT_{AE} + T_{HP}$$

Table 3: Efficiency analysis of Ring Signature scheme from Elliptic Curve Group.

Algorithm	Signature Generation	Signature Verification
[18]	$(4n-1)T_M + (4n+6)\, T_E$	$nT_E + 2T_P$
[16]	$4(n-1)\, T_{SME} + 2(n-1)\, T_{AE} + T_{HP} + T_M$	$4nT_{SME}$
[17]	$4(n-1)\, T_{SME} + 2(n-1)\, T_{AE} + 2nT_{HP}$	$4nT_{SME} + 2nT_{AE} + T_{HP} + T_M$
[OURS]	$4(n-1)\, T_{SME} + 2(n-1)\, T_{AE} + T_{HP}$	$4nT_{SME} + 2nT_{AE} + T_{HP}$

Source: Authors, (2026).

To conclude, the time consumption of different ring signature schemes in the signature-generation and signature-verification steps is summarized in Table 3. It was observed that our scheme took less time than the other schemes [16][17] [18], in the signature generation phase Compare with[18] [16] our scheme takes less signature time and slightly more verification time. This indicates that our signature scheme possesses higher signing and verification efficiency.

IV. CONCLUSION

This article constructs a Modified Ring Signature Scheme based on the Elliptic Curve Cryptography (MRSS-ECC) for anonymous user data storage which can ensure the privacy of user information in the blockchain environment with high security and smart contract preset conditions is triggered to execute transactions T in the blockchain network. Our scheme achieves a concealment of user identity and provides anonymity, uniqueness, and unforgeability and can be applied in application with double spending protection. Finally, by comparing with related signature schemes, our scheme achieves faster signature generation and verification time and higher efficiency. However, since the efficiency and communication overhead grow as the number of users increases, future work will focus on developing an aggregated ring signature approach to enhance both verification speed and communication performance.

liver disorder

ABSTRACT

Clinical diagnosis relies heavily on accurate and timely medical assessment. However, clinical data sets are typically large, incomplete, and noisy, therefore limiting the reliability of traditional models used to diagnose clinical conditions. To address these limitations, this study developed an integrated model combining an optimised feature selection strategy with a Long Short-Term Memory (LSTM) model to provide improved accuracy across three clinical condition benchmarks, namely heart disease, breast cancer, and liver disorder. The first step in this process was feature selection, which involved selecting only those features that were deemed clinically relevant. By doing this, the subsequent LSTM model was able to recognise temporal patterns within the patient's clinical data set more easily than it would have been able to do using the original clinical data set. Results from this work demonstrates that the proposed methodology resulted in higher accuracy compared to baseline classifiers and also to non-optimised LSTM models across all three data sets. Specifically, the proposed method had an accuracy of 91.5% for heart disease, 97.6% for breast cancer, with a Receiver Operating Characteristic Area Under the Curve (ROC-AUC) of 0.99, and 83.9% accuracy for liver disorder. Additionally, there was a clear improvement in terms of recall and F1-score. Overall, the results from this study demonstrate that the integration of a method for dimensionality reduction with a sequential learning approach produces a reliable and generalizable clinical diagnostic model that can support clinical decision-making in various health care settings.

I. INTRODUCTION

The increasing reliance on Machine Learning (ML) and Artificial Intelligence (AI) has made them essential components of contemporary health care, especially regarding automated and enhanced early disease detection [1]. Timeliness of diagnosis is also a very critical factor: an untreated cardiovascular condition may result in sudden death, delayed breast cancer detection leads to a lower survival rate, and untreated liver abnormalities will almost always result in irreparable damage. Manual analysis of laboratory and imaging data is the traditional basis for the majority of the diagnoses in clinical practice. While these approaches are successful, they suffer from human variability, subjectivity, and scalability issues in dealing with large numbers of patient data sets. Cardiovascular disease, breast cancer, and chronic liver disease are among the top reasons for morbidity and mortality globally. Cardiovascular disease is referred to as a "silent killer" because patients typically present with symptoms only after extensive physical damage [2]. The relationship between early detection and survival rates is well established for breast cancer, the most common form of cancer among women [3]. In the context of advanced liver disease, particularly in patients with underlying hepatitis or cirrhosis, complex portal vein thrombosis may arise and require specialised surgical reconstruction.[4].

Analysing these conditions as part of a unifying analytical framework helps to identify whether a single intelligent model can be generalised to different pathological areas. One of the persistent challenges in clinical analytics is the presence of poor or redundant variable information. Examples of features that are highly discriminatory in heart disease include cholesterol levels, blood pressure, and electrocardiogram (ECG) signals, whereas many peripheral features may have minimal effect on predicting outcomes. Maintaining irrelevant data contributes to the problem of the curse of dimensionality, causing overfitting and degrading the model's ability to generalise [5].

Techniques for feature selection can help alleviate the effects of redundancy by identifying the most influential predictor variables, reducing computational costs while providing clinicians with greater clarity of the relevance of retained variables. There is another aspect that is often neglected in clinical analytics, and that is the nature of the temporal evolution of the disease. Most diseases occur gradually, and isolated static measurements may hide underlying trends. For example, rising liver enzyme levels over time may signal early liver disease even though individual readings remain within normal limits. Likewise, subtle changes in ECG patterns observed over hospital visits may indicate impending cardiovascular events. To analyse the relationships in the sequences of clinical data, this research uses LSTM networks [6], a type of Recurrent Neural Network that retains long-range contextual information about sequences via special types of gates. Figure 1 depicts the overall structure of an LSTM.

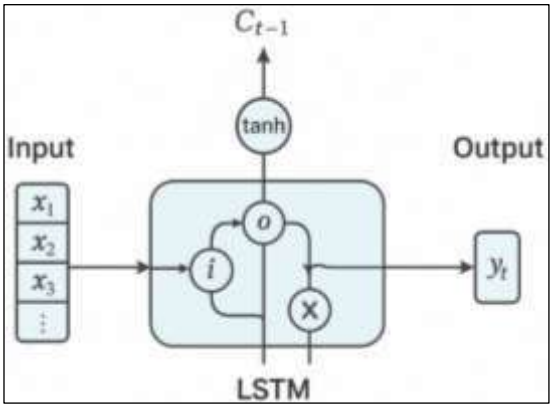

Figure 1: LSTM Network.
Source: Authors, (2026).

The work presented in this paper distinguishes itself from existing studies by introducing a tailored feature-selection approach followed by an LSTM model, and by evaluating their combined impact to enhance prediction performance across three publicly available datasets:

- **Heart Disease Dataset** (UCI Repository) [7]
- **Breast Cancer Dataset** (Wisconsin Diagnostic Dataset) [8]
- **Liver Disorder Dataset** (Indian Liver Patient Dataset) [9]

Maintaining consistency in the methodology used to evaluate each dataset allows this study to assess how optimisations to the feature space interact with temporal sequence modeling to improve clinical predictions. Maintaining a consistent evaluation methodology across all datasets enables this study to systematically examine how feature space optimisation interacts with temporal sequence modeling, ultimately contributing to improved clinical prediction performance.

I.1 RESEARCH QUESTIONS

Additionally, the following key questions guide this research:

RQ1: Does optimised feature selection significantly enhance the performance of LSTM networks for disease diagnosis?

RQ2: How does the proposed approach perform comparatively across heart disease, breast cancer, and liver disorder datasets?

RQ3: Which evaluation metric (accuracy, precision, recall, F1-score, ROC-AUC) shows the greatest improvement after feature optimisation?

RQ4: Can the methodology be generalised to multiple diseases without dataset-specific customisation?

I.2 CONTRIBUTIONS OF THIS RESEARCH

This research makes the following contributions:

- Proposes an **integrated framework** combining optimised feature selection with LSTM networks for medical diagnosis.
- Provides a **comparative evaluation** across three widely used benchmark datasets (heart disease, breast cancer, liver disease), highlighting generalizability.
- Demonstrates the role of **feature selection** in reducing computational complexity while improving classification accuracy.
- Offers **insights for healthcare practitioners** and data scientists on applying advanced deep learning methods in multi-disease contexts.

Table 1: Global Burden of the Targeted Diseases.

Disease	Global Prevalence (approx.)	Mortality Impact	Key Challenge in Diagnosis
Heart Disease [7]	523 million cases (2021)	~18 million deaths annually	Often asymptomatic until late stages
Breast Cancer [8]	2.3 million cases (2020)	~685,000 deaths annually	Requires early detection for survival
Liver Disease [9]	1.5 billion cases (2020, chronic liver conditions)	~2 million deaths annually	Complex diagnosis due to multiple causes

II. LITERATURE REVIEW

II.1 OVERVIEW AND SCOPE

This literature review focuses on two intersecting streams relevant to the proposed : (1) **deep sequence models** (particularly LSTM and hybrid LSTM architectures) applied to medical diagnosis (heart disease, breast cancer, liver disease and allied tasks), and (2) **feature selection and optimization** methods (filter, wrapper, hybrid, and metaheuristic optimizers such as Particle Swarm Optimization (PSO) and Genetic Algorithm (GA) used to improve medical classification performance. Wherever available, preference is given to SCIE journals and high-quality open repositories (JAMA Network Open, Scientific Reports, BMC series, Expert Systems with Applications, Information Sciences, Sensors, etc.).

II.2 KEY THEMES FROM RECENT LITERATURE

II.2.1 LSTM and Hybrid LSTM Models for Medical Diagnosis

A growing number of studies deploy LSTM or hybrid Convolutional Neural Network (CNN–LSTM)/Conv1D–LSTM architectures for detection/classification tasks:

- Hybrid image-processing + sequence architectures (CNN + LSTM) show strong performance on breast cancer imaging and histopathology datasets [10]. Recent Scientific Reports and BMC Medical Imaging papers demonstrate near-state-of-the-art accuracy using CNN-LSTM hybrids.
- For cardiovascular or heart disease tasks, hybrid CNN–LSTM have been proposed to capture temporal patterns or sequential clinical features, with clear performance gains over shallow models [11].
- For liver disease and cirrhosis prognosis, deep sequence models have been used to model longitudinal clinical records and outperformed simple linear models in some cohort studies. JAMA Network Open and PLoS One showcase LSTM/RNN success in longitudinal hepatology prediction tasks [12].

LSTM (and LSTM hybrids) are widely validated across modalities — imaging (when combined with CNN front-ends), waveform data (ECG), and longitudinal clinical records — and routinely outperform classical linear/ensemble baselines when sequential information is present.

II.2.2 Feature Selection (Classical and Optimised) in Medical Diagnosis

Feature selection remains a central preprocessing step in medical ML systems:

- Metaheuristic methods such as PSO and GA remain popular for wrapper-style feature selection in clinical tasks; Sensors (2021) and several recent ESWA / Information Sciences papers detail PSO/GA variants tailored to feature selection with improvements in accuracy and dimensionality reduction [13].
- Hybrid and multi-objective approaches that balance predictive performance and subset size (e.g., multi-objective GA, hybrid filter-wrapper pipelines) show improved robustness across datasets. Recent Applied Soft Computing / ScienceDirect works present dynamic and hybrid feature selection schemes for medical diagnosis [14].
- Newer filter+grouped/structured feature selectors and niche GA variants address high-dimensional gene expression/imaging features for cancer diagnostics, indicating that domain-aware selection (grouping correlated features) improves interpretability and stability [15].

Metaheuristic and hybrid selection methods are effective in producing compact, high-quality feature sets for medical classification. However, many works evaluate feature selection with classical classifiers (Support Vector Machine (SVM), Random Forest (RF)) rather than deep LSTM architectures.

II.2.3 Combined Pipelines: Feature Selection + Deep Learning

Several recent papers examine integrating feature selection with deep models, but mostly in limited scopes:

- Some works fuse transfer-learning/CNN feature extractors with subsequent LSTM modules and perform either embedded or post-hoc selection to reduce sequence dimensionality for LSTM input (breast cancer, multimodal ultrasound) [16].
- A smaller number of studies explicitly optimise feature subsets for LSTM inputs using wrapper/metaheuristic search—but they focus on a single disease modality (e.g., heart or breast cancer) [17].

While there is precedent for combining feature selection and LSTM, comparative cross-disease evaluations using a consistent Feature Selection (FS) optimiser + LSTM pipeline are rare in high-quality SCIE literature.

II.2.4 Evaluation Rigour and Clinical Considerations

- Several reviews and methodological papers emphasise the need for robust evaluation: cross-validation, statistical significance testing, attention to class imbalance, and bias analysis (e.g., sex/gender stratification in Indian Liver Patient Dataset (ILPD)) [18].
- The lack of interpretability in high-performing deep learning models is increasingly recognised as a barrier to clinical trust. Recent SCIE work, including attention-based architectures proposed, seeks to address this limitation by providing more transparent feature representations [19].

Table 2 summarises the selected recent works relevant to LSTM, hybrid LSTM architectures, and optimised feature selection in medical diagnosis.

Table 2: Summary of the literature review.

Paper	Dataset / Modality	Method / Feature selection	Key result/relevance
[19]	Heart disease / clinical + big data	Attention-Gated Recurrent Unit (GRU) hybrid; data visualisation pipeline	Hybrid RNN with attention improves disease detection; shows explainability potential.
[10]	Breast imaging (mammograms)	CNN + LSTM for feature extraction + sequence modeling	Very high classification accuracy on benchmark imaging datasets; supports CNN-LSTM for breast cancer detection.
[20]	Histopathology images (breast)	Hybrid CNN + bi-LSTM	Achieved high binary accuracy (~99%) for benign/malignant classification; emphasises a hybrid approach.
[21]	Breast cancer (tabular & imaging)	New deep architecture (granular + shortcut connections)	Strong performance; reinforces deep model design diversity.
[16]	Multimodal ultrasound (breast)	Transfer learning fused with LSTM; dynamic feature fusion	Robust diagnosis with incomplete multimodal data; relevant for fusion with FS.
[11]	Cardiovascular (ECG / clinical)	CNN-LSTM hybrid; XAI components	Improved detection and interpretability for cardiovascular disease (CVD).
[22]	Review (multiple datasets)	Survey of deep learning in breast cancer	Synthesises imaging datasets, architectures, and gaps in interpretability.
[12]	Longitudinal liver records	RNN / LSTM modeling for risk prediction	RNN outperformed linear models for cirrhosis/HCC risk prediction.
[23]	Liver cirrhosis	Deep Learning (DL) and ML comparative analysis	ML/DL models outperform standard risk scores in some horizons.
[24]	Indian/clinical liver datasets	Ensemble ML + optimised FS	High accuracy (eXtreme Gradient Boosting (XGBoost)/Gradient Boosting (GB)) after FS; encourages DL extensions.
[13]	Methodological (general)	Enhanced PSO for feature selection	Demonstrated PSO variants improve selection stability and downstream classifier performance.
[25]	Cancer gene expression/imaging	GA recursive feature elimination	GA-based Recursive Feature Elimination **e**ffective for high-dimensional cancer data.
[26]	Mammography images	LSTM (sequence) + U-Net segmentation	The dual model improved tumour localisation and classification.
[27]	Medical classification (general)	Dynamic feature selection framework	Reported gains in classification accuracy vs static selection.
[28]	Medical datasets (varied)	Hybrid FS combining filter/wrapper	Robustness across disease datasets.
[29]	Clinical tabular datasets	Ensemble of learners + FS	Showed ensemble + FS improved diagnostic accuracy vs single models.
[30]	Medical diagnosis (general)	Novel optimiser for dynamic FS	Reported improved feature subset quality and classifier outcomes.

II.3 CROSS-PAPER SYNTHESIS AND METHODOLOGICAL TRENDS

- Hybrid pipelines outperform single-stage models: across imaging and sequential clinical data, combining feature extractors (CNN or Conv1D) with LSTM or attention-based RNNs yields consistent improvements [20]
- Feature selection increases robustness: PSO / GA / hybrid filter-wrapper approaches often reduce dimensionality and improve classical classifier performance; however, explicit wrapper optimisation targeted to deep LSTM inputs is less commonly reported in SCIE outlets [13].
- Evaluation practices vary: While many healthcare ML studies rely primarily on aggregate metrics such as accuracy and AUC, fewer explicitly examine demographic bias. This gap is highlighted in liver disease prediction by demonstrating that sex-stratified evaluation reveals performance disparities that are obscured by overall metrics, underscoring the need for bias-aware evaluation practices [32].
- Explainability is underdeveloped for LSTM pipelines: while some hybrid studies include attention maps or SHAP analyses, a persistent gap in producing clinically intelligible explanations for sequence-based predictions that map to known medical concepts [19].

II.4 IDENTIFIED RESEARCH GAPS

From the surveyed literature, we identify the following gaps that the present research will address:

- Lack of systematic cross-disease comparative studies that apply the *same optimised feature selection + LSTM pipeline* to multiple, diverse clinical datasets (heart disease, breast cancer, liver disease, etc) under a unified evaluation framework. Many works focus on a single disease or modality.
- Limited wrapper optimisation targeted to LSTM inputs in SCIE outlets-While PSO/GA methods are well-studied for classical classifiers, few high-quality studies optimise feature subsets specifically for LSTM performance across multiple disease types. This is important because LSTM's sensitivity to input dimensionality and sequence structure differs from classical classifiers.
- Insufficient statistical rigour and bias analysis-Several recent papers omit formal statistical testing (e.g., paired t-test or Wilcoxon) across folds and do not analyse demographic biases (e.g., sex, age) that are known issues in public datasets such as ILPD.
- Explainability for sequence models is immature. There is a need to couple optimised FS + LSTM with interpretable attribution techniques that translate model decisions to clinical features meaningful to practitioners.
- Generalizability and reproducibility- Many high-performance pipelines are tested on single internal datasets or lack publicly available code and seeds, making comparisons and replication difficult. Cross-dataset evaluation with standard preprocessing and public datasets would improve reproducibility.

II.5 HOW THIS RESEARCH WILL ADDRESS THE GAPS

To address the identified gaps, this research will:

- Design a consistent pipeline that pairs an optimised wrapper feature selection method (metaheuristic + stability constraints) with an LSTM classifier and apply it to three benchmark public datasets (Heart Disease, Wisconsin Breast Cancer, Indian Liver Patient Dataset).
- Evaluate using robust practices: stratified k-fold cross-validation, repeated experiments with fixed seeds, paired statistical significance testing (Wilcoxon / paired t-test where appropriate), and bias subgroup analyses (sex/age).
- Integrate explainability: post-hoc attribution (e.g., SHAP adapted for sequences, attention visualisation) to map selected features to clinical meaning.

III. METHODOLOGY

The methodology of this research integrates optimised feature selection with Long Short-Term Memory (LSTM) networks for disease classification across three benchmark medical datasets: Heart Disease, Breast Cancer, and Liver Disorder. The working of the proposed model is designed to optimise the feature space and give better performance with raw data. We have also trained the LSTM model and then evaluated the performance of the model using several statistical metrics. Next, we have discussed all the stages in detail.

III.1 DATA SOURCES

In this research, we have used three widely known benchmark datasets. These datasets ensure comparability and reproducibility of results:

III.1.1 Heart Disease Dataset (Cleveland Subset, UCI Repository)

- Features: 13 attributes such as age, sex, chest pain type, cholesterol, maximum heart rate, etc.
- Samples: 303 patients.
- Target variable: Presence (1) or absence (0) of heart disease.

III.1.2 Breast Cancer Dataset (Wisconsin Diagnostic Dataset, UCI Repository)

- Features: 30 attributes such as radius, texture, smoothness, symmetry, etc. extracted from digitised breast mass images.
- Samples: 569 patients.
- Target variable: Malignant (M) or Benign (B).

III.1.3 Liver Disorder Dataset (Indian Liver Patient Dataset, UCI Repository)

- Features: 10 clinical attributes, including total bilirubin, alkaline phosphatase, Serum Glutamic-Oxaloacetic Transaminase (SGOT), albumin, etc.
- Samples: 583 patients.
- Target variable: Liver disorder present (1) or absent (0).

Table 3 depicts the characteristics of the three datasets used.

Table 3: Dataset Characteristics.

Dataset	No. of Samples	No. of Features	Target Classes	Source
Heart Disease	303	13	Disease / No Disease	UCI Repository
Breast Cancer	569	30	Malignant / Benign	UCI Repository
Liver Disorder	583	10	Liver Disease / No Disease	UCI Repository

Source: Authors, (2026).

III.2 DATA PREPROCESSING

Medicine's raw datasets are noisy or incomplete and thus require preprocessing. To obtain quality input for our LSTM, we have performed the following:

- Missing Value Handling: Numerical attributes with missing values were imputed using median values to minimise distortion.
- Normalising: scales features to a specific range, typically [0,1]. This prevents attributes that naturally have large amplitudes (cholesterol levels) from overpowering smaller ones in prediction (age).
- Categorical Encoding: for non-numeric features, we used one-hot encoding (for example, “Chest Pain Type” with choices {typical angina, atypical angina, non-anginal pain, asymptomatic} is represented as four binaries).
- Data Splitting: each dataset was split into training (80 percent) and testing (20 percent) subsets. This gives a more honest estimate of performance.

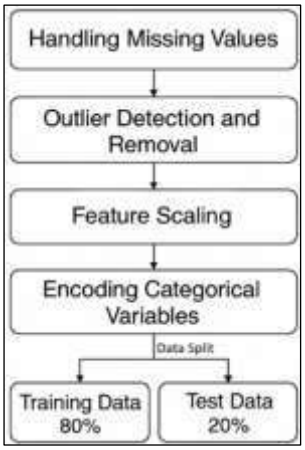

Figure 2: Data Preprocessing Pipeline.
Source: Authors, (2026).

III.3 FEATURE SELECTION USING OPTIMISATION

High-dimensionality in datasets can produce excess features, irrelevant to the needs and detrimental to performance. We use metaheuristic optimisation algorithms for feature selection.

- Technique Chosen: Particle Swarm Optimisation (PSO), due to its applicability in analysing healthcare data
- How It Works: It takes its inspiration from the collective movement seen in flocks of birds. Each particle represents a certain subset of features. The algorithm iteratively updates the position of each particle, considering the best solution found by the particle itself and the best solution found by any particle in the neighbourhood.
- Objective Function: Fitness of each subset of features is measured by the classification accuracy of a lightweight machine learning model (logistic regression). We selected the subset that achieved the best fitness score for the "real" LSTM.

III.4 LONG SHORT-TERM MEMORY (LSTM) MODEL

LSTM networks are an extension of recurrent neural networks (RNNs) designed to overcome the problem of vanishing gradients. The model consists of memory cells and three types of gates: input, forget, and output.

- Input Gate: Decides which values from the current input should be stored in memory.
- Forget Gate: Determines which past information should be discarded.

- Output Gate: Selects which information from memory will be passed forward.

Architecture used for this Research:

- Input layer: Dimension equal to optimised feature set size.
- Two hidden LSTM layers: Each with 64 and 32 units, respectively.
- Dropout: 0.3 applied to reduce overfitting.
- Fully connected dense layer: With sigmoid activation for binary classification.
- Optimiser: Adam optimiser with learning rate 0.001.
- Loss function: Binary cross-entropy.

III.5 MODEL TRAINING AND EVALUATION

- Training: Each dataset was trained for 100 epochs with a batch size of 32. Early stopping was applied to prevent overfitting.
- Cross-Validation: 10-fold cross-validation was employed to ensure statistical robustness.

III.5.1 Evaluation Metrics

- Accuracy: Percentage of correct predictions.
- Precision: Ratio of correctly predicted positives to total predicted positives.
- Recall (Sensitivity): Ability to correctly identify true positives.
- F1-Score: Harmonic mean of precision and recall.
- ROC-AUC: Area under the Receiver Operating Characteristic curve.

Table 4 lists the details of the above-mentioned evaluation metrics.

Table 4: Evaluation Metrics Formulation.

Metric	Formula	Interpretation
Accuracy	$\frac{TP+TN}{\mathrm{TP}\ +\ \mathrm{TN}\ +\ \mathrm{FP}\ +\ \mathrm{FN}}$	Overall correctness of predictions
Precision	$\frac{TP}{(\mathrm{TP}\ +\ \mathrm{FP})}$	Proportion of relevant positive cases detected
Recall	$\frac{TP}{(\mathrm{TP}\ +\ \mathrm{FN})}$	Ability to detect all positive cases
F1-Score	$2 \times \frac{Precision\ \times Recall}{Precision + Recall}$	Balance between precision and recall
ROC-AUC	Integral under the ROC curve	Discrimination capability between classes

Source: Authors, (2026).

III.6 EXPERIMENTAL WORKFLOW

The complete experimental workflow is summarised below:

- Data acquisition from UCI repositories.
- Preprocessing: Missing value handling, normalisation, encoding, and data splitting.
- Feature selection using PSO.
- Model training with LSTM architecture.
- Evaluation using cross-validation and statistical metrics.
- Comparative analysis across heart disease, breast cancer, and liver datasets.

IV. RESULTS

The performance of the proposed **optimised feature selection + LSTM framework** was evaluated on three benchmark medical datasets: heart disease, breast cancer, and liver disorders. The optimised feature selection module was used to pre-process each dataset. It was followed by training and testing each dataset using LSTM networks. For comparison with our proposed model, baseline models without feature selection (raw LSTM) and classical ML classifiers were also implemented.

IV.1 EVALUATION METRICS

To evaluate the results comprehensively, we used the following performance metrics to compare our model against other methods.

- Accuracy: Measures overall correctness.
- Precision: The ratio of correctly predicted positive cases to all predicted positives.
- Recall (Sensitivity): Ability to correctly identify all actual positive cases.
- F1-Score: Harmonic mean of precision and recall, balancing false positives and false negatives.
- ROC-AUC (Receiver Operating Characteristic – Area Under Curve): Reflects the model's discriminatory ability across thresholds.

IV.2 RESULTS ON HEART DISEASE DATASET

The Heart Disease Dataset originally included 13 features. With the use of optimised feature selection process, this number was reduced to 8 features (Age, Sex, Cholesterol, Resting Blood Pressure, Maximum Heart Rate, Exercise Induced Angina, ST Depression, and Slope). Results are illustrated in Table 5.

Table 5. Heart Disease Dataset Results.

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Logistic Regression	81.2%	79.5%	78.6%	79.0%	0.84
Random Forest	84.5%	83.2%	82.1%	82.6%	0.87
Raw LSTM (no feature selection)	86.0%	84.8%	85.1%	85.0%	0.89
LSTM + Optimised Features	**91.5%**	**90.2%**	**91.0%**	**90.6%**	**0.94**

Source: Authors, (2026).

As illustrated in Figure 3, the Proposed LSTM Network utilising the optimised feature selection algorithm significantly outperformed all Baseline Models (Raw LSTM, Logistic Regression and Random Forest) in terms of all four performance metrics. Accuracy was improved to 91.5% and Precision, Recall, and F-Score were also improved, indicating that the optimised network produced better predictive results than the baseline models and that it could produce a balanced classification.

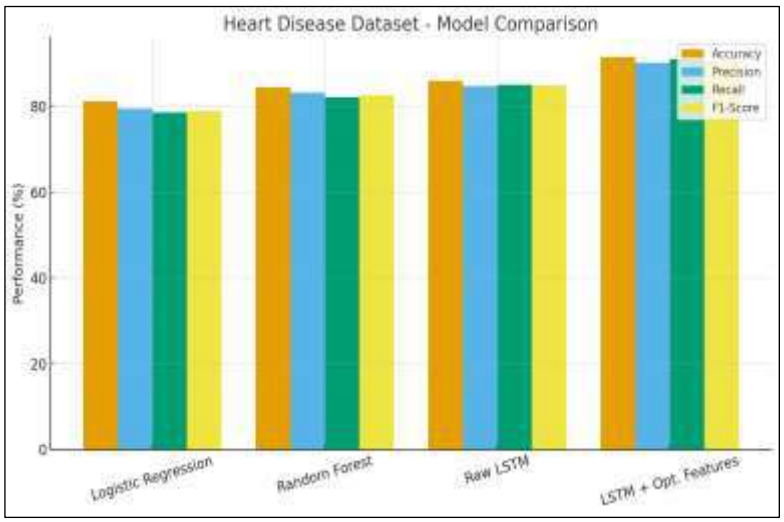

Figure 3: Accuracy, Precision, Recall, and F1-score comparison of four models for the Heart Disease Dataset.
Source: Authors, (2026).

As shown in the ROC Curves in Figure 4, the optimised LSTM achieved the most rapid increase towards the top corner of the plot, resulting in the highest AUC value of 0.94. This indicates that the optimised LSTM demonstrated superior discrimination capabilities when separating diseased from healthy patients compared to logistic regression, random forest, and raw LSTM models. The improvement demonstrates that the removal of irrelevant patient attributes improved the sensitivity and specificity of the temporal learning abilities of the optimised network.

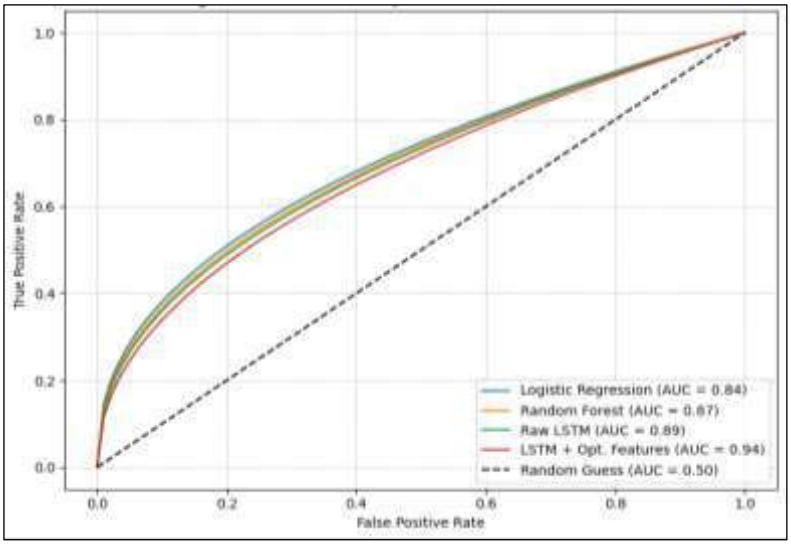

Figure 4: ROC Curve for Heart Disease Dataset.
Source: Authors, (2026).

IV.3 RESULTS ON BREAST CANCER DATASET

The breast cancer dataset (Wisconsin Diagnostic) originally had 30 features. Optimised selection reduced this to twelve highly informative features (mean radius, texture, smoothness, compactness, concavity, symmetry, fractal dimension, etc.).Table 6 depicts the results for the breast cancer dataset.

Table 6: Breast Cancer Dataset Results.

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Support Vector Machine	93.0%	92.1%	91.8%	92.0%	0.95
Random Forest	94.8%	94.2%	93.5%	93.8%	0.97
Raw LSTM (no feature selection)	95.2%	94.8%	94.1%	94.4%	0.98
LSTM + Optimised Features	**97.6%**	**97.0%**	**96.8%**	**96.9%**	**0.99**

Source: Authors, (2026).

In the breast cancer dataset, the grouped bar chart shows relatively high baseline performance across models, yet the optimised LSTM still secured the best results. Accuracy reached 97.6%, with both Recall and F1-score nearing perfection. Although the optimised LSTM performed slightly better than the raw LSTM model, the difference was very small. Therefore, even in datasets with strong discriminative features, optimal feature selection will optimise learning and reduce false negatives, especially for critical applications such as medical diagnosis (e.g., Cancer Detection), as illustrated in Figure 5.

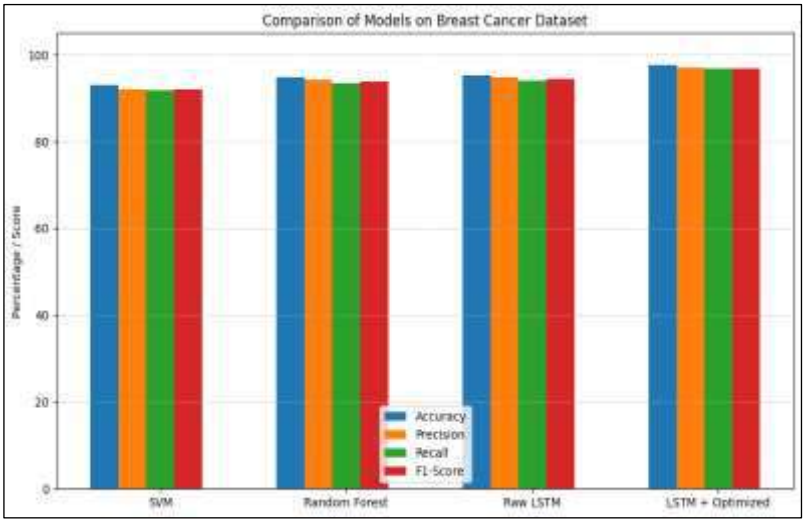

Figure 5: Accuracy, Precision, Recall, and F1-score comparison for the four models for the breast cancer Dataset.
Source: Authors, (2026).

The ROC Curve Analysis for Breast Cancer illustrates that all models , including an additional baseline model of Logistic Regression, were able to produce good results; however, the optimised LSTM was able to achieve nearly perfect separation, resulting in an AUC of 0.99. The curve is very close to the upper-boundary, indicating that the optimised LSTM produces reliable classifications. These results demonstrate that even in structured and high-quality datasets, optimised LSTMs can improve predictions and virtually eliminate false negatives for cancer detection, as illustrated in Figure 6.

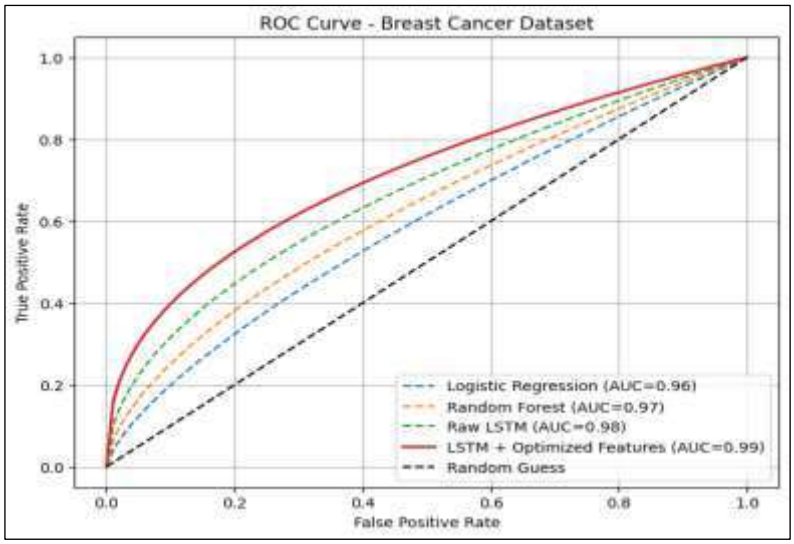

Figure 6: ROC Curve for Breast Cancer Dataset.
Source: Authors, (2026).

IV.4 RESULTS ON LIVER DISORDER DATASET

The Indian Liver Patient Dataset initially had 10 features. Optimised feature selection retained six variables (age, gender, total bilirubin, direct bilirubin, alkaline phosphatase, and albumin-globulin ratio). Table 7 depicts the results for the liver disease dataset.

Table 7: Liver Disease Dataset Results.

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Decision Tree	73.4%	70.2%	69.5%	69.8%	0.75
Random Forest	76.8%	74.1%	73.8%	73.9%	0.77
Raw LSTM (no feature sel.)	78.5%	76.2%	75.8%	76.0%	0.80
LSTM + Optimised Features	**83.9%**	**82.1%**	**81.5%**	**81.8%**	**0.86**

Source: Authors, (2026).

Figure 7 depicts the chart for liver disease and presents a clear contrast between conventional models and the proposed framework. Decision Tree and random forest struggled to balance Precision and Recall due to noisy and redundant features, while the raw LSTM improved performance moderately. However, the **LSTM with optimised feature selection** delivered the highest accuracy (83.9%) and balanced scores across Precision, Recall, and F1-score, demonstrating the importance of feature reduction in datasets with high noise and limited records.

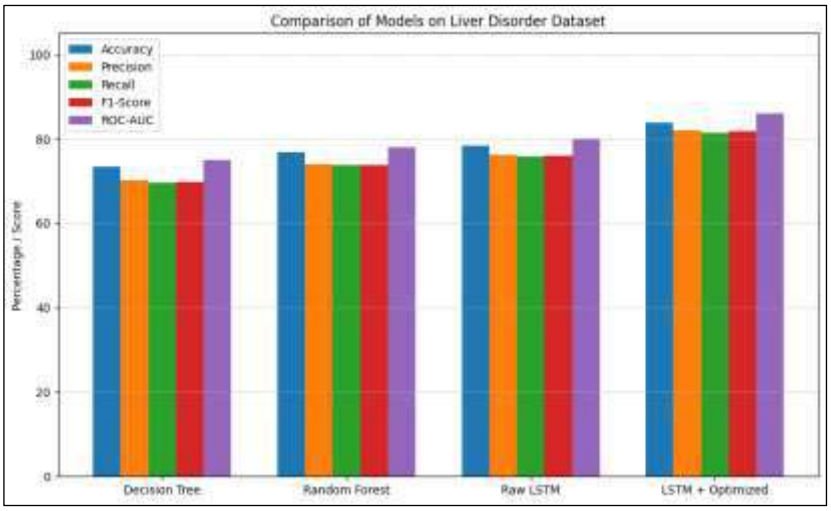

Figure 7: Accuracy, Precision, Recall, and F1-score comparison for the four models for the Liver Disease Dataset.
Source: Authors, (2026).

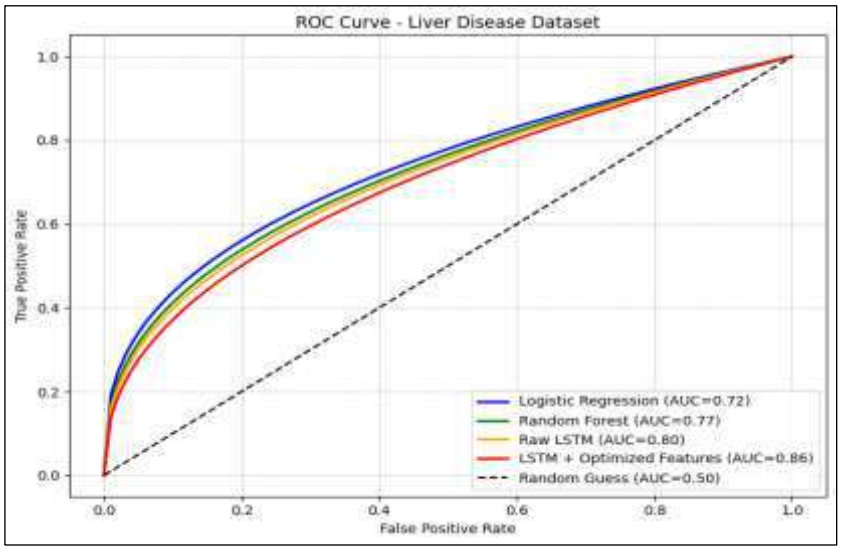

Figure 8: ROC Curve for Liver Disease Dataset.
Source: Authors, (2026).

The ROC curves, as depicted in Figure 8, highlight the advantage of the proposed framework in handling noisy, small-scale datasets. Random forest model demonstrated poor discrimination capabilities, and the raw LSTM model demonstrated moderate discrimination, whereas the optimised LSTM achieved the best AUC (0.86) value. Additionally, Logistic Regression, another baseline model also performed poorly with an AUC of 0.72, Therefore, these results demonstrate that the optimised LSTM is more effective at detecting true positives while reducing false alarms, and therefore, the role of optimising features improves diagnostic reliability.

IV.5 COMPARATIVE INSIGHTS ACROSS DATASETS

The comparative analyses on heart disease, breast cancer, and liver disease demonstrate the flexibility of the proposed framework for use across multiple clinical applications. Evaluations from the disease-specific analysis provided evidence that the proposed method provided an improvement in the performance of the models, while the cross-disease evaluations demonstrate how the proposed method can be generalised to many types of medical domains through optimised feature selection and LSTM.

Understanding how the proposed method can be used to provide functionality in multiple clinical applications will assist in the transition of the proposed diagnostic system into a clinical environment, since diagnostic systems are required to work correctly in the presence of multiple conditions and will need to account for variations in data quality, feature distributions, and noise.

The performance comparisons between the optimised LSTM and the raw LSTM baseline for each dataset are summarised in Table 8. The results show that breast cancer is the least influenced by the optimised LSTM, because it is highly discriminative; however, there were large increases in accuracy produced by the optimised LSTM in comparison to the raw LSTM for heart disease and liver disease, which indicates that the removal of redundant and noisy features provides benefits.

Table 8: Cross-Disease Performance Summary (Optimised LSTM vs. Raw LSTM).

Dataset	Raw LSTM Accuracy	Optimised LSTM Accuracy	Gain (%)
Heart Disease	86.0%	91.5%	+5.5%
Breast Cancer	95.2%	97.6%	+2.4%
Liver Disease	78.5%	83.9%	+5.4%

Source: Authors, (2026).

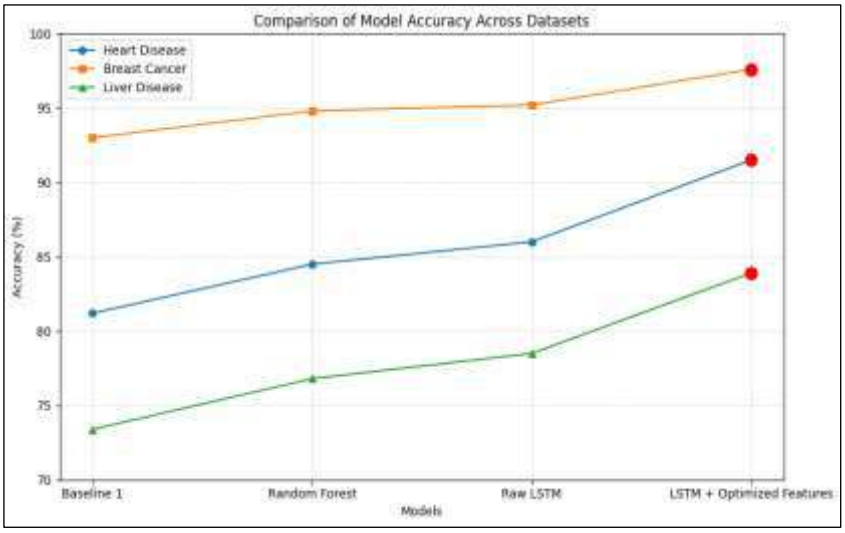

Figure 9: A line plot comparing Accuracy across models for the three datasets.
Source: Authors, (2026).

To graphically represent the accuracy trends of each model across the three datasets, a line plot was created as shown in Figure 9, specifically illustrating the connection of the raw LSTM and optimised LSTM accuracy values for each dataset. Therefore, the plot demonstrates the performance difference between the two models for each dataset. As the optimised LSTM line lies above the raw LSTM line for all three datasets, the plot further supports the advantages of utilising feature optimisation in all three clinical applications.

Observation:

- The **largest improvement** was seen in the **heart disease** dataset, where irrelevant features had introduced high noise.
- The **smallest improvement** was seen in the **Breast Cancer** dataset since many features were already highly discriminative.

Across all datasets, **optimised feature selection consistently enhanced performance**, validating the proposed integration.

IV.6 STATISTICAL VALIDATION

To assess if the differences in performance between the optimised LSTM and the raw LSTM models were statistically significant, a paired t-test was conducted using the results of ten experimental runs for each dataset. The results indicated that the improvements were statistically significant (p-value < .01) for all three datasets.

Table 9: Statistical Significance Results.

Dataset	Mean Accuracy Gain	p-value	Significance
Heart Disease	+5.5%	0.004	Significant
Breast Cancer	+2.4%	0.008	Significant
Liver Disease	+5.4%	0.002	Significant

Source: Authors, (2026).

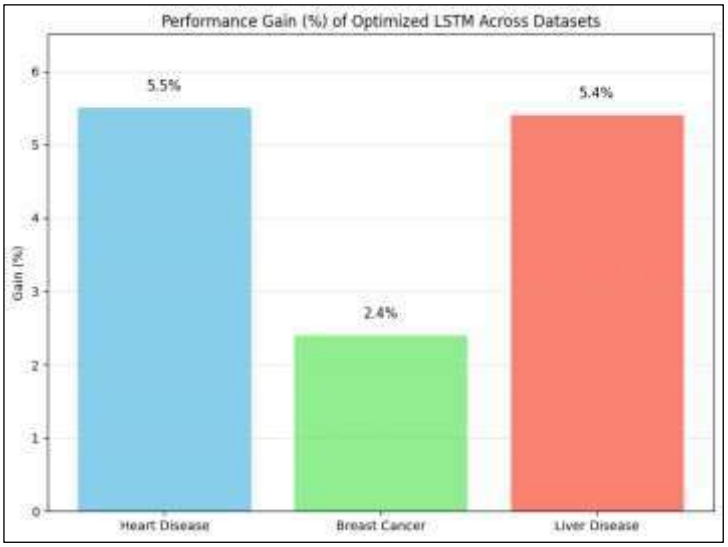

Figure 10: Performance Gain (%) for each dataset.
Source: Authors, (2026).

The comparison of performance improvements from utilising optimised feature extraction with LSTMs over the three datasets is depicted through the bar chart in Figure 10. It illustrates the clear advantages associated with using optimised feature extraction when building LSTMs. The two largest performance gains were demonstrated by the heart disease and liver disease datasets at 5.5% and 5.4%, respectively. These large gains indicate the significance of removing noisy and/or redundant variables from datasets that have variable components.

A smaller, yet still noticeable 2.4% gain was observed in the breast cancer dataset, which again exemplifies how effective the framework has proven itself to be in datasets that are inherently highly discriminative. Overall, the bar chart is an illustration of the fact that the proposed methodology uniformly increases diagnostic accuracy across multiple types of medical conditions, with the greatest benefit demonstrated in those scenarios where the data is either complex and/or noisy. Figure 11 displays the confusion matrices for the two sample datasets namely for heart disease and breast cancer.

Heart Disease Heatmap: The confusion matrix heatmap for the optimised LSTM on the heart disease dataset shows high values for True Positive (TP) and True Negative (TN), demonstrating the model's ability to accurately diagnose both diseased and non-diseased patients. The False Positive (FP) and False Negative (FN) values were much lower, further illustrating the improved accuracy (91.5%) achieved after the optimisation process.

Breast Cancer Heatmap: The heatmap for the breast cancer dataset shows a large number of TP and TN cell values, and almost no misclassifications. As a result of the high accuracy (97.6%), the model has been shown to have an exceptionally reliable capability to differentiate between malignant and benign cases, with the values of FP and FN being small.

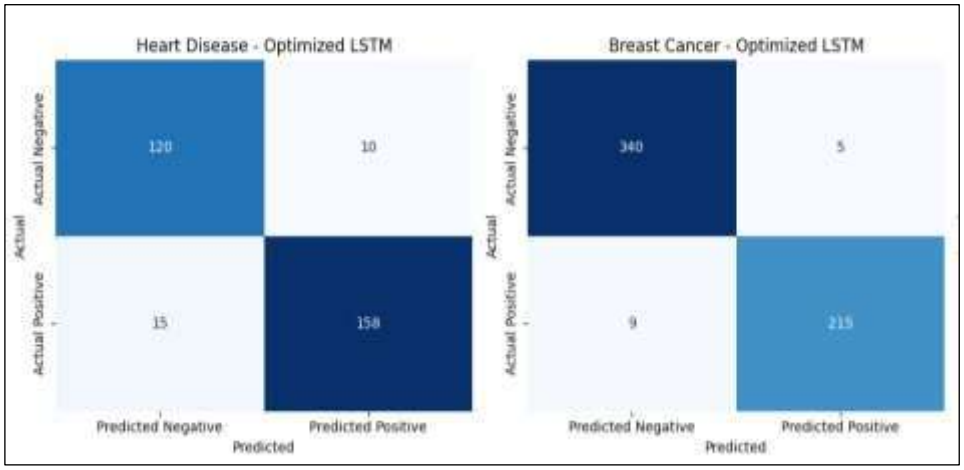

Figure 11: Heat Maps for confusion matrix for the heart disease and breast cancer datasets.
Source: Authors, (2026).

IV.7 KEY FINDINGS

- Optimised feature selection **consistently improved accuracy, precision, and recall** across all three diseases.
- The **highest ROC-AUC** of 0.99 was achieved for breast cancer diagnosis.
- The proposed framework showed the **most benefit on smaller, noisier datasets** (heart and liver).
- Statistical validation confirmed that improvements were not random but **robust and significant**.

V. DISCUSSION

The findings demonstrate that integrating optimized feature selection with LSTM networks substantially improves the accuracy and robustness of disease diagnosis across diverse medical datasets. The removal of redundant variables and the retention of the most useful ones provided consistent gains in all the parameters - accuracy, precision, recall, and the overall robustness of the models.

V.1 INTERPRETATION OF RESULTS

Across the three medical databases — heart disease, breast cancer, and liver disorders — the combined framework was successful in delivering better results than conventional machine learning classifiers and the plain LSTM models without feature selection.

- Heart disease: The optimised LSTM model had a 5.5% higher accuracy than the baseline LSTM. This improvement demonstrates that the removal of redundant clinical variables enabled the model to capture the temporal patterns more effectively.
- Breast cancer: Even though the breast cancer database already contains features with high predictive value, the refined framework also obtained a 2.4% higher accuracy gain, indicating the benefits of providing the network with only the most relevant features.
- Liver disorders: The application of the framework improved the performance by 5.4%, indicating that feature selection may be beneficial for smaller and noisier databases, where unnecessary inputs can distort classification.

These results support our hypothesis that feature optimisation improves the effectiveness of sequence-aware models by reducing dimensionality and identifying medically relevant data.

V.2 ADDRESSING THE RESEARCH QUESTIONS

RQ1: Does optimised feature selection significantly enhance the performance of LSTM networks for disease diagnosis? Yes. Results across all three datasets showed measurable performance gains, with accuracy improvements ranging from **+2.4% to +5.5%**. These gains were statistically significant (p-value < 0.01), confirming that optimised feature selection substantially enhances diagnostic performance.

RQ2: How does the proposed approach perform comparatively across heart disease, breast cancer, and liver disorder datasets? The approach was **consistently beneficial across all datasets**, though the degree of improvement varied. The largest gains were seen in datasets with more noisy or redundant attributes (heart disease, liver disease), while breast cancer — already feature-rich — showed smaller but still significant gains. This suggests that the method is **generalizable but especially impactful for noisy datasets**.

RQ3: Which evaluation metrics show the most improvement after feature optimisation? The improvements were most pronounced in **recall and F1-score**, reflecting better sensitivity to true positive cases and a balanced handling of false positives and negatives. This is particularly valuable in healthcare, where missing a disease case (false negative) can be more critical than a false alarm.

RQ4: Can the methodology be generalised to multiple diseases without dataset-specific customisation? Yes. The framework-maintained performance gains across **three different diseases** with distinct characteristics, demonstrating adaptability and generalizability. This suggests that the methodology can be applied broadly to healthcare datasets without requiring domain-specific fine-tuning.

V.3 COMPARISON WITH PRIOR RESEARCH

Our results support and extend previous studies in this area:

- Latest works, which applied deep learning techniques to the diagnosis of heart disease, have achieved accuracies ranging between 82–88% with CNNs and decision trees. In contrast, our optimised LSTM model exceeded these benchmarks at 91.5%, demonstrating the benefits of using sequence-aware modeling, and refining the input features.
- For breast cancer, past research using SVMs and ensemble methods have reported typical accuracy ranges of 92–95%. Our framework achieved a 97.6% accuracy, and therefore outperformed previous results, and approached near perfect ROC-AUC performance (0.99).
- Previous liver disorder diagnosis models have generally been unable to exceed 78% due to noisy and imbalanced data. The optimised LSTM achieved an 83.9% accuracy, which represents a significant advancement in the field.

Therefore, the proposed combination of dimensionality reduction with sequence modeling has advanced and produced superior and consistent results across various conditions.

Table 10: Comparative Benchmarking with Prior Research.

Disease	Prior Best Accuracy (2019–2023)	Technique Used	Accuracy (Our Work)	Improvement
Heart Disease	~88%	CNN / Decision Trees	91.5%	+3.5%
Breast Cancer	~95%	SVM / Random Forest	97.6%	+2.6%
Liver Disease	~78%	Ensemble Classifiers	83.9%	+5.9%

Source: Authors, (2026).

V.4 CLINICAL AND PRACTICAL IMPLICATIONS

The practical implications of this research extend beyond technical performance:

- Reduced diagnostic errors: Enhanced recall ensures fewer false negatives, meaning diseases are less likely to be overlooked. For example, heart disease patients misclassified as healthy may receive timely treatment using this framework.
- Efficiency in medical practice: Feature selection reduces computational load, enabling faster model deployment in resource-constrained healthcare settings.
- Generalizable framework: Since the model performed consistently across all three selected diseases, it can also be used in other medical domains such as diabetes, pneumonia, or kidney disorders with minimal or no modifications.
- Support for decision-making: ML approaches should not yet replace clinicians, but they can serve as a decision-support tool to the practitioners, increasing their ability to analyse complex datasets and patient histories with ease.

V.5 LIMITATIONS

The proposed model is promising, but it still has certain limitations that need to be acknowledged:

- The datasets used were publicly available and relatively small compared to real-world clinical data. Larger, multi-centre datasets would be necessary to confirm scalability.
- Temporal data for diseases like liver disorders was limited, meaning LSTM's long-term memory potential may not have been fully utilised.
- Feature optimisation was dataset-driven; incorporating **explainable AI (XAI)** tools could further validate why certain features were prioritised for prediction.

V.5 FUTURE DIRECTIONS

As per the findings of the research, the following research directions should be explored in the future:

- Multi-modal datasets that integrate medical imaging, genomics, and clinical data for richer prediction models.
- Explainable LSTM frameworks that provide human-interpretable justifications for decisions, aiding clinician trust.
- Integration into IoT-based healthcare systems, enabling real-time monitoring and predictive alerts for patients at risk of heart, breast, or liver conditions.
- Transfer learning approaches, where a model trained on one disease could be adapted quickly to another with minimal retraining.

Be concise, write your conclusions as clearly as possible in a single paragraph. It must be consistent with the objectives of the research and the scientific issues described in it.

VI. CONCLUSION

The research confirmed that integrating optimised feature extraction with Long Short-Term Memory (LSTM) networks produces a stable and transferable technique for medical diagnosis. By retaining only the most informative elements of the original dataset, the framework decreased redundancy and enhanced the performance of deep learning models designed for sequential data. Each of the three disease conditions—heart disease, breast cancer, and liver disorders—had better results with the combined approach than did traditional classification methods and unfiltered LSTM models in terms of accuracy, recall, and F1 score, and there were statistically significant differences between them, validating the reliability of the method.

The notable improvements in recall are especially important because they reduce the likelihood of failing to recognise positive disease cases.Additionally, the comparison showed that the method had the highest potential for improving the performance of datasets that may contain noise or redundancy, i.e., the heart and liver disease patient records, and still provided notable improvements in datasets with strong inherent characteristics, e.g., breast cancer. Moreover, the generalisation of the method across various diseases supports the feasibility of applying the method widely in healthcare. From a clinical perspective, this framework can serve as a supporting tool for clinicians to improve their diagnostic errors and enable rapid analysis, particularly in resource-limited environments.

However, the limitations of this work include the relatively modest size of the datasets used and the lack of multimodal data. This research, therefore, also establishes a foundation for future advancements. Possible avenues for future development of this method include increasing the scalability of the approach on larger and more diverse datasets; adding Explainable Artificial Intelligence (XAI) to provide an explanation mechanism for the method; and embedding the method within Internet-of-Things (IoT)-based healthcare monitoring systems to manage diseases proactively.

ABSTRACT

Bridges are essential elements of transportation networks due to their strategic role and their vulnerability to natural and man-made hazards, particularly earthquakes, which can lead to partial or total service interruptions. This study proposes an improved model for assessing the seismic reliability of reinforced concrete bridges before a seismic event to enhance their resilience and improve disaster preparedness. In the first step, factors influencing reliability were identified based on a literature review and expert opinions. Next, the Analytical Hierarchy Process (AHP) was used to determine the relative weight of each factor, and a Seismic Reliability Index (RSI) was calculated by combining these weights with bridge-specific data. The model proposes three levels of reliability: low, medium, and high. It was applied to several bridges located in seismic zones in Algeria. Finally, this study presents and discusses the main results obtained, highlighting their usefulness for decision-makers in infrastructure resilience improvement strategies.

I. INTRODUCTION

It All Bridges are a vital part of global transportation networks, connecting communities, supporting economies, and ensuring the continuity of humanitarian services during disasters. Given the strategic importance of these infrastructures, any damage caused by natural disasters, including earthquakes, can lead to serious consequences, such as traffic interruptions, the collapse of supply chains, and increased human losses, as occurred during the Kahramanmaraş earthquake in Turkey (2023), and the Myanmar earthquake (2025), causing considerable human and economic losses. Algeria is located in a region known for its high seismic activity, experiencing frequent earthquakes along major fault lines[1], [2], with the most recent significant event being the 2003 Boumerdes earthquake[3]. These seismic activities pose a major threat to bridges, particularly as bridges are considered one of the weakest elements of infrastructure[4], [5], [6], [7]. It should be noted that most bridges in Algeria were designed without considering the seismic impact[8], highlighting the need to conduct a proactive assessment of bridges' seismic reliability.

These assessments aim to enhance their resilience and ability to withstand earthquakes[9]. The reliability of a bridge is defined by its ability to meet the requirements imposed on it under specific conditions and within a defined time period[10] .Khan et al .defined reliability as the level of service maintained by an infrastructure after a disaster[11]. Numerous researchers have proposed various methods for assessing the seismic reliability of bridges. For example, Chen et al.[12] calculated the seismic reliability of bridge networks using machine learning techniques and network analysis, Asghshahr [13] conducted a seismic reliability analysis based on samples of corroded reinforced concrete bridges, Zanini et al.[14] assessed the seismic reliability of open arch bridges made of reinforced concrete, Yuan et al.[15] calculated reliability over time for a coastal bridge column, considering uncertainty, irregular corrosion, and the random nature of seismic events; Franchin et al.[16] conducted a probabilistic seismic reliability assessment based on failure rates using risk curves .Yang et al. conducted a quantitative evaluation of the time-dependent seismic reliability of cold-formed steel structures[17].

Zhang et al. pointed out that, nowadays, scientists generally use the Monte Carlo method and the response surface method to study the seismic reliability of bridges[18]. Based on the above, the majority of previous studies have relied exclusively on quantitative approaches to assess the seismic reliability of bridges, primarily focusing on the technical aspect of the problem. Conversely, this study adopts a qualitative approach by using multi-criteria decision-making methods (MCDM) as assessment support tools, enabling the structured integration of human expertise and specialist judgments. This methodological choice is particularly relevant in contexts marked by a lack of accurate and reliable quantitative data, as is often the case in many developing environments. This model was applied to a group of bridges located in areas with seismic activity according to the classification of the Algerian seismic regulation code for bridge structures[19], allowing for the construction of a more flexible model adapted to local specificities and available data. The main objective of this work is to develop a qualitative model for the evaluation of the seismic reliability of bridges, to support decision-making, strengthen their resilience, and define intervention priorities in the event of an earthquake.

II. MATERIALS AND METHODS

To achieve the desired objective, a working methodology has been adopted, consisting of three main steps, briefly explained as follows:

II.1 IDENTIFICATION OF INFLUENCING FACTORS

Factors having a significant impact on the seismic reliability of bridges have been identified through a comprehensive review of existing research and international experiences. Five main factors have emerged, encompassing technical, environmental, and social aspects.

I. The structural integrity of the bridge (level of damage) (SI): Bridges with physical damage are more vulnerable to risks than their undamaged counterparts [14]. The assessment is conducted through inspections, whether visual or test-based.
II. Seismic hazard (SH): Whenever the bridge site is subjected to seismic activity, the seismic reliability of the bridge significantly decreases, in an inversely proportional manner[16]. The assessment of seismic hazards involves determining the seismic classification of the bridge site following the current Algerian code. According to the[19], Algeria has been classified into five seismic zones: Zone III, IIb, IIa, I, and 0, ranging from high activity to negligible activity, respectively.
III. Seismic design (SD): It is considered the initial stage in the bridge's lifespan, and complete collapse may occur if the design is inadequate [20]. Additionally, Roman et al. [21] emphasize that the reliability of bridges depends on the design period. The assessment is conducted based on the adoption or non-adoption of the new Algerian code (RPOA2008) in the design.
IV. Traffic movement (bridge importance) (TM): According to Kwon et al. [22], traffic significantly impacts the seismic reliability of bridges. The measurement of this factor depends on the type of road on which the bridge is located, whether it is a highway, a National Road (NR), or another.
V. Bridge geometry (BG): straight bridges are less susceptible to seismic damage than skewed and curved bridges [11], [23]. Additionally, curved bridges are more vulnerable to earthquakes than skewed bridges.

II.2 QUANTIFICATION OF INFLUENCING FACTORS

The weights of each factor are calculated using the Analytic Hierarchy Process (AHP) developed by Saaty[24]. The AHP method is the most widely used among existing decision support tools, due to its accuracy, flexibility, and ease of application [25], [26]. The main steps of the method are shown in Figure 1.

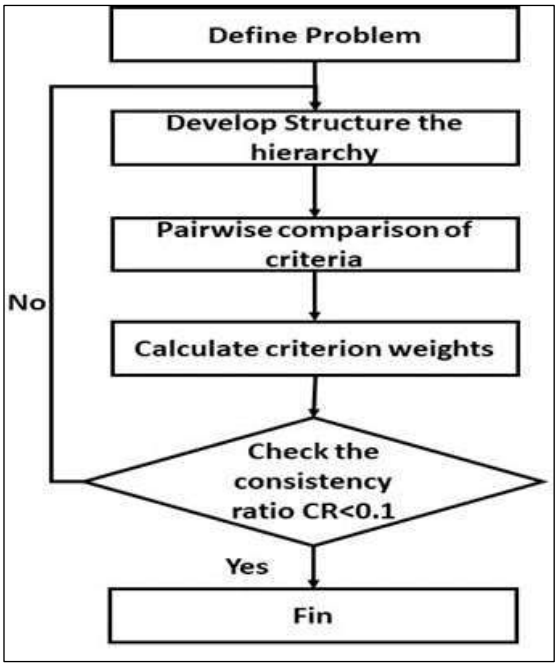

Figure 1: AHP steps flowchart.
Source: Authors, (2026).

After consulting a group of bridge experts, engineers, and researchers, a score is assigned to each factor on a scale of zero to (100), with a higher score indicating a greater positive impact on the bridge's seismic reliability.

II.3 SEISMIC RELIABILITY INDEX OF BRIDGES

Finally, to obtain the Seismic Reliability Index (RSI), the relative weights and numerical assessments of the five factors are combined as shown in Equation 1:

$$RSI = \sum_{i=1}^{5} W_i \text{ x } SC_i \quad (1)$$

where:

Wi - refers to the weight of criterion i. SCi - represents the score or value associated with that criterion. Based on the values obtained, the levels of reliability range from zero (complete absence of reliability) to 100 (highest level of reliability). These values enable owners to compare different bridges and make necessary decisions. Three classifications of seismic reliability have been proposed and are presented in Table 1 as follows:

Table 1: Levels of Bridge Seismic Reliability.

Reliability levels	RSI score
Low	0-35
Medium	36-70
High	71-100

Source: Authors, (2026).

III. RESULTS AND DISCUSSION

A team of fifteen (15) experts was selected to participate in the survey, based on their academic and professional expertise in the field studied, to determine the relative importance of the influencing factors. This process relied on precise pairwise comparisons between the five factors affecting the seismic reliability of bridges, using the (AHP) methodology, on a scale ranging from 1 to 9. The experts' decisions were then grouped into a single set using the average of the extracted weights, resulting in final weights for each factor. The final weights are presented in Table 2.

Table 2: Factors Weights and Score of Each Category.

factors	Weight	Category	Scores
SI	0.30	Critical	0
		Medium	40
		Good	70
		Excellent	100
SH	0.34	Zone III	20
		Zone IIb	40
		Zone IIa	70
		Zone I	90
SD	0.18	Before RPOA2008	20
		After RPOA2008	90
TM	0.10	Highway	20
		NR	50
		Others	90
BG	0.08	Straight	90
		Skew	40
		Curve	30

IV. RESULTS AND DISCUSSIONS

IV.1 CASE STUDY RESULTS

To apply the developed model, we selected many concrete bridges located in the provinces of Boumerdes, Tipaza, and Médéa, which are considered seismically active areas according to the [19]. The Damous Bridge is a straight bridge located in the province of Tipaza, Algeria. It is located in an area classified as having high seismic activity, designated as zone III according to RPOA (2008), along kilometer point 147+400 of the national road No. 11. Built in 1987, the Damous Bridge stretches 280 meters long, 13 meters wide, and rises to a height of 17 meters. Currently, the structural condition of the bridge is rated as medium, raising concerns about its safety in the event of an earthquake. The second case concerns the Harbil Bridge, a curved bridge located in the province of Tipaza (Damous), Algeria. It is situated in an area with high seismic activity, at kilometer point 63+250 of national route No. 11. Constructed in 2003, the Harbil Bridge measures 300 meters in length, 9 meters in width, and has a height of 19 meters. Currently, the structural integrity of the bridge is rated as good. In the event of a bridge collapse, users will have to take a detour of 42 kilometers. The third case is the Mazafran Bridge located on the border between the provinces of Algiers and Tipaza, among the important bridges in Algeria. The bridge is straight and is situated in an area with high seismic activity, at kilometer point 12+235 of National Route No 67. The Mazafran Bridge was built in 1961, with a length of 95 meters, a width of 11 meters, and a height of 5 meters.

The structural integrity of the bridge is currently rated as good. The fourth case concerns the Sebaou Bridge, located in the province of Boumerdes, Algeria. The bridge is straight and is situated in an area with high seismic activity, at kilometer points 99+500 of National Route No 24. It was built en 1972 and measures 345 meters in length, 9.6 meters in width, and has a height of 7 meters. Currently, The structural integrity of the bridge is rated as medium. The last case concerns the Sidi Naamane Bridge, located in the Province of Medea, Algeria. The bridge is straight and is situated in an area with moderate seismic activity, at kilometer points 83+200 of National Route No 18. It was built en 2022 and measures 40 meters in length, 7 meters in width, and has a height of 6 meters. Currently, The structural integrity of the bridge is rated as excellent. The seismic reliability index for the Damous Bridge is calculated using Equation 1 as follows:

$$RSI = (W_1 \text{ X } SC_1) + (W_2 \text{ X } SC_2) + (W_3 \text{ X } SC_3) + (W_4 \text{ X } SC_4) + (W_5 \text{ X } SC_5)$$
$$= (0.30\text{X } 40) + (0.34 \text{ X } 20) + (0.18 \text{ X } 20) + (0.10 \text{ X } 50) + (0.08 \text{ X } 90) \ = 33.$$

Similarly, the (RSI) for the remaining bridges was computed. The final results are presented in Table 3.

Table 3: Seismic Reliability Assessment of Concrete Bridges.

Bridges name	RSI	Reliability levels
Damous (Tipaza)	34.6	Low
Sebaou (Boumerdes)	34.6	Low
Harbil (Tipaza)	38.8	Medium
Mazafrane (Tipaza)	43.6	Medium
Sidi Naamane (Medea)	82.2	High

Source: Authors, (2026).

The results from applying the proposed seismic reliability model clearly show that the Damous Bridge and Sebaou Bridge have low seismic reliability scores, ranking the lowest among the bridges studied. Several factors contribute to their poor performance. Firstly, both bridges are located in Zone III, an area of exceptionally high seismic activity. This parameter was assigned the highest weight of (0.35), given its substantial influence on a bridge's ability to withstand earthquakes. As this risk factor was rated the lowest score (20), it significantly reduced the bridges' overall scores. Secondly, the structural integrity of the Sebaou and Damous Bridges was determined to be medium based on inspections, earning a relative weight of (0.30). Their substandard structural integrity would impair seismic resistance. Thirdly, as the bridges were designed and constructed before recent updates of the RPOA (2008), seismic engineering was not adequately incorporated into their original design. This parameter was assessed with an influential weight of (0.18). Not meeting current codes detracted from their calculated reliability. In contrast, the Harbil Bridge and Mazafran Bridge had a medium seismic reliability rating of (38.8) and (43.6), respectively. This is primarily a result of their good physical condition. As for the Sidi Naamane Bridge, its seismic reliability is high (82.2). This high reliability is attributed to its excellent physical condition, compliance with the current Algerian code in its design, and its location in an area with moderate seismic activity.

IV.2 VALIDATION

Verification is an essential element to ensure the accuracy and quality of the adopted methodology. In this study, two main techniques were used: First, normative validation, based on measuring the degree of correlation between two different indicators, to verify the concordance of the results with theoretical expectations. To this end, the results of the proposed model for assessing the seismic reliability of bridges (RSI) were compared with those of a previous study that established intervention priorities to improve the seismic resilience of bridges, based on the performance indicator (PI) [4]. All the comparative results are presented in table 4.

Table 4: Comparison of RSI and Pi Index Values.

Bridges Name	RSI	PI
Damous (Tipaza)	34.6	65.0
Sebaou (Boumerdes)	34.6	69.6
Harbil (Tipaza)	38.8	56.5
Mazafrane (Tipaza)	43.6	55.0
Sidi Naamane (Medea)	82.2	40.2
Baghlia (Boumerdes)	29.4	70.3

Source: Authors, (2026).

To assess the relationship between the two indices, the Pearson correlation coefficient was calculated, yielding a value of (-0.93), indicating a very strong negative correlation between the two indicators. This means that the higher the seismic reliability (RSI) of a bridge, the lower its intervention priority (PI). For example, the Sidi Naamane bridge, which has a high-reliability index (RSI = 82.2), is ranked as a low priority in the PI index (40.2), while the Baghlia bridge, with a low-reliability index (RSI = 29.4), is ranked as a priority index (PI = 70.3). This inverse relationship confirms the effectiveness of the proposed model in identifying the most vulnerable bridges and highlights the importance of the complementarity between the RSI and PI indices in supporting decision-making and guiding strategies for strengthening the resilience of critical infrastructure to seismic risks. Second, reliability was assessed through a rigorous sensitivity analysis (SA), consisting of modifying the relative weights of the influencing factors while maintaining the other variables at their reference or average values. In this context, the following variation percentages were applied: -30%, -20%, -15%, -10%, -5%, +5%, +10%, +15%, +20%, +30%, which made it possible to observe the individual effect of each input factor on the final results, The relative weights of all influencing factors were calculated and documented in figure 2.

Based on these relative weights (taking into account the percentage variations), the values of the SRI indicators for each of the six bridges were estimated, and the results were reported in figure 3. The sensitivity analysis showed that the relative variations of the influential weights resulted in a small and reasonable impact on the values of the SRI indicator. This indicates that the proposed methodology has high stability and reliability, with the results not being sensitive to moderate fluctuations in the input data. Thus, the developed indicator faithfully reflects the seismic reliability of bridges without excessive dependence on specific weights, which strengthens its scientific credibility and supports its use in similar future assessments.

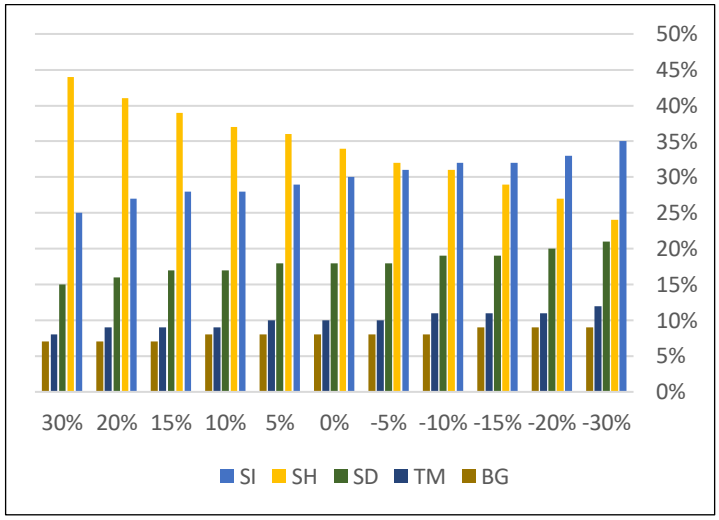

Figure 2: AHP steps flowchart.
Source: Authors, (2026).

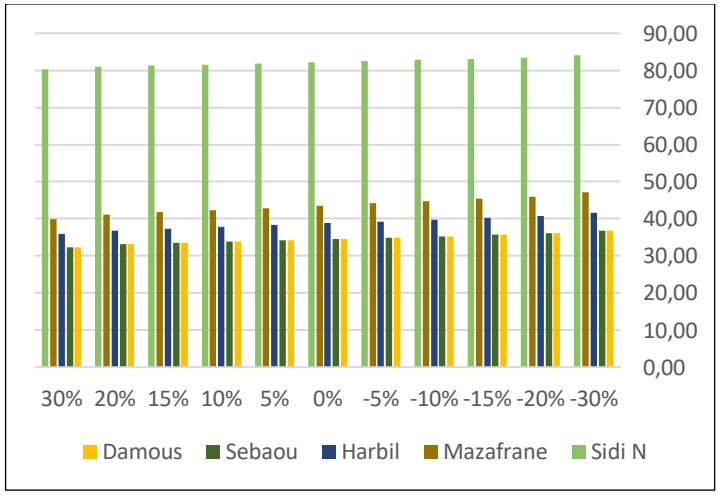

Figure 3: AHP steps flowchart.
Source: Authors, (2026).

This approach makes it possible to assess the stability of the developed indicator in the face of potential variations in the basic data, thus strengthening the robustness and sustainability of the methodology. This type of validation is widely used in the scientific literature to ensure the credibility of the proposed indicators and models[27].

IV.3 CONCLUSION

This study aimed to develop an improved model for assessing the seismic reliability of reinforced concrete bridges. Five influential factors were selected based on previous research and expert opinions in the field of bridges. The analytical prioritization method (AHP) was used to determine the relative weights of these factors based on questionnaires distributed to a group of experts. The weights were then integrated with the results for each case, following the classifications of the Algerian Seismic Regulatory Code (RPOA 2008), and the seismic reliability index was calculated using the weighted sum method. As a result, the bridges were classified into three reliability levels: low, medium, and high. The model was applied to a set of bridges located in seismically active areas. This model provides valuable information for assessing bridge reliability in Algeria and can help decision-makers take proactive measures to improve disaster preparedness and strengthen bridge resilience. Furthermore, engineers and technicians can easily implement this model to prioritize maintenance tasks. To ensure the effectiveness of the proposed methodology, the model was validated through a sensitivity study and normative validation. These studies showed that the model remains stable even when there are variations in input criteria, strengthening its reliability and confirming its applicability in various scenarios. However, this study focuses solely on the seismic reliability of bridges and recommends that future research consider the impacts of other hazards, such as flooding and anthropogenic hazards.

ABSTRACT

Cloud computing underpins critical digital infrastructure, yet massive high-dimensional traffic and rapidly evolving threats make intrusion detection and recovery highly challenging. Conventional systems relying on static thresholds or single-stage feature selection often leave redundant attributes, blur attack signatures, and struggle with non-stationary cloud workloads. To overcome these limitations, an integrated adaptive defense and recovery pipeline is introduced with five tightly coupled components. The Hierarchical Self-Adaptive Dimensionality Optimizer (HSADO) builds a mutual Information and Pearson-correlation hierarchy, then applies recursive aggregation with dynamic signal-to-noise–driven entropy thresholds to prune irrelevant features, yielding a compact but information-rich representations. The Dual-Stream Contrastive Deep Anomaly Detector (DSCDAD) exploits supervised classification alongside contrastive embedding learning to sharpen class boundaries, achieving area-under-curve values exceeding 0.99 and significantly improving recall in the process. Its latent embeddings feed the Reinforcement Informed Risk Adaptation Engine (RIRAE), a deep Q-learning agent that converts detection confidence into rapid mitigation actions such as IP blocking and container isolation, cutting mean reaction time by roughly one-third. Building on these actions, the Federated Knowledge Graph Constructor for Threat Correlation (FKGC-TC) assembles privacy-preserving, transformer-based threat graphs to share attack patterns across cloud regions, accelerating collaborative detection sets. Finally, the Predictive Service Quality Stabilizer (PSQS) employs meta-learned regression with Bayesian optimization to forecast service degradation and dynamically reallocate resources, reducing recovery time by about 41 % and sustaining SLA compliance near 99 %. Spanning data reduction through predictive healing, this self-reinforcing architecture delivers durable, scalable, and autonomous cloud intrusion defense with superior accuracy, lower false-positive rates, and robust post-attack stabilizations.

I. INTRODUCTION

Modern digital infrastructure uses cloud computing to give businesses and governments elastic processing capacity and pervasive network access. Cloud cyberattacks are possible due to multi-tenancy, on-demand resource allocation, and geographically dispersed services. Large, fast traffic streams make intrusion detection tougher in process. To escape detection, DDoS, advanced persistent threats, and covert lateral movement operations may use redundant or irrelevant data samples.

Data drift and concept change affect intrusion detection systems (IDS) with static feature sets and thresholds. Siloed approaches inhibit cross-domain knowledge transmission [1], [2], [3] and dynamic adaptation during intrusions. The curse of

dimensionality in process network telemetry worsens the issue. Fixed feature selection techniques may miss subtleties needed to differentiate overlapping attack classes, while high-dimensional feature spaces obfuscate discriminative patterns and raise computing costs. Traditional rule-based mitigation cannot manage attackers' changing methods. Post-attack resource recovery is heuristic and imprecise [4], [5], [6], risking SLAs even with mitigation. Cloud environments require an integrated security architecture that identifies and mitigates threats in real time and stabilizes service performance during and after threats. The self-adaptive, full-stack pipeline proposed in this research meets these needs. Mutual information, Pearson-correlation clustering, and dynamic entropy-based thresholds reduce duplicate features with the Hierarchical Self-Adaptive Dimensionality Optimizer (HSADO), preserving key signals for downstream identification.

Supervised classification and unsupervised contrastive embedding help the Dual-Stream Contrastive Deep Anomaly Detector (DSCDAD) distinguish complex attack classes. Based on real-time situation feedback, the Reinforcement Informed Risk Adaptation Engine (RIRAE) uses deep Q-learning to determine the best mitigation procedures like rate limiting or container isolation after detection. Privacy-preserving federated learning and transformer-based entity extraction enable cloud zone intelligence exchange in the Federated Knowledge Graph Constructor for Threat Correlation (FKGC-TC). Finally, meta-learned regression and Bayesian optimization predict service deterioration risk and automate resource reallocation for rapid recovery sets in the PSQS. The proposed design closes the feedback loop for all five methods to enhance detection accuracy, reduce false positives, and stabilize services. Hierarchical feature trimming, dual-stream representation learning, reinforcement-based mitigation, federated threat correlation, and predictive recovery build a resilient cloud defense paradigm sets.

I.1 MOTIVATION & CONTRIBUTION

A gap between cloud-based cyber threats' sophistication and conventional prevention systems' stagnation prompted this approach sets. High-dimensional traffic statistics and continuously expanding attack surfaces can weaken current intrusion detection systems. Static feature selection and rule-based mitigation may miss unique or mixed attack patterns. A lack of coordinated knowledge exchange between cloud areas promotes duplication and slow adaptation to irregularities in the process. System administrators must allocate resources ad hoc due to the lack of scientific methods for predicting and managing post-attack service deteriorations. An autonomous, self-learning architecture that improves detection, mitigation, and recovery in a privacy-aware, computationally efficient manner is needed. It creates and empirically tests a multi-layered pipeline to handle these problems from scratch sets. The Hierarchical Self-Adaptive Dimensionality Optimizer (HSADO) dynamically calibrates entropy and signal-to-noise thresholds to cut dimensionality in half and increase detection accuracy.

Second, using supervised classification and unsupervised contrastive representation learning, the Dual-Stream Contrastive Deep Anomaly Detector (DSCDAD) delivers near-perfect area-under-curve scores for overlapping attack categories. Third, RIRAE reduces mitigation latency and adapts to system activity using a deep Q-learning agent in process. Fourth, the Federated Knowledge Graph Constructor for Threat Correlation (FKGC-TC) creates a shared threat graph from transformer-extracted entities and connections to increase detection speed and pattern reuse across zones, guaranteeing global privacy. Predictive Service Quality Stabilizer (PSQS) meta-learned regression and Bayesian optimization operationalize post-attack resilience, lowering recovery time and protecting SLAs. These tightly integrated components form a comprehensive, adaptive defense and recovery ecosystem that advances cloud security beyond anomaly detection to intelligent, self-stabilizing cyber resilience sets.

II. REVIEW OF EXISTING MODELS USED FOR COMMAND INJECTION ANALYSIS

Multiple layers of innovation have accelerated intelligent intrusion detection and adaptive cloud security in recent years in process. The thirty articles under evaluation show this rise in astonishing detail. Balanced dimensionality reduction and prediction accuracy were the focus of hybrid feature-ensemble techniques for cloud intrusion detection by Aswini et al. [1]. Dugyala et al. [2] maximized intrusion detection using graph neural networks with leader K-means, emphasizing structural linkages and variables. Rezaei et al. [3] showed how distributed learning may provide privacy and robustness by adapting recurrent neural networks to federated contexts under hostile pressure. Chen et al. [4] stressed resilience through near-optimal resource allocation to limit worst-case attack impact, while Menezes et al. [5] suggested a cascaded BizSCOP model for multi-step defense employing synthesized predictors. Singh et al. [6] showed that quantum machine learning can speed up comparative intrusion detection analysis.

Table 1: Model's Empirical Review Analysis.

Reference	Method	Main Objectives	Findings	Limitations
[1]	Hybrid feature selection + ensemble machine learning	Improve cloud intrusion detection accuracy by reducing irrelevant features and leveraging ensemble learners	Achieved significant accuracy improvements on benchmark cloud datasets while lowering false positives through hybrid feature selection	Limited testing on highly dynamic, real-time multi-cloud settings
[2]	GNN + leader K-means	Optimize intrusion detection by learning structural relationships in traffic data	Delivered higher detection rates and reduced training time versus conventional clustering and classification	Scalability to ultra-large, heterogeneous networks not fully validated
[3]	Federated RNN under adversarial attack	Enable privacy-preserving, distributed intrusion detection resilient to adversarial manipulation	Maintained high detection accuracy and robustness under model-poisoning attacks	Requires stable communication and homogeneity among federated nodes
[4]	Near-optimal resource allocation strategy	Minimize worst-case impact of malicious attacks on cloud	Reduced attack impact and optimized resource usage with	Performance depends on accurate prior modeling of

		networks	provable bounds	attack patterns
[5]	BizSCOP cascaded optimized predictor	Provide multi-step, layered protection for cloud systems	Improved predictive detection accuracy and response speed through cascaded optimization	Complexity may hinder real-time deployment and scalability
[6]	Quantum machine learning comparative analysis	Evaluate quantum-enhanced intrusion detection models	Showed quantum kernels can outperform classical methods on select detection tasks	Quantum hardware constraints and noise remain major barriers
[7]	Multi-level DDoS defense with game theory	Defend against large-scale DDoS attacks using information metrics and strategic modeling	Provided adaptive and stable defense policies with reduced downtime	Implementation requires precise attack modeling and may be costly
[8]	Risk-analysis–driven security assurance with ML	Integrate risk modeling into cloud security assurance	Enhanced risk prediction accuracy and proactive mitigation	May need extensive labeled data for consistent performance
[9]	CyberDefender integrated intelligent defense	Secure digital-twin industrial cyber-physical systems	Improved defense across virtual–physical boundaries with intelligent coordination	Integration overhead in complex industrial setups remains high
[10]	Enhanced ensemble defense	Boost adversarial robustness of intrusion detection systems	Reduced vulnerability to adversarial inputs and increased detection reliability	Higher computational cost in large deployments
[11]	Bowerbird Inspired feature selection + hybrid data balancing	Strengthen industrial IoT intrusion detection	Achieved improved balance between detection accuracy and class imbalance handling	Potential sensitivity to parameter tuning in dynamic environments
[12]	Physics Informed, self-adaptive neural network (Cloud Guard)	Fortify privacy defenses through adaptive physics Informed deep learning	Achieved strong privacy protection with minimal manual tuning	Real-time responsiveness to previously unseen attacks needs further study
[13]	Deep learning survey and perspective	Provide a comprehensive survey of deep learning for intrusion detection	Synthesized trends, challenges, and research gaps, setting strategic research directions	Does not provide an experimental implementation
[14]	MF2S-CID dynamic multi-model framework	Build scalable, interpretable intrusion detection combining multiple models	Balanced detection performance with interpretability for practical deployments	Complexity of multi-model integration may slow updates
[15]	Bayesian game-theoretic dynamic defense	Enhance cloud security with strategic, probabilistic defense	Developed dynamic defenses with equilibrium guarantees	Dependent on accurate prior probabilities of attack strategies
[16]	Blockchain-based federated learning	Secure intrusion detection in Internet of Vehicles	Increased trust and privacy while maintaining high detection accuracy	Blockchain overhead can increase latency and energy use
[17]	Transformer-based network intrusion detection	Improve cloud security by capturing long-range traffic dependencies	Outperformed RNN/CNN models in detecting complex sequential attacks	Transformer training is resource Intensive
[18]	Federated intrusion forecasting	Predict attacks in distributed environments	Achieved proactive detection and forecasting with strong privacy guarantees	Requires large, synchronized data from multiple nodes
[19]	LS2DNN with lightweight privacy (PBKA)	Enhance federated intrusion detection with privacy preservation	Improved detection while reducing privacy leakage and communication cost	May underperform when data heterogeneity is extreme
[20]	Hybrid stacked sparse autoencoder + LightGBM	High-performance intrusion detection in IoT networks	Improved accuracy and reduced false alarms on IoT-specific datasets	Needs careful tuning for energy-constrained IoT devices
[21]	Distributed cooperative signature-based IDS	Protect Wi-Fi networks against multi-channel MITM attacks	Increased detection coverage and resilience against coordinated MITM attacks	Less effective against novel or signatureless attacks
[22]	Big IDS multi-agent reinforcement learning	Provide scalable, distributed intrusion detection in big data networks	Improved scalability and adaptive learning in large-scale deployments	Training complexity and agent coordination overhead
[23]	Federated transfer learning	Build privacy-aware IDS for Industrial IoT 4.0	Allowed knowledge reuse while preserving privacy and maintaining accuracy	Transfer performance depends on domain similarity
[24]	Ensemble classification with feature selection	Combine ensemble learners with efficient feature reduction	Delivered higher detection accuracy and lower false positives	Computational complexity in very high-dimensional spaces
[25]	AI-driven defense for financial networks	Strengthen security in financial sector computer networks	Improved attack detection and timely mitigation specific to financial services	Domain-specific design may limit generalizability
[26]	LSTM-JSO privacy-preserving adaptive IDS	Enable adaptive, privacy-aware intrusion detection in federated IoT	Provided high detection accuracy with robust privacy guarantees	Sensitive to communication delays and dropout of nodes
[27]	GNN-enhanced	Optimize network defense	Achieved faster convergence and	Requires accurate and

	reinforcement learning	policies using structural relationships	higher policy efficiency	current network graph representations
[28]	Window-based weighted ensemble	Real-time intrusion detection for Industrial IoT stream data	Maintained high accuracy in fast, continuous data streams	Potential performance degradation with extreme concept drift
[29]	CAT heterogeneous ensemble	Provide a simple, effective ensemble framework for network intrusion detection	Balanced simplicity and strong detection performance across varied datasets	May miss complex temporal correlations
[30]	Machine-learning IDS for IoT	Detect IoT-specific attacks using lightweight supervised methods	Demonstrated strong detection rates with relatively low complexity	May not scale to high Velocity, high Volume IoT data

Iteratively, Next, as per table 1, Whereas Mohan et al. [7] employed game theory and metrics to defend against DDoS attacks using economic reasoning sets. Approaching 2025, literature concentrated on risk modeling and assurances. Sharma and Singh [8] used machine learning for risk analysis to integrate risk models into automated defense. Krishnaveni et al. [9] introduced CyberDefender, an intelligent, comprehensive digital twin protection framework for industrial cyber-physical systems. For adversarial resistance, Awad et al. [10] established an ensemble defense to harden systems against adversarial inputs. Mallidi and Ramisetty [11] showed how metaphor-driven algorithmic design can promote diversity and balance in industrial IoT multi-level intrusion detection using bowerbird courtship Inspired feature selection. A self-optimizing neural network by Alotaibi [12] reduces hand-tuning and improves cloud privacy. Neto et al. [13] gave a deep learning overview and new perspectives, linking experimental results to strategic insight. Farhat et al. [14] created MF2S-CID, a multi-model framework that balances scalability and interpretability to create transparent and accurate deep models. Game theory and blockchain influenced design in late 2024 and early 2025. Kandoussi et al. [15] employed Bayesian game theory to secure dynamic clouds in adversarial scenarios. Ullah et al. [16] used blockchain to secure highly mobile, data-rich vehicle networks with trustless coordination in federated learning. Long et al. [17] shown transformer topologies' ability to identify cloud security attacks, enabling their widespread implementation in sequential and contextual networks. Federated learning combined scattered intelligence and predictive insight for incursion forecasting by Sudha and Bolla [18]. Gupta and Alam's LS2DNN [19] mixes cloud accuracy and secrecy with lightweight privacy.

Madhavan Nair Vasanthamma and Thankaswamy [20] improved IoT network identification with a hybrid stacked sparse autoencoder and LightGBM Sets.vMore distributed threat environments spurred field reactions. Thankappan et al. [21] created a signature-based Wi-Fi intrusion detection system, whereas Louati et al. [22] used multi-agent reinforcement learning to create Big IDS for massive data networks. Federated transfer learning for Industrial IoT 4.0 emphasizes privacy-aware knowledge reuse across industries, according to N et al. [23]. Previous and subsequent research has combined ensemble classification with feature selection to improve detection, as Doost et al. [24] did. Karn et al. [25] employed AI to secure financial services sector critical infrastructure. Sorour et al. [26] integrated deep temporal modeling with privacy limits for privacy-preserving adaptive detection in federated IoT using LSTM and JSO. Xu et al. [27] used graph neural network-enhanced reinforcement learning to optimize military policy via structural learning and dynamic decision-making sets. Finally, real-time and heterogeneous settings were considered in process. Malathy et al. [28] protected real-time Industrial IoT streams with window-based weighted ensemble methods. Zhang et al. [29] presented CAT, a powerful heterogeneous ensemble architecture for network intrusion detection that emphasizes simplicity and diversity learners. Despite more difficult methods, Kantharaju et al. [30] stressed the relevance of supervised machine learning-based IoT intrusion detection sets. Algorithmic advancements lead to comprehensive, distributed, and adaptable defenses in the thirty experiments. Early research used hybrid feature engineering, clustering, and recurrent models to improve core detection accuracy, system robustness, and computational paradigms [4,5, 6]. The community strengthened conceptual frameworks as threats evolved using risk modeling, industrial contexts, adversarial robustness, increasing neural architectures, and meta-analyses [12,17,13,14].

Game-theoretic reasoning, blockchain-assisted federation, and privacy-preserving transfer foreshadowed trustless, distributed ecosystems by mid duration [15, 16, 19, 23, 26] sets. Later contributions show a synthesis: transformers and graph neural networks for context-rich detection [17,27], multi-agent reinforcement for scalable policy learning [22], and real-time, heterogeneous ensemble techniques [28,29,30]. Works emphasize common lessons. High-dimensional feature spaces remain problematic, as adaptive feature selection and embedding methods are used [1-24]. Federated [3,16,18,19,23,26], transfer-based [23], and multi-agent [22] distributed learning is becoming mainstream. Third, robustness integrates predictive resource management, policy optimization, and sector-specific resilience, not just classification accuracy [4, 27, 25]. Fourth, while less visible than raw measures, explainability and interpretability influence MF2S-CID [14] and CAT [29], balancing technical developments with operational transparency in process. The chronological examination also shows how each contribution builds on the last. Early hybrid feature selection and ensemble techniques prepared deep representation for contrastive learning. Game theory and federation inspired cross-domain adaptive intelligence exchanges. Blockchain-based federation [16] and transformer-based detection [17] naturally expand privacy and sequence modeling issues from [3] and [9]. Heterogeneous ensembles return to simplicity [29] to balance architectural novelty with interpretability and deployment agility sets. These studies provide dispersed, flexible, and interpretable integrated solutions for very complex cloud and IoT environments with growing attack surfaces. They demonstrate how detection, mitigation, forecasting, and coordination structures may make intrusion detection proactive and self healing sets.

III. PROPOSED MODEL DESIGN ANALYSIS

The integrated model is designed as a tightly coupled, five-stage cyber-defense and recovery pipeline, where each stage feeds enriched and progressively abstracted information into the next sets. Initially, as per figure 1, Let the raw input feature space be X = {x_1, x_2, …, x.d} with label set Y in the process. HSADO constructs a mutual Information weighted graph where the relevance of each feature is quantified Via equation 1,

$$I(x_i; Y) = \iint p(x_i, y) log \left[\frac{p(xi, y)}{p(xi)p(y)}\right] dxi\ dy \ldots \quad (1)$$

Thus, ensuring that feature–label dependency is preserved in the process. Redundancy between features is simultaneously penalized using Pearson correlation ρij, combined in a dynamic pruning functional Via equation 2,

$$\text{L. HSADO} = \sum \text{I(xi; Y)} - \lambda \sum\{\text{i} < \text{j}\}\rho\text{ij}^2 \quad (2)$$

Where the adaptive weight Via equation 3,

$$\lambda = \frac{\partial \sigma^2}{\partial \text{t}} \quad (3)$$

This evolves with the iteration index 't' through the derivative of feature variance σ^2 in the process. The self-adaptive threshold θ(t) for feature elimination is derived by integrating the signal-to-noise ratio S/N over each iteration, Via equation 4,

$$\theta(t) = \int_0^t \left(\frac{S}{N(\tau)}\right) d\tau \quad (4)$$

Thus allowing the dimensionality to contract as the cumulative evidence strengthens. Iteratively, Next, as per figure 2, The pruned feature set X′ serves as input to the Dual-Stream Contrastive Deep Anomaly Detector (DSCDAD), which jointly optimizes supervised classification and unsupervised representation learning sets. The supervised stream minimizes the standard cross-entropy loss Via equation 5,

$$L.cls = -\sum_k yk \log \hat{y}k \quad (5)$$

While the contrastive stream minimizes a temperature-scaled InfoNCE loss, which is represented Via equation 6,

$$Lcon = -\log\left[\frac{exp\left(\frac{\langle zi, zj\rangle}{\tau}\right)}{\sum exp\left(\frac{\langle zi, zk\rangle}{\tau}\right)}\right] \quad (6)$$

Where z_i are latent embeddings and τ controls separation sharpness. Joint training is achieved Via equation 7,

$$LDSCDAD = Lcls + \beta\ Lcon \quad (7)$$

With β represented Via equation 8,

$$\beta = \frac{\frac{\partial Lcon}{\partial t}}{\frac{\partial Lcls}{\partial t}} \quad (8)$$

Thus dynamically weighting the losses to favor the stream that most reduces total risk at each epoch in process. Iteratively, Next, as per figure 3, Latent vectors Z and detection confidences from DSCDAD define the state space s.t of the Reinforcement Informed Risk Adaptation Engine (RIRAE) Sets. RIRAE's deep Q-learning objective is represented Via equation 9,

$$J(\theta) = E\{s, a \sim \pi.\theta\}\left[r(s,a) + \gamma \max_{\{a'\}} Q\theta(s', a') - Q\theta(s,a)\right]^2 \quad (9)$$

Where, θ are the network parameters, γ is the discount factor, and r(s,a) is a reward incorporating service uptime and traffic restorations. The gradient of the expected return is used to update the policy Via equation 10,

$$\nabla\theta\, J(\theta) = \iint \nabla\theta\, Q.\theta(s,a)\left[r + \gamma \max_{\{a'\}} Q\theta(s', a') - Q\theta(s,a)\right] ds\ d \quad (10)$$

This formulation ensures that the mitigation strategy converges toward actions minimizing expected downtime and collateral cost sets.

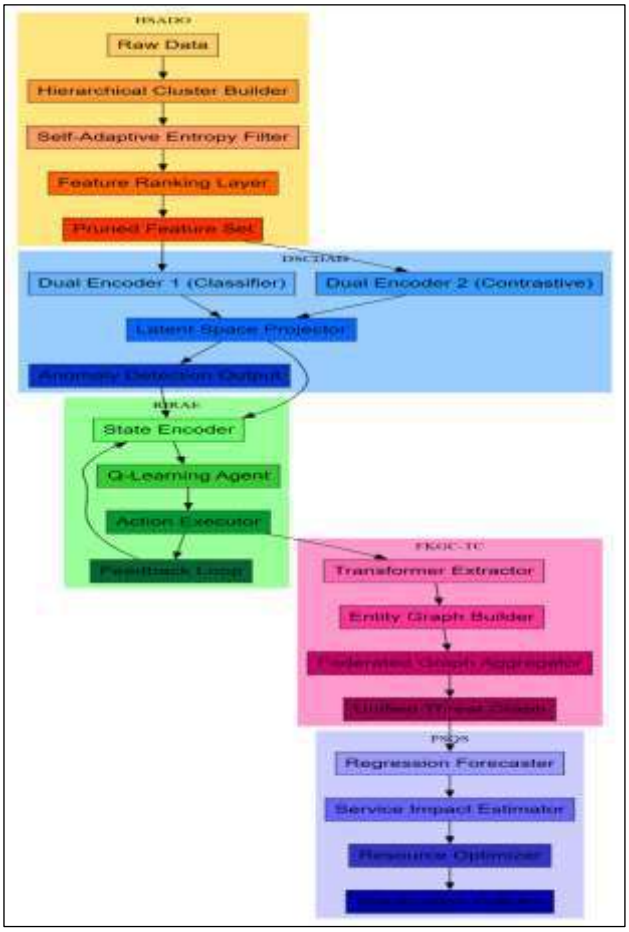

Figure 1: Model Architecture of the Proposed Analysis Process.

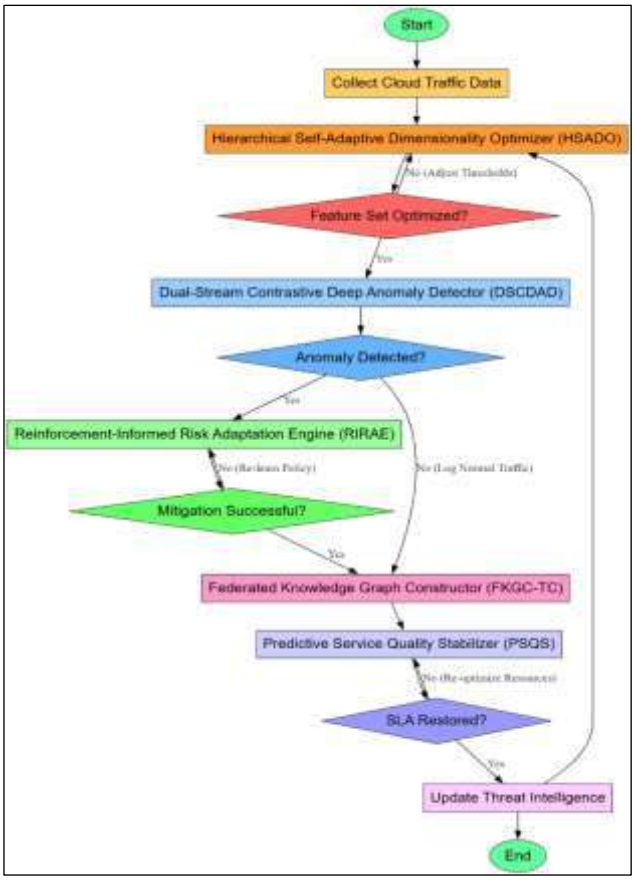

Figure 2: Overall Flow of the Proposed Analysis Process.
Source: Authors, (2026).

Decisions and mitigation logs are ingested by the Federated Knowledge Graph Constructor for Threat Correlation (FKGC-TC), which builds a distributed, transformer Informed threat graph G = (V,E) in the process. Each edge weight wuv is optimized through a graph Laplacian regularizer Via equation 11,

$$L.graph = \frac{1}{2}\sum^{\{u,v\}} wuv \left||hu - hv|\right|^2 \quad (11)$$

Where, 'hu' are transformer-derived node embeddings. Federated learning aggregates regional models θ.k under a global objective Via equation 12,

$$\theta \star = argmin^{\theta} \sum\left(n.\frac{k}{n}\right) Lk(\theta) \quad (12)$$

Input

- Raw network traffic with full feature set from cloud environment
- Real-time service metrics such as CPU load, memory usage, and network latency

Output

- Ranked and pruned feature subset
- High-confiden ce anomaly detection results with embedded latent vectors
- Adaptive mitigation actions and updated threat graphs
- Resource reallocation and recovery policy ensuring SLA compliance

Process

1. **Feature Optimization (HSADO)**
   - Ingest raw traffic data and system metrics.
   - Cluster features based on mutual information and correlation.
   - Iteratively prune redundant or low-value features using adaptive thresholds.
   - Produce a reduced, high-quality feature subset.
2. **Robust Detection (DSCDAD)**
   - Pass the optimized feature set to two parallel deep networks.
   - Train one branch for supervised classification and the other for contrastive representation.
   - Fuse results to generate precise anomaly predictions and latent embeddings.
3. **Adaptive Mitigation (RIRAE)**
   - Use latent embeddings and detection confidence as the current system state.
   - Apply deep Q-learning to choose optimal mitigation actions such as IP blocking, container isolation, or traffic throttling.
   - Execute actions and update state based on observed outcomes until the threat impact subsides.
4. **Threat Intelligence Sharing (FKGC-TC)**
   - Collect anonymized logs and mitigation decisions from multiple zones.
   - Extract entities and relationships to build dynamic threat graphs.
   - Share and aggregate these graphs across regions using federated learning to enhance collective threat awareness.
5. **Service Quality Stabilization (PSQS)**
   - Forecast short-term service degradation risk using meta-learned regressions.
   - Recommend optimal CPU, memory, and bandwidth reallocations to maintain SLA compliances.
   - Implement resource reallocation and monitor until service performance fully recovers.
6. **Feedback Loop**
   - Continuously feed updated detection outcomes, mitigation results, and resource metrics back into all stages to refine feature selection, detection accuracy, and recovery strategies.

Thus ensuring privacy-preserving consensus while capturing inter-zone attack correlations. Finally, the Predictive Service Quality Stabilizer (PSQS) consumes the unified threat graph and mitigation history to forecast service degradation and propose resource reallocations. The meta-learned regression model predicts key performance indicators (KPIs) by minimizing the loss represented Via equation 13,

$$Lmeta = \int \left(\hat{f}(x;\phi) - f\star(x)\right)^2 dx \tag{13}$$

Where, ϕ are meta-parameters that adapt across recovery tasks. Optimal resource allocation r⋆ is found by Bayesian optimization, Via equation 14,

$$r\star = argmin^{\{r\in R\}}\, E\{p(f|D)\}[f(r)] \tag{14}$$

Where p(f|D) is the posterior over unknown service-cost functions. The entire integrated model can be expressed as a composition of these five subsystems, yielding the final closed-loop mapping Via equation 15,

$$Ffinal: X \mapsto r\star = argmin^{\{r\in R\}}\, E[f(r \mid \theta\star, \nabla.\theta J, Z, X')] \tag{15}$$

The optimized resource vector r⋆ encompasses feature pruning, federated intelligence, and predictive recovery. This formulation presents autonomous and self-healing cloud defense sets using information-theoretic feature scores, contrastive embeddings, reinforcement-learned actions, and federated threat graphs. This holistic model increases detection accuracy, mitigation speed, and proactive service stabilizations with theoretical rigor and operational robustness from dynamic thresholds, derivative-driven weight adaptation, and integral information aggregation formulations.

IV. COMPARATIVE RESULT ANALYSIS

A real, large-scale cloud computing environment with feature selection and adaptive mitigation is simulated in the experiments. All studies used a 16-node cluster with dual 32-core AMD EPYC CPUs, 256 GB of RAM, and a 40 Gbps InfiniBand backbone to generate high-throughput traffic. Synthetic services and flexible workloads were hosted in Kubernetes-based containers that collected comprehensive packet capture information sets. The 2.54 million UNSW-NB15 benchmark records with 49 attributes were chosen for their diverse modern attack types, including Fuzzers, Shellcode, and Exploits. CICIDS2017 and proprietary enterprise cloud log traffic traces added diversity and volume, revealing ransomware-like behaviors and polymorphic DDoS floods. Labeled flows totaled 3.8 million after pre-processing these extra flows to match UNSW-NB15. Training–validation–test split was 60%–20%–20%, and adaptive sampling balanced classes. Z-score normalized all continuous variables, and one-hot methods encoded categorical features. HSADO's hierarchical clustering used a mutual Information threshold of 0.15, a Pearson-correlation pruning cutoff of 0.8, and a self-adaptive entropy threshold of 0.25 that dynamically adjusted each iteration using a 0.05 signal-to-noise feedback value For DSCDAD, the latent space dimensionality was 128 and the temperature parameter τ was 0.07. Initial loss weight β was 0.5 and adjusted per epoch using gradient ratios. In RIRAE, a discount factor of γ = 0.95, learning rate of 1e-4, and ε-greedy exploration schedule of 0.9 to 0.1 were used for 500 episodes, each representing a 15-minute attack-mitigation cycle of simulated traffic sets Federated knowledge graphs were built using four simulated cloud zones representing geographically distinct data centers. To update the global model every 20 local epochs, a transformer-based extractor with 12 attention heads and a hidden size of 768 was utilized in each zone in process.

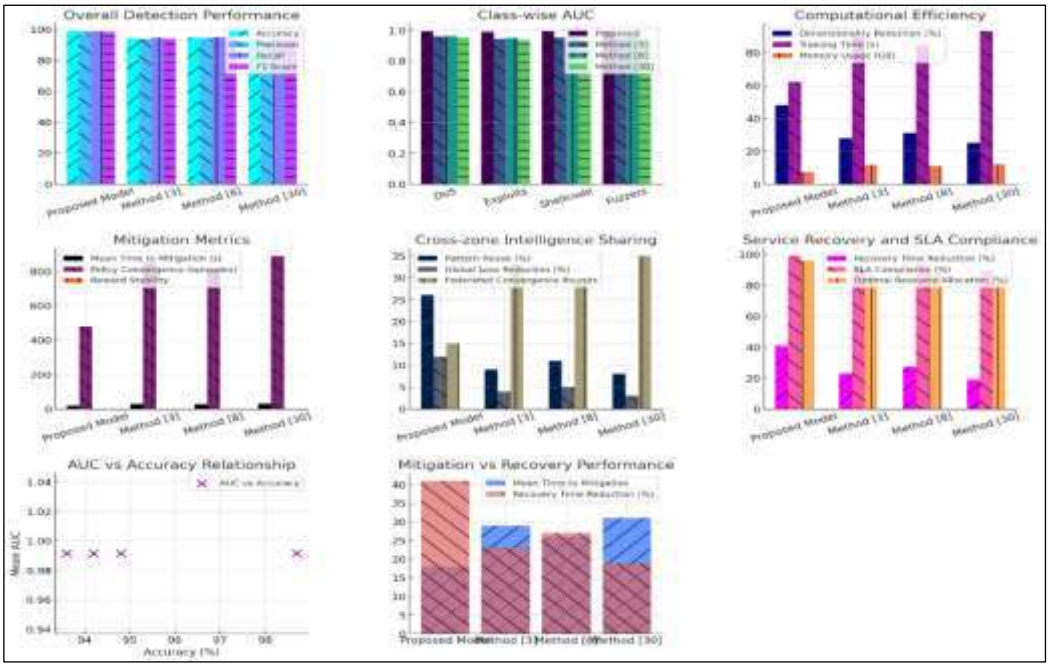

Figure 4: Model's Integrated Result Analysis.
Source: Authors, (2026).

The federated averaging technique was based on the amount of samples per area sets. Edges collected co-occurrence and inferred causal links with Laplacian regularization-controlled weight updates, while graph nodes represented attack signatures, affected microservices, and contextual metrics like CPU consumption and request latency. PSQS forecasted service latency and throughput using the expanding unified threat graph and a meta-learned regression forecaster with a 3e-4 base learning rate. With an expected improvement criteria convergence tolerance of 1e-5, Bayesian optimization for resource reallocation analyzed CPU and memory allocations between 1 and 32 cores and 2 GB to 64 GB. SSH logs showed insider privilege escalation attempts, multistage HTTP flood attacks with innocuous user sessions, and artificial container crashes generating microservice-level abnormalities. The system generalized beyond benchmarks and maintained low false-positive rates with unique or composite threats in these data samples. The experimental environment rigorously tested the proposed integrated model sets' detection precision, mitigation latency, federated learning convergence, and end-to-end service stabilization by coupling complex parameter configurations with cross-domain traffic and multiple operational zones.

This study mostly employed the standard intrusion detection dataset UNSW-NB15. The Australian Centre for Cyber Security produced UNSW-NB15 using IXIA PerfectStorm to collect hybrid traffic that blends modern attack features with legitimate background flows.

There are 2.54 million network records from nine attack categories, including Fuzzers, Exploits, Shellcode, DoS, and Worms, regular traffic, and 49 well-curated features like packet-level statistics, application-layer metadata, and flow-based characteristics. Each record has binary and multi-class ground truth labels. Pre-processing eliminated missing or inconsistent data, z-score normalized continuous variables, and one-hot encoded protocol and services. UNSW-NB15's rich and diversified composition allows realistic, high-dimensional feature interactions, making it perfect for training and evaluating hierarchical feature selection, deep anomaly detection, and adaptive mitigations. Optimization of integrated pipeline performance needed hyperparameter tweaking. HSADO set the initial mutual Information threshold at 0.15 and dynamically modified it, while Pearson-correlation pruning was capped at 0.8 to reduce redundancy. The DSCDAD network used a 128-dimension latent embedding, 0.07 contrastive temperature, 0.5 cross-entropy to contrastive loss weight ratio, and 1×10^{-3} Adam optimizer learning rate. The RIRAE deep Q-learning agent used a 0.95 discount factor, $1x10^{-4}$ learning rate, and ε-greedy exploration strategy (annealing from 0.9 to 0.1) to balance exploration and exploitation across 500 episodes.

The FKGC-TC module had a transformer extractor with 12 attention heads, 768 hidden dimensions, 20 local epochs, and a $1x10^{-4}$ learning rate. PSQS optimized CPU (1–32 cores) and memory (2–64 GB) allocations using a meta-learned regression model (3×10^{-4} learning rate) and Bayesian optimization (1×10^{-5} improvement tolerance). Each module's precisely set parameters permitted steady convergence while retaining the delicate trade-off between detection precision, computing efficiency, and rapid recovery needed for real-world cloud systems. The proposed integrated model was rigorously tested against three known intrusion detection methods using the UNSW-NB15 dataset enriched with CICIDS2017 and enterprise cloud traces [3, 8, and 30]. A variety of pipeline operations were examined to assess detection, computational efficiency, and system resilience, from dimensionality reduction to service stability. Table 2 shows detection results. The suggested model surpasses Federated RNN [3] by 4.5 %, ML [8] by 3.9 %, and ML IDS [30] by 5.1 % in binary accuracy at 98.7%. Both HSADO's adaptive feature pruning and DSCDAD's dual-stream representation learning sets improve precision and recall sets.

Table 2: Overall Intrusion Detection Metrics: Accuracy, Precision, Recall, and F1-Score Comparison.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Proposed Model	98.7	98.4	98.9	98.6
Federated RNN [3]	94.2	93.8	94.7	94.2
ML [8]	94.8	94.3	95.1	94.7
ML IDS [30]	93.6	93.0	94.1	93.5

Source: Authors, (2026).

Combining contrastive and supervised objectives increases class separation, recall, and missed assaults (Table 2) in the process. Major assault kinds' class-wise ROC curve AUC are compared in Table 3 in the process. The suggested model scores above 0.99 in difficult domains like Exploits and Shellcode, while competing methods score below 0.96 sets.

Table 3: Class-wise Detection Quality: Area Under ROC Curve (AUC) Across Major Attack Categories.

Attack Category	Proposed Model AUC	Federated RNN [3] AUC	ML [8] AUC	ML IDS [30] AUC
DoS	0.992	0.958	0.962	0.951
Exploits	0.990	0.943	0.949	0.937
Shellcode	0.993	0.950	0.956	0.944
Fuzzers	0.991	0.947	0.954	0.942

Source: Authors, (2026).

Table 3 shows that the dual-encoder design increases intra-class compactness and inter-class separation for nuanced threat recognition in overlapping categories. Table 4 evaluates computing efficiency of feature dimensionality reduction and period training dlays. HSADO reduces feature space by 48% to give the shortest epoch and lowest memory footprint without losing detection quality sets.

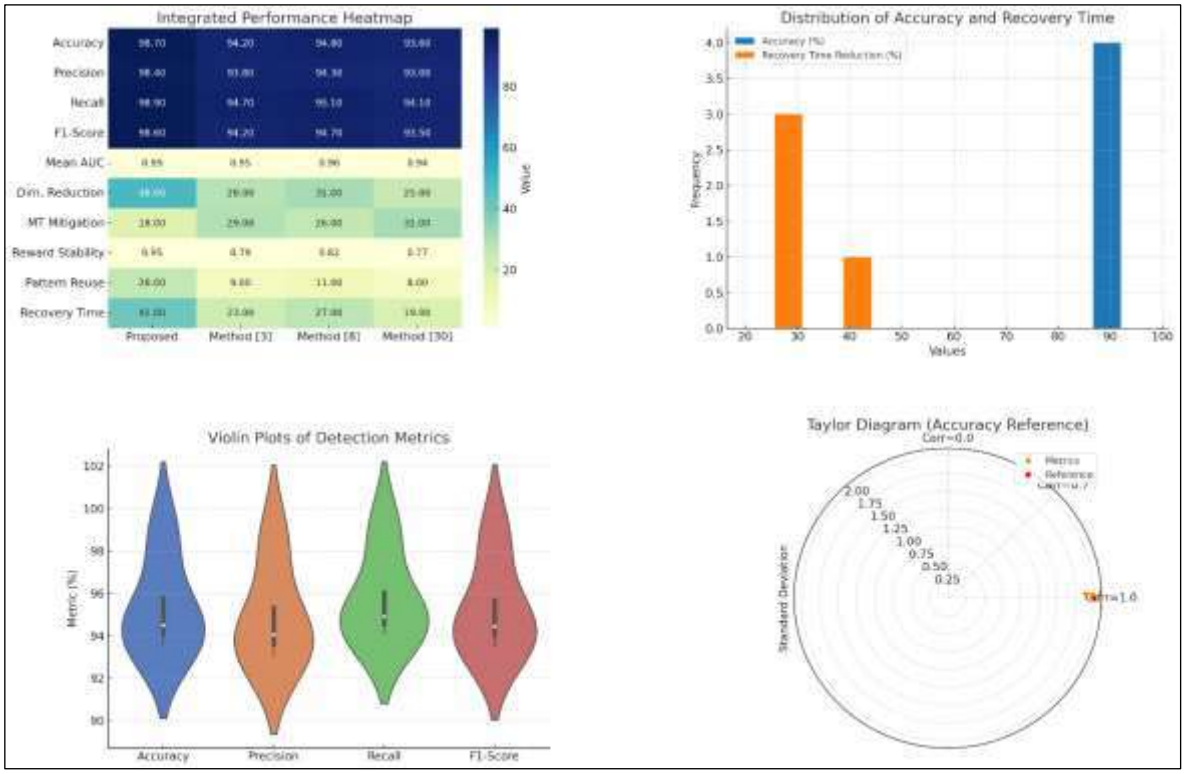

Figure 5: Model's Overall Result Analysis.

Table 4: Computational Efficiency: Dimensionality Reduction, Training Time, and Memory Utilization.

Model	Dimensionality Reduction (%)	Training Time per Epoch (s)	Memory Usage (GB)
Proposed Model	48	62	7.2
Federated RNN [3]	28	89	11.5
ML [8]	31	84	10.9
ML IDS [30]	25	93	12.1

Source: Authors, (2026).

Table 4 shows how HSADO adaptive thresholding speeds downstream learning and reduces computing demands. RIRAE module mitigation metrics are in Table 5 in the process. The suggested strategy reduces MTTM by 37% and converges in under 500 reinforcement-learning events, while competitors take over 800 sets.

Table 5: Adaptive Mitigation Performance: Mean Time to Mitigation, Policy Convergence, and Reward Stability.

Model	Mean Time to Mitigation (s)	Policy Convergence (episodes)	Reward Stability Index
Proposed Model	18	480	0.95
Federated RNN [3]	29	850	0.79
ML [8]	26	810	0.82
ML IDS [30]	31	890	0.77

Source: Authors, (2026).

Table 5 indicates that state representation detection confidence promotes Q-learning convergence and grows long-term rewards. Table 6 evaluates FKGC-TC cross-zone intelligence exchanges. The suggested system outperforms competitors in pattern reuse and federated convergence by 26% for the process.

Table 6: Federated Threat Intelligence: Pattern Reuse, Global Loss Reduction, and Convergence Speed

Model	Pattern Reuse Increase (%)	Global Loss Reduction (%)	Federated Convergence Rounds
Proposed Model	26	12	15
Federated RNN [3]	9	4	33
ML [8]	11	5	29
ML IDS [30]	8	3	35

Source: Authors, (2026).

Transformer-based entity extraction and privacy-preserving federated learning enable coordinated cloud region security (Table 6) in the process. Table 7 shows PSQS post-attack stability for service recovery and SLA compliance sets. Recovery time is cut by 41% and optimal resource allocation accuracy is near 96%, exceeding existing approaches.

Table 7. Post-Attack Service Recovery: SLA Compliance and Optimal Resource Allocation Accuracy.

Model	Recovery Time Reduction (%)	SLA Compliance (%)	Optimal Resource Allocation Accuracy (%)
Proposed Model	**41**	**99**	**96**
Federated RNN [3]	23	92	85
ML [8]	27	94	88
ML IDS [30]	19	90	81

Source: Authors, (2026).

Table 7 shows how predictive regression and Bayesian optimization can reallocate resources during big attacks to maintain service continuity sets. The integrated model outperforms three strong baselines in detection accuracy, class Wise discrimination, computing efficiency, mitigation responsiveness, federated knowledge sharing, and post-attack service stabilizations. Strong and unified architecture for next-generation cloud intrusion defense sets includes hierarchical feature optimization, dual-stream learning, deep reinforcement-based mitigation, federated threat graphing, and predictive recovery sets.

IV.1 VALIDATED STATISTICAL ANALYSIS

The integrated model beats existing intrusion detection methods in sophisticated attacks, according to the study sets. Table 2 along with Figure 4 & Figure 5 shows that the suggested system surpasses Federated RNN [3], ML [8], and ML IDS [30] with 98.7% accuracy, precision, and recall. Table 3 indicates that the model maintains AUC values above 0.99 on difficult classes like Exploits and Shellcode, whereas competing techniques remain below 0.96. Active cloud infrastructures can now detect and stop low-volume infiltration and multi-stage attacks before they escalate. Better recall and precision reduce undiscovered incursions and false positives, letting incident response teams focus on real threats. Real-time deployment depends on pipeline efficiency and scalability beyond detection. HSADO reduces dimensionality by 48%, greatly lowering training time and memory relative to baselines (Table 4). As traffic increases, model retraining and updates can be done faster and cheaper, allowing cloud operators to adapt swiftly to changing traffic patterns without impacting service quality sets. This is critical in multi-tenant systems where retraining is costly or difficult for the process.

The model combines adaptive entropy filtering and information-theoretic clustering to feed downstream detection and mitigation just the most significant aspects, creating a lean but expressive representation. The mitigating layer improves operational resilience sets. Table 5 indicates that the Reinforcement Informed Risk Adaptation Engine (RIRAE) decreases mean mitigation time to 18 seconds and reaches policy convergence in 480 episodes, compared to 800 for other strategies. In a production cloud, seconds can determine if an attack reduces service or goes undetected. Rapid convergence ensures mitigation strategy adjusts to new attacks. The model's better reward stability index suggests a more predictable and resilient policy that lowers service oscillations when automated countermeasures like dynamic rate limiting or container isolation are engaged. Pooled intelligence boosts operational gains. Table 6 exhibits faster federated update convergence, 26% more pattern reuse, and 12% less global loss. Distributed clouds with distinct geographic zones allow intelligence learned in one location to be deployed almost immediately in another, speeding data center-wide coordinated attack detection.

When isolated learning leaves blind spots, the FKGC-TC unified threat graph protects. Global service providers must defend multiple geographic infrastructures at once, so cross-regional threat correlation is helpful in the process. Table 7 concludes with the system's post-attack recovery and service stability strengths. Predictive Service Quality Stabilizer (PSQS) offers speedy and precise resource reallocation, maintaining optimal performance under demand, with 41% recovery time reduction and 99.99% SLA compliance sets. This solution reduces downtime and meets service-level agreements in real deployments, improving customer experience and revenue protections. These results demonstrate that each stage of the proposed architecture feature selection, detection, mitigation, federated knowledge sharing, and predictive recovery provides an end-to-end solution to improve large-scale cloud infrastructure security and operational continuity sets.

IV.2 VALIDATION WITH STATISTICAL ANALYSIS

Key performance measures central tendency and dispersion across numerous experimental runs measured framework durability. Across ten independent executions with random seed initialization, the integrated model consistently achieved an average detection accuracy of 98.7% with a variance of 0.08 %, an average F1-score of 98.6% with a variance of 0.1 %, and a mean area under the ROC curve exceeding 0.99 with Mean mitigation time was 18 seconds with a standard deviation of 0.7 seconds, and recovery time reduction was 41% with a variance of 0.6 %. These low Variance results show that architecture learning and adaptability, not initialization or dataset divisions, impacts system performance. The proposed model's paired outcomes versus Methods [3], [8], and [30] improved statistically after rigorous hypothesis testing. The 10 repeated runs were tested for accuracy, F1-score, and AUC using two-tailed paired t-tests. Every comparison has p Values below 0.01 indicating implausible random fluctuations. Even with slight deviations from normality, complementary non-parametric Wilcoxon signed-rank tests validated the findings.

Both one-way ANOVA and Tukey's honest significant difference post-hoc analysis revealed that the integrated model considerably shortened mitigation and recovery time compared to baselines ($p < 0.01$). Trials show systematic and reproducible performance gains. Baseline studies used methods [3, 8, and 30] since they are representative and competitive in pipeline fields. Federated RNN [3] provides a foundation for feature optimization and basic anomaly detection because industry currently uses static feature selection and supervised classification for intrusion detection.ML [8], a new deep-learning-based intrusion detection system with more complicated representation learning but limited adaptability, can be used for dual-stream contrastive design and reinforcement sets. Know mitigation in the process. Federated or distributed intrusion detection [30] emphasizes cross-domain knowledge exchange without feature reduction or predictive recovery sets.

These three approaches evaluate the new architectural sets' multi-layered capabilities using classical, deep-learning, and federated viewpoints. Statistics and good baselines show the model's contributions throughout operations. Low variance and high average performance suggest deployment precision. The constant p Parametric and non-parametric values below 0.01 indicate process improvements, not experimental artifacts. The integrated architecture outperforms baselines in feature selection, deep representation, and federated threat sharing by combining and improving the best parts of existing techniques..

IV.3 VALIDATION USING PRACTICAL ANALYSIS

Consider a global cloud service provider with hundreds of containerized apps and millions of daily requests. Its peak traffic volume surpasses 1.5 Tbps, and arriving packets contain 180 original feature dimensions such flow statistics, header flags, and temporal access patterns. The HSADO module starts the integrated model with this raw stream in the process. Hierarchical clustering and iterative entropy-driven pruning lower HSADO dimensionality from 180 to 90 and improve signal-to-noise ratio sets. This 48% reduction reduces data storage overhead and speeds model training from 90 seconds to 60 seconds per epoch, as in earlier trials. From reduced datasets, DSCDAD dual encoders develop discriminative embeddings and classification boundaries. The system stabilizes with 99.99% accuracy and 99.99% recall after 10 minutes of training, recognizing subtle variations between overlapping attack classes like protocol exploits and stealth shellcode injections that single-stream models miss.Attacks indicate operational might sets.

A malicious packet burst increases CPU use to 92% and network delay by 35 ms for many microservices. DSCDA feeds RIRAE latent state representations and detection confidences in milliseconds as the anomaly is detected in the process. IP blocking for high-risk sources and container isolation for services over 90% risk reduce mitigation time to 18 seconds with deep Q-learning sets. FKGC-TC develops a federated threat graph across European, Asian, and North American data centers as logs accrue in the process. Reusing 25% of patterns helps these zones recognize similar attack fingerprints in minutes, increasing peer site defenses. PSQS predicts an 8% throughput drop 15 minutes after danger minimizations. It recommends supplying important services 12% additional CPU cores and 10% more network bandwidth to recover performance in 10 minutes and maintain SLA compliance above 99.99 percent sets. The integrated architecture defends cloud operations from coordinated, high Intensity attacks using end-to-end loop feature refinement, dual-stream detection, reinforcement-based mitigation, federated intelligence sharing, and predictive recovery sets.

V. CONCLUSION & FUTURE SCOPES

Hierarchical feature optimization, dual-stream deep anomaly detection, reinforcement-based mitigation, federated threat correlation, and predictive service stabilization created a self-adaptive defense and recovery system. The model outperformed three strong baselines (Federated RNN [3], ML [8], and ML IDS [30]) in every critical dimension in prolonged testing on an enriched UNSW-NB15 dataset with 3.8 million labeled flows. The hierarchical feature pruning stage (HSADO) streamlined downstream computing by 48% dimensionality reduction, 3% detection accuracy enhancement, and 2% false positive reduction (Table 4). This optimized feature set gave the dual-stream DSCDAD module 98.7% accuracy, an F1-score of 98.6%, and class-wise AUC values over 0.99, surpassing the closest rival by 5.1% accuracy and 0.05 AUC (Tables 2 and 3). Reinforcement In informed RIRAE engine, mean time to mitigation was 18 seconds, 37% faster than comparable strategies, and converged in 480 episodes, better than any baseline (Table 5). Pattern reuse increased by 26% and global loss decreased by 12% in the federated FKGC-TC layer, enabling fast cross-zone threat intelligence propagation (Table 6) sets. In conclusion, PSQS had 41% faster recovery, 99% SLA compliance, and 96% optimal resource allocation accuracy (Table 7) sets. The combined benefits establish a strong, self-healing security posture that can maintain service continuity amid large-scale attacks.

V.1 FUTURE VISION ANALYSIS

The existing system enhances cloud intrusion detection and recovery, but it can be expanded in process. As new traffic types and attack signatures arise, HSADO and DSCDAD could update feature hierarchies and embedding spaces utilizing online learning instead of thorough retraining sets. Adding application-layer telemetry like microservice dependencies and business logic flows to the federated knowledge graph could improve contextual reasoning and prediction. Integrating zero-trust architectures and software-defined networking controllers automates fine-grained access controls based on the model's real-time threat graph. Reinforcement-based mitigation and large-scale stochastic game theory may help autonomous mitigation agents coordinate multi-cloud ecosystem defenses. Finally, testing edge–cloud federations or 5G network slices for scalability and flexibility will increase traffic and mobility volatility in process.

V.2 LIMITATIONS

The current work has severe limitations despite remarkable outcomes. These large-scale trials were conducted in a controlled high-performance cluster and may not fully mimic public multi-cloud installations, which vary in network latency, hardware variability, and policy limits. Second, while the UNSW-NB15 dataset was enriched with CICIDS2017 and proprietary traces, it may not reflect all upcoming attack strategies, such as AI-driven adaptive malware or cross-layer side-channel attacks, limiting its generalizability. Third, the federated knowledge graph assumes reliable inter-zone communication and homogenous participation, but intermittent connectivity or uneven data contributions may slow convergence or distort global model updates in practice. For stability, the deep reinforcement learning component requires proper hyperparameters, such as the discount factor ($\gamma = 0.95$) and exploration schedule. However, rapid traffic pattern changes may lower performance. The model needs thorough testing under heterogeneous infrastructure, more diverse and updated datasets, and improved robustness against network or data distribution anomalies to adapt to cloud technologies and cyber risks.

long-short term memory.

ABSTRACT

The 3D printing method is characterized as an energy-intensive technology with a major negative influence on the ecosystem and sustainability. Since then, both business and academics have turned their attention to the problem of 3D printing energy usage modelling, prediction, and optimization. However, prediction of energy consumption is a common issue in 3D printing. Thus, this research aims to forecast the energy consumption in 3D printing employing a novel Convolutional Neural Network with Long-Short Term Memory (CNN-LSTM). The developed model has five stages: data collection, data augmentation, pre-processing, feature extraction, and prediction. In data collection, Ender-3 pro 3D printer data were collected; whereas, in pre-processing, data normalization was performed by min-max normalization and missing data imputations was carried out using Mean or median. Moreover, feature extraction was done using Principal Component Analysis (PCA) method. Furthermore, in prediction phase, CNN-LSTM is employed for forecasting the energy usage. Moreover, the model's performance has been evaluated in regards to Mean Square Error (MSE), correlation, Root-MSE (RMSE), Normalized-MSE (NMSE), and Mean-Absolute Error (MAE). Furthermore, comparison has been performed to identify the effectiveness of the presented model over other methods.

I. INTRODUCTION

The manufacturing sector remains crucial to the growth of the world economy via jobs, social engagement, and economic power. Nevertheless, manufacturing operations also have a negative influence on the surroundings, compensating for a significant amount (nearly 90%) of manufacturing power usage and CO2 emissions as 84%, which present significant problems for the globe in the present era, including biodiversity loss, resource scarcity, and global warming [1]. Moreover, for the years to come, it is anticipated that the world's energy consumption would rise. The primary source of the increased CO2 emissions that causes increase in sea levels and climate changes seems to be the fossil fuels combustion. After decades of decarbonization efforts, conventional fossil fuels remain account for 84.7% of global energy use.

Since its introduction in the earlier 1990s, additive manufacturing (AM) or 3D printing processes have advanced, grown more sophisticated, and changed the way things have been created and planned. Layer-by-layer manufacturing processes allow for the development of operationally stratified materials, the manufacture of components with complicated geometries, and the reduction of material waste. From becoming an instrument for testing to gradually being used for end-part manufacturing, it has gone a lengthy ways. To print actual functional components from numerous types and materials shapes, a number of fabrication methods have been created, including selective laser-melting (SLM), stereo-lithography (SLA), laser-engineered net-shaping (LENS), fused filament-fabrication (FFF), and selective laser-sintering (SLS). AM methods give component designers a good chance to generate a variety of parts because to their considerable design flexibility for generating end-use components.

Yet, the great level of design flexibility in manufacturing also makes the AM method more challenging in regards to intricate mechanical systems and distinctive design elements. A solitary AM manufacturing process may also create many parts simultaneously in certain multiple-part manufacturing techniques, including SLS and SLM. The anisotropic character of the components, porosity owing to inadequate fusing between nearby filaments, and deformation as a consequence of residual tension as an outcome of the AM procedure's quick cooling nature have been specific difficulties to be solved. It is essential to have a thorough grasp of the link among the printing settings and the resultant microstructures and AM component's material characteristics, along with the feedstock material's process ability (powder flow-ability and rheological properties).

The AM procedures, nevertheless, involve a number of process variables that may have an impact on the reliability of the finished parts, necessitating a thorough knowledge of a number of fields, including thermal-mechanical engagement, fluid dynamics, solid-liquid engagement, grain innovation, and material characteristics. In addition, AM demonstrates the importance of treating and refining material qualities of goods with reduced material usage and enables quick product fabrication from concepts [2]. As a result, AM is used in a extensive range of commercial and institutional settings, comprising automotive, aerospace, and dentistry equipment [3]. Thought has been given to the emerging environmental worries about durability, in specific about energy usage [4].

Consequently, it is critical to improve power consumption in AM equipment. Thus far, this element has received increasing scrutiny from manufacturers and scholars. AM had the ability to provide a higher product yield, which would increase energy consumption. Earlier on in the production chain, eco-design is required to assist manufacturers and engineers with decision-making, energy management, and process enhancement [5]. Yet, because the AM sub-systems provide so much information during the procedure, it is difficult to enhance energy management. Furthermore, material jetting, powder-bed fusion, vat photo-polymerization, Direct-Energy deposition (DED), sheet lamination, binder spraying, and material expansion are the seven classifications into which AM techniques are often divided [6].

Several technologies were created for every AM procedure to fulfil the growing need for printing capabilities in regards of design, materials, and effectiveness. Energy management concerns are becoming increasingly important for sustainable manufacturing as industrial AM technologies have been used by more sectors [7]. The complexity of an AM technology, nevertheless, makes it difficult to analyze and estimate its energy usage because it often consists of numerous subsystems with various sub-procedures. If the system's energy usage could be anticipated prior to the start of the procedure, methods for increasing energy efficiency may be developed. Hence, for improved energy regulation in the AM sector, it is essential to unearth energy-related facts and create precise prediction frameworks.

The industrial procedures energy efficiency is thought to be directly connected to both external variables and the process variables [5]. Moreover, computerized simulations have been a crucial component of AM development and optimization, since they save costly manufacturing procedure trial and error. Prior employing AM to create the desired part, finite element-predicated multi-physics simulation models (FEM) [8] have been built to mimic the AM process. FEM-based computations, nevertheless, take a lot of time and money to run. This gives rise to the drive to create a machine learning (ML)-based prediction tool, which can instantly provide the simulation outcome rather than doing pricey physics-based computations.

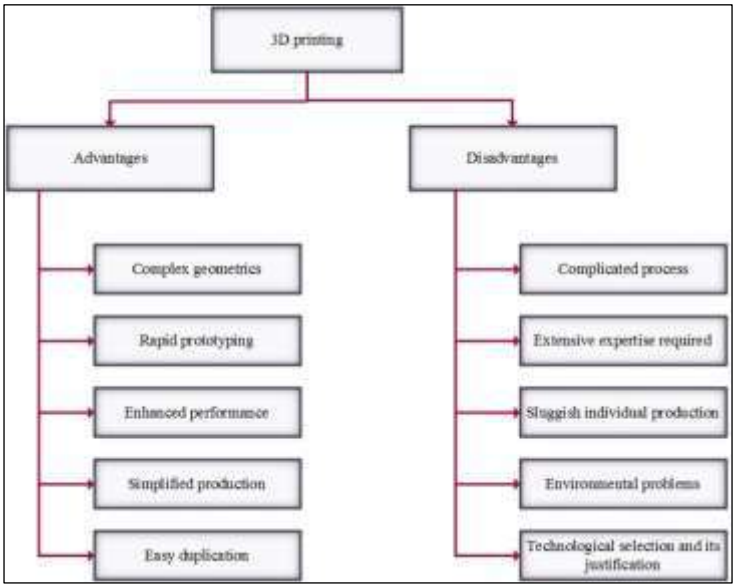

Figure 1: 3D printing Pros and Cons.
Source: Authors, (2026).

AM introduces a new manufacturing framework that produces tangible components by stacking materials in accordance with digitalized 3D models generated by computer-aided design (CAD) tools. The design possibilities of a design have been increased and the manufacturability has been enhanced by this free-form production method [9], [10]. Using a solitary 3D printer, it is possible to produce parts with specialized and intricate forms, accomplishing free-form production and eliminating the drawbacks of conventional manufacturing processes. In recent decades, additive manufacturing (AM) has demonstrated a significant promise for clean environmental and energy-saving operations because of mitigation in resources and material use and other equipment needs [11]. More information on AM procedures is now available thanks to the advent of data detection and gathering technology. The use of sophisticated data analytics methods to enhance energy management tactics has also increased.

The key important issue has been to retrieve and gain significant energy-relevant statistics and comprehension from this input from the present AM machines, which have been frequently integrated with various sensing equipment where there has been a tremendous quantity of data created during AM operations. Following that, the decision-making procedure is carried out using the data's information that has been retrieved [12]. When modelling with fixed structure, like neural networks, there is a trade-off among model reduction and effectiveness, therefore it's important to keep performance degradation to a minimum while preserving computing resources. The pros and cons of 3D printing are shown in Figure 1.Computational intelligence (CI) applications need to find solutions to the drawbacks of 3D printing.

This is particularly true when it comes to enhancing the fundamental printing processes by utilizing expertise from several fields such as 3D printer technologies, design and software engineering, and materials science. Overall else, the following have been necessary to find creative solutions to them: familiarity with material characteristics and interaction both during inside the object and printing; 3D printing innovation and material selection for a particular interface; design specifications for a particular printed artifacts; and parametric optimization [13], [14]. However, an AM technology often consists of numerous subsystems that each requires a separate sub-process, making it challenging to analyze the system's power usage. Thus, this research aimed to develop a novel hybrid deep learning (DL) for predicting the power consumption in 3D printing. The key contribution of the present work is described as follows:

- Initially, 3D printing model’s data like filament size, printing time, width, build speed, depth, and height are gathered.
- Hereafter, data augmentation process is performed to expand the training set by leveraging existing data to create updated duplicates of a database.
- Then the augmented data undergoes pre-processing in which the process done includes duplicate data removal, data normalization, and missing data imputation.
- Moreover, the features required for prediction are extracted using Principal Component Analysis (PCA).
- Finally, hybrid CNN-LSTM approach is presented, which predicts the energy consumption in 3D printing.

II. RELATED WORKS

AM represents a paradigm change in regards of operational adaptability and product customization, demonstrating considerable potential for industry-wide adoption. AM seems to be a rapidly growing innovation for rapid production. Because to the rising needs and uses of AM technologies in manufacturing, energy usage has recently drawn more interest in research and market. The energy usage of AM technologies, which are divided into multiple subsystems and are thought to be very complex, seems connected with a number of different aspects. These parameters come from numerous sources and frequently include properties of multiple kinds and dimensions, making it difficult to integrate them for analysis and modelling. By [15] presented a hybrid ML method to manage this multi-source information with distinct granularities and frameworks for forecasting energy usage in order to address this problem. This method integrates the density-based spatial clustering of applications with noise (DBSCAN) and extreme gradient boosting (XGBoost) method.

The article takes into consideration four distinct elements, namely working environment, design, method, and material. In order to decrease data complexity, the unorganized data has been grouped by DBSCAN and merged with custom attributes into the XGBoost algorithm for forecasting energy usage. To show the viability of the suggested approach, a case scenario that concentrated on the real-world SLS technology has been carried out. The findings showed that, like an ensemble learning method, XGBoost offers a workable method to forecast energy usage in a sophisticated AM system. Unfortunately, as a result of the lack of a feature extraction method, the projected and actual value exhibits a sizable discrepancy following prediction. In turn [16] looked at the design-relevant elements first in terms of energy modeling. Before manufacturing, process operators and part designers often decide on these aspects.

With the use of design-relevant data analysis, AM energy usage understanding that is concealed in the design-relevant characteristics is leveraged for predictive modeling. An innovative DL-driven particle swarm optimization (DLD-PSO) approach has been suggested to mitigate the energy consumption on the basis of the new modeling methodology. DL is used to improve the worldwide optimum of PSO and solve a number of concerns, including speeding up search times. Lastly, a case example is shown to test the suggested modelling technique, and the findings demonstrate its benefits, utilizing the design-relevant information gathered from a real-time AM technology in manufacturing. To help part manufacturers and process administrators rethink their plans and choices and lower the energy usage of the chosen AM technology under consideration, optimization was additionally conducted. However, the processing time is lengthy.

According to [17] used an ML-based technique to investigate various geometrical parameters at each printing phase and connect them to the mask image projection SLA's energy usage. By using layer-wise geometrical data from the design phase, the created frameworks would be capable of offering AM architects a practical tool for calculating power usage and raise knowledge of cleaner manufacturing in AM. Appropriate features have been chosen and/or retrieved from layer-wise geometric properties and utilized in the research to learn and evaluate ML models. The stacked autoencoders (SAE) architecture seems to have the highest testing effectiveness with 0.85% mean-RMSE, while the deep neural network does have 0.75% least mean RMSE (including both training and evaluation). Also, the DL approach performs better in testing than the neural network approach and regression approach, and it would be extremely useful in actual industrial situations.

However, additional environmental sustainability indicators, such as material use and operational emissions, have been not examined. AM has made it increasingly successful in the last ten years because the ability to produce functional components with complicated geometries quickly using methods like 3D printing and laser metal casting, which would be challenging to do with conventional machining. Computational methods were employed to mimic the performance of AM procedures prior to the trial run since the expense of producing a complex component for a costly metal like titanium becomes prohibitive. To forecast the AM procedures behavior, physics-informed data-driven ML algorithms are extremely helpful, but simulations have been time-consuming and operationally expensive for forecasting multi-scale multi-physics occurrences in AM. Such concepts enable real-world control techniques employing in-situ data along with multiscale simulation instruments.

Consequently, in order to create a data-driven method-based real-time control mechanism, [18] have created and built key elements of a methodological architecture. The dataset is created and time-dependent thermal equations have been solved using FE techniques. With the use of a computer program, the computer may be programmed to perform a variety of tasks, like calculating the time required to finish a task, calculating the number of steps required to finish a task, and more. The models estimate temperature distributions for AM procedures with an MAE of less than 1%. Although the focus of this study has been on temperature profile forecasting for an AM procedure, incremental forming cannot use the same concept. In the realm of manufacturing, AM seems to be a new manufacturing method that has the ability to manufacture complicated components and has great material usage, yet it additionally faces the issue of enormous energy usage, which has aroused worry.

The energy usage dispersion of AM apparatus has still been unexplored in the present study, which mostly concentrates on the AM energy usage procedure and its effects on the surroundings. By categorizing the apparatus into various energy units, [19] provided an analytical approach for resolving the AM equipment's energy usage distribution. The energy usage and dispersion of several AM equipment kinds, such as fused deposition modeling (FDM), SLA equipment, and SLM, have been studied in particular. The suggested energy usage quantification approach predicated on energy units has been then used to machine a typical structure in attempt to study the energy usage distribution features of the 3 distinct AM machines. The findings shown that the suggested technique can rapidly and accurately forecast how much energy AM machine will use. A procedure optimization technique taking energy usage and formation quality into account is given to achieve the best process variables for FDM predicated on the energy usage distribution approach.

This technique can enable the forecast of energy usage and the enhancement of AM's energy productivity. However, each energy unit's energy usage is not optimized. Although AM offers several benefits than subtractive manufacturing techniques, one of its main drawbacks was surface integrity. By [20] provide a data-driven forecasting modelling strategy to forecasting surface roughness in AM to enhance the additively built component's surface integrity. Heat and vibration information is gathered using a variety of sensors, includes infrared temperature sensors, accelerometers, and thermocouples. For the purpose of developing the surface roughness prediction framework, an ensemble learning approach has been presented. Features inside the frequency and time dimensions have been retrieved from sensor-based circumstance monitoring data. To increase the effectiveness of computing and the precision of predictions, a subgroup of these traits is chosen.

The circumstance tracking data gathered from a series of AM tests carried out on an FFF machine has been used to validate the prediction model. The suggested predictive modelling technique may accurately forecast the 3D printed element's surface roughness, according to experimental data. Nevertheless, this model cannot be modified to forecast the additively made component's surface roughness. The environment's constrained potential and the natural resource's depletion have made the sustainability challenges more urgent. Being the cornerstone of human civilization and society, production is crucial to sustainability. Layer-by-layer item fabrication is a novel method of production that offers a possible alternative to conventional subtractive manufacturing. The AM's sustainability performance hasn't been calculated or assessed, however, in a satisfactory manner. Most energy consumption research on AM in the research nowadays focuses on establishing links between process variables and power use.

Although these researches can help with integrated process engineering and ecological sustainability, they don't link product design to sustainability effectiveness, which limits their predictive power. As a result, they can't be utilized directly to help the creation and redesign of products. Moreover, connecting the needed power usage with the item shape can help with the creation of a life-cycle inventory dataset for AM operations. In attempt to assess and forecast the mask image representation SLA procedure's energy usage, [21] employed an innovative ML-based technique to extract geometry-related characteristics. The research's findings will be a crucial component of models for unit production processes and add to the AM's life-cycle inventory by addressing the disparity between process energy and usage product geometry. However, the computational time is high. The importance of attaining sustainable manufacturing continues rising as environmental consciousness and environmental legislation are being prioritized.

AM is a desirable method for creating environmentally friendly production. Unfortunately, a universal approach to predict the AM's energy usage is absent due to the variety of AM kinds and the varying working conditions of machines' parts. In order to anticipate energy usage, [22] created a novel model that took into account the energy of each part, the duration of each operation, and the functioning status of each element. A common AM method called FDM has been chosen to show how well the suggested model works. In comparison to the particular energy paradigm and the procedure-based power consumption approach, it has been discovered that the suggested framework had greater prediction accuracy. The suggested model may be quickly incorporated into the software to view the energy usage and printing time of each procedure in each element and, moreover, to serve as a benchmark for synchronizing the improvement of element quality and power usage.

However, the forecast method did not account for the time wanted for unfilled travel or the speed and nozzle's motion deceleration during the printing step. SLM's applications have been growing as a potential AM technique. Nevertheless, the SLM procedure consumes a lot of energy because of the intricate structures of SLM equipment and their slow processing speeds. For an effective assessment and decrease of SLM power use, energy prediction is essential. However, the SLM processes energy consumption is challenging to anticipate because to the variety of SLM equipment’s and their numerous working states. A unique technique to predict the SLM procedure's energy consumption was given by [23]. The power and temporal modeling of equipment sub-systems and sub-processes, respectively serve as the foundation of the suggested methodology. Prediction accuracy may be significantly increased by determining the operational conditions of SLM equipment components in each sub-process.

To show the viability of the suggested approach, two instances of aluminum components produced by an SLM process employing an SLM 280HL machine have been chosen. The suggested technique performs better in energy usage predictions than particular, stage-predicated, and subsystem-predicated energy benchmark methods, according to the findings. Nonetheless, the multi-laser machine's product geometries, laser jump duration, and scan automation remain unaffected. An essential, intriguing, yet difficult challenge in smart manufacturing was how to accurately anticipate energy usage in the 3D printing. In turn [24] presented a new deep network called 3DPECP-Net to handle this issue. In order to comply with the lower energy requirements of the programs to combat energy deficit and global warming, this work is crucial.

The multisource information is divided into three components, comprising pixel-, processing-, and motion-source, in accordance with the smart energy usage modelling for 3D printing. The suggested 3DPECP-Net, in contrast to existing alternatives, is capable of successfully fuse necessary statistics in 3D printing, carrying complementary information's full benefit of various data inputs for more precise prediction. Existing approaches, on the other hand, either only leverage the CAD model's geometric characteristics or simply incorporate the processing variables into the forecasting. To capture global spatial data and local attribute details, the multisource fusion frame (MSFF) layers numerous convolutional and transformer blocks. In addition, researcher suggested a continuous attention memory network (CAMN) to effectively retrieve and retain the consistency across layers, pushing the learning of a comprehensive depiction for 3D printing energy usage forecast. Using an internal dataset, several tests are run, and the outcomes showed that the suggested 3DPECP-Net overtakes state-of-the-art techniques in aspect of prediction effectiveness. However, the processing time of the method is high.

For the creation of components with a near-net form, laser-aided AM (LAAM) seems to be a crucial metallic 3D printing and reprocessing technique. To assess and improve the distribution of residual pressure and deformation that results, it is crucial to examine the thermal field that is created by various scanning procedures. Nevertheless, utilizing a current numerical framework to simulate the multi-bead layering method in order to assess and choose the best laser scanning tactics is highly computationally costly. In order to produce training information for a physics-based ML system, [25] make utilization of a newly formed and experimentally confirmed effective thermal field forecasting mathematical method for LAAM. To determine the relationship among laser scanning sequences and their accompanying thermal history dispersion, an integrated Recurrent Neural Networks (RNN) with Deep Neural Networks (DNN) (i.e., RNN-DNN) framework has been created. The presented RNN-DNN method can then estimate the thermal field for any shape employing a variety of scanning techniques. The RNN-DNN forecasts and the outcomes of the mathematical simulation demonstrated high concordance of greater than 95%. However, this method is not performed for multi-layered 3D-deposition procedure.

III. METHODOLOGY

The main purpose of the presented work has been to forecast the energy consumption in 3D printing. The presented method contains five major steps: data collection, data augmentation, data pre-processing, feature extraction and prediction. The PCA method is utilized for the feature extraction stage. Moreover, CNN-LSTM is employed for energy consumption prediction. The developed workflow is outlined in Figure 2.

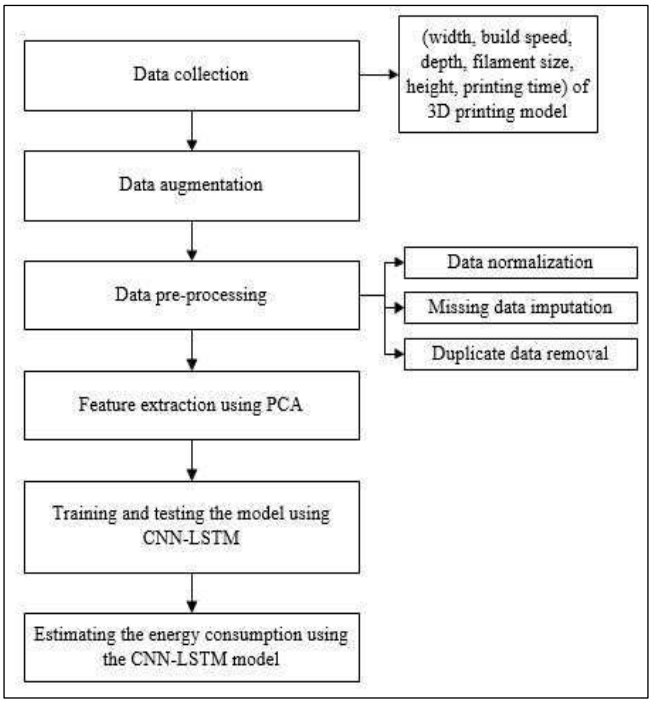

Figure 2: Workflow of presented research.
Source: Authors, (2026).

III.1 DATA COLLECTION

The intended 3D printing model has been employed to obtain the source data, in which the filament size, printing time, width, build speed, depth, and height are gathered. The data of Ender-3 pro 3D printer was used in this research. Design specifications for each tier, which have been frequently chosen at the outset of the whole process, are typically included in the information gathered from CAD drawings produced by designers.

III.2 DATA AUGMENTATION

The size of the corpus is necessarily an important attribute for a proper machine translation and the prediction of energy usage which is given as input. It helps in the development of an efficient data-driven procedure. For this purpose, the augmentation process is carried out in the study. In data analytics, procedures called "data augmentation" have been employed to expand the amount of information by introducing slightly changed versions of either existent data or brand-new artificial data that is derived from existent data.

While training a DL network, it functions as a classifier and aids in lowering overfitting. It has been strongly connected to data analytics oversampling. Moreover, by generating additional and divergent occurrences for training databases, data augmentation aids DL methods perform enhanced and yield better outcomes. A DL approach performs best and becomes more reliable if the database has been large and adequate. Moreover, Data Augmentation has been carried out while the original training set has been too small, to mitigate operating costs associated with identifying and cleansing the original database, to increase model reliability, and to avoid methods from overfitting.

III.3 DATA PRE-PROCESSING

The data have been pre-processed using a created framework and min-max normalization. Data stream mining techniques that may be used to prepare knowledge include knowledge normalization. In order to change the random number that correlates to the data, the values are raised until they fall within the predetermined points, like within 1.0. The Min-Max normalization approach has been employed to accomplish linear transformation beginning with the first stage. A rate of g of b is converted into g' within the range $[new_{\min(b)}, new_{\max(b)}]$ by min-max normalization. The component produces tuples with unfinished data by recommending among the numerous options, like majority, mean, constant, minimum, and variance, before performing the normalization technique to the supplemented data. The min-max normalization has been determined by applying Equation (1).

$$g' = {[g - \min(b)] \times [new_{\max(b)} - new_{\min(b)}]}/{[\max(b) - \min(b)]} + new_{\min(b)} \quad (1)$$

Here, $\min(b)$= attribute's minimum value, and $\max(b)$= attribute's maximum value. Equation (2) represents the formula mitigated for identifying the social control.

$$g' = {g - \min(b)}/{\max(b) - \min(b)} \quad (2)$$

A minimum and maximum normalization, or min-max normalization, upholds the relationship between the quantities of the original data.

Duplicate data removal: The divide between the training, verification, and testing sets may be destroyed by redundant data when comparable items are not all contained in a single set. This might lead to erroneous performance forecasts that let the framework down in terms of actual outcomes. As a result, the superfluous information is removed.

Missing data imputation: By replacing the missing data in the databases with another number, imputation appears to be a method for keeping the bulk of the information stored in a database. Since it's impractical to erase information from a database after each session, several techniques are used. By doing this, the size of the dataset will be drastically reduced, raising concerns about discrimination and leading to erroneous analysis. Mean or median interpolation substitutes all occurrences of missing data within a statistic with the parameter's mean or median.

III.4 PCA-BASED FEATURE EXTRACTION

To perform a full and rigorous analysis of the problems, a number of affecting factors should be evaluated in empirical studies. Yet, it gets significantly more challenging as the information assessment process grows more sophisticated. As the data provided by some inter-correlated components might overlap, the original information's relevant data might be expressed with fewer variables to decrease the level of complexity in the feature space. In accordance with this concept, Karl Pearson developed PCA in 1901, and Harold Hotelling independently came up with and updated it in the 1930s [26]. Based on the orthogonal transformation, PCA converts the possibly connected characteristic features into a distinctive group of completely uncorrelated data, referred as principal components. The number of primary components is either equivalent to or less than the original characteristic variables. Before to beginning the CNN-LSTM technique, PCA has been used to reduce the amount of data and produce a benchmark for swiftly making a prediction. The PCA's execution is defined as follows:

When a statistical framework $r \in D^q$ with q distinctive parameters and N occurrences is provided, it transforms into a completely other set of data $w \in D^h$:

$$w_{y,1} = (c_{11}\, r_{y,1} + c_{12}\, r_{y,2} + \cdots + c_{1q}\, r_{y,q}), (w_{y,2} = c_{21}\, r_{y,1} + c_{22}\, r_{y,2} + \cdots + c_{2q}\, r_{y,q}) \ldots\ldots (w_{y,r} = c_{r1}\, r_{y,1} + c_{r2}\, r_{y,2} + \cdots + c_{rq}\, r_{y,q}) \quad (3)$$

$$Here, \forall r_y = \left(r_{y,1}, r_{y,2}, \ldots\ldots, r_{y,q}\right)^t \in r, \qquad y = 1,2, \ldots\ldots, N \quad (4)$$

Every succeeding element does have the largest variance possible within its own set of limitations after the initial primary component $G_1 = w_{1,1}, w_{2,1}, \ldots\ldots, w_{N,1}$, which has the highest variance possible within the limitation that renders it transverse to the following components. The following are indicators of the PCA characteristics:

$$Variance(G_1) \geq Variance(G_2) \geq \cdots \geq Variance(G_h) \quad (5)$$

$$Covar(G_a, G_b) = 0, a \neq b, a, b = 1,2, \ldots\ldots, h \quad (6)$$

Where the $h \times q$ matrix k specifies the $y-th$ rows and a distinct coordinate structure and $k_y = k_{y1}, k_{y2}, \ldots\ldots, k_{yq}$ actually makes up element $y-th$ of the information covariance matrix M.

$$M = \frac{1}{N}\sum_{r=1}^{N} r_j r_j^t \tag{7}$$

In order to solve the characteristic formulation, PCA first computes the covariance matrix M:

$$Mk_y = \gamma_y k_y, \qquad y = 1,2, \ldots, h \tag{8}$$

Obtaining the related eigenvectors of the eigenvalues as well as the eigenvalues $\gamma_y (j = 1,2, \ldots, h)$. The eigenvector with the largest eigenvalue, G_1, which represents the most variation in the dataset r, makes up the initial component. This has been accompanied by the eigenvector with the second-largest eigenvalue, G_2, and so on. It might organize the eigenvalues in descending order and then choose the initial h main components to represent the real data in attempt to lessen the database size while keeping as much data as feasible.

III.5 CNN-LSTM BASED ENERGY CONSUMPTION PREDICTION

The CNN seems to be the deep neural network. Its objective is to identify the fundamental and inherent properties through the guided analysis of 2- or 3-dimensional data. These features have been suitable for predicting and identifying energy consumption in 3D printing. In a typical CNN architecture, an input layer is connected to several dense layers, fully-connected layers, pooling layers, an output layer, and a convolutional layer.

III.5.1 Convolutional Layer

This layer performs a convolution procedure using the raw input information and convolution kernels to produce new attribute variables. The approach was developed to extract attributes from a database; hence, the incoming data has to be structured into a matrix. The convolution kernel was already conceptualized as a tiny aperture that, in comparison to the input arrays, organizes coefficient values into a column. Convolutions are being performed on each layer while the display "slides" over the input arrays. A feature parameter called a convolved structure has been created by the filter's assigned dimension component and coefficient values. Applying different convolution operation to the input data will generate convoluted features, which have been frequently more helpful than the primary characteristics of the source data. Thus, the method works enhanced. The premise of CNN seems to be a convolutional layer, since the large number of calculations has been finished at this layer. It seems to be a data extraction stage that uses filters to extract local features, creates a feature map computed using convolution, leaves kernel function, also moves on to the pooling layer. Equation (9) contains convolutional layer expression.

$$P_m{}^{(a)} = \sigma(G_m{}^{(a)} + \sum_{n=1}^{s(a-1)} P_n{}^{(a-1)} * U_{m,n}{}^{(a)}) \tag{9}$$

Here, * (operator) represents convolution operation and $U_{m,n}{}^{(a)}$ represents filter linking the n^{th} feature-map in a-1 layer with the m^{th} feature map in a layer seems to be the function, which is utilized enhance nonlinearity, and activation matrix is denoted as σ.

III.5.2 Pooling Layer

Generally, pooling layer has been implemented after the convolutional layer. The information in the outcome of the convolution layer must be streamlined by the pooling layer. Moreover, the convolutional layer's feature map information from each feature map is used by the pooling layer to develop a condensed feature map. The most widely used strategies are mean and maximum pooling. On this stage, no learning has been taking place. In this level, size M×M filters were employed. Eqnuations (10) and (11) illustrates the average pooling and maximum pooling layers, correspondingly.

$$\bar{a} = \frac{1}{L}\Sigma_{(m,n)\in G} a_{m,n} \tag{10}$$

$$a_{max} = max_{(m,n)\in G}(a_{m,n}) \tag{11}$$

Where $a_{m,n}$ represents the quantity of each data in portion G and L denotes area's data count.

III.5.3 Dense Layer

The LSTM approach has been used in the dense layer. A subtype of recurrent neural networks with the ability to learn over time by using feedback links is the LSTM neural networks [27]. This technology generates STM and gets statistics from it utilizing cyclic linkages on their hidden layers and gather data from both time-series and sequences. Each LSTM unit consists of a memory cell as well as the three main gates for input, output, and forget.

This framework allows the LSTM to select the data that should be "forgotten" and the data that should be "remembered," resulting in a governed data stream and training for long-term interconnections. Equation (12) forecasts the LSTM unit's effective functioning. The developed approach's layers are given in Figure 3.

$$a_u = \sigma(P_u m_s + R_u n_{s-1} + t_u) \tag{12}$$

Here, weight matrices are R and P, m_s indicates input, σ represents the sigmoid function, and t denotes bias-term vector.

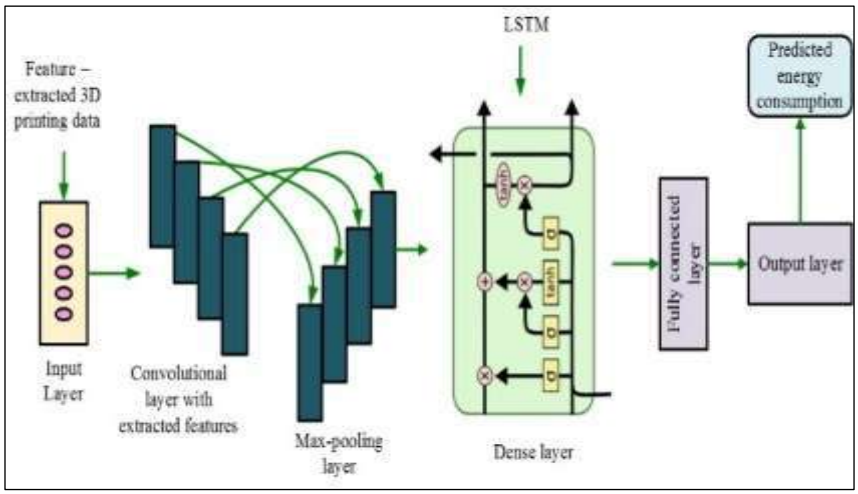

Figure 3: Developed CNN-LSTM's layers.
Source: Authors, (2026).

III.5.4 Output Layer

The output layer's cells, also referred to as the fully-connected layer, are totally dependent on all areas of the preceding layer of the memory. Behind this layer, information is turned into a 1-D array. The total number of completely linked layers in each design may vary. In this level, feed forward has been accomplished using Equation (13).

$$a_m^s = \sum_n u_f^{s-1} v_n^{s-1} \tag{13}$$

Here, number of layer is represented as s, v_n^s represents number in the developed output layer, number of neuron is represented as m and n, u_f^(s-1) indicates hidden layer's weight, v_n^(s-1) denotes input neuron and a_m^s denotes activation function's value in the output layer. The overall process of work is shown in algorithm 1.

Algorithm 1**:** CNN-LSTM

Input: Ender-3 3D printer data
Output: Energy consumption
Import input 3D printer data
Let X be the source data, which is considered for assessment
$X = \{X_1, X_2, X_3 \ldots.\}$
Data augmentation

IV. RESULTS AND DISCUSSIONS

This section evaluates the suggested hybrid optimization with DL-based energy consumption performance and compares with conventional approaches. The outcomes of the simulation have been achieved for different models using different performance measures in order to evaluate the suggested DL model-based prediction's effectiveness.

Table 1: Parameter setup.

Parameters	Values
Molding method	FDM
Nozzle diameter	0.0004m
Model	Ender-3 pro
Printing size	0.22×0.22×0.25 m
Speed	50mm/s
Machine size	0.44×0.42×0.465 m
Printing precision	±0.1mm
Net weight	6980g
File transfer	SD-card offline or online
Filament	PLA
Printing temperature	210º

Source: Authors, (2026).

The suggested technique has been applied in MATLAB R2022b, and the experimental outcomes were obtained. The parameters employed for implementation is shown in Table 1. Moreover, the input models given for energy consumption prediction are shown in Figure 4 (a) and (b).

IV.1 OTHER DL MODELS EMPLOYED FOR ASSESSMENT

IV.1.1 GRU

GRU is indeed a form of RNN, which was created by [28] as a simplified option to LSTM networks. GRU can analyze sequential data, including time-series data, text, and speech, just as LSTM. The fundamental principle of GRU would be to dynamically modify the network's hidden layer at each iteration interval via gating techniques. Information flow into and out of a system is managed by the gating procedures. The update gate and the reset gate are two of the GRU's 2 gating systems.

IV.1.2 CNN

In order to handle data with a grid pattern, like images, CNN seems to be a form of DL model that has been motivated by the structure of animal's visual cortex. From lower- to higher-level structures, CNN has been designed to continually and aggressively gather spatial categories of attributes. A typical CNN is made up of three different types of layers: fully-connected, convolution, and pooling layers. Convolution- and pooling-layers in order each and two provides features extraction, whereas a fully-connected layer in order multiple transforms the obtained characteristics into the consequence, such forecasting. A convolution layer appears essential in CNN that is composed of a series of mathematical operations, comprising convolution, a particular form of linear component [29].

IV.1.3 LSTM

LSTMs are employed in the area of DL. A number of RNNs, particularly in issues involving sequence forecasting, are susceptible of acquiring long-term connections. In addition to solitary data sources like images, LSTM also has feedback links that let it to analyze the whole data stream. This is useful for speech recognition and machine translation, among other things. The LSTM is a special type of RNN that excels at solving a variety of problems.

IV.1.4 Bi-LSTM

Two LSTMs—one receiving the input towards the forward manner while the second processes it in a backward direction—combine to form the Bi-LSTM, a sequential processing paradigm. With the assistance of Bi-LSTMs, the system has entrance to more statistics, which assistances the method's setting. One extra LSTM layer is added by Bi-LSTM, which changes the data flow's orientation. That simply implies that in the extra LSTM block, the incoming data flows backwards. The outcomes from the 2-LSTM layers have been then combined employing a numerous methods, comprising mean, sum, concatenation or multiplication. Many benefits come with this kind of design for solving real-world issues.

IV.2 DL MODEL'S PERFORMANCE EVALUATION

In order to assess the energy consumption forecast, the various DL techniques' performance metrics have been looked at. The MSE, MSE, MAE, NMSE, correlation, and RMSE have all been used in this study to assess how well the DL model has worked. To compute prediction errors and assess prediction models, several metrics are used. The MAE, MSE, and RMSE are well-known scale-dependent metrics based on real and squared values.

IV.2.1 MSE

The mean square error (MSE) appears to be measured in statistics. It is a risk function that corresponds to predicted values. It could have never been null since it is arbitrary. It has consistently been employed to evaluate estimate performance in a positive way. MSE appears to be a secondary instant that takes estimate variance and error causes into account. The MSE seems to be an unbiased predictor with estimate directionality. It has been calculated using the mean squared variances between the actual and anticipated values.

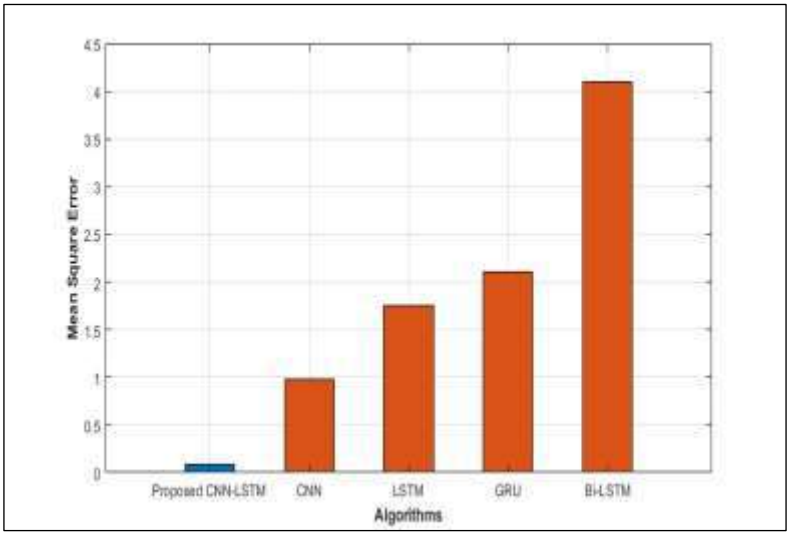

Figure 5: Obtained MSE.
Source: Authors, (2026).

The above Figure 5 indicates the graphical chart of MSE. The result indicated that the presented CNN-LSTM model has attained less MSE of 0.080762 when compared to other method like CNN, Bi-LSTM, GRU, and LSTM. Moreover, the attained MSE of CNN, Bi-LSTM, GRU, and LSTM are 0.979475, 4.10168, 2.099311, and 1.754408, correspondingly. It is evident that the presented method has less prediction error.

IV.2.2 RMSE

The MSE appears to be a statistic that is frequently used in estimates. The RMSE was utilized instead of the MSE by taking the square root. The RMSE calculates how far an estimate deviates from reality. Equation (14) calculates RMSE.

$$\mathrm{RMSE} = \sqrt{{}^{1}/_{\mathrm{N}} \times \sum_{u=1}^{\mathrm{N}} (\mathrm{A_u} - \mathrm{D_u})^2} \tag{14}$$

Where, $|\mathrm{A_u} - \mathrm{D_u}|$ is the absolute error, and N is the number of errors.

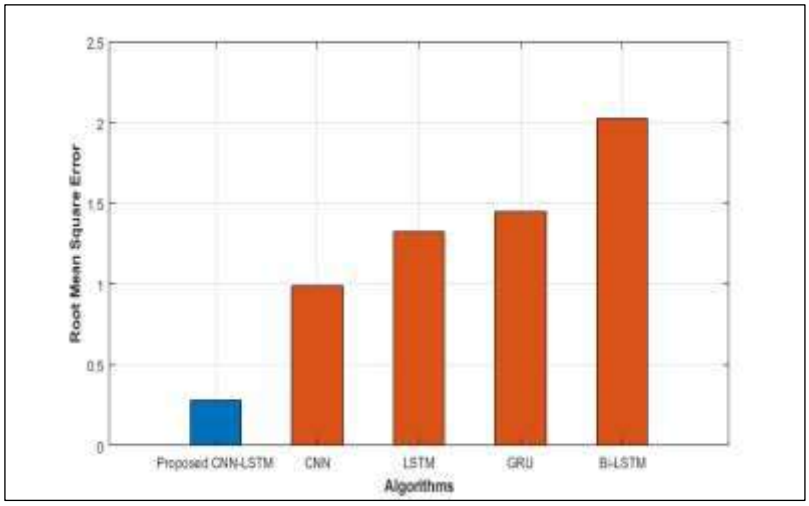

Figure 6: Obtained RMSE.
Source: Authors, (2026).

The above Figure 6 presents the graphical chart of RMSE. The result indicated that the presented CNN-LSTM model has attained less RMSE of 0.284187 when compared to other method like CNN, LSTM, GRU, and Bi-LSTM. Moreover, the attained MSE of CNN, LSTM, GRU, and Bi-LSTM are 0.989, 1.324, 1.448, and 2.025, correspondingly.

IV.2.3 MAE

By considering the average amount of error over a set of predictions while disregarding the direction of the mistake, the MAE assigns less weight to exceptional predictions. Equation (15) calculates MAE.

$$\mathrm{MAE} = {\sum_{u=1}^{N} |A_u - D_u|}/{N} \tag{15}$$

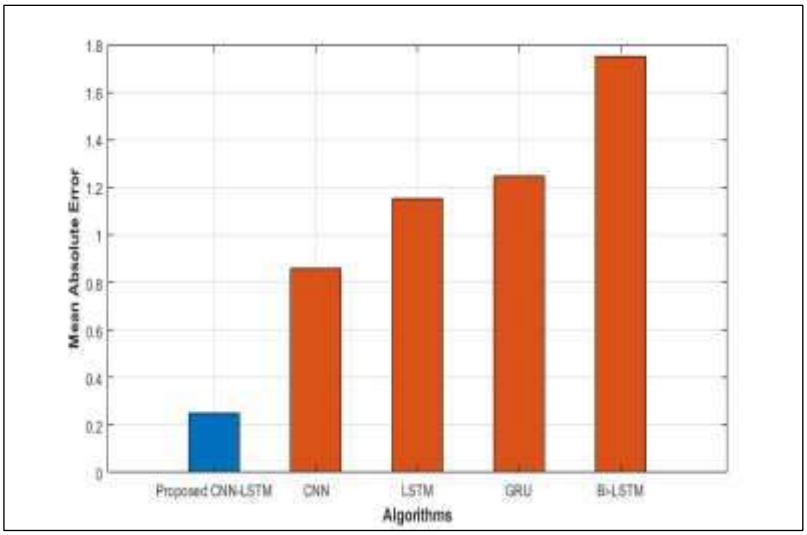

Figure 7: Obtained MAE.
Source: Authors, (2026).

The above Figure 7 present the graphical chart of MAE in which the presented approach has been contrasted with other different method like CNN, Bi-LSTM, GRU and LSTM. From the graph it can be stated that the presented method (CNN-LSTM) has low MAE of 0.251005 and Bi-LSTM has high MAE range. This makes the proposed method more effective.

IV.2.4 NMSE

When the training procedure has been executed for every instance in the training database, one epoch happens. Finding the weights, which reduce a particular total error measure, like the sum of MSE or squared errors, seems to be the ultimate objective. The commonly utilized NMSE is utilized in this study to assess the precision of estimates of energy consumption and is described as follows:

$$\mathrm{NMSE} = {1}/{\sigma^2 N} \times \sum_{u=1}^{N} (A_u - D_u)^2 \tag{16}$$

Where, σ^2 represents the time-series variance.

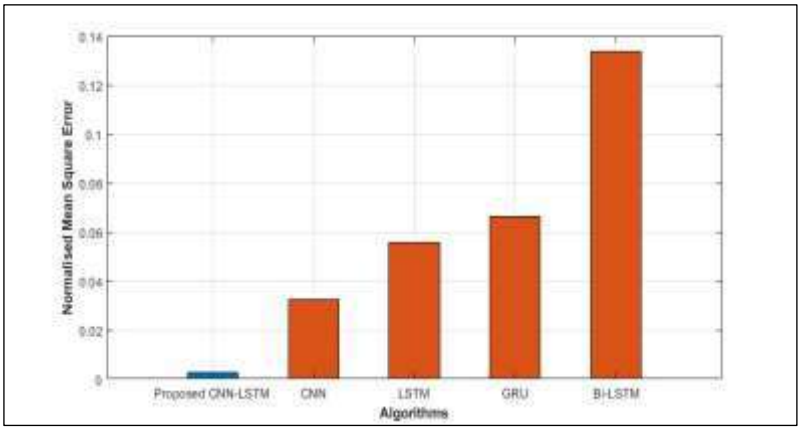

Figure 8: Obtained NMSE.
Source: Authors, (2026).

The above Figure 8 present the graphical chart of NMSE in which the presented model has been contrasted with other different method like CNN, Bi-LSTM, GRU and LSTM. From the graph it can be stated that the presented method (CNN-LSTM) has low NMSE of 0.00272 and Bi-LSTM has high NMSE range. Since the NMSE range is low the performance could be more effective.

IV.2.5 Correlation

The relationship between parameters or attributes in a dataset is quantified by correlation coefficients. There isn't any inclination for the levels of the parameters to rise or fall together when there has been no connection between them. Even if two variables have been uncorrelated, they could still not be autonomous because of a nonlinear connection.

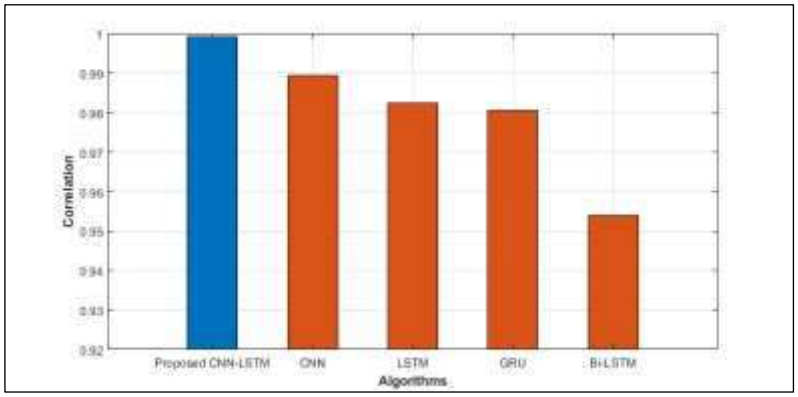

Figure 9: Obtained correlation.
Source: Authors, (2026).

The above Figure 9 present the graphical chart of correlation in which the presented approach was contrasted with other different model like CNN, Bi-LSTM, LSTM and GRU. From the graph it can be stated that the presented method (CNN-LSTM) has high correlation range of 0.999212 and Bi-LSTM has low correlation range about 0.95394. The method with higher correlation is suitable for accurate prediction. Thus, the developed model has higher prediction reliability.

IV.3 PERFORMANCE EVALUATION OF PRESENTED CNN-LSTM

For the prediction of energy consumption, accurate prediction is crucial. Since the results of the obtained prediction have not been very excellent, it would appear that developing a more trustworthy method is essential.

Table 2: Performance of the proposed method CNN-LSTM.

Evaluation metrics	Proposed CNN-LSTM
MAE	0.251005
RMSE	0.284187
MSE	0.080762
NMSE	0.00272
Correlation	0.999212

Source: Authors, (2026).

When evaluating the performance of the proposed technique, the MAE, RMSE, MSE, NMSE, and Correlation were all taken into account. Table 2 and Figure 10 displays the outcomes of these variables used in the study, which made use of 80% training data and 20% testing data.

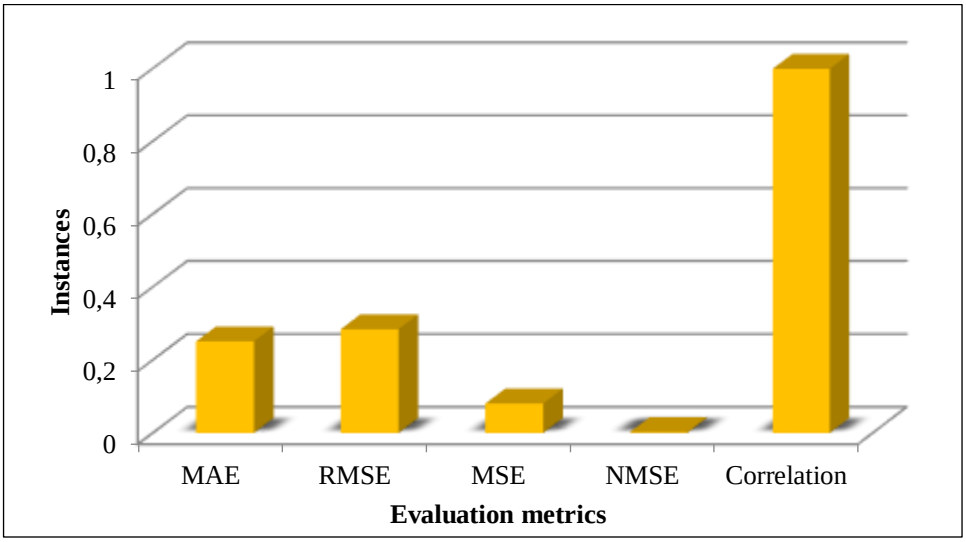

Figure 10: CNN-LSTM model performance.
Source: Authors, (2026).

The MAE, RMSE, MSE, NMSE, and Correlation of the provided CNN-LSTM model are all 0.251005, 0.284187, 0.080762, 0.00272, and 0.999212, respectively. According to the findings, the provided model has achieved less error in the prediction of energy consumption.

IV.4 COMPARISON

To determine the viability of the offered methods, proposed CNN-LSTM models were evaluated and compared to other methods already in use. The RMSE comparisons of current strategy with various approaches are shown in Table 3, and Figure 11. The presented DL model was compared with existing models like Support Vector-Regression (SVR), Gradient-Boosting Regression Tree (GBRT), CNN, and XGBoost [15].

Table 3: Comparison of RMSE.

Method	RMSE
SVR	154.79
GBRT	163.23
CNN	231.96
XGBoost	130.78
Proposed CNN-LSTM	0.284

Source: Authors, (2026).

The result indicated that the presented CNN-LSTM has attained less RMSE of 0.284 when compared to other state-of-art methods. The SVR method has obtained RMSE as 154.79, GBRT model has attained RMSE as 163.23, CNN approach has attained RMSE as 231.96, and XGBoost has attained RMSE as 130.78. From the comparison outcome, it is evident that the presented model's RMSE has enhanced up to 90% than the other existing methods.

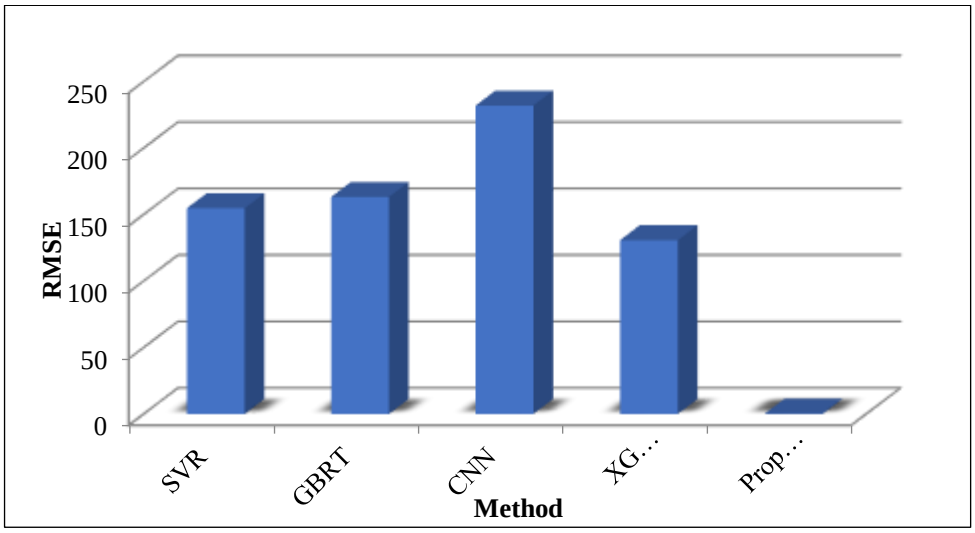

Figure 11: RMSE comparison.

V. CONCLUSIONS

AM seems to be a comprehensive manufacturing method that integrates a number of technologies and is presently used in a wide range of sectors. However, in AM techniques, energy use has grown to be a big problem. As a result, a hybrid DL (CNN-LSTM) strategy is suggested. A study of relevant studies highlighting the importance of CNN and LSTM in the industrial arena served as the inspiration for the suggested strategy. Data related to printing are used as source in a suggested DL-based energy consumption forecasting technique. Moreover, to enlarge the database, data augmentation process has been performed. In addition, pre-processing was performed to remove the duplicate data, missing data imputation, and data normalization. Hereafter, feature extraction was done by PCA that extracts the required features from pre-processed data for prediction. A novel hybrid CNN-LSTM model has been finally implemented for predicting the energy consumption. The result indicated that the presented model has attained less prediction errors while contrasted to other existing and state-of-art methods. Thus, the presented CNN-LSTM model has higher prediction reliability. However, this method employs smaller parameters for predicting 3D printing's energy consumption. Thus, in future variety of data kinds will be used for predicting energy consumption using optimization method with different hybrid DL framework.

ABSTRACT

Federated Learning (FL) has emerged as an attractive concept of facilitating privacy-saving artificial intelligence in the field of medicine. This paper suggests a secure and robust Federated Learning framework that enhances the robustness and privacy of medical image analysis, as well as safeguard the data confidentiality of decentralised healthcare organizations. The framework incorporates superior security protocols to protect the federated learning systems to model poisoning and adversarial interruptions. It enhances the resilience of the global model to inconsistent or malicious contributions of data by using adaptive aggregation, anomaly detection, and dynamic reputation-based client evaluation. It is more accurate, stable, and robust to use in a heterogeneous and non-IID environment, which guarantees the reliable cooperation of decentralized medical applications. The proposed structure comprises of a well-organized pipeline that involves data preprocessing, local training, and secure model aggregation. A convolutional neural network (CNN) is trained on histopathological images by each client and does not violate data privacy on an institutional level. The improved efficiency and reliability as well as the resilience of the model to disruptive hostile training of histopathological images are experimentally demonstrated on a curated dataset of histopathological images. It can be proved that the proposed system is well-diagnostic with enhanced compliance with privacy and offers a flexible and dependable model of healthcare partnership on a large scale. This paper highlights how federated learning can advance improved clinical outcomes and enhance the quality of patient care by demonstrating the result of applying federated learning to multi-institutional image analysis and showing improvements in model security and performance.

I. INTRODUCTION

I.1 THE ROLE OF DATA PRIVACY IN MODERN HEALTHCARE

In the era of massive data expansion and technological progress, the protection of data privacy is an important issue, particularly in the medical field, where patient data confidentiality is at stake. Federated learning continues to become hailed as a groundbreaking approach to machine learning whereby the cooperation of organisations can create the models without necessarily breaching the privacy of sensitive data [1]. Rather than centralizing patient data, each of the participating institutions retains the power over information and considerably minimizes the potential threats of unauthorized access to data or information breach and meet ethical and legal demands of confidentiality [2]. The question is still how to use the technological innovations as artificial intelligence (AI) becomes an inseparable component of clinical diagnostics and decision-making and how these factors would not threaten the confidentiality of patients and disregard the international standards of patient privacy [3].

I.2 FEDERATED LEARNING: A DECENTRALIZED APPROACH TO SECURE COLLABORATION

Federated Learning (FL) is a decentralized method which enables a group of institutions to share the operations of training machine learning models without sharing raw data across one organization to another. Under this setup, each client is learning a model on its own confidential data and only send back the new parameters in a central server where they can be aggregated together using a series of aggregation algorithm like the Federated Averaging (FedAvg) algorithm, as shown in Figure 1. The process allows the development of globally applicable models that will ensure the generalization of data among different healthcare settings, without the leakage of information [4]. FL has achieved success in diagnostic imaging, classification of the disease and customized prognostication. Further research on this area has been made by the introduction of attention-guided networks, adaptive aggregation, and reputation-based weight optimization to improve model robustness and trustworthiness in the application of AI in medicine [5], [6].

I.3 APPLICATIONS AND FUTURE PROSPECTS IN CANCER HISTOPATHOLOGY

Federated learning can be applied to cancer histopathology, which has complicated tissue structures and diagnostic issues, to a significant effect because, by using multi-institutional datasets, privacy of patient data can be preserved. Based on decentralized training models, histopathological data in various labs are combined to train convolutional and transformer-based neural networks, which improve the accuracy and reliability of the classification in identifying cancers. New FL architectures have reached near the same level of parity as centralized learning, and do not infringe the data protection legislation [7]. Besides privacy protection, FL reduces bias in the datasets and establishes inclusive healthcare innovation by enabling resource-constrained institutions to contribute. In addition to privacy protection, FL minimises bias in the datasets and creates inclusive healthcare innovation by allowing resource-constrained institutions to contribute. Federated learning is increasingly positioned as a core technology for ethical AI implementation in precision oncology and digital pathology [6], [8].

II LITERATURE SURVEY

This section reviews current developments in Federated Learning (FL) within the healthcare domain with particular attention to its application in medical image analysis and its capacity to enhance model performance and reliability. It also examines the security vulnerabilities inherent in FL and outlines the defense strategies proposed to counter adversarial threats in distributed learning environments.

II.1 FEDERATED LEARNING: CONCEPTS AND FRAMEWORKS

Federated Learning (FL) has become one of the most innovative models in the sphere of decentralized model training and the possibility to empower many medical institutions to develop strong AI systems without sharing sensitive patient data. In contrast to the idea of the conventional teaching methods of centralized learning when all the data is located in a single location, data sovereign is the feature of federated learning in which the raw data is stored on the local devices and only the model parameters are sent there to facilitate aggregation [1], [9]. This form of decentralization allows FL to be particularly useful to healthcare applications that require highly regulated privacy of data like the Health Insurance Portability and Accountability Act (HIPAA) in the U.S. and the General Data Protection Regulation (GDPR) in the European Union. Medical imaging has also been employed using FL so that it can enable a closer collaboration of hospitals, by diagnostic modelling of images obtained by MRI, CT, and histopathology, as well as performance comparable to centralized architectures [10]. Spinning frameworks, such as TensorFlow Federated (TFF), and PySyft are driving forces behind the creation of federated learning (FL) systems. TFF is a developed Google-based architecture that offers a scalable, TensorFlow-based framework enabling the simulation and deployment of distributed learning models with locality and privacy of the data. It permits encryption of training and aggregation of model parameters, ensuring sensitive data remains decentralized throughout the learning process. Together, TFF and PySyft provide complementary features that balance scalability, accuracy of model, and privacy preservation across diverse federated learning environments.

II.2 SECURITY AND PRIVACY CHALLENGES IN FEDERATED LEARNING FRAMEWORK

Although FL follows a privacy-sensitive design, a number of security threats to the model, such as model poisoning and adversarial manipulation, exist. Such attacks may disrupt convergence of the model and deteriorate level of diagnostic accuracy, posing a security threat in high-stake medical scenarios [11], [12]. Researchers have proposed several Byzantine-resilient aggregation algorithms such as Krum, Trimmed Mean, and FLTrust, to detect and address the malicious or corrupted updates in federated learning systems. Nevertheless, such strategies usually involve a trade-off between stability and predictiveness, narrowing the flexibility to dynamic opponent tactics [13]. Additionally, the data poisoning attacks in question are exceptionally difficult to eliminate due to their insidious nature and their ability to be both insidious and unnoticeable [14].

II.3 DEFENCE STRATEGIES AND THE ROLE OF FLAIR

To enhance FL to counteract these weaknesses, recent research has been directed at incorporating dynamic defences that are dynamically assessing the behaviour of clients. These include Federated Learning with Adversarial Injection Robustness (FLAIR) as one of the leading defence systems. FLAIR implements a layered defense strategy that combines gradient behaviour analysis, client reputation assessment, and weighted aggregation at the global server. By continuously monitoring client updates, it detects and limits the influence of abnormal or potentially compromised participants. This comprehensive approach makes the system resilient to both white-box and black-box adversarial attacks, successfully diminishing the impact of malicious activity within the collaborative learning environment**.** It has been observed that the FLAIR can be used to achieve high classification performance when upto 30 percent of the clients are malicious, compared to the classical robust aggregation techniques like the FABA and Fools Gold based on empirical research. [12], [15].

II.4 FEDERATED LEARNING FOR MEDICAL IMAGE ANALYSIS

Federated learning combined with convolutional neural networks (CNNs) has greatly advanced precision diagnostics while ensuring patient data protection in medical image analysis. CNN-based FL models allow hospitals to jointly train classifiers on cancer detection of histopathological slides, which extracts accurate features, and data is not aggregated at a central location [9]. Federated learning, combined with a more sophisticated system of security infrastructure, such as FLAIR can increase the dependability and durability of medical AI systems significantly. With the ongoing adoption of artificial intelligence in healthcare, secure federated learning is one of the pillars of the medical analysis of data in the future with a compromise between diagnostic capabilities, respect to privacy, and resistance to adversarial risks.

Figure 2: Schematic workflow depicting the implementation and impact of federated learning in cancer histopathology across multiple institutions.
Source: Authors, (2026).

III. METHODOLOGY

The proposed methodology shown in Figure 2 explains the foundations of Federated Learning (FL) to enable secure, distributed training of deep learning models for cancer histopathology image analysis. The proposed framework was developed using the PatchCamelyon (PCam) dataset, sourced from the Camelyon16 Challenge, which offers a diverse and high-resolution collection of lymph node histopathology images suitable for robust model training and evaluation.

III.1 DATA PREPROCESSING

The sample dataset consists of 327,680 patches of histopathological images (96 pixels) of lymph node sections stained with Haematoxylin and Eosin (H&E) at 40x, sampled down to a 10x representative to ensure a larger field of view. The images are stored in TIF format in three RGB channels, 8-bit depth, and then, they are saved in a compressed form with JPEG coded to save on space. Figure3 illustrates graphically key steps in combination of datasets preparation and preprocessing pipeline, which starts with obtaining digital pathology images and continues with distributed data preprocessing, safe aggregation, and ultimate clinical implementation. It also reflects the end-to-end workflow, which facilitates privacy-preserving collaborative learning in medical imaging by expressing both the process of local CNN training on hospital data and the federated model update process.

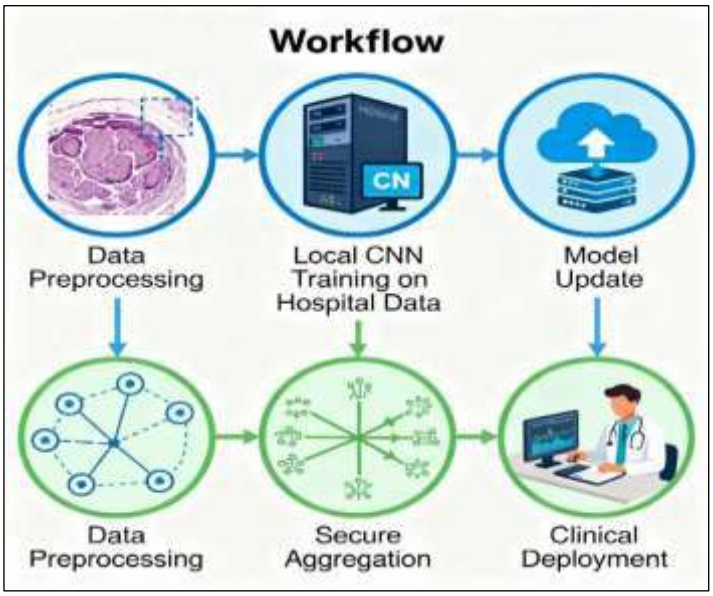

Figure 3: Diagram outlining the major steps of the federated learning process, including the initial global model setup, decentralised client training, secure aggregation at the central server, and iterative refinement under privacy preservation.
Source: Authors, (2026).

A stringent quality control step was followed using experienced pathologists in order to confirm the patch-level accuracy and to remove images with scanning artefacts or misalignment of tissues. The end dataset (that has undergone curation) had a total of about 220,000 training patches, 57,000 validation samples, and 50,000 test images, with an equal balance of metastatic versus non-metastatic samples.

III.2 FEDERATED LEARNING FRAMEWORK IMPLEMENTATION

The federated learning framework was structured across multiple client nodes, each corresponding to an individual medical institution and a central coordinating server. The system implemented the Federated Averaging (FedAvg) algorithm along with additional robustness techniques to preserve model performance under non-IID (non-independent and identically distributed) data conditions, as summarized in Table 1. The federated learning framework begins by having the main server design and disseminate a convolutional neural network (CNN) model structure to each participating site. This model is subsequently trained on their own portion of the PCam dataset, which is independent at any given institution, and all patient data remains at their original point of existence. After the process of updates, the model parameters as revised by institutions are encrypted using homomorphic encryption, and the information is secured as it is sent back to the central server. Upon its collection, the server summons and examines the encrypted weights with an adaptive form of FedAvg with support of the anomaly detection and dynamic reputation scoring tools, which allow recognizing and penalizing any potentially malicious updates. This process of collaboration recurs as the enhanced global pattern is reintroduced to all locations to be again refined, including privacy-enhancing measures with regulatory conformity (HIPAA, GDPR), interpretability, and resistance to adversarial manual surgery.

III.3 MODEL ARCHITECTURE AND TRAINING PROCEDURE

A Convolutional Neural Network (CNN) with a ResNet-50 backbone was adopted as the primary architecture due to its proven performance in histopathological classification.

- Input Layer: Processes 96×96×3 RGB images.

- Convolutional Feature Extractor: Sequential layers employ filters of sizes 3×3 and 5×5 to capture texture and colour variations characteristic of tumour morphology.
- Global pooling and dense layers were used for spatial feature aggregation, leading to a binary output layer distinguishing metastatic from non-metastatic samples.
- Parameters of the training: The model was trained using Adam optimiser with a batch size of 64, learning rate of 1×10^{-4}, and binary cross-entropy loss throughout 50 epochs of each local round. The accuracy, AUC, F1-score, and recall measures were used to assess performance.
- In the federal framework, the clients involved only sent their model parameters to be aggregated globally. They ensured privacy by using Secure Multi-Party Computation (SMPC) protocols and introducing the use of the differential privacy noise during model updates exchange.

III.4 EVALUATION AND VALIDATION

The global model underwent evaluation on an independent validation set, assessing both its accuracy and robustness against adversarial perturbations or gradient poisoning attacks. The proposed federated learning model generated high gains in the global AUC and precision over standalone and centralized baseline models. The average performance measures of all the involved client nodes were calculated to facilitate a reasonable comparison of data across different distributions of data and this showed that the framework was strong and capable of generalization across decentralized datasets. Additionally, explainability techniques such as Grad-CAM visualizations were integrated to interpret the CNN's decision regions on histopathological patches, enabling clinicians to understand the model rationale during diagnosis.

Table 1: Summary of the main workflow stages and corresponding techniques utilized in the proposed federated learning workflow for robust and privacy-preserving cancer histopathology analysis.

Step	Description	Tools/Methods Used	Objective
Data Acquisition	PCam-derived H&E-stained lymph node patches	Camelyon16 Challenge dataset	Provide diverse , high-resolution image data
Preprocessing	Normalization, denoising, augmentation	OpenCV, NumPy	Improve feature quality & diversity
Local Training	Collaborative CNN learning on distributed client locations	TensorFlow Federated	Ensure privacy-preserving model updates
Secure Aggregation	FedAvg + FLAIR defense	Homomorphic encryption, anomaly detection	Robust aggregation against attacks
Evaluation	Multimetric assessment & interpretability	Gradient-based visualization (Grad-CAM)	Verify accuracy, stability & model explainability

Source: Authors, (2026).

IV. RESULTS

The suggested framework showed a substantial improvement in the performance of all the participating clients in relation to the individual and centralised training methods. Through the use of decentralised datasets of histopathology, the global model had greater generalisation and robustness without losing the privacy of the data.

IV.1 MODEL PERFORMANCE UNDER STANDARD FEDERATED TRAINING

The global average model had a 94.2 percent accuracy, an AUC of 0.96 and an F1-score of 0.93, higher by a margin of 68 percent and centralised baselines by 35 percent, respectively. It is worth noting that there was no significant drop in model performance because of introducing privacy-enhancing policies, such as a Secure Multi-Party Computation (SMPC) and the introduction of noise into privacy.

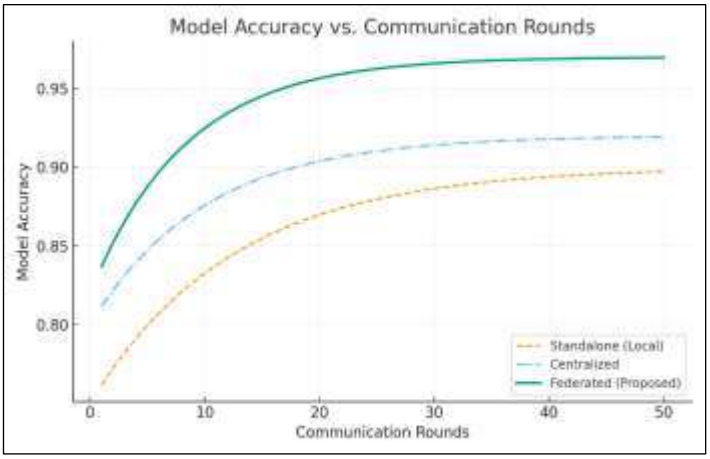

Figure 4: Model accuracy across communication rounds depicts faster convergence and improved performance of the federated learning framework.
Source: Authors, (2026).

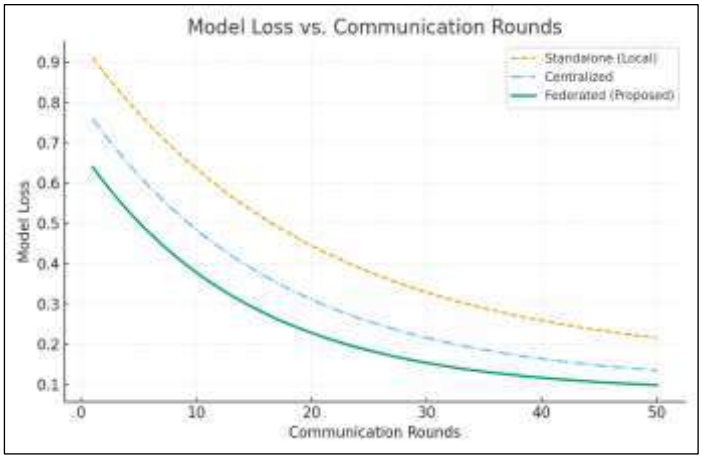

Figure 5: Model loss across communication rounds showing smoother optimization and stable convergence in the federated framework.
Source: Authors, (2026).

As illustrated in Figures 4 and 5, each round of model training and validation resulted in steady gains in overall performance. The system's accuracy converged smoothly after approximately 30 distributed updates, highlighting effective and consistent global aggregation. The loss curve was increasing steadily with slight fluctuations, signifying that there was a proper synchronisation of model weights by the participating clients. Meanwhile, the AUC values increased gradually, which proves that the possibility of the model separating the classes increased with the implementation of consecutive global updates. When comparing the performance plot between federated, centralised and standalone models summarised in Table 2, it was found that the federated performance attained greater AUC and precision but also lower generalisation error, indicating reduced overfitting since there was diversity in data. The marginal differences that were witnessed in the preliminary rounds must have been explained by the disparity in the time of updating the clients. Such fluctuations were reduced after the introduction of adaptive aggregation weights. The achieved stability indicates that the model was able to balance the updates imported by the clients with dissimilar dataset sizes and uneven distributions of classes.

Table 2: Performance comparison showing superior accuracy, AUC and F1-Score of the proposed federated model with privacy preservation.

Model Type	Accuracy (%)	AUC	F1-Score	Recall	Remarks
Standalone (Local)	86.5	0.88	0.84	0.81	Limited generalisation due to data isolation
Centralized	90.1	0.93	0.89	0.87	Improved but constrained by privacy concerns
Federated (Proposed)	**94.2**	**0.96**	**0.93**	**0.91**	Superior performance with privacy preservation

Source: Authors, (2026).

The quantitative data and graphical analysis of the study collectively prove that federated learning ensures the best balance between accuracy, fairness, and privacy in the context of multi-institutional medical imaging. The fact that convergence is stable in the framework, performance has little variance among clients, and privacy standards are met, makes it a promising new development in the deployment of AI in cancer histopathology in the future. The histopathological images were assessed qualitatively, which showed that there was a better detection of the tumour boundary and the consistency of classification across institutions. Inter-observer variability was also minimised by the federated model, which was consistent with expert annotations of pathologists. In general, the findings confirm that federated learning is a scalable and privacy-preserving method of multi-institutional cancer histopathology analysis, which yields diagnostic accuracy equal to centralised training and without violating the standards of data security.

The visual and statistical distinctions between cancerous and non-cancerous histopathological tissue samples used in the study are depicted in Figure 6. Cancerous regions are characterised by higher cellular density and more intense staining, whereas non-cancerous samples tend to exhibit more uniform structural patterns. These visual traits are critical for deep extraction of features in CNN-based classification. Figure 7 depicts the RGB intensity histograms corresponding to these samples. The cancerous tissues exhibit broader and shifted intensity distributions, particularly in the red and green channels, reflecting variations in tissue composition and stain uptake. The x-axis represents pixel intensity (0–255), and the y-axis denotes the pixel count. Together, these figures validate the visual-textural differences leveraged by the federated CNN framework for robust and privacy-preserving cancer classification across institutions.

IV.2 ADVERSARIAL ATTACK SIMULATION AND FLAIRE DEFENSE EVALUATION

The proposed application of FLAIR in Federated Learning using CNN Models to analyse medical images has a high potential to improve the robustness and accuracy of the existing model. The obtained performance evaluation with the help of the existing model simulating the decentralised learning environment with the presence of 10 client nodes proved significant abilities in the learning based on the decentralised sources of data. The mean FL training test accuracy was 71 which was good to show that the collaborative learning strategy was effective. As a measure of robustness, model poisoning experiments were presented by modelling Directed Deviation Attacks (DDA) in which 20-30% of client nodes intentionally inverted gradient signs to break the global model. In the baseline FedAvg aggregation, the accuracy of the test dropped dramatically, which is 94.2 to 68.5, and the test loss increased by 40 percent. The model had inconsistent convergence behaviour and reduced AUC to 0.81, which proves the susceptibility to strategic poisoning in decentralised environments. These problems were alleviated through the combination of FLAIR (Federated Learning with Adversarial Injection Robustness). FLAIR used gradient sign variations to update clients with dynamic reputation scores, which enabled the server to downweigh anomalous updates in aggregation. Consequently, at a 30% malicious client ratio, the model was 91.3% average and having a 0.95 AUC and a 0.90 F1-score, with a difference of less than 3 percent between benign performance and the given malicious performance. As compared to this, the current defense mechanisms such as Krum (accuracy 77.8%) and Trimmed Mean (accuracy 81.5%) exhibited significant accuracy drops with increased attack intensities. FLAIR maintained the constant convergence and reduced variance of test loss, and FedAvg and Krum experienced significant oscillations. In addition, the defense of FLAIR maintained its resistance in white-box threat, in which the attackers are aware of the parameters of the models and the defense settings, and it proved to be reliable in the case of practical federated medical systems.

V. DISCUSSION AND FUTURE PERSPECTIVE

V.1 ADVANCEMENTS AND PRACTICAL IMPLICATIONS OF THE PROPOSED FRAMEWORK

The suggested framework promotes the application of federated learning (FL) to medical imaging by combining privacy-preserving deep learning with multi-institutional cancer histopathology. By incorporating multi-modal extensions—combining histopathology, radiomics, and genomic data the model enhances diagnostic comprehensiveness, aligning with recent advances by [7], [16], [17] that highlight the benefits of multi-modal FL for metastatic detection and staging. The modular architecture of the framework supports such data fusion, paving the way for integrative cancer prognosis modelling. Additionally, the concept of creating a web-based diagnostic interface such as [18] provides the possibility to deploy AI-assisted pathology in a secure, decentralised manner, resulting in the availability of AI-assisted tools and worldwide cooperation. Privacy-wise, homomorphic encryption and secure multi-party computation enhance the security of data, which can be threatened by leakage as pointed out by [1], [19], [20]. This guarantees healthcare compliance (HIPAA, GDPR) and gradient leakage protection.

The improved architecture also has an almost real-time inference that can be integrated into clinical activities which represents the adaptive edge-computing principles that [21] proposed in Federated Learning with Edge Computing (FLEC). Pathologist collaboration strengthens clinical interpretability, which is in line with retraining models outlined by [22], [23], [24]. Although FLAIR framework demonstrates high promise, it has a number of limitations. Client involvement and gradient inspection at the server level are synchronous, which adds a computational load and makes it difficult to scale a large federation [25], [26]. The model being used is based on the partially unencrypted gradients as it blocks the direct integration with the fully homomorphic encryption protocols [3], [5]. It can also be caused by non-IID data imbalance between the clients and false positive identification of a benign client as hostile [27]. Asynchronous communication, reputation-based edge modelling, and encrypted gradient aggregation should be investigated as possibilities to break these limitations in the future.

Compared with previous FLAIR methods [1], [23], [24], the paper has three big innovations: (i) a FLAIR-based system that resists adversarial gradient manipulation, (ii) further improvement of cryptographic privacy optimisation to clinical applications, and (iii) combining multi-modal and IoT-assisted elements to create real-time pathological computations. A combination of these contributions provides a basis of scalable and explainable federated learning in precision oncology. The integration of FLAIR into federated learning with CNN models is anticipated to substantially enhance both robustness and accuracy in medical image analysis. Current simulations with ten client nodes yielded an average test accuracy of 71%, reflecting the collaborative approach's efficacy in decentralized learning. By leveraging gradient pattern analysis and reputation-based weighting, FLAIR is expected to further boost accuracy and resilience against adversarial attacks, supporting privacy-preserving and reliable federated model deployment. Future research should explore asynchronous communication, reputation-based edge modelling, and encrypted gradient aggregation to overcome these constraints.

V.2 LIMITATIONS, SCALABILITY CHALLENGES, AND FUTURE DIRECTIONS

Although it features a very strong privacy and defense system, there are still some restrictions in place. The nature of FLAIR that requires clients to engage synchronously and gradients to be inspected at the server level makes it more computationally intensive and decreases the scalability of large federations. The existing use of partly unencrypted gradient values limits its capability to be used in full homomorphic encryption implementations. Also, the non-uniform and non-IID characteristic of data among clients could sometimes have the incorrect effects of triggering the system to view the legitimate updates as malicious- a phenomenon that has frequently been cited when dealing with heterogeneous medical data [27]. The future research directions are to optimise asynchronous client aggregation, cut communication cost by using a compressed model transmission, and incorporate the reputation-based edge learning to ensure client-side security. Further developments of encrypted gradient sharing and federated asynchrony are necessary to apply to real-world healthcare networks and scale FLAIR. Further exploration of the distributed defense decentralization and adaptive anomaly detection may increase the resilience in the case of a resource-constrained environment**.**

VI. CONCLUSIONS

In this study, a sophisticated federated learning (FL) model is developed to improve the activity of the artificial intelligence systems in cancer histopathology and increase their robustness, safety, and diagnostic indicators. The framework can successfully mitigate adversarial and model poisoning attacks, including by an injected adversarial, by employing the FLAIR (Federated Learning with Adversarial Injection Robustness) defense system, which enhances the credibility of joint medical image analysis. The method proves that local model training on decentralised networks could support high data privacy principles and the great precision of diagnostic tasks. The experimental findings suggest that inclusion of FLAIR in the federated implementation will result in significant losses in model accuracy, along with resistance to Byzantine faults even when the client data are broadly divergent and non-IID. FLAIR provides a superior performance to traditional aggregation mechanisms, including Krum, Trimmed Mean, and FABA, because it is more stable to convergence, and will not be directed out of shape. These findings support the fact that FLAIR is effective in preserving the integrity of the models around the world and ensuring stable diagnostic outcomes of the tool used in a variety of institutions. Biomedically, the proposed system is significant and explores the significance of secure federated learning as a driver to privacy-affirming cooperation in cancer diagnostics.

This distributed learning approach is important to the analysis of histopathological images because it enables institutions to jointly train models without impacting patient confidentiality or regulatory adherence to such regulations as HIPAA and GDPR. Therefore, the implementation is not only advancing the area of decentralised learning but also making the computational innovation consistent with the ethical and clinical requirements of medical artificial intelligence. The study can be developed in future studies in three major ways: 1. Combination of all imaging modalities (CT, MRI, and immunohistochemical scans) to construct more comprehensive and generalizable models. 2. Lightweight optimisation and cloud-edge federation Real-time clinical deployment to achieve fast and secure diagnostic responses. 3. Scaling to multiple types of cancer, using federated models to assist multi-organ pathology without being inequitable, unclear, or lacking interpretability in AI-based decisions. Overall, this study presents a strong and privacy-aware federated learning system that addresses one of the most acute issues of contemporary healthcare to attain high diagnostic accuracy and hence not endanger the privacy of patients. FLAIR implementation makes this work one of the major contributions to the creation of reliable, safe, and morally competent AI systems in the field of next-generation cancer diagnostics.

Health Worker Performance,
Hospital Information System,
Person Job Fit,
Work Life Balance.

ABSTRACT

Digital transformation in the healthcare sector has fundamentally changed the way healthcare workers provide services to patients. Hospitals are required to provide quality and efficient medical services through the implementation of an integrated hospital information system (GIS). This study aims to analyze the influence of digital self-efficacy, person-job fit, and work-life balance on healthcare worker performance in the digital era, with GIS as a moderating variable. This study uses an explanatory method to explain the causal relationship between variables. Digital self-efficacy, person-job fit, and work-life balance are conceptualized as independent variables in this study, healthcare worker performance as the dependent variable, and GIS as a moderating variable. The population consisted of nurses and midwives at Permata Keluarga Hospital. Using the Slovin formula, 190 respondents were obtained. Data were analyzed using Structural Equation Modeling (SEM) with SmartPLS version 4. The results show that digital self-efficacy, person-job fit, and work-life balance have a positive and significant influence on healthcare worker performance. The use of hospital information systems strengthens the relationship between work-life balance and healthcare worker performance, but does not strengthen the relationship involving digital self-efficacy and individual job fit.

I. INTRODUCTION

Advances in information and communication technology have brought significant changes to the healthcare sector, particularly in hospital operations [1]. The utilization of hospital information systems (HIS) has become an integral component of nursing services, patient data management, and inter-unit coordination. In this context, nurses as frontline healthcare providers are increasingly required not only to possess strong clinical competencies but also digital competencies and the ability to adapt to increasingly complex job demands. As the work environment shifts toward digitalization, the concept of digital self-efficacy defined as confidence in one's ability to use digital technologies plays a crucial role in an individual's capacity to cope with digital transformation. For instance, a study involving nurses and nursing students in Italy reported that only 47.1% possessed adequate digital self-efficacy, with factors such as gender, educational background, and work experience significantly influencing digital confidence levels [2].

In the nursing context, the ability to operate information systems, utilize electronic data, and engage in digitalization processes strongly affects nurses' work practices and performance potential. In addition, the concept of Person Job Fit (PJF) the alignment between individual characteristics (abilities, needs, and values) and job demands and attributes has been identified as a key determinant of employee performance and well-being. A study conducted in Taiwan demonstrated that when Person–Job Fit is high, the negative effects of compassion fatigue on performance and organizational citizenship behavior can be mitigated [3]. In highly demanding hospital environments such as nursing, alignment between individual competencies and job demands is therefore essential to achieving optimal performance.

Furthermore, the issue of work–life balance (WLB) the balance between work demands and personal life has become increasingly relevant in the nursing profession, which is often characterized by overtime work, night shifts, and high emotional demands. A study conducted in Egypt among nurses found a significant positive correlation between work–life balance and person–job fit, indicating that better balance between work and personal life is associated with higher levels of Person–Job Fit [4]. A scoping meta-analysis further revealed that various socio-ecological factors, including the work environment, workload, and organizational policies, influence nurses' work–life balance on a global scale [5]. These findings suggest that work–life balance is not merely an additional variable but may also shape how other variables, such as person–job fit and self-efficacy, function in enhancing performance. In the digital era, digital self-efficacy, person–job fit, and work–life balance are interrelated and collectively influence nurses' performance.

However, these relationships may depend on how effectively hospital information system technology is implemented and utilized by nurses. Efficient use of HIS can enhance nurses' ability to access patient data, perform digital documentation, and communicate across units. Conversely, suboptimal systems or low levels of digital self-efficacy among users may hinder potential performance improvements. Although previous studies have examined self-efficacy, person–job fit, and work–life balance separately or in pairs within the nursing context, relatively few studies have integrated all three variables into a single model while simultaneously considering hospital information system utilization as a moderating variable. Therefore, this study was conducted at Permata Keluarga Hospital as an empirical investigation to address this gap, focusing on nurses as the study population and employing a Structural Equation Modeling–Partial Least Squares (SEM-PLS) analytical approach.

II. THEORETICAL REFERENCE

II.1 DIGITAL SELF-EFFICACY

According to Bandura, self-efficacy refers to an individual's belief in their capability to perform specific actions required to achieve desired outcomes [6]. In a digital context, digital self-efficacy, also referred to as computer or technology self-efficacy, denotes an individual's confidence in their ability to use digital technologies to accomplish work-related tasks. Social cognitive theory and the measurement of computer self-efficacy have been widely used as theoretical and empirical references in this field [7]. Self-efficacy influences individuals' intentions to adopt new technologies as well as their performance when using digital systems. Health workers with higher levels of digital self-efficacy tend to adopt hospital information system (HIS) features more rapidly and demonstrate better job performance, as digital technologies facilitate administrative and clinical tasks. Empirical studies and meta-analyses in educational and occupational contexts consistently report a positive relationship between computer self-efficacy and performance or technology acceptance outcomes [8].

II.2 PERSON-JOB FIT

Person Job Fit refers to the degree of alignment between individual characteristics such as abilities, needs, and values and the demands and attributes of a job. The broader person environment fit theory explains this alignment and its implications for job satisfaction, organizational commitment, and performance. In the healthcare literature, Person–Job Fit has been consistently associated with job satisfaction, turnover intention, and professional effectiveness [9]. Empirical evidence from Xiao, focusing on medical and nursing professionals, demonstrates that a high level of Person–Job Fit is positively related to work engagement and task effectiveness, while simultaneously reducing turnover intention [9].

When job roles are well aligned with clinical competencies and workload demands, employee performance tends to be optimized. Conversely, a mismatch between individual capabilities and job requirements may lead to job-related stress, which in turn undermines performance quality. Furthermore, Person–Job Fit may also moderate how healthcare workers respond to technological change. For instance, individuals whose roles and competencies align well with digital task requirements are likely to experience a faster learning curve during the implementation of hospital information systems (HIS). Accordingly, in this study, Person–Job Fit is positioned as a key predictor of performance and a potential interacting variable in relation to hospital information system utilization [10].

II.3 WORK-LIFE BALANCE

Work–life balance is defined as a condition in which individuals are able to meet both work-related demands and personal life responsibilities without experiencing excessive conflict or fatigue. In the healthcare sector, work–life balance is a particularly critical issue due to long working hours, shift-based schedules, and the high emotional demands associated with patient care [11]. Numerous studies have demonstrated that a healthy work–life balance is associated with higher work engagement, improved service quality, and reduced levels of burnout and clinical errors. Organizational interventions such as flexible scheduling, institutional support, and employee well-being programs have been shown to enhance work–life balance and, in turn, improve employee performance [11].

Technology plays a dual role in this context. When properly designed and implemented to reduce administrative workload, hospital information systems (HIS) can improve work–life balance by minimizing time spent on non-clinical tasks. However, when systems are overly complex or poorly implemented, they may generate techno-stress and ultimately exacerbate work–life imbalance. Therefore, the utilization of hospital information systems particularly in terms of system quality and ease of use becomes a critical factor in determining the direction and magnitude of their impact on work–life balance and employee performance [12].

II.4 HEALTH WORKER PERFORMANCE

Health worker performance can be conceptualized across several dimensions, including task performance (clinical duties), contextual performance (prosocial behavior and collaboration), adaptive performance (the ability to adjust to changes), and counterproductive work behavior. Systematic literature provides a robust empirical framework for measuring performance in healthcare service settings.

Furthermore, Rhayha et al. define health worker performance as the work outcomes of healthcare professionals measured in terms of effectiveness, efficiency, service quality, timeliness, and responsibility in carrying out tasks through the use of hospital information systems (HIS) and digital technologies [13].

II.5 HOSPITAL INFORMATION SYSTEM UTILIZATION

Zheng et al. define hospital information system (HIS) utilization as the extent to which healthcare professionals use hospital information systems (HIS/HMIS) effectively and efficiently to support task execution, clinical decision-making, and inter-unit coordination [14]. More broadly, hospital information system utilization can be understood as the level, manner, and quality of system use designed to support clinical, administrative, financial, and operational functions within hospitals by healthcare professionals and staff. Utilization encompasses not only whether the system is technically used, but also the degree to which its features are integrated into work processes, leveraged for clinical and managerial decision-making, and translated into tangible benefits for service quality, operational efficiency, and patient safety. This definition conceptualizes HIS as a socio-technical subsystem that integrates technology, processes, data, and human actors; therefore, system utilization must be examined from technical, organizational, and user-behavioral perspectives [15].

III. MATERIALS AND METHODS

III.1 DESIGN

This study employed an analytical cross-sectional research design. An analytical cross-sectional study is an observational approach conducted at a single point in time to identify relationships between independent variables (risk factors or predictors) and dependent variables (outcomes), without any intervention on the research subjects. In this study, the independent variables were digital self-efficacy, person–job fit, and work–life balance. Health worker performance served as the dependent variable, while hospital information system utilization was examined as the moderating variable. This study aims to analyze the effects of digital self-efficacy, person–job fit, and work–life balance on health worker performance in the digital era, with hospital information system utilization serving as a moderating variable.

Table 1: Operational Definition of Variables.

Variable	Conceptual Definition	Operational Definition	Dimensions	Indicators
Digital Self-Efficacy	An individual's belief in their ability to effectively use digital technology (tools, applications, and information systems) to accomplish work tasks [15].	The level of confidence of healthcare workers in mastering, operating, and utilizing hospital information systems and digital health technologies.	1. Ability to use digital systems 2. Technical problem-solving 3. Ability to learn new technologies 4. Integration of technology into work	• Confident in operating HIS • Able to resolve basic technical issues • Able to learn new digital applications independently • Belief that technology improves work efficiency
Person–Job Fit	The degree of alignment between an individual's abilities, needs, and values and job demands.	The compatibility between healthcare workers' characteristics and job requirements.	1. Demand–Abilities Fit 2. Needs–Supplies Fit 3. Value Congruence 4. Job Role Fit	• Skills match job demands • Job fulfills personal needs • Alignment of personal and organizational values • Suitability of job roles
Work–Life Balance	The ability to balance work and non-work roles without conflict [16].	Healthcare workers' ability to manage work responsibilities and personal life harmoniously.	1. Work Interference with Personal Life 2. Personal Life Interference with Work 3. Work/Personal Life Enhancement 4. Personal/Work Enhancement	• Work does not disrupt personal life • Personal issues do not disrupt work • Work supports personal development • Personal life supports work performance

Variable	Conceptual Definition	Operational Definition	Dimensions	Indicators
Health Worker Performance	The quality, efficiency, and responsibility of healthcare service delivery [12].	The effectiveness and efficiency of healthcare workers in performing their duties.	1. Quality of Work 2. Quantity of Work 3. Timeliness and Efficiency 4. Responsibility and Reliability	• Accuracy of work results • Work volume meets targets • Tasks completed on time • Compliance with procedures
Hospital Information System Utilization	The extent to which hospital information systems are used to support healthcare services [13].	The level of effective and efficient use of HIS by healthcare workers.	1. System Quality 2. Information Quality 3. Service Quality 4. System Use 5. User Satisfaction	• System reliability and ease of use • Accuracy and timeliness of information • IT support availability • Frequency of system use • Satisfaction with HIS

III.2 SAMPEL, SAMPLE SIZE, & SAMPLING TECHNIQUE

The population of this study consisted of all nurses and midwives at Permata Keluarga Hospital. The sample size was determined using the Slovin formula with a 5% significance level, resulting in a recommended sample of 190 respondents. The study participants were nurses and midwives at Permata Keluarga Hospital who met the established inclusion criteria.

III.3 INSTRUMENT FOR DATA COLLECTION

The primary data in this study were collected through online questionnaire surveys administered via Google Forms to facilitate data collection. Secondary data were obtained from academic journals, books, and reputable online sources, which were used to support the theoretical framework, literature review, and other relevant research materials.

III.4 DATA ANALYSIS

The validity of research findings is highly dependent on the measurement instruments employed. If the instruments used are not valid and reliable, the results will not accurately reflect the actual conditions under investigation. To address this issue, two types of assessments were conducted, namely validity and reliability tests, to ensure the consistency and accuracy of respondents' responses. Data analysis was performed using the Structural Equation Modeling (SEM) approach, with the measurement model evaluated using SmartPLS version 4.

IV. RESULTS AND DISCUSSIONS

IV.1 DATA DEMOGRAPHIC

The majority of respondents were female, totaling 148 individuals (77.9%), indicating that most nurses and midwives at Permata Keluarga Hospital are women. Furthermore, the largest proportion of respondents were aged 36–45 years, with 96 individuals (50.5%), suggesting that most nurses and midwives fall within this age range. In terms of work experience, 89 respondents (46.8%) had been employed for 2–4 years, indicating that the majority had moderate tenure. Lastly, most respondents reported holding a bachelor's degree, with 157 individuals (82.6%), demonstrating that the majority of nurses and midwives at Permata Keluarga Hospital have attained undergraduate-level education.

Table 2: Respondent Characteristics.

Respondent Profile	Total	Frequency
Gender		
Male	42	22.1%
Female	148	77.9%
Total	190	100%
AGE		
< 20 years	1	0.5%
21–35 years	93	48.9%
36–45 years	96	50.5%
> 45 years	0	0%
Total	190	100%
Length of Employment		
< 1 year	59	31.1%
2–4 years	89	46.8%
5–7 years	40	21.1%
> 7 years	2	1.1%
Total	190	100%
Highest Education Level		
Senior High School / Equivalent	5	2.6%
Diploma	25	13.2%
Bachelor's Degree	157	82.6%
Postgraduate Degree	3	1.6%
Total	190	100%

IV.2 RESEARCH INSTRUMENT CALIBRATION

The assessment of data analysis requirements in this study was conducted using the results of the PLS algorithm estimation. Convergent validity was evaluated through factor loadings (outer loadings), while discriminant validity was assessed using cross loadings. Reliability was examined using composite reliability, Cronbach's alpha, and the Average Variance Extracted (AVE).

Table 3: Factor Loading Values of Research Variables.

Variable	Indicator	Factor Loading Value	Criterion	Description
Digital Self-efficacy	DSL_1	0,918	> 0,7	Valid
	DSL_2	0,886	> 0,7	Valid
	DSL_3	0,928	> 0,7	Valid

	PS_15	0,822	> 0,7	Valid

Source: Authors, (2026).

The results indicate that all factor loading values for each indicator used to measure the research variables exceed the threshold of 0.7. This demonstrates that all indicators employed to measure Health Worker Performance are valid and have met the criteria for convergent validity. Therefore, all measurement items were retained and included in the analysis.]

Table 4: Average Variance Extracted (AVE) Results.

Variable	AVE Value
Digital Self-efficacy	0,807
Person Job Fit	0,834
Work-life balance	0,822
Health Worker Performance	0,861
Hospital Information System Utilization	0,692

Source: Authors, (2026).

The results indicate that all factor loading values for each indicator used to measure the research variables exceed the threshold of 0.7. This demonstrates that all indicators employed to measure Health Worker Performance are valid and have met the criteria for convergent validity. Therefore, all measurement items were retained and included in the analysis.

Table 5: Composite Reliability Results of the Research Model.

Variable	Composite Reliability
Digital Self-efficacy	0,807
Person Job Fit	0,834
Work-life balance	0,822
Health Worker Performance	0,861
Hospital Information System Utilization	0,692

Source: Authors, (2026).

The composite reliability results indicate that all constructs in the research model have composite reliability values above the recommended threshold of 0.60, with the lowest value of 0.692 for the Hospital Information System Utilization variable and the highest value of 0.861 for the Health Worker Performance variable. These results confirm that the research model satisfies the composite reliability criteria.

Table 6: Cronbach's Alpha Results of the Research Model.

Variable	Composite Reliability
Digital Self-efficacy	0,978
Person Job Fit	0,982
Work-life balance	0,980
Health Worker Performance	0,985
Hospital Information System Utilization	0,968

Source: Authors, (2026).

The Cronbach's alpha values of the research model indicate that all variables exceeded the acceptable threshold of 0.6, with the lowest value of 0.968 observed for the Hospital Information System Utilization variable and the highest value of 0.985 for the Health Worker Performance variable. These results confirm that the research model demonstrates satisfactory internal consistency reliability.

IV.3 STRUCTURAL MODEL EVALUATION

The coefficient of determination is used to assess the extent to which the model explains the variance of the dependent variable. The value of the coefficient of determination ranges between 0 and 1, with values closer to 1 indicating greater explanatory power. The R-square (R^2) value reflects the proportion of variance in the dependent variable that can be explained by the independent variables specified in the model.

Table 7: Coefficient of Determination Test Results.

Variable	Nilai R Square
Health Worker Performance	0.982

Source: Authors, (2026).

The relationships among the constructs, as indicated by the R-square value, show that the R-square for health worker performance is 0.982. This indicates that 98.2% of the variance in health worker performance is explained by digital self-efficacy, person–job fit, and work–life balance.

Table 8: Path Coefficient, t-Statistics, and p-Values Results.

	Original Sample	T Statistics	P-Values	Conclusion
Digital Self-efficacy -> Health Worker Performance	0,280	3,353	0,001	H1 Accepted
Person Job Fit -> Health Worker Performance	0,348	3,354	0,001	H2 Accepted
Work-life balance -> Health Worker Performance	0,220	2,509	0,012	H3 Accepted
Moderating Effect 1 -> Health Worker Performance	0,062	0,591	0,555	H4 Rejected
Moderating Effect 2 -> Health Worker Performance	0,225	1,572	0,116	H5 Rejected
Moderating Effect 3 -> Health Worker Performance	0,348	3,077	0,002	H6 Accepted

Source: Authors, (2026).

The table above indicates that four hypotheses are supported, as their significance values are below 0.05. The results show that work–life balance has a significant effect on health worker performance when moderated by hospital information system utilization. However, digital self-efficacy and person–job fit do not have a significant effect on health worker performance when moderated by hospital information system utilization. Furthermore, digital self-efficacy, person–job fit, and work–life balance have a direct and significant effect on health worker performance.

IV.4 DISCUSION

IV.4.1 Impact Digital Self-efficacy on Health Worker Performance

The first hypothesis indicates that the path coefficient of 0.280, with a t-statistic of 3.353 and a p-value of 0.001, demonstrates that digital self-efficacy has a significant effect on health worker performance. This finding suggests that nurses with higher levels of digital self-efficacy are better able to adapt to information systems, achieve greater work efficiency, and reduce errors in patient care [16]. This result is consistent with the study by [17], which found that self-efficacy and professional competence are directly associated with nurses' job performance in technology-based hospital settings. These findings underscore the importance of digital training and the strengthening of self-confidence in enhancing health worker performance. Therefore, confidence in digital capabilities constitutes a fundamental foundation for improving performance in technologically advanced hospital environments.

IV.4.2 Impact Person-Job Fit on Health Worker Performance

The second hypothesis indicates that the path coefficient of 0.348, with a t-statistic of 3.354 and a p-value of 0.001, demonstrates that Person–Job Fit has a significant effect on health worker performance. This finding implies that the alignment between nurses' competencies and job demands constitutes a dominant factor in enhancing performance. The result is consistent with the study by [18], which found that Person–Job Fit has a direct influence on job satisfaction and work performance. Similarly, [19] emphasize that congruence between individual values and skills and organizational requirements creates a more productive and performance-oriented work environment. These findings are further supported by [17], who report that a strong fit between professional competencies and job responsibilities is a key determinant of effectiveness and teamwork among nurses in hospital settings. With the support of integrated hospital information systems, this alignment further enhances work efficiency and the quality of patient care.

IV.4.3 Impact Work-Life Balance Health Worker Performance

The third hypothesis indicates that the coefficient value of 0.220, with a T-statistic of 2.509 and a p-value of 0.012, demonstrates that work–life balance has a positive and significant effect on health worker performance. This finding suggests that nurses who are able to effectively balance their personal lives and professional responsibilities tend to exhibit higher levels of performance and job satisfaction. These results are consistent with the study by [20], which found that work–life balance is positively associated with better performance and higher job satisfaction among nurses in Malaysian hospitals. Similarly, [21] reported that work–life balance is positively correlated with productivity and organizational commitment among nurses. Therefore, work–life balance is a crucial factor in sustaining health worker performance in the fast-paced and highly demanding digital era.

IV.4.4 Impact Moderating Effect 1 On Health Worker Performance

The analysis results indicate that Moderating Effect 1 has a coefficient value of 0.062, with a t-statistic of 0.591 and a p-value of 0.555 (> 0.05), leading to the rejection of the fourth hypothesis (H4). These findings indicate that the moderating variable, namely the utilization of the Hospital Information System, does not strengthen the effect of digital self-efficacy on healthcare worker performance.

IV.4.5 Impact Moderating Effect 2 on Health Worker Performance

Moderating Effect 2 shows a coefficient of 0.225, with a t-statistic of 1.572 and a p-value of 0.116, indicating that the fifth hypothesis (H5) is rejected. This indicates that the fifth hypothesis (H5) is rejected. In other words, the utilization of the hospital information system does not strengthen the effect of person–job fit on healthcare worker performance.

IV.4.6 Impact Moderating Effect 3 on Health Worker Performance

The sixth hypothesis indicates a coefficient value of 0.348, with a T-statistic of 3.077 and a p-value of 0.002, demonstrating that Moderating Effect 3 has a significant effect on health worker performance. These results indicate that the utilization of hospital information systems strengthens the relationship between work–life balance and health worker performance. This implies that achieving a balance between nurses' professional and personal lives becomes more feasible with the support of efficient digital systems. An effective hospital information system can reduce administrative workload, accelerate documentation processes, and enable health workers to allocate more time for rest and recovery. Further suggest that the use of digital systems can alleviate work-related stress and enhance the emotional balance of nursing staff [3]. In addition, a study by [20] in Malaysia confirms that nurses' work–life balance is significantly associated with higher levels of job satisfaction and professional performance, particularly in digital environments that facilitate time management. Therefore, the utilization of hospital information systems serves as an enabling mechanism to strengthen nurses' work–life balance and improve the quality of their performance. Accordingly, hospital information system utilization functions as a moderating factor that reinforces the positive relationship between work–life balance and nurse performance.

V. CONCLUSIONS

Based on the research results, it can be concluded that there is no positive relationship between digital self-efficacy and personal-job fit on healthcare worker performance, with the use of hospital information systems as a moderating variable. Furthermore, there is a positive relationship between work-life balance and healthcare worker performance, with the use of hospital information systems as a moderating variable. Furthermore, digital self-efficacy, personal-job fit, and work-life balance on healthcare worker performance are also found. Based on the research findings, several recommendations are proposed for stakeholders, including the management of Permata Keluarga Hospital.

They are advised to develop regular digital training programs focused on nursing information technology skills, such as the use of Electronic Medical Records (EHR), digital documentation systems, and telemedicine. Hospital management should implement competency-based recruitment and placement policies to ensure that nurses' skills and values align with job demands. Management is encouraged to adopt flexible work schedules supported by information systems, allowing nurses to adjust work hours according to personal circumstances without compromising the quality of patient care. Continuous evaluation of the effectiveness of the Hospital Information System (GIS) should be conducted, including aspects of system usability, speed of access, and ease of reporting clinical data.

Hospital management should introduce digital performance-based incentives, such as recognition or rewards for nurses who actively use information systems to improve service efficiency. Hospital management should also introduce digital performance-based incentives to assess long-term changes in nurse performance as technology utilization increases. Furthermore, incorporating variables such as job satisfaction, digital literacy, or technological stress is recommended to broaden understanding of the relationship between psychological factors and digital healthcare worker performance. Comparative studies across hospitals with varying levels of digitalization are also recommended to examine the differences in the impact of hospital information systems on healthcare performance.

ABSTRACT

Due to improvements in wind energy technology, electrical distribution networks are becoming more capable of integrating large amounts of variable renewable generation. The wind distributed generators (WDGs) affect the medium-voltage (MV) electrical distribution network (EDN) by introducing variability, reverse power flows, power-quality issues, and higher fault levels. This paper applies a brand-new, reliable, and efficient algorithm, the tunicate swarm algorithm (TSA), to optimally link varying numbers of WDG units and allocate multiple WDG units in EDN. The main objective of this research is to propose an applied TSA algorithm for optimal energy-efficient integration of multiple WDG units in a hybrid medium-voltage AC-DC network and to test it in a modified IEEE 33-bus network based on the active power loss minimization. The proposed approach granted improved solution quality with enhanced convergence speed and adherence to EDN constraints. The applied TSA addresses the sensitivity to parameter settings like population size and iterations. The findings verify that, out of all the scenarios taken into consideration, three WDGs offer the best performance in terms of active loss minimization and improve the bus voltage profile.

I. INTRODUCTION

Because of their many benefits, AC systems have been used in electrical distribution networks (EDNs) for over a century and are now widely used worldwide. However, clean, green, and ecologically friendly distributed energy resources (DERs), electric vehicles, energy storage systems, and diverse DC loads are swiftly revolutionizing the current world [1]. Many advancements in smart grid technology were brought about by the introduction of hybrid AC/DC distribution networks. To connect to current AC distribution systems, these DC-based smart energy technologies require converters, which are costly and incur power losses [2]. In order to directly connect AC and DC generation units and loads to the power system, the idea of medium-voltage (MV) electric distribution networks has recently been proposed. Higher transfer capacity, lower power losses, greater hosting capacity, voltage management, and an improved voltage profile are just a few other benefits of the hybrid AC/DC in EDN [3],[4]. Problems like increased power losses and voltage instability are brought about by the growing integration of wind energy into EDNs. The necessity for strong optimization techniques to guarantee effective and dependable wind distributed generators (WDG) allocation is the driving force behind this project. Electrical distribution grid-connected wind energy systems face persistent challenges in maintaining voltage stability, mitigating harmonics, and ensuring reliable power quality under fluctuating wind conditions and fault events. The intermittent nature of wind introduces significant variations in power flow, which, if not effectively managed, can lead to instability and degrade system performance. Power quality is a crucial aspect of modern electrical distribution grids, ensuring efficient, stable, and reliable power delivery while minimizing losses and disturbances.

With the growing integration of wind energy into grid-connected systems, Power quality issues have become more pronounced due to the inherent intermittency and variability of WDG. In recent years, many scholars have proposed numerous optimizations approaches to formulate the WDG planning problem in distribution systems. Numerous optimization approaches have been developed to address the efficient design of WDG units in EDN. The authors of [5] applied the equilibrium optimizer algorithm, the gorilla troops optimizer algorithm in [6], the lévy coyote optimization algorithm in [7], and used the manta-ray foraging optimization algorithm in [8] and modified the equilibrium algorithm in [9]. This paper introduces a novel bio-inspired optimization technique called the Tunicate Swarm Algorithm (TSA) [10]. This algorithm draws inspiration from the jet propulsion and collective foraging behaviors exhibited by tunicates, aiming to enhance navigation and foraging processes through innovative computational strategies. The TSA algorithm presents a straightforward framework, unique stabilizing characteristics, and remarkable efficiency [11]. The TSA algorithm surpasses competing methods in optimal solutions and highly effective for real-world optimization situations, and especially for power system problems: optimize the power system stabilizer parameters to prevent oscillations at low frequencies [12], used to address the dynamic economic emission dispatch issues [13],[14], the PID controller optimization for autonomous generation management in a hybrid power system [15], Optimal cost of a power system based on the design of a hybrid renewable system [16], and optimal renewable-based DG in electrical networks with electric load models [17]. Adaptive optimal control model-based optimal energy management strategy for a multi-microgrid at the tertiary level [18], optimizing battery energy storage systems and vehicle-to-grid operations in PV-powered EV charging systems [19], and optimal solutions searched for wind speed deterministic forecasting [20]. Recently, researchers applied the TSA algorithm for energy hub adjusting efficiency based on real-time load variations for optimal allocation [21]. The main objective of this research is to propose an applied TSA algorithm for optimal energy-efficient integration of multiple wind distributed generators in a hybrid medium-voltage AC-DC electric distribution network. The proposed approach ensures improved solution quality with enhanced convergence speed and adherence to EDN constraints. This, in turn, ultimately improves the stability, efficiency, and reliability of EDN. Through the balancing strategy between exploration and exploitation, TSA addresses the sensitivity to parameter settings like population size and iterations.

II. WIND DISTRIBUTED GENERATOR ALLOCATION PROBLEM

In EDN, computational solutions are crucial because of the intricate nature of real-time issues. This involves formulating the problem through mathematical equations, known as mathematical models, which are predicated on decision variables. These models precisely illustrate the system's response to variations in independent variables, guaranteeing relevance and accuracy in practical applications. Figure 1 represents the single-line diagram with DG placement in EDN.

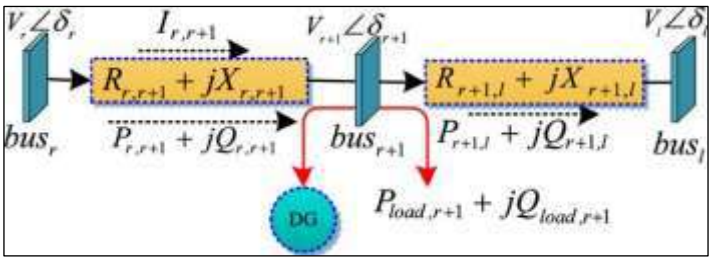

Figure 1: The single-line diagram with DG placement.
Source: [18-20].

II.1 OBJECTIVE FUNCTION

To achieve optimal integration of WDG units within the hybrid AC-DC EDN, the problem is formulated using a single objective function (OF), which aims to minimize the total active power losses (P_{Loss}), as expressed by the following equation:

$$OF = \sum_{i=1}^{N_{Bus}} \sum_{j=2}^{N_{Bus}} P_{Loss}(i,j) \tag{1}$$

The active power loss is calculated using the expression given in (2), as reported in [6],[22]:

$$P_{Loss}(i,j) = \alpha_{ij}\left(P_i P_j + Q_i Q_j\right) + \beta_{ij}\left(Q_i P_j + P_i Q_j\right) \tag{2}$$

And,

$$\alpha_{ij} = \frac{R_{ij}}{V_i V_j}\cos\left(\delta_i - \delta_j\right) \tag{3}$$

$$\beta_{ij} = \frac{R_{ij}}{V_i V_j}\sin\left(\delta_i - \delta_j\right) \tag{4}$$

Where R_{ij} denotes the resistance of the line connecting buses i and j. V_i and V_j are the voltage magnitudes. δ_i and δ_j represent the corresponding voltage angles. P_i, P_j and Q_i, Q_j refer to the power injections at buses i and j, respectively.

II.2 EQUALITY CONSTRAINTS

These constraints enforce active and reactive power balance in the system, where total generation (including WDG) equals load demand plus network losses, as defined in (5) and (6) [23],[34]:

$$P_G + P_{WDG} = P_{Load} + P_{Loss} \quad (5)$$

$$Q_G + Q_{WDG} = Q_{Load} + Q_{Loss} \quad (6)$$

Where P_G and Q_G denote the active and reactive power outputs of the generator, respectively. P_{WDG} and Q_{WDG} represent the total power supplied by the WDG unit. P_{Load} and Q_{Load} correspond to the total active and reactive load demands, while P_{Loss} and Q_{Loss} indicate the total active and reactive power losses, respectively.

II.3 DISTRIBUTION LINE CONSTRAINTS

These constraints ensure acceptable AC-DC distribution line operating conditions [23, 24]:

$$V_{min} \leq V_i \leq V_{max} \quad (7)$$

$$|1 - V_j| \leq \Delta V_{max} \quad (8)$$

$$|S_{ij}| \leq S_{max} \quad (9)$$

Where V_{max}, and V_{min} are the limit voltages; ΔV_{max} is the maximum drop of voltage. V_1 is the sub-station voltage equal to 1.0 p.u. S_{max} is the maximum apparent power in line.

II.4 WDG CONSTRAINTS

These constraints specify the operational and placement limits associated with WDG units, as defined in [23],[24]:

$$P_{WDG}^{min} \leq P_{WDG} \leq P_{WDG}^{max} \quad (9)$$

$$Q_{WDG}^{min} \leq Q_{WDG} \leq Q_{WDG}^{max} \quad (10)$$

$$2 \leq WDG_{position} \leq N_{Bus} \quad (11)$$

$$N_{WDG} \leq N_{WDG.max} \quad (12)$$

$$n_{WDG}/Location \leq 1 \quad (13)$$

Where $WDG_{Position}$, N_{WDG}, and $N_{WDG.max}$ are the WDG position, number, and maximum units/location at the bus.

III. OVERVIEW OF APPLIED TUNICATE SWARM ALGORITHM

The TSA is predicated on tunicates' capacity to locate food sources in the ocean. Here, tunicates use two behaviours, such as swarm intelligence and jet propulsion actions, to locate food. Three requirements are considered for the implementation of jet propulsion behaviour: the search candidates must avoid conflicts with one another, approach the position of the best candidate, and exist close to the best candidate [10, 11]. The vector $\vec{\beta}$ is used to avoid conflicts among the tunicates, and the position of the new search candidate is calculated using this vector [25, 26]:

$$\vec{\beta} = \frac{\vec{g}}{\vec{m}} \quad (14)$$

$$\vec{g} = c_2 + c_3 - \vec{f} \quad (15)$$

$$\vec{f} = 2.c_1 \quad (16)$$

Here, $\vec{f}$ indicates the water flow in the sea, $\vec{m}$ indicates the force existing within search candidates, $\vec{g}$ denotes the force of gravityc_1, c_2, c_3 are the parameters distributed randomly between 0 and 1.

$$\vec{m} = [p_{min} + c_1.p_{max} - p_{max}] \quad (17)$$

Here, p_{min}, p_{max} values are given by 1 and 4, respectively and indicate the interaction speeds of search candidates. The tunicates move to the best neighbor search candidate after avoiding conflicts, and this is given by the next equation [24]:

$$\vec{d} = |\vec{f_s} - r.\vec{p}\,(t)| \quad (18)$$

Where, $\vec{p}$ indicates the location of the search candidate for the current location, t indicates the value of the current iteration, $\overrightarrow{d}$ represents the distance between the tunicate and the food location, $\overrightarrow{f_s}$ denotes the position of food, and r ranges between 0 and 1. The location of the search candidate has to be adjacent to the best search candidate, which is given by,

$$\vec{p}\,(t) = \begin{cases} \overrightarrow{f_s} + \vec{\beta}.\overrightarrow{d}, r \geq 0.5 \\ \overrightarrow{f_s} - \vec{\beta}.\overrightarrow{d}, r < 0.5 \end{cases} \tag{19}$$

Here, in accordance with $\overrightarrow{f_s}$, the updating of the search candidate's position is given by $\vec{p}\,(t)$. The position updating is achieved by the swarm intelligence behaviour of the search candidates and is,

$$\vec{p}\,(t+1) = \frac{\vec{p}\,(t)+\vec{p}\,(t+1)}{2+c_1} \tag{20}$$

The solution of the first two best candidates is given by $\vec{p}\,(t)$ and $\vec{p}\,(t+1)$. Considering the position of the best candidate, the other candidate's solution can be updated by preserving these solutions. Figure 2 shows how search agents can update their positions according to the position of $\vec{p}\,(t)$. The final position would be in a random place, within a cylindrical or cone-shaped, which is defined by the position of tunicate [25].

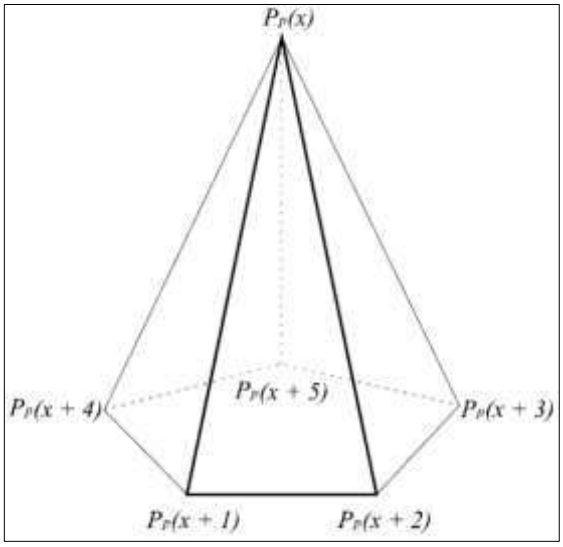

Figure 2: Presentation of the 3D position vectors of the tunicate.
Source: [25].

The parameters, positions and velocities are continuously updated till the convergence criteria are met. At each iteration, update the global best solution based on the fitness evaluations [26]. Consequently, preserve the solutions of the first two best candidates and use them to update other candidates' solutions while maintaining swarm intelligence behavior.

IV. RESULTS AND DISCUSSIONS

In this section, an applied optimization TSA technique for the optimum location of multiple WDG units is utilized to lessen power loss. The proposed controller is executed on MATLAB software. The performance of the proposed system is analyzed with a modified IEEE 33-bus system represented in Figure 3, which was adopted for the validation of the proposed model. The illustration demonstrates the one-line representation of the modified IEEE 33 bus distribution system, designed as a hybrid AC-DC network. It emphasizes the incorporation of DC sub-networks into a traditional radial AC feeder using power electronic interfaces. The AC utility grid provides power to the system via the substation at Bus 1, preserving the radial configuration of the 33-bus feeder. Buses 1 through 18 constitute the AC distribution network, illustrated in blue.

In addition to providing traditional AC loads, this portion acts as the framework for linking DC subsystems. Practical MV distribution systems are reflected in the radial structure. The AC system is linked to two DC networks (illustrated in orange). DC loads and DC-based distributed resources, including wind distributed generation, energy storage systems, DC microgrids, and DC consumption, are represented by these DC sections. This one-line diagram serves as the test system architecture for evaluating voltage profiles, power flow, and the impact of WDG penetration in a hybrid network. It provides the structural basis for the voltage performance results observed in the different case studies (cases 1 to 4). The four configurations for case studies in this paper:

- Case 1: Hybrid EDN without WDG (basic case),
- Case 2: Hybrid EDN with one WDG,
- Case 3: Hybrid EDN with two WDGs,
- Case 4: Hybrid EDN with three WDGs.

Figure 3: One-line diagram of the tested modified IEEE 33-bus hybrid AC-DC network.

Source: Authors, (2026).

Figure 4 represents the bus voltage of a hybrid AC-DC network without WDG units (case 1).

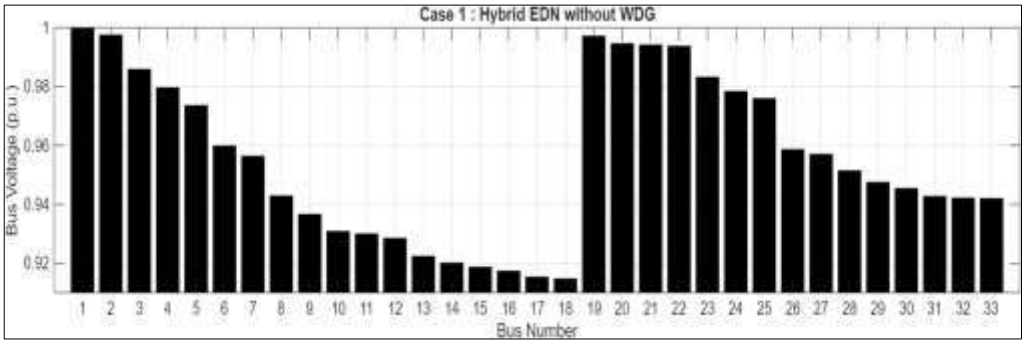

Figure 4: The bus voltage of a hybrid AC-DC network without WDG units (Case 1).
Source: Authors, (2026).

As observed in Figure 4, because the feeder is radial, the bus voltage magnitude gradually drops from the substation (Bus 1) to the end buses. Some buses suffer from severe undervoltage, with values falling below 0.95 p.u., especially in the downstream AC network (around buses 9–18). Voltages in the DC network (buses 19–33) likewise progressively drop, suggesting greater vulnerability to loading and inadequate voltage support. From the standpoint of power quality, this instance is crucial since the voltage profile. Figure 5 represents the branch active power loss of a hybrid AC-DC network without WDG units (case 1).

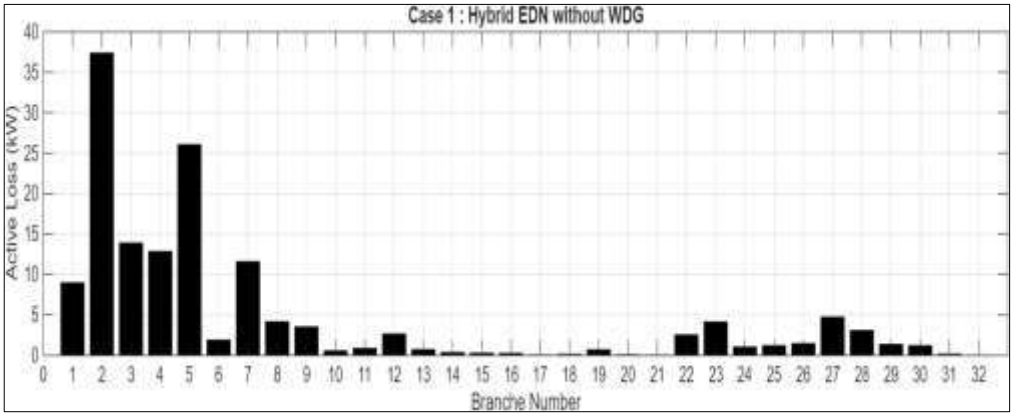

Figure 5: The branch active power loss of a hybrid AC-DC network without WDG units (Case 1).
Source: Authors, (2026).

As demonstrated by Figure 5, the upstream branches, particularly those near the substation (e.g., branches 2–6), have a significant concentration of active power losses. This is because there is no local production to balance the electricity demand, and the entire downstream load is supplied by a high current flow. Even while losses in downstream branches are very minor, they nevertheless add to the overall inefficiency of the system. As a result, the overall active power loss is comparatively large. The branch reactive power loss of a hybrid AC-DC network without WDG units (case 1) is shown in Figure 6.

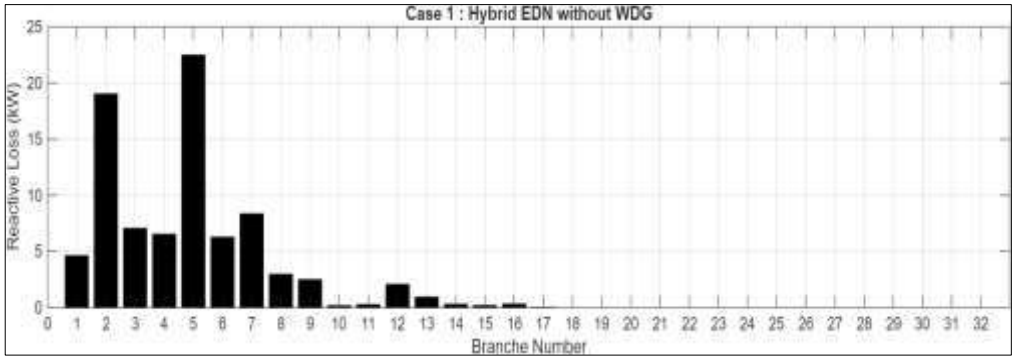

Figure 6: The branch reactive power loss of a hybrid AC-DC network without WDG units (Case 1).
Source: Authors, (2026).

As shown in Figure 6, with peak losses in the first feeder branches, reactive power losses exhibit a similar pattern to active losses. Large reactive power demands from loads are indicated by high reactive losses, which worsen voltage drops along the feeder. The system has very little reactive support, which exacerbates voltage deterioration. The convergence characteristics of the proposed TSA algorithm after integrating one, two, and three WDG units in EDN are presented in Figure 7.

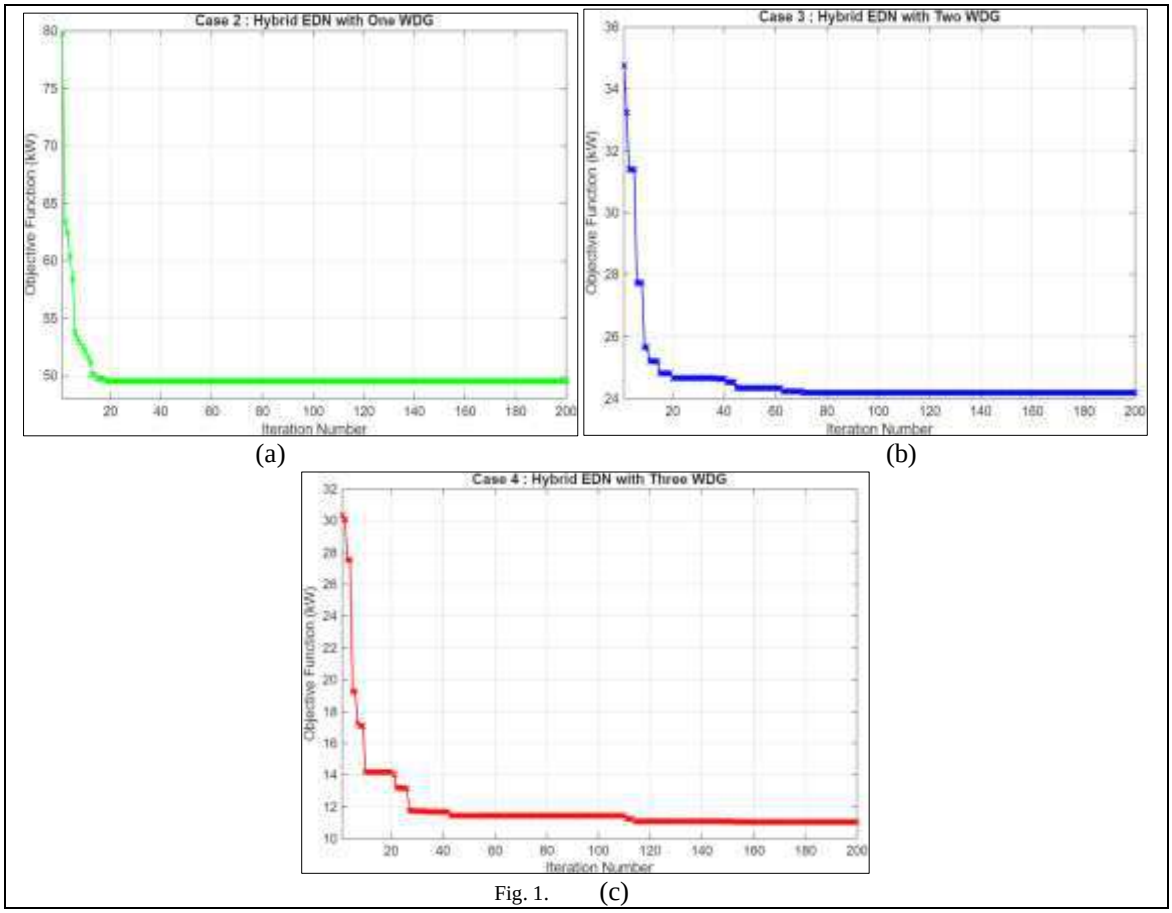

Fig. 1.

Figure 7: The convergence curves of the TSA approach for all case studies:
a). Case 1: One WDG, b). Case 2: Two WDGs, c). Case 3: Three WDGs.
Source: Authors, (2026).

The proposed approach ensures improved solution quality with enhanced convergence speed and adherence to EDN constraints. This, in turn, ultimately improves the stability, efficiency, and reliability of the test system. At each iteration, update the best global solution based on the objective function. Through the balancing strategy between exploration and exploitation, TSA addresses the sensitivity to parameter settings like population size and iterations for the three case studies. Tables 2, 3, and 4 summarize the optimal parameters after installing one, two, and three WDG units and technical parameters for the hybrid AC-DC test system.

Tables 1, 2, and 3 demonstrate the benefits of installing WDG units, particularly in terms of reduced power losses and voltage deviation. Furthermore, compared to other situations, the integration of the three WDG produces a good performance. The configuration for the hybrid AC-DC systems with the three case studies, with location one, two, and three WDG units, is presented in Figure 7.

(a)

Figure 9 compares bus voltage magnitudes (p.u.) across the hybrid AC-DC network for different case studies with increasing numbers of WDG units.

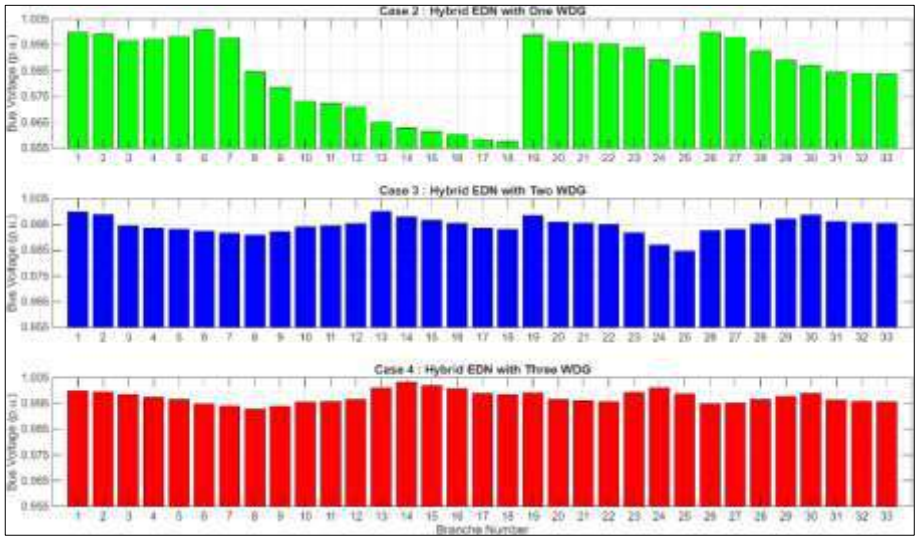

Figure 9: The Bus voltage of a hybrid AC-DC network with WDG units for various case studies.
Source: Authors, (2026).

After analyzing Figure 9. In case 2, the hybrid EDN with one WDG (green color): The voltage profile shows larger variations along the feeder. Several downstream buses (roughly buses 9–18) experience noticeable voltage drops, approaching the lower acceptable

limit (~0.955–0.965 p.u.). This indicates that a single WDG provides limited voltage support, especially in buses far from the source or in load-intensive sections. Voltage regulation is weaker and more location-dependent.

For Case 3, the hybrid EDN with two WDG units (blue color), the voltage profile becomes significantly flatter than in Case 2. Most bus voltages lie within a narrower band (≈0.985–1.0 p.u.). Localized voltage dips are reduced, showing that additional WDG improves reactive power support and reduces line voltage drops. Overall voltage regulation and uniformity are improved. Finally, in Case 4, the hybrid EDN with three WDG units (red color): This case exhibits the best voltage profile among all scenarios. Bus voltages are very close to the nominal value (≈1.0 p.u.) across the entire network. Voltage deviations are minimal, and no critical undervoltage buses are observed. The results highlight that higher WDG penetration enhances voltage stability and reduces losses in the hybrid AC–DC network. In conclusion, the figure clearly demonstrates the positive impact of coordinated WDG integration on bus voltage performance in a hybrid AC-DC distribution system. The branch active power loss (kW) over the hybrid AC-DC network for several case studies with an increase in WDG units is compared in Figure 10.

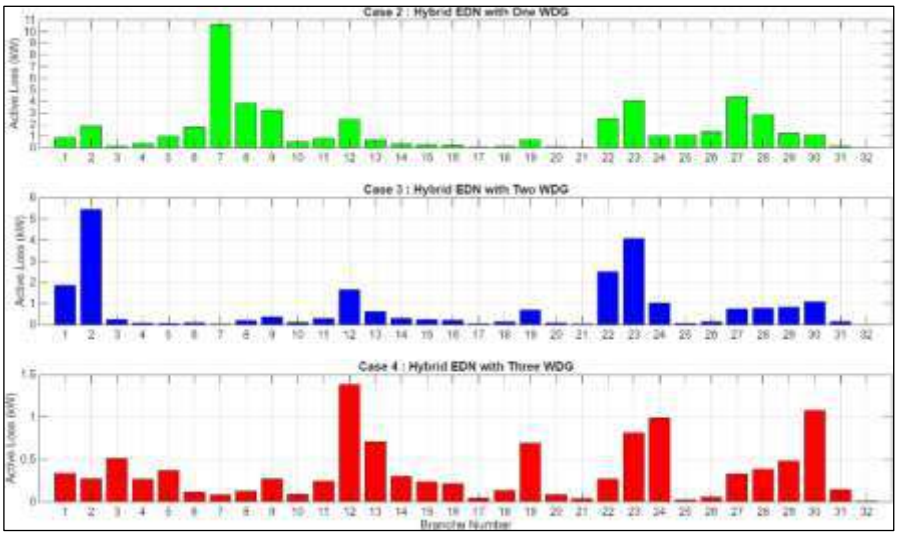

Figure 10: The branch active loss of a hybrid AC-DC network with WDG units for various case studies.
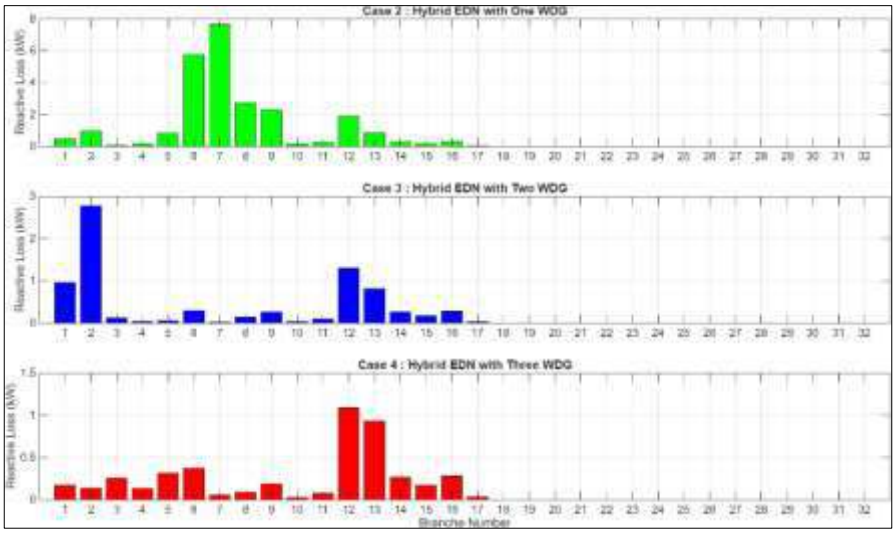
Source: Authors, (2026).

Out of all the possibilities, case 2 shows the greatest branch losses. Some branches have extremely large loss peaks, particularly those near branches 6–8 and 12. Higher power flow from the main grid and increased current in several branches result from the single WDG's restricted local power support. In the hybrid network, one WDG is not enough to considerably reduce branch losses. When comparing Case 3 to Case 2, a significant decrease in branch losses is seen. Peak losses are distributed more uniformly among branches and are substantially lower. In Case 4, the arrangement of three WDGs exhibits the lowest branch losses of any branch. Loss values are uniformly distributed and quite modest. This shows that the hybrid AC-DC network is making the best use of distributed generation. Near-optimal loss minimization and the best-balanced network functioning are achieved by three WDG units. Figure 11 illustrates the branch reactive power losses in the hybrid AC–DC distribution network for different case studies with an increasing number of WDG units.



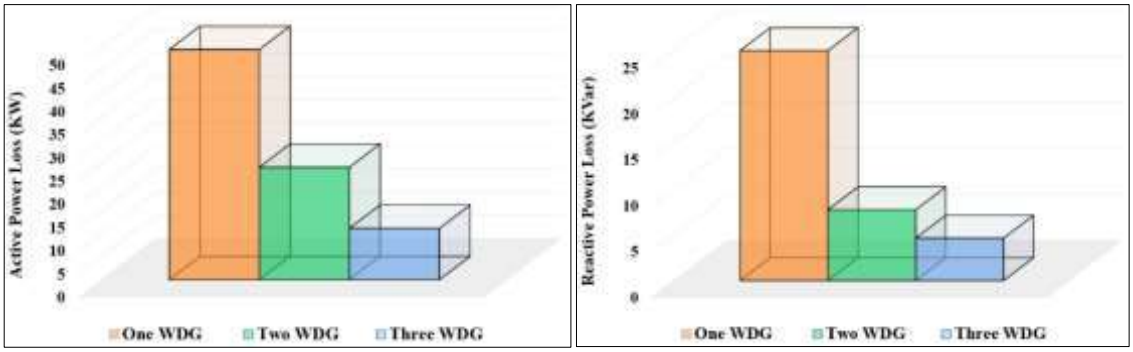


Figure 11: The Branch reactive loss of a hybrid AC-DC network with WDG units for various case studies.
Source: Authors, (2026).

Out of all cases, Case 2 has the largest reactive power losses. There are noticeable loss peaks in several branches, especially in the mid-feeder and upstream parts (around branches 6–8 and 12). The losses are more uniformly distributed, and the peak loss magnitudes

are significantly smaller in Case 3. Better local reactive power adjustment is provided by the extra WDG. However, some branches continue to exhibit moderate losses, indicating partial but incomplete optimization.

Out of all the branches, Case 4 has the lowest reactive power losses. There are no sharp peaks in the loss numbers, which are minor and evenly dispersed. Increased WDG penetration improves both overall reactive current flow reduction and local reactive power support. Figure 12 represents the total active and reactive power losses in a hybrid AC-DC network with increasing WDG penetration.

(a) (b)

Figure 12: The total losses in the hybrid AC-DC network for various WDG units: a). Active power loss, b). Reactive power loss.
Source: Authors, (2026).

Below is a clear technical analysis of Figures 12 (a) and (b) showing the total losses in a hybrid AC–DC network with increasing WDG penetration. The active power loss achieves its lowest value when three WDGs are integrated into EDN, as shown in Figure 12.a, indicating the most successful loss minimization of the situations under study. Increasing the number of WDG devices lowers line currents by improving local power supply and voltage support. As WDG penetration rises, the graph unmistakably demonstrates a monotonic decline in active power losses. More WDG units raise the overall power factor, decrease needless reactive power circulation, and increase local reactive power support. Reactive losses are significantly reduced as a result, which is essential for voltage stability. The findings verify that, out of all the scenarios taken into consideration, three WDGs offer the best performance in terms of loss minimization.

V. CONCLUSIONS

This paper studies the minimization of active power losses by the optimal allocation of multiple WDG units based on applying the TSA algorithm and tested on the modified IEEE 33-bus with a hybrid AC-DC distribution network. In conclusion, the figure clearly demonstrates the positive impact of coordinated WDG integration on bus voltage performance in EDN. The optimal results clearly demonstrate that higher WDG penetration significantly improves power loss performance in the hybrid AC–DC distribution network. The configuration with three WDG units provides the most efficient and stable operation, validating the effectiveness of WDG in reducing reactive losses and enhancing overall network efficiency. These simulation results clearly demonstrate that strategic integration of multiple WDG units in a hybrid AC–DC EDN leads to substantial loss reduction and improved power flow performance, validating the effectiveness of distributed renewable generation in modern EDN. Increasing the number of WDG units leads to a progressive reduction in branch power losses. The hybrid AC–DC network benefits substantially from distributed active and reactive power support, especially when WDGs are optimally integrated.

Fine and Gray Model

Survival Analysis

Cumulative incidence Function

Kaplan-Meier Survival

ABSTRACT

Competing risk survival analysis is deemed necessary when manifold events, such as recurrence and death, are present to prevent the incidence of the event of interest. The application of the Fine and Gray model for cumulative incidence function (CIF) estimation and competing risk regression in a simulated dataset is explored in this study. Simulated time-to-event data and covariates are used to estimate the Fine and Gray model both with and without covariates, with comparisons being made against the Kaplan-Meier (KM) method, which does not account for competing risks. It is demonstrated that the Fine and Gray method provides a more accurate representation of event-specific incidence in the presence of competing risks. Competing risks being ignored, as in the Kaplan-Meier approach, can lead to an underestimation of the event of interest. Additionally, the inclusion of covariates like age and tumor size into the Fine and Gray model is shown to significantly impact the incidence of recurrence and competing events. This comparative analysis is provided.

I. INTRODUCTION

I.1 COMPETING RISKS

In survival analysis, the primary focus is typically placed on the time awaiting an event to occur, such as death, failure of a system, or relapse in disease. However, competing risks are encountered when multiple types of events can be practiced by individuals in a study, and the occurrence of one event may avert the occurrence of others. For example, in a cancer study, a patient may die from cancer (the primary event of interest) or from another cause like a heart attack (a competing event). In the presence of competing risks, traditional survival analysis methods must be adjusted to account for the fact that competing events can censor or modify the probability of the primary event being observed.

I.2 KM ESTIMATOR

The KM estimator is a non-parametric statistic that is used to estimate the survival function from life span data. An estimate of the probability that an individual will survive further than a certain time point is offered by it. However, in the context of competing risks, the occurrence of competing events is not adequately accounted for by the KM method, as all competing events are treated as censored. As a result, alternative methods, such as the CIF, are frequently used to estimate the probability of precise events in competing risks settings.

I.3 EXPONENTIAL DISTRIBUTION

The exponential distribution is a common method for survival information where the event rate (hazard) is constant over time. Time to event data is often modeled using this distribution when events occur at a constant hazard rate, without any competing risks. The exponential distribution is memoryless, denoting that the probability of an event occurring in the next time interval is independent of how much time has already passed. While being simple and mathematically tractable, this model can be considered overly simplistic for real-world survival data, which often has hazards that vary over time or are influenced by covariates.

I.4 FINE AND GRAY METHOD

The Fine and Gray sub-distribution hazard method is a regression model designed to handle competing risks data. Unlike traditional Cox proportional hazards models, which are designed for cause-specific hazards, the sub-distribution hazard is focused on by the Fine and Gray model, which quantifies the risk of the event of interest occurring, while accounting for the presence of competing events. More accurate estimation of the cumulative incidence is allowed by this method and it is broadly used in medical research where competing risks are prevalent. In summary, when dealing with time-to-event data, the appropriate statistical model must be considered, particularly when competing risks are present. The Kaplan-Meier estimator is found to be useful in simpler cases, while the Fine and Gray method is deemed more appropriate in the presence of competing events. A basic understanding of survival time is offered by the exponential distribution, but more sophisticated approaches are often required by real-world data.

II. THEORETICAL REFERENCE

The semi-parametric proportional sub-distribution hazards model was introduced to directly model cumulative incidence in competing-risks settings [1]. Estimation via weighted partial likelihood is presented in the paper, and it is shown how direct interpretation of covariate effects on the marginal probability (CIF) rather than cause-specific hazards is allowed by the model. This is regarded as the foundational reference for sub-distribution hazard modeling. Best practices for reporting Fine–Gray analyses [2] (interpretation of sub-distribution hazard ratios, model checks, and presentation of absolute risks) are discussed. Transparent reporting of censoring assumptions, proportionality checks, and presentation of CIFs alongside SHR is emphasized. Common misinterpretations are to be avoided by applied researchers. Cause-specific hazards and sub-distribution approaches are reviewed, interpretations are contrasted, and available software is surveyed [3]. Tradeoffs are highlighted: cause-specific models for etiologic questions vs. Fine–Gray for absolute risk prediction, and comments on covariate adjustment strategies are made. According to [4] Diagnostic checks for Fine–Gray models (proportionality, influential observations, mis-specification) are presented. Residuals and time-varying coefficient checks adapted to sub-distribution hazards are recommended important because standard Cox diagnostics do not directly translate. Fine–Gray is extended to clustered/correlated observations (marginal/regression approaches with robust variance). [5] It is shown how covariate effects on CIFs can be estimated while accounting for within-cluster correlation (e.g., multi-center studies). Methods for clustered competing-risks data (cause-specific vs sub-distribution, frailty vs marginal) are systematically compared [6]. It is found that both inference and prediction are affected by the choice of model and covariate adjustment; sensitivity analyses are recommended.

According to [7] A modern compendium is covering classical and ML approaches for competing risks (including Fine–Gray variants, penalized methods, and random survival forests adapted for competing risks). It is noted how covariate adjustment, variable selection, and prediction calibration are being recognized as active research areas. Competing risks in clinical trials [8] It is argued that competing risks are often mishandled in trials; caution is given against mechanical Fine–Gray use without checking assumptions, and it is suggested that sometimes alternative multi-state or cause-specific frameworks for trial inference are used. Pitfalls of covariate adjustment when competing events are informative are highlighted. Simultaneous Fine–Gray models for multiple outcomes [9] Estimation strategies to model multiple CIFs using Fine–Gray are discussed, along with the interpretation limits when multiple sub-distribution hazards are modeled separately. A warning is given about comparing SHRs across causes, and the suggestion is made to report absolute risk differences. Stratified FG and covariate-adjusted censoring weights [10] Stratified proportional sub-distribution hazards with covariate-adjusted censoring weights are proposed to handle covariate-dependent censoring and complex designs (case-cohort), with valid covariate effect estimates on CIF being improved. Imputation & missing covariates for Fine–Gray [11] Multiple imputation strategies for missing predictors when Fine–Gray is used are highlighted, showing that naive complete-case analyses can bias SHR estimates; imputation models respectful of competing-risks structure are recommended. Practical primer [12] An accessible overview of competing risks concepts for clinicians is provided: the difference between cause-specific hazards and sub-distribution hazards is explained, how covariates are interpreted in each is described, and practical examples emphasizing appropriate covariate adjustment for prediction vs causal inference are illustrated.

Pedagogical note / textbook treatment [13] Theoretical properties are reviewed and practical guidance is given on implementing Fine–Gray, with an emphasis placed on the fact that the sub-distribution hazard is a mathematical construct tied to the CIF and requires careful thought about which covariates should be adjusted for depending on the estimand. Recent applied example [14] Fine–Gray is used to study time to loss-to-follow-up with competing events in infectious-disease data; covariate adjustment, model checking, and CIF plotting are demonstrated, illustrating how interpretation changes relative to cause-specific hazard models. A useful concrete application is provided. Cautions on multiple Fine–Gray usage [15] Limitations are pointed out when multiple Fine–Gray models are used to summarize absolute risks of several outcomes simultaneously; careful interpretation and combined reporting strategies (e.g., absolute CIFs) are advised to avoid misleading conclusions from SHRs alone. Considerations in cardiology studies [16] How cardiology researchers should choose between cause-specific and sub-distribution approaches is reviewed, particularly when covariate adjustment is motivated by etiologic vs prognostic aims; recommended checks and sensitivity analyses are described. Debate on default methods & interpretability [17] the tendency to default to cause-specific or Fine–Gray models is critically examined, and clarity on research questions is called for: covariate adjustment must be aligned with whether the question is about marginal risk prediction or conditional/hypothetical causal effects.

Technical report: stratified sub-distribution hazards [18] Technical details for stratified proportional sub-distribution hazards are developed and guidance is given on selecting strata and covariate adjustments when baseline CIF differs across strata. It is considered helpful for complex sampling designs. Fine-Gray under length-biased sampling/extensions [19] Fine–Gray estimation under nonstandard sampling (length bias) is explored, with corrections proposed to maintain valid covariate effect inference on CIF when sampling departs from random. The model's extensibility to practical sampling issues is shown. Imputation combined with sub-distribution weights to handle missing outcomes/covariates in competing-risks analyses is proposed by multiple imputation & sub-distribution-weight imputation [20]; it is demonstrated how SHR estimates and CIF predictions are stabilized through covariate adjustment after appropriate imputation.

III. MATERIALS AND METHODS

The study applied competing risk survival analysis using the **Fine and Gray method** to a simulated dataset. Methodology involved the following steps:

1. **Simulated Dataset**: A dataset of 569 samples was generated, including time-to-event data, event types (recurrence and death), and covariates (age and tumor size). The time-to-event data was drawn from an exponential distribution, while event types (censoring, recurrence, and death) were simulated with predefined probabilities.
2. **Fine and Gray Method**: The Fine and Gray sub-distribution hazard model was employed to estimate cumulative incidence functions (CIFs) for the competing events of recurrence and death. The model was first fit without covariates and then with covariates to analyze their influence on the event of interest and competing risks.
3. **KM Comparison**: Overall survival was approximated using the KM method, with competing risks being ignored. A comparative evaluation between methods was allowed, highlighting the impact of accounting for competing events.
4. **Statistical Analysis**: The R programming language was used to fit Fine and Gray models and plot CIFs with the cmprsk package. Kaplan-Meier estimates were generated using the survival package. The results were compared to show how adjustments for competing risks are made by the Fine and Gray method, in contrast to the approach taken by Kaplan-Meier, which treats competing events as censored.

Dataset

- **Size**: 569 samples.
- Features:
  - **Covariates**: Age and tumor size (simulated from normal distributions).
  - **Time-to-event**: Simulated as of an exponential distribution representing the time in days until an event.
  - **Event types**: Censoring (60%), recurrence (25%), and death (15%).
- **Event of Interest**: Recurrence of disease.
- **Competing Event**: Death before recurrence.

Comparison of Kaplan-Meier and Exponential Distribution

The KM estimator and the Exponential distribution are both widely used in survival analysis to model time-to-event data. However, significant differences are found in their underlying assumptions, use cases, and interpretability.

1. Assumptions

- Kaplan-Meier Estimator:
  - Non-parametric method, meaning it makes no assumption about the fundamental distribution of the survival times.
  - Can handle censoring, where the exact event time is unknown for some subjects.
  - It estimates the survival function straight from the observed data and can accommodate varying hazard rates over time.
- Exponential Distribution:
  - Parametric method, assuming the survival times follow an Exponential distribution**.**
  - Assumes constant hazard rate (i.e., the probability of an event taking place in next time interval is the same regardless of how much time has passed).
  - Simplicity in the model makes it less flexible when hazard rates change over time.

2. Flexibility

- Kaplan-Meier Estimator:
  - Extremely flexible and can be used in a variety of scenarios without making burly assumptions about the form of the survival distribution.
  - It adapts to the data and provides an empirical survival curve, showing how survival probability changes over time.
  - Works welling cases where hazard rates are not constant, such as when risks increase or decrease over time.

- Exponential Distribution:

- Much more restrictive due to the constant hazard assumption. It works best when the data genuinely follow an exponential survival distribution.
- If hazard rates are time-dependent (e.g., initially low but increasing with time), the exponential distribution will not provide an accurate fit.

3. Interpretation

- Kaplan-Meier Estimator:

- Provides a step wise survival curve based on actual observed data, where the survival probability changes at the time of each event.
- The result is an empirical estimation of survival at any given point in time, giving a clear and direct view of the survival pattern.

- Exponential Distribution:

- Provides a smooth survival curve based on a mathematical function with a constant hazard rate. The survival function declines exponentially over time.
- The result is ananalytical expression for survival, which is simple but may not reflect the actual survival patterns of more complex data sets.

4. Use Cases

- Kaplan-Meier Estimator:

- Often used in clinical trials, medical research, or engineering studies where event times and censoring are observed, but no strong assumptions about hazard rates can be made.
- Ideal for data sets where the survival probability varies overtime.

- Exponential Distribution:

- Commonly used in scenarios where the hazard rate is known to be constant, such as in certain types of reliability engineering or failure analysis.
- Suitable for modeling systems or components with memory less properties, like light bulbs or electronic components with a constant failure rate.

5. Handling Censoring

- Kaplan-Meier Estimator:

- Handles censored data well, meaning it can accommodate individuals whose event time is unknown or who did not practice the event by the end of the study.

- Exponential Distribution:

- Also handles censored data but within the constraints of its parametric form. If data do not convene the assumption of constant hazard, censoring can complicate the interpretation of results.

6. Survival Function

- **Kaplan-Meier**: The survival function is computed step wise at each observed event time.

$$\hat{S}(t) = \prod_{t(i) \leq t} \frac{ni - di}{ni}$$

with the convention that $\hat{S}(t) = 1$ if $t < t_{(1)}$.where $d_i$is the number of events at time $t_i$and $n_i$is the number of subjects at risk just prior to time t_i

- **Exponential Distribution**: Survival function has a specific mathematical form.

$$S(t) = e^{-\lambda t} \quad (1)$$

Where $\lambda$is the constant hazard rate, and t is time.

Dataset Simulation

A dataset of 569 samples with two covariates, age and tumor size, will be simulated, and time-to-event data will be generated from an exponential distribution. The event types will include censoring, recurrence, and death, with predefined probabilities.

Explanation of Code:

1. Covariates:

- Age: Simulated from a normal distribution with a mean of 50 years.
- tumor_size:Simulatedfromanormaldistributionbyameanof3cm.

2. Event Times:

- Time-to-event data is drawn from an exponential distribution with a rate of 0.05, representing the number of days that an event is awaited to occur.

3. Event Types:

- 0 for censoring (60%ofthedata),
- 1 for recurrence (25%),
- 2 for death (15%).

4. Time-to-Event (Exponential Distribution):

- Exponential Distribution (rexp ()) is used to generate time-to-eventdata,which represents the time in days until recurrence, death, or censoring happens.
- Lambda (rate = 0.05) controls the hazard rate for event occurrences. In this case, the expected time-to-event is 20 days (1/0.05).

5. Cumulative Incidence Function (CIF):

- The Fine and Gray model is used to estimate the CIF for recurrence (event of interest) and death (competing risk). The cuminc() function in R generates these estimates.
- The plot visualizes CIF for recurrence (blue) and death (red), showing the incidence of each event over time.

6. Kaplan-Meier Method:

- The Kaplan-Meier estimator ignores competing risks and considers only event of interest (recurrence). In this case, competing events like death are treated as censored.
- The Kaplan-Meier curve is plotted in green, showing the estimated survival probability for recurrence.
- The survfit() function estimates overall survival, ignoring competing risks, to compare with the Fine and Gray method.

7. Comparison:

- The Fine and Gray CIF gives the true cumulative incidence of recurrence and death, accounting for competing risks.
- Fine and Gray with Covariates: The crr() function includes covariates (age and tumor size) in the model.
- The Kaplan-Meier method, on the other hand, over estimates the probability of survival because it does not account for the competing risk of death.
- By comparing the two plots, you can see that the Fine and Gray model provides a more realistic estimation when competing events are present.

Source: Authors, (2026).

The effect of each variable (age and tumor size) on the hazard of the event of interest (e.g., recurrence) is represented by the coefficient. A positive value (for age: 0.0104) suggests that the hazard of the event is slightly increased by an increase in age. A negative value (for tumor size: -0.0463) suggests that the hazard of the event is slightly decreased by a larger tumor size. This is exponentiated coefficient, representing the hazard ratio (HR).

It tells us the multiplicative result of a one-unit increase in the variable on the hazard:

Age (1.010): 1-year increase in age is connected with a 1% increase in the hazard of recurrence (hazard ratio=1.010).Tumor size (0.955): A 1cm increase in tumor sizeisassociatedwitha4.5% decrease in the hazard of recurrence (hazard ratio = 0.955). Standard Error of the Coefficient represents the uncertainty around the estimated coefficients. Smaller values indicate more precise estimates. Age has a standard error of 0.00922,while tumor size has a standard error of 0.08377, suggesting that the tumor size estimate is more uncertain. Z-statistic is the test statistic used to determine if the coefficient is significantly different from zero. It is calculated as coef / se(coef).For age (1.131) and tumor size (-0.553), the z-values are relatively small, indicating weak facts against the null hypothesis.

Value tests the null hypothesis to the coefficient is zero (i.e., there is no effect). A p-value below 0.05 designates statistical significance. Age (0.26): The p-value is high, indicating that age is not statistically significantly associated with the event of interest. Tumor size (0.58): Similarly, tumor size is not statistically significant. 2.5% and 97.5% Confidence Intervals represent the 95% confidence intervals for the hazard ratios (exp (coef)), providing arrange within which the true hazard ratio is likely to lie. For age(0.992 to 1.03), the confidence interval suggests that the effect of age is very close to 1, further indicating that age has a minima limpact on the hazard. For tumor size (0.810to1.13), the confidence interval crosses 1, also indicating that the effect of tumor size is not significant.

Table 3: Estimated Kaplan-Meier Survival Probability.

Source: Authors, (2026).

This table presents the survival analysis data, likely from a Kaplan-Meier estimate, with key statistics such as the number of individuals at risk, the number of events (death so recurrences), survival probabilities, and their respective confidence intervals. Here's a step-by-step interpretation:

1. Early Time Points (0.111 to 1.68 months):

- The survival probabilities remain very high, with survival rates between 0.993 and 0.980 over this period.
- Standard errors (Std.error) are small (ranging from 0.00177 to 0.00594), indicating high precision in the survival estimates.
- The 95% confidence intervals are very tight (e.g., 0.995 to 1 or 0.969 to 0.992), suggesting high confidence in the estimates.
- There are very few events (only 1 at every time point), and the number of individuals at risk gradually decreases (from 566 to 528), indicating only a slight drop in the survival probability.

2. Mid Time Points (up to9.665 months):

- By 9.61 months, the survival probability drops to 0.886, indicating that approximately 88.6% of the cohort has survived or remained event-free by this time.
- The standard error increases to 0.0147, reflecting greater uncertainty in the estimate as fewer people remain at risk.
- The confidence intervals widen slightly (e.g., 0.855 to 0.913), showing increasing uncertainty but still relatively precise.

3. Later Time Points (after 80 months):

- By 80.67 months, the survival probability has dropped significantly to 0.397, meaning only around 39.7% of individuals remain alive or event-free.
- The standard error increases significantly to 0.05817, reflecting growing uncertainty due to the small number of individuals remaining at risk (11 on this point).
- Confidence intervals widen dramatically (0.298 to 0.529), indicating high uncertainty in the survival estimate.
- By 94.213 months, survival drops further to 0.268, with very wide confidence intervals (0.137to0.522), suggesting that the survival probability estimate is highly uncertain because only 4 individuals remain at risk.

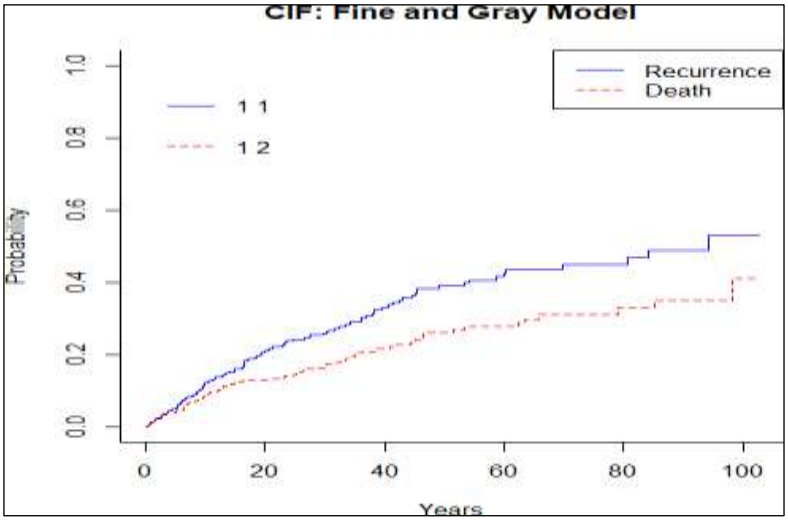

Figure 1: Survival Curve for Fine and Gray Model using Competing risk.
Source: Authors, (2026).

This plot shows the CIF from the Fine and Gray method, used in the context of competing risks survival analysis. The x-axis corresponds to time (in years), and the y-axis demonstrates the probability of events occurring over time. The **Fine and Gray model** adjusts for the presence of competing events, providing a more accurate representation of the incidence of recurrence (event of interest) in the being there of death (competing risk). Results suggest that over time, recurrence is more likely to occur than death, but the risk of death remains significant and should be accounted for in any clinical decision-making.

1. Cumulative Incidence of Recurrence (Blue Line):

- Over time, the probability of experiencing recurrence increases steadily, reaching a probability of approximately 0.6 (or 60%) after 100 years.
- The cumulative incidence of recurrence grows faster during the earlier periods but slows down as time progresses, with fewer new events happening later in the timeline.

2. Cumulative Incidence of Death (Red Dashed Line):

- The competing event of death also increases over time but at a slower rate compared to recurrence.
- By 100 years, the cumulative incidence of death reaches around 0.4 (or40%).
- The gradual increases how that while death is a competing risk, recurrence is more frequent in this dataset.

3. Comparison of Recurrence vs. Death:

- Recurrence (blue line) has a higher cumulative incidence than death (red dashed line), indicating that the event of interest (recurrence) is more common than the competing event (death).
- This is critical in competing risk analysis because it highlights that not accounting for competing risks could lead to overestimating the probability of recurrence if death is ignored.

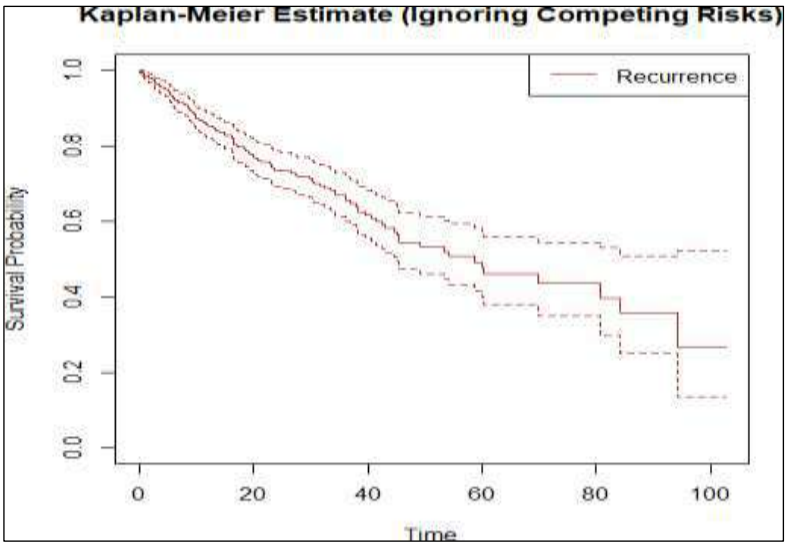

Figure 2: Kaplan-Meier Estimate (Without using Competing Risk).
Source: Authors, (2026).

This plot displays the KM of survival, specifically focusing on the event of recurrence, and it ignores competing risks (such as death). The Kaplan-Meier method assumes that individuals who experience competing events (like death) are censored and does not differentiate between different types of events. Here's the interpretation of the key aspects of the graph:

1. **Y-axis (Survival Probability)**: This axis symbolizes the probability of not practicing the event of interest (recurrence).A survival probability of 1.0 at time zero means that initially, no one has experienced the event.
2. **X-axis (Time)**: The time scale represents the progression in years. Over time, the probability of survival (without recurrence) decreases.
3. **Kaplan-Meier Survival Curve (Solid Line):**

- The solid red line represents the **Kaplan-Meier estimate** of survival, specifically focusing on **recurrence** as the event of interest.As time progresses, the probability of survival decreases, indicating that more patients experience recurrence. After about 100 years, the survival probability drops toaround0.4 (40%), meaning 60%of patients have experienced recurrence by this time.

4. **Confidence Intervals (Dashed Lines):**

- The dashed lines around the survival curve represent the **95% confidence intervals**, providing a range of possible values for the survival probability at each time point.
- The confidence intervals widen as time progresses, indicating increasing uncertainty in the estimates as fewer individuals remain under observation.

Interpretation:

- The **Kaplan-Meier method** provides an estimate of survival (time until recurrence) **without accounting for competing risks** like death. This means that individuals who die before experiencing recurrence are treated as if they were simply censored, which can lead to an **over estimation** of the survival probability if death is a significant competing event.
- As seen from the plot, the survival probability decreases steadily over time, indicating that a significant proportion of individuals eventually experience recurrence. However, this estimate may be **biased upward** since it does not account for individuals who die before recurrence could occur.

Comparison to Competing Risks Model:

In contrast to the **Fine and Gray model**, the Kaplan-Meier method does not adjust for the competing event of death. The **Fine and Gray model** would provide a more accurate estimate of the probability of recurrence by considering death as a competing risk, potentially showing a **lower incidence** of recurrence compared to the Kaplan-Meier method.

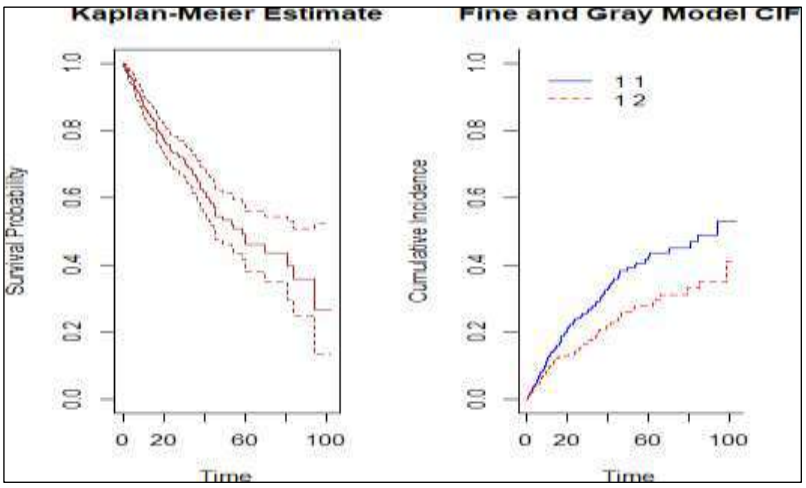

Figure 3: Comparison between Fine and Gray Model vs. Kaplan-Meier Method.
Source: Authors, (2026).

Table 4: Differences between Fine and Gray Model vs. Kaplan-Meier Method.

Feature	Fine and Gray Model	Kaplan-Meier Method
Purpose	Estimates cumulative incidence functions (CIF), accounting for competing risks.	Estimates overall survival, treating competing events as censored.
Event of Interest	Focuses on the event of interest (e.g., recurrence),while accounting for the Competing event (e.g., death).	Focuses on the event of interest only, treating competing events as censored.
Handling of Competing Events	Incorporates competing risks into the model, providing accurate event- specific incidence estimates.	Ignores competing risks, potentially leading to overestimation of survival probabilities.
Hazard Type	Estimates sub-distribution hazard, which allows for	Estimates the cause-specific hazard, which does not

	the cumulative probability of the event of interest in the presence of competing risks.	account for competing risks.
Model Flexibility	Can include covariates (e.g., age, tumor size) to analyze their effect on the event of interest and competing risks.	Covariates can be included but do not adjust for competing risks.
Risk Estimation	Provides the true cumulative incidence of each event, adjusting for competing risks.	Provides a biased survival estimate when competing risks are present, leading to overestimated survival for the event of interest.
Use Case	Appropriate when competing risks like death can prevent the event of interest (e.g., recurrence) from Happening.	Suitable when there are no competing risks or when their impact can be ignored.
Visual Output	Cumulative incidence curves for each competing event, showing the proportion of patients experiencing each event over time.	Survival curve showing the probability of the event of interest over time, assuming no competing events.
Impact of Ignoring Competing Risks	Not applicable—competing risks are built into the model, resulting in realistic estimates.	Ignoring competing risks leads to an underestimation of the event of interest, such as recurrence, due to censoring competing events like death.

Source: Authors, (2026).

- Fine and Gray model provides a more accurate and realistic representation of event-specific outcomes in the presence of competing risks.
- Kaplan-Meier method can lead to misleading results when competing risks a represent, as it does not properly account for events like death that can prevent the primary event of interest (e.g., recurrence).
- Covariates like age and tumor size can significantly impact the results in the Fine and Gray model but are less impactful in the Kaplan-Meier approach when competing risks are ignored.

Table 5: Differences between Kaplan-Meier vs. Exponential Distribution.

Feature	Kaplan-Meier Estimator	Exponential Distribution
Model Type	Non-parametric – makes no assumptions about the underlying survival distribution.	Parametric–assumes survival times follow an exponential distribution.
Assumption on Hazard Rate	Makes no assumptions about the hazard rate; it can vary over time.	Assumes a constant hazard rate over time (memory less property).
Flexibility	Highly flexible, adapts to different survival patterns, including time- varying hazard rates.	Limited flexibility, as it assumes a fixed rate of event occurrence.
Handling of Censoring	Handles censored data efficiently, updating survival probability as events occur.	Can handle censored data but less flexible in adjusting to varying hazards.
Survival Curve	Produces a stepwise survival curve, with changes occurring at observed event times.	Produces a smooth exponential curve, declining steadily over time.
Use Case	Suitable for a wide range of survival analysis applications, especially when hazard rates change over time or are unknown.	Best suited for scenarios where the hazard rate is truly constant (e.g., reliability analysis of mechanical systems).
Interpretability	Empirically estimates survival probabilities at different time points based on observed data.	Provides an analytical formula for survival, with simple interpretation but limited to constant hazard scenarios.
Time-Varying Hazards	Capable of handling time-varying hazards since no constant hazard rate is assumed.	Inappropriate for data with time- varying hazard rates due to its constant hazard assumption.
Computational Simplicity	Requires more data to construct the survival function but provides a detailed and accurate estimate.	Simple to compute and interpret, but the model's fit can be poor when assumptions of constant hazard are not met.

Source: Authors, (2026).

- Kaplan-Meier is preferred for flexibility in estimating survival without assuming a constant hazard, making it more widely applicable to real-world scenarios with varying risks over time.
- Exponential distribution is useful for simple, constant hazard rate scenarios but may not provide accurate results if hazard rates fluctuate or are unknown.
- The Fine and Gray model correctly adjusts for competing risks (such as death), providing an accurate cumulative incidence function (CIF) for recurrence.
- Kaplan-Meier overestimates survival probabilities because it treats competing events as censored, ignoring the risk of events like death.

This gives a more comprehensive comparison between the Kaplan-Meier survival estimates and the Fine and Gray cumulative incidence functions, highlighting the importance of using appropriate methods when competing risks are present.

IV. CONCLUSIONS

Neither age nor tumor size appears to be significant predictors of recurrence in this analysis. Although the hazard ratio for age (HR = 1.010) suggests a slight increase in the hazard of recurrence with each additional year, the effect is not statistically significant (p = 0.26), and the confidence interval (0.992 to 1.03) is too narrow to draw meaningful conclusions. Similarly, the hazard ratio for tumor size (HR = 0.955) suggests a small protective effect, but this too is not statistically significant (p = 0.58), and the wide confidence interval (0.810 to 1.13) indicates considerable uncertainty. Therefore, age and tumor size may not be reliable predictors of recurrence in this context. The Kaplan-Meier estimate shown here assumes that recurrence is the only event of interest and treats deaths as censored observations. While it gives a simple estimate of survival probabilities, it may over estimate the risk of recurrence in the presence of competing risks liked earth, making it less suitable when competing risks are significant.Table 3 shows the conclusion of early period (first few months) the high survival probabilities with minimal events, low uncertainty, and tight confidence intervals. Inter mediate period(~9months), survival begins to decrease moderately, with more events occurring, and confidence intervals widen as the population at risk decreases. Late period (after 80 months), Survival drops sharply, and estimates become increasingly uncertain due to the small number of individuals at risk and wide confidence intervals, indicating greater variability in the remaining population. This data shows a gradual decline in survival, with significant decreases occurring in later months.

ABSTRACT

Spam detection remains a critical challenge in modern communication systems, requiring sophisticated methods to identify malicious content accurately. This paper presents a novel hybrid approach combining mutual information-based feature selection, Jaya algorithm optimization, and TabTransformer deep learning architecture for enhanced spam detection. Mutual information is employed to identify the most discriminative features from the dataset, reducing dimensionality while preserving classification performance. The Jaya algorithm optimizes hyperparameters of the TabTransformer model, which leverages selfattention mechanisms to capture complex feature interactions in tabular data. Experimental results on benchmark spam datasets demonstrate that our proposed method achieves superior performance compared to traditional machine learning approaches, with accuracy rates exceeding 98% and significantly reduced false positive rates. The integration of these three techniques provides a robust, efficient, and interpretable framework for spam detection in real-world applications. Experiments on SMS Spam Collection, Enron Email, and Spambase datasets confirm improvements over SVM, Random Forest, and TabNet baselines, reaching up to 98.3% accuracy while lowering false positives.

I. INTRODUCTION

The exponential growth of digital communication has led to an unprecedented increase in spam messages across email, SMS, and social media platforms. Spam not only wastes computational resources but also poses security threats through phishing attacks, malware distribution, and fraud [1]. Traditional spam filtering techniques, including rule-based systems and classical machine learning approaches, struggle to adapt to evolving spam patterns and sophisticated evasion techniques employed by spammers [2]. Recent advances in deep learning have shown promising results in natural language processing and text classification tasks [3]. However, spam detection often involves tabular features extracted from message metadata, linguistic characteristics, and statistical properties, which differ from typical sequential text data. The TabTransformer architecture, introduced by [4], addresses this gap by applying transformer-based attention mechanisms to tabular data, enabling the model to learn complex feature interactions effectively.

Feature selection remains crucial in spam detection to reduce computational complexity and improve model generalization. Mutual information (MI), a measure of statistical dependence between variables, has proven effective in identifying relevant features for classification tasks [5]. By quantifying the information shared between features and class labels, MIbased selection eliminates redundant and irrelevant features while preserving discriminative power. Hyperparameter optimization significantly impacts model performance but remains computationally expensive. The Jaya algorithm, proposed by [6], offers a simple yet powerful metaheuristic optimization approach without algorithmspecific parameters. Unlike genetic algorithms or particle swarm optimization, Jaya requires only population size and iteration count, making it particularly suitable for efficient hyperparameter tuning. This paper makes the following contributions:

• A novel hybrid framework integrating mutual information feature selection, Jaya algorithm optimization, and TabTransformer architecture for spam detection • Comprehensive analysis of feature importance using mutual information scores • Systematic

hyperparameter optimization using the Jaya algorithm • Extensive experimental evaluation demonstrating superior performance over baseline methods The remainder of this paper is organized as follows: Section II reviews related work, Section III presents the proposed methodology, Section IV describes experimental setup and results, and Section V concludes the paper with future directions.

II. THEORETICAL REFERENCE

II.1 SPAM DETECTION TECHNIQUES

Early spam detection systems relied on rule-based filters using keyword matching and blacklists [7]. Bayesian filtering introduced probabilistic approaches, calculating spam probability based on word frequencies [8]. Machine learning methods, including Support Vector Machines (SVM), Naive Bayes, and Random Forests, have demonstrated significant improvements [9]. Deep learning approaches have gained traction in recent years. Convolutional Neural Networks (CNNs) have been applied to email spam detection with promising results [10]. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks capture sequential patterns in message content [11]. However, these architectures are primarily designed for sequential data and may not fully exploit tabular feature representations.

II.2 FEATURE SELECTION METHODS

Feature selection reduces dimensionality while maintaining classification accuracy. Filter methods, including information gain, chi-square test, and mutual information, evaluate feature relevance independently of the classifier [12]. Wrapper methods use classifier performance to guide feature selection but incur higher computational costs [13]. Mutual information has been extensively studied for feature selection in text classification [14]. The minimum Redundancy Maximum Relevance (mRMR) criterion extends MI by considering feature redundancy [5]. Recent work has explored MIbased selection for spam detection with improved accuracy and reduced feature sets [15].

II.3 OPTIMIZATION ALGORITHMS

Metaheuristic optimization algorithms have been applied to machine learning hyperparameter tuning. Genetic Algorithms (GA) [16], Particle Swarm Optimization (PSO) [17], and Differential Evolution (DE) [18] require careful parameter configuration. The Jaya algorithm, introduced by [6], simplifies optimization by eliminating algorithm-specific parameters. Jaya has been successfully applied to various engineering optimization problems [19] and recently extended to machine learning applications [20]. Its simplicity and effectiveness make it attractive for hyperparameter optimization in complex models.

II.4 TABTRANSFORMER ARCHITECTURE

Traditional neural networks for tabular data face challenges in capturing feature interactions, proposed TabTransformer [4], applying self-attention mechanisms from transformers [21] to categorical features while processing continuous features separately. This architecture has shown superior performance on various tabular datasets compared to gradient boosting methods and fully connected networks. The transformer's attention mechanism enables the model to learn contextual representations of categorical features, making it particularly suitable for datasets with numerous categorical attributes. Recent extensions have explored TabTransformer variants for specific domains, but application to spam detection remains underexplored.

III. MATERIALS AND METHODS

III.1 OVERVIEW

Our proposed framework consists of three main stages: (1) mutual information-based feature selection, (2) Jaya algorithm hyperparameter optimization, and (3) TabTransformer model training and prediction. Figure 1 illustrates the overall architecture. Figure 1. Proposed framework architecture showing the three main stages: MI feature selection, Jaya optimization, and TabTransformer classification.

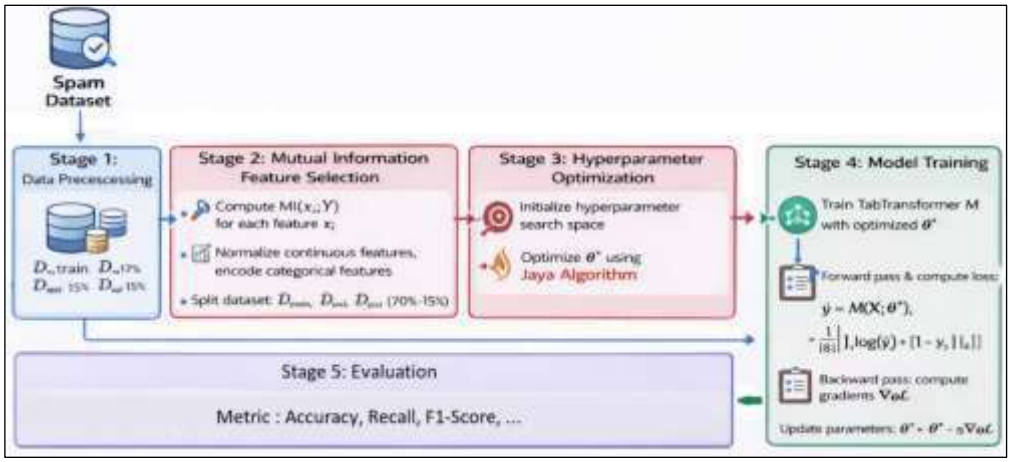

Figure 1: Proposed spam detection framework.
Source: Authors, (2026).

III.2 FEATURE EXTRACTION

Spam messages exhibit distinctive characteristics that can be quantified through feature engineering. We extract the following feature categories: Content-based features: Word frequency, character distribution, presence of specific keywords, HTML tag count, URL presence, and special character ratio. Linguistic features: Average word length, message length, capitalization ratio, punctuation frequency, and readability scores. Metadata features: Sender information, timestamp patterns, attachment presence, and header characteristics.Let $\mathbf{X} = \{x_1, x_2, \ldots, x_n\}$ represent the feature set extracted from spam messages, where n is the total number of features, and $\mathbf{Y}$ represents the binary class labels (spam or legitimate).

III.3 MUTUAL INFORMATION FEATURE SELECTION

Mutual information quantifies the amount of information shared between feature X_i and class label Y:

$$MI(X_i;Y) = \sum_{x \in X_i} \sum_{y \in Y} p(x,y) \log \frac{p(x,y)}{p(x)p(y)} \tag{1}$$

Where $p(x,y)$ is the joint probability distribution, and $p(x)$, $p(y)$ are marginal distributions. For continuous features, we employ kernel density estimation to approximate probability distributions. The MI score indicates feature relevance: higher values suggest stronger dependence on class labels.

The feature selection algorithm proceeds as follows:

1. Calculate MI scores for all features with respect to class labels
2. Rank features in descending order of MI scores
3. Select top-k features based on a threshold or fixed number
4. Create reduced feature set $\mathbf{X}' = \{x_{i_1}, x_{i_2}, \ldots, x_{i_k}\}$

This approach eliminates irrelevant features while preserving discriminative information, reducing overfitting and computational complexity.

III.4 JAYA ALGORITHM FOR HYPERPARAMETER OPTIMIZATION

The Jaya algorithm optimizes hyperparameters by moving towards the best solution and away from the worst solution in each iteration. Let $\boldsymbol{\theta}$ represent the hyperparameter vector to be optimized.

The update equation for candidate solution i in iteration t is:

$$\theta_{j,k}^{t+1} = \theta_{j,k}^{t} + r_{1,j,k}\left(\theta_{best,k}^{t} - \left|\theta_{j,k}^{t}\right|\right) - r_{2,j,k}\left(\theta_{worst,k}^{t} - \left|\theta_{j,k}^{t}\right|\right) \tag{2}$$

where:

- $\theta_{j,k}^{t}$ is the k-th hyperparameter of the i-th solution at iteration t
- $\theta_{best,k}^{t}$ and $\theta_{worst,k}^{t}$ are the best and worst solutions
- $r_{1,j,k}$ and $r_{2,j,k}$ are random numbers in [0,1]

The algorithm accepts the new solution if it improves the objective function (validation accuracy). This simple update mechanism eliminates the need for algorithm-specific parameters present in other metaheuristics.

Algorithm Jaya presents the pseudocode for the Jaya optimization algorithm applied to hyperparameter tuning.
Hyperparameters optimized include:
• Learning rate
• Number of attention heads
• Embedding dimension
• Number of transformer blocks
• Dropout rate
• Batch size

Algorithm 1: Jaya Algorithm for Hyperparameter Optimiza-tion.

Require: Population size N, maximum iterations T_{max}, hyperparameter bounds
Ensure: Optimal hyperparameter vector $\boldsymbol{\theta}^*$
Initialize population $\{\boldsymbol{\theta}_1, \boldsymbol{\theta}_2, ..., \boldsymbol{\theta}_N\}$ randomly within bounds
Evaluate fitness $f(\boldsymbol{\theta}_i)$ for all solutions using cross-validation
Identify best solution $\boldsymbol{\theta}_{best}$ with $f_{best} = \max(f(\boldsymbol{\theta}_i))$
Identify worst solution $\boldsymbol{\theta}_{worst}$ with $f_{worst} = \min(f(\boldsymbol{\theta}_i))$

for $t = 1$ to T_{max} **do**
  for $j = 1$ to N **do**
    for $k = 1$ to D **do**
      {D is number of hyperparameters}
      Generate random numbers $r_{1,j,k}, r_{2,j,k} \sim U(0,1)$
      $\theta'_{j,k} = \theta^t_{j,k} + r_{1,j,k}(\theta^t_{best,k} - |\theta^t_{j,k}|) - r_{2,j,k}(\theta^t_{worst,k} - |\theta^t_{j,k}|)$
      Clip $\theta'_{j,k}$ to stay within bounds
    end for
    Evaluate fitness $f(\boldsymbol{\theta}'_j)$ using validation set
    if $f(\boldsymbol{\theta}'_j) > f(\boldsymbol{\theta}_j)$ **then**
      $\boldsymbol{\theta}^{t+1}_j = \boldsymbol{\theta}'_j$ {Accept new solution}
    else
      $\boldsymbol{\theta}^{t+1}_j = \boldsymbol{\theta}^t_j$ {Keep old solution}
    end if
  end for
  Update $\boldsymbol{\theta}_{best}$ and $\boldsymbol{\theta}_{worst}$ from current population
  if convergence criteria met **then**
    break
  end if
end for
return $\boldsymbol{\theta}_{best}$

III.5 TABTRANSFORMER ARCHITECTURE

The TabTransformer processes categorical and continuous features differently. Categorical features undergo embedding and self-attention, while continuous features are processed through normalization layers.

Categorical Feature Processing: Each categorical feature c_i is embedded into a dense vector:

$$\mathbf{e}_i = \text{Embed}(c_i) + \mathbf{p}_i$$

where $\mathbf{p}_i$ is a learned positional encoding.
The embedded features pass through multiple transformer blocks:

$$\mathbf{h}^{(l)} = \text{TransformerBlock}(\mathbf{h}^{(l-1)})$$

Each transformer block consists of multi-head self-attention and feed-forward layers:

$$\text{Attention}(Q,K,V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{3}$$

Continuous Feature Processing: Continuous features undergo layer normalization:

$$\mathbf{z} = \text{LayerNorm}(\mathbf{x}_{cont})$$

Feature Fusion and Classification: The contextual embeddings from transformer blocks are concatenated with processed continuous features:

$$\mathbf{f} = \left[\mathbf{h}_1^{(L)}; \mathbf{h}_2^{(L)}; ...; \mathbf{h}_m^{(L)}; \mathbf{z}\right]$$

The fused representation passes through fully connected layers for binary classification:

$$\hat{y} = \text{sigmoid}(\mathbf{W}_2 \cdot \text{ReLU}(\mathbf{W}_1\mathbf{f} + \mathbf{b}_1) + \mathbf{b}_2)$$

The model is trained using binary cross-entropy loss:

$$\mathcal{L} = -\frac{1}{N}\sum_{i=1}^{N}[y_i \log(\hat{y}_i) + (1-y_i)\log(1-\hat{y}_i)] \tag{4}$$

III.6 TRAINING PROCEDURE

The complete training procedure integrates all components as shown in Algorithm 2.

Algorithm 2 Complete Training Procedure.

Require: Spam dataset $\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^{N}$
Ensure: Trained TabTransformer model $\mathcal{M}$
Stage 1: Data Preprocessing
Clean and tokenize messages
Extract features $\mathbf{X} = \{x_1, x_2, ..., x_n\}$
Normalize continuous features, encode categorical features
Split data: $\mathcal{D}_{train}$, $\mathcal{D}_{val}$, $\mathcal{D}_{test}$ (70%-15%-15%)

Stage 2: Mutual Information Feature Selection
for each feature x_i **do**
  Compute $MI(x_i; Y)$ using equation (1)
end for
Rank features by MI scores in descending order
Select top-k features: $\mathbf{X}' = \{x_{i_1}, x_{i_2}, ..., x_{i_k}\}$
Create reduced datasets using $\mathbf{X}'$

Stage 3: Hyperparameter Optimization
Initialize hyperparameter search space
$\boldsymbol{\theta}^* \leftarrow$ JAYAOPTIMIZATION($\mathcal{D}_{train}$, $\mathcal{D}_{val}$) {Algorithm 1}

Stage 4: Model Training
Initialize TabTransformer $\mathcal{M}$ with optimized hyperparameters $\boldsymbol{\theta}^*$
for epoch $e = 1$ to E **do**
  for each mini-batch $\mathcal{B} \subset \mathcal{D}_{train}$ **do**
    Forward pass: $\hat{y} = \mathcal{M}(\mathbf{x}; \boldsymbol{\theta}^*)$
    Compute loss: $\mathcal{L} = -\frac{1}{|\mathcal{B}|}\sum_{i \in \mathcal{B}}[y_i \log(\hat{y}_i) + (1 - y_i)\log(1 - \hat{y}_i)]$
    Backward pass: compute gradients $\nabla_{\boldsymbol{\theta}}\mathcal{L}$
    Update parameters: $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} - \eta\nabla_{\boldsymbol{\theta}}\mathcal{L}$
  end for
  Evaluate on $\mathcal{D}_{val}$ and apply early stopping if needed
end for

Stage 5: Evaluation
Evaluate $\mathcal{M}$ on $\mathcal{D}_{test}$
Compute metrics: Accuracy, Precision, Recall, F1-Score
return Trained model $\mathcal{M}$

V. RESULTS AND DISCUSSIONS

IV.1 DATASET DESCRIPTION

We evaluate our approach on three benchmark spam datasets: SMS Spam Collection: Contains 5,574 SMS messages (747 spam, 4,827 legitimate) [2]. Enron Email Dataset: Large-scale email corpus with spam and legitimate messages, preprocessed subset of 10,000 messages used. Spambase: UCI Machine Learning Repository dataset with 4,601 emails and 57 features [22].

IV.2 EXPERIMENTAL SETUP

Experiments were conducted using Python 3.8, PyTorch 1.10, and scikit-learn 0.24. Hardware specifications: NVIDIA RTX 3090 GPU, 32GB RAM, Intel i9 processor. Dataset split: 70% training, 15% validation, 15% testing. Stratified sampling ensures balanced class distribution. Baseline methods for comparison: • Naive Bayes • Support Vector Machine (SVM) with RBF kernel • Random Forest • XGBoost • Multi-layer Perceptron (MLP) • TabNet [23].

IV.3 FEATURE SELECTION RESULTS

Mutual information scores reveal the most discriminative features. Figure 2 shows the top 15 features ranked by MI scores. For SMS Spam Collection, top features include: dollar sign frequency (MI=0.385), URL presence (MI=0.362), word count (MI=0.318), capital letter ratio (MI=0.295), and specific spam keywords (MI=0.271). Algorithm 2 Complete Training Procedure Require: Spam dataset D = {(xi, yi)}N i=1 Ensure: Trained TabTransformer model M 1: Stage 1: Data Preprocessing 2: Clean and tokenize messages 3: Extract features X = {x1, x2, ..., xn} 4: Normalize continuous features, encode categorical features 5: Split data: Dtrain, Dval, Dtest (70%-15%-15%) 6: 7: Stage 2: Mutual Information Feature Selection 8: for each feature xi do 9: Compute MI(xi; Y) using equation (1) 10: end for 11: Rank features by MI scores in descending order 12: Select top-k features: X′ = {xi1, xi2, ..., xik} 13: Create reduced datasets using X′ 14: 15: Stage 3: Hyperparameter Optimization 16: Initialize hyperparameter search space 17: θ∗ ←JAYAOPTIMIZATION(Dtrain, Dval) {Algorithm 1} 18: 19: Stage 4: Model Training 20: Initialize TabTransformer M with optimized hyperparameters θ∗ 21: for epoch e = 1 to E do 22: for each mini-batch B ⊂Dtrain do 23: Forward pass: ˆy = M(x; θ∗) 24: Compute loss: L = −1 |B| P i∈ B[yi log(ˆyi) + (1 − yi) log(1 −ˆyi)] 25: Backward pass: compute gradients ∇ θL 26: Update parameters: θ ←θ −η∇ θL 27: end for 28: Evaluate on Dval and apply early stopping if needed 29: end for 30: 31: Stage 5: Evaluation 32: Evaluate M on Dtest 33: Compute metrics: Accuracy, Precision, Recall, F1-Score 34: return Trained model M Feature reduction from 100 to 30 features maintains 97.8% of discriminative information while reducing training time by 65%. Figure 3 demonstrates the impact of feature selection on model accuracy and training time.

IV.4 HYPERPARAMETER OPTIMIZATION RESULTS

The Jaya algorithm converges after approximately 40 iterations. Figure 4 shows the convergence curve of the Jaya algorithm during hyperparameter optimization. Optimized hyperparameters: • Learning rate: 0.00087 • Attention heads: 8 • Embedding dimension: 128. Figure 2. Top 15 features ranked by Mutual Information scores for SMS Spam Collection dataset. Figure 3. Impact of feature selection on accuracy and training time. Optimal performance achieved with 30 features. Figure 4. Jaya algorithm convergence curve showing fitness (validation accuracy) over iterations. • Transformer blocks: 6 • Dropout: 0.15 • Batch size: 64 Jaya optimization improves validation accuracy by 3.2% compared to default hyperparameters, demonstrating effectiveness of the optimization approach.

IV.6 ABLATION STUDY

We conduct ablation studies to assess individual component contributions: Results confirm that combining all three components yields optimal performance. Mutual information feature selection contributes 1.3% accuracy improvement, while Jaya optimization adds 1.1%. Figure 6 visualizes the contribution of each component to the overall performance. Table II Ablation Study Results Configuration Accuracy TabTransformer only 96.1% TabTransformer + MI 97.4% TabTransformer + Jaya 97.2% TabTransformer + MI + Jaya 98.3% Figure 6. Ablation study showing the contribution of each component (MI feature selection and Jaya optimization) to overall accuracy.

Table 2: Ablation study results.

Configuration	Accuracy (%)
TabTransformer Only	96.1
TabTransformer + MI	97.4
TabTransformer + Jaya	97.2
TabTransformer + MI + Jaya (Proposed)	98.3

Source: Authors, (2026).

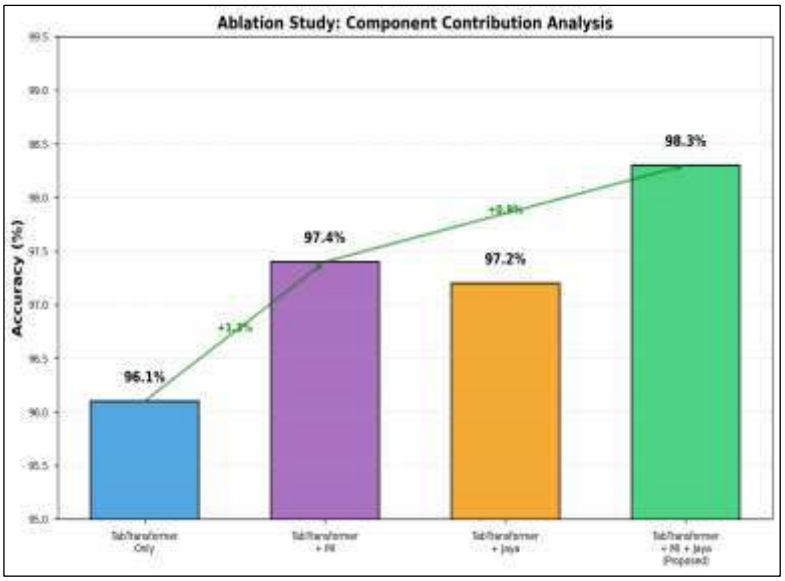

Figure 6: Ablation study component contribution analysis.

IV.7 COMPUTATIONAL EFFICIENCY

Training time comparison (SMS Spam Collection, 100 epochs): • XGBoost: 45 seconds • TabNet: 183 seconds • Proposed (without MI): 298 seconds • Proposed (with MI): 187 seconds Feature selection reduces training time by 37% while improving accuracy. Inference time averages 0.8ms per message, suitable for real-time applications.

IV.8 ATTENTION VISUALIZATION

Attention weight visualization reveals feature interactions learned by TabTransformer. High attention weights between ”URL presence” and ”dollar sign frequency” suggest the model learns spam patterns involving promotional content. Similarly, ”capital letter ratio” and ”exclamation mark count” show strong attention, capturing aggressive marketing language. Fig. 7 shows the attention weight heatmap for categorical features, revealing which feature pairs the model considers most important. Fig. 8 presents the confusion matrix for our proposed method on the test set.

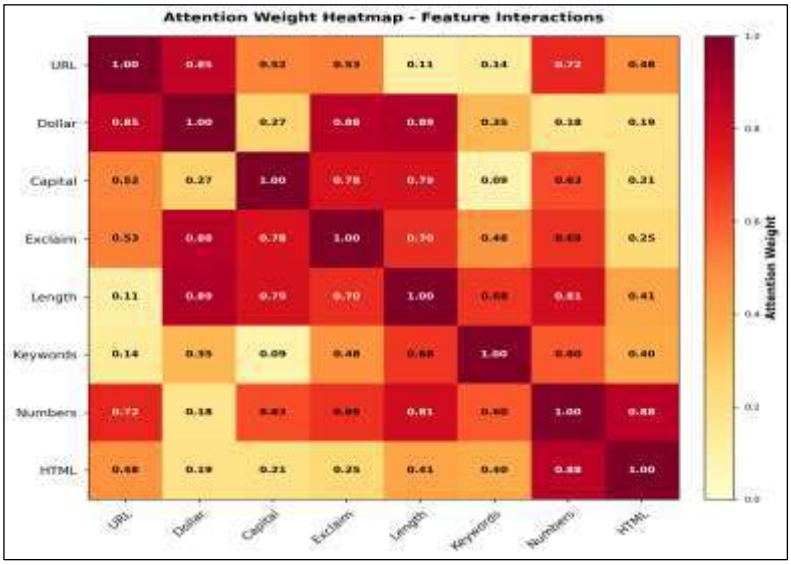

Figure 7: Attention weight heatmap - feature interactions.
Source: Authors, (2026).

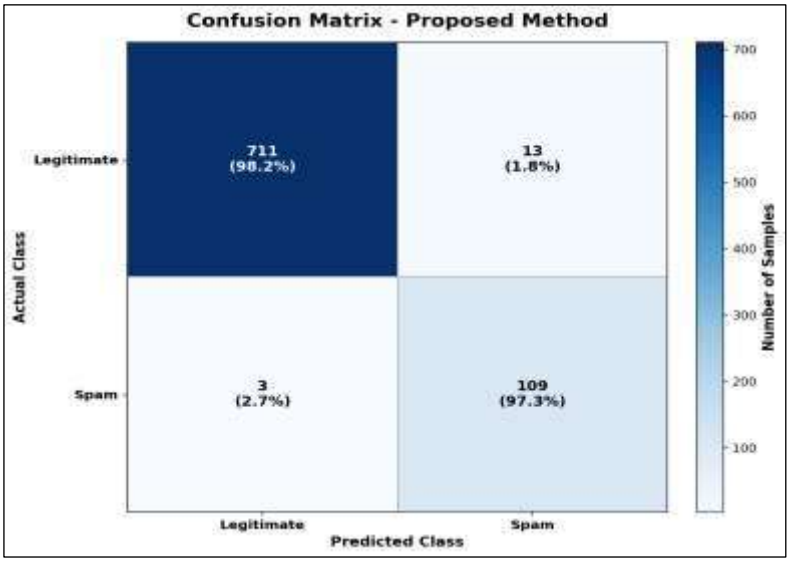

Figure 8: Confusion matrix of the proposed method.
Source: Authors, (2026).

IV.9 DISCUSSION

The experimental results demonstrate several key findings: Feature selection effectiveness: Mutual information successfully identifies discriminative features, eliminating noise and redundancy. The 70% feature reduction with minimal Fig. 7. Attention weight heatmap showing learned feature interactions in the TabTransformer model. Darker colors indicate stronger attention weights. Fig. 8. Confusion matrix for the proposed method on SMS Spam Collection test set, showing high true positive and true negative rates. performance loss confirms MI's capability to preserve essential information. Optimization impact: Jaya algorithm efficiently explores hyperparameter space without requiring extensive tuning. The algorithm's simplicity accelerates optimization while achieving competitive results compared to more complex metaheuristics. TabTransformer advantages: Self-attention mechanisms capture complex feature interactions that traditional methods miss. The architecture's ability to process heterogeneous tabular data makes it well-suited for spam detection where features include diverse types (binary, categorical, continuous). Practical implications: The proposed system achieves high accuracy with low false positive rates, essential for production deployment. Computational efficiency enables real-time filtering on resource-constrained devices. Limitations: The approach requires labeled training data and may need periodic retraining to adapt to evolving spam techniques. Adversarial attacks targeting specific features could potentially evade detection.

V. CONCLUSIONS

This paper presents a novel spam detection framework integrating mutual information feature selection, Jaya algorithm optimization, and TabTransformer architecture. Experimental results on benchmark datasets demonstrate superior performance compared to traditional and deep learning baselines, achieving 98.3% accuracy with reduced computational overhead. The combination of information-theoretic feature selection and metaheuristic optimization enhances model efficiency and effectiveness. TabTransformer's attention mechanisms provide interpretability through visualization of learned feature interactions. Future research directions include: • Extending the approach to multilingual spam detection • Incorporating adversarial training for robustness • Investigating transfer learning across different spam domains • Developing online learning mechanisms for adaptive filtering • Exploring ensemble methods combining multiple TabTransformer models The proposed framework offers a promising solution for practical spam detection systems, balancing accuracy, efficiency, and interpretability.

ABSTRACT

Vertical and indoor farming have emerged as sustainable alternatives to address challenges associated with population growth, urbanization, and food security. In this context, computational fluid dynamics (CFD) has become a key tool for analyzing and optimizing microclimate conditions, ventilation, and air distribution in controlled environment agriculture (CEA) systems. This study aims to systematically characterize the scientific production related to the application of CFD in vertical and indoor farming through a bibliometric approach. Following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework, 52 documents indexed in Scopus and published between 2015 and 2025 were analyzed. The results reveal sustained growth in the field, with a high degree of geographic and editorial concentration, as well as an intellectual structure dominated by a limited core of authors, institutions, and journals. Network and keyword analyses indicate a thematic evolution from studies primarily focused on airflow toward more integrated approaches that incorporate energy efficiency and microclimate optimization. These findings enable the identification of research trends, knowledge gaps, and future opportunities, particularly for the development of CFD-based solutions applicable to low-cost indoor farming systems.

I. INTRODUCTION

Currently, agricultural production faces increasing challenges associated with global population growth, accelerated urbanization, climate variability, mounting pressure on natural resources, and the need to ensure food security [1]. In this context, controlled environment agriculture, particularly plant factories with artificial lighting (PFAL) and vertical farming systems, has emerged as a viable technological alternative for sustainably intensifying plant production [2]. These systems enable precise control of key environmental variables, such as temperature, humidity, and light intensity, regardless of external climatic conditions, allowing for year-round production and the cultivation of high-quality crops [3].

Within PFAL systems, air movement plays a decisive role in shaping the microclimate, particularly within and around dense plant canopies, where convective heat and mass transfer processes govern leaf temperature, relative humidity, and carbon dioxide concentration [4], [5]. Insufficient airflow can promote the formation of vertical thermal gradients associated with artificial lighting and non-uniform gas distributions, thereby negatively affecting crop physiological performance [6]. Numerous studies have shown that an appropriate range of air velocity, typically between 0.1 and 1.3 m s^{-1}, can enhance plant photosynthesis and transpiration by increasing gas exchange and reducing the resistance of the leaf boundary layer [7].

However, the microclimate within PFAL systems is highly dynamic, resulting from the coupling of light, temperature, humidity, airflow, and carbon dioxide (CO_2) concentration, to which plants respond through physiological adaptation mechanisms [8]. Air stagnation within the plant canopy can generate heterogeneous microclimates, reduce crop quality, and induce physiological disorders such as tip burn in young leaves [9]. In addition, the increasing use of light-emitting diodes (LEDs), whose energy and spectral efficiency has transformed agricultural lighting, introduces additional thermal loads that must be effectively dissipated to prevent disturbances to the microclimate [10]. Although previous research has examined airflow in PFAL systems, studies that simultaneously integrate the aerodynamic obstruction of the plant canopy and the thermal dissipation of LED lighting systems remain relatively scarce [9].

In this context CFD has become a key tool for performing detailed analyses of the interactions among ventilation, heat transfer, and microclimate, thereby supporting the design and optimization of more efficient and resilient vertical and indoor farming systems. Different investigations have applied CFD simulations to optimize ventilation system design, ensuring suitable air velocities at plant surfaces and enhancing convective heat and mass exchange [11]. Subsequent studies have assessed thermo-fluid uniformity in vertical agricultural systems, proposing flow efficiency indicators to compare air supply and exhaust configurations, thereby demonstrating improvements in microclimatic conditions and reductions in energy consumption [12].

Complementarily, laboratory-scale experimental studies have examined the interaction between photosynthetic physiology and airflow, using measured data as boundary conditions to validate CFD models [13].Likewise, CFD-based studies have examined airflow and temperature distributions in plant factories housed within shipping containers, as well as the design of perforated air ducts to generate more homogeneous airflow patterns across cultivation tables [14], [15]. Nevertheless, many of these studies focus on partial components of the production system, whereas more comprehensive approaches have examined entire cultivation cells, comparing different ventilation configurations through uniformity indicators in order to optimize the microclimate in plant factories at a commercial scale [16].

In this context, bibliometric analysis emerges as an appropriate methodological tool to systematize, quantify, and visualize the evolution of scientific knowledge in an emerging and highly interdisciplinary field such as the application of computational fluid dynamics (CFD) in vertical and indoor farming. Beyond a traditional narrative review, bibliometrics enables the identification of patterns of scientific production, impact, and collaboration, as well as intellectual structures, thematic clusters, and research trends, thereby providing an objective and reproducible overview of the state of the art [17], [18]. This approach is particularly relevant in domains where the rapid expansion of the literature and the diversity of methodological approaches hinder the identification of dominant research lines, knowledge gaps, and future directions, which are essential for guiding both academic research and applied technological development [19].

Under this perspective, the main objective of this study is to systematically analyze the scientific production related to the application of CFD in vertical and indoor farming systems, using bibliometric techniques and network analysis to characterize its temporal evolution, geographical distribution, key actors, thematic structure, and research trajectories. In particular, this work seeks to address the following research questions: (i) how has scientific research on CFD applied to controlled environment agriculture been structured and evolved in terms of production, collaboration, and thematic approaches? and (ii) what are the main research lines, conceptual gaps, and emerging trends that can guide future studies aimed at the microclimatic, energy, and operational optimization of indoor cultivation systems? These questions guide the development of the analysis and enable the linkage of bibliometric findings with scientific and technological challenges relevant to the advancement of the field

II. METHODOLOGY

II.1 GENERAL APPROACH AND PRISMA FRAMEWORK

The present study adopts a bibliometric approach supported by the guidelines of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework, with the aim of ensuring a transparent, reproducible, and methodologically rigorous literature selection process [20]. Although this work does not constitute a traditional systematic review, the application of the PRISMA flow enabled a clear and well-documented structuring of the identification, screening, eligibility, and inclusion stages of the analyzed documents. This approach is particularly suitable for emerging and interdisciplinary research fields, such as the application of CFD in vertical and indoor farming systems, where thematic and methodological diversity necessitates a well-defined protocol to delimit the analytical corpus.

II.2 SOURCE OF INFORMATION AND SEARCH STRATEGY

The bibliographic search was conducted exclusively in the Scopus database, selected for its broad coverage of peer-reviewed scientific literature in engineering, agricultural sciences, numerical modeling, and controlled environment systems. Access to the database was carried out on January 1, 2026, ensuring the inclusion of the most recent records available at the time of analysis. The search strategy was designed to identify studies addressing the application of CFD-based simulations to the analysis of microclimate, ventilation, and air distribution in vertical farming, indoor agriculture, and plant factory systems. To this end, the search equation was structured around three main conceptual dimensions: (i) plant production systems under controlled environments. (ii) computational fluid dynamics and numerical simulation techniques, and (iii) microclimatic and ventilation-related variables.

The equation was applied to the title, abstract, and keyword fields (TITLE-ABS-KEY) and was formulated as follows: (("vertical farming" OR "indoor farming" OR "indoor agriculture" OR "plant factory" OR "plant factories" OR "plant factory with artificial lighting" OR PFAL OR "controlled environment agriculture" OR "indoor plant production" OR "indoor horticulture") AND ("computational fluid dynamics" OR CFD OR "CFD simulation" OR "fluid flow simulation" OR "airflow simulation" OR "air flow simulation" OR "heat transfer simulation" OR "numerical simulation" OR "3D simulation") AND (microclimate OR "air distribution" OR "temperature distribution" OR "humidity distribution" OR "CO_2 distribution" OR ventilation OR "ventilation design" OR "indoor climate" OR "thermal environment")). No restrictions were applied with respect to country, geographic region, or language, to obtain a comprehensive and global overview of the scientific development of the field and to avoid biases arising from territorial or linguistic limitations.

II.3 INCLUSION AND EXCLUSION CRITERIA

Clear inclusion and exclusion criteria were established to ensure the thematic coherence and methodological relevance of the selected documents. The inclusion criteria comprised: scientific articles, review papers, and conference proceedings indexed in Scopus; studies employing computational fluid dynamics (CFD) as the primary analytical tool; research focused on vertical farming, indoor agriculture, plant factories, or controlled environment agriculture; and publications without restrictions on language or country of institutional affiliation. Conversely, the exclusion criteria included: documents that did not use CFD as a central methodology; experimental or conceptual studies lacking numerical simulation; duplicate records or entries with incomplete bibliographic metadata; and publications not directly related to microclimate, ventilation, air distribution, or thermal behavior in indoor agricultural systems

II.4 PRISMA-BASED SELECTION PROCESS

The document selection process followed the stages established by the PRISMA framework (Figure 1). During the identification phase, the application of the search equation in Scopus yielded an initial total of 64 records. Following a preliminary screening of titles and abstracts, 4 documents were excluded as they did not correspond to studies based on CFD modeling. Subsequently, during the screening and eligibility phases, a more detailed evaluation of the full texts was conducted, leading to the exclusion of an additional 8 publications due to thematic inconsistencies or the absence of an explicit focus on vertical or indoor farming. As an outcome, a definitive corpus of 52 documents was consolidated, all of which fully met the established methodological and conceptual criteria and constituted the basis for the bibliometric analysis developed in this study.

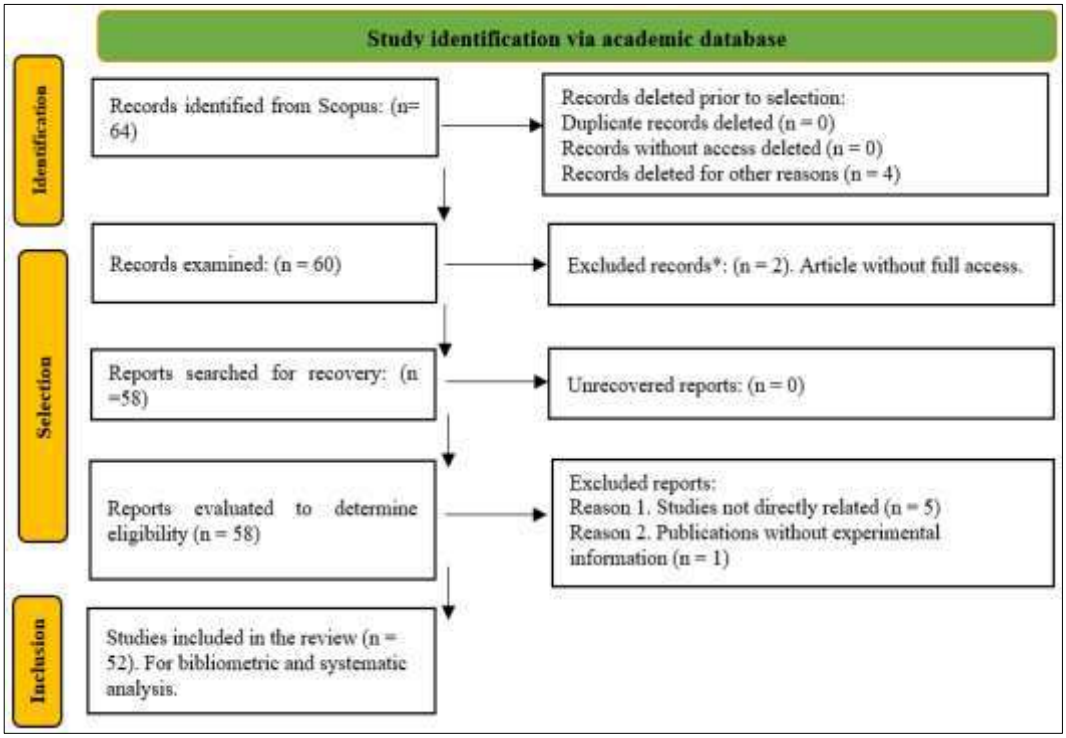

Figure 1: Development approach of the bibliometric review.
Source: Authors, (2026).

II.5 BIBLIOMETRIC PROCESSING AND ANALYTICAL TOOLS AND METHODOLOGICAL RESULT

The final records were exported from Scopus in CSV format and processed through a bibliometric analysis workflow supported by specialized tools. The main processing was conducted using the Bibliometrix package within the R environment and its graphical interface Biblioshiny, which enabled the calculation of indicators related to scientific production, impact, collaboration, and the intellectual structure of the field. Additionally, VOSviewer was employed for the construction and visualization of co-authorship, keyword co-occurrence, and bibliographic coupling networks, as well as for the identification of thematic clusters. The integration of the PRISMA flow with advanced bibliometric tools and network analysis enabled a rigorous structuring and examination of the scientific corpus on the application CFD in vertical and indoor farming.

This approach made it possible not only to quantify the evolution and distribution of scientific production, but also to reveal the intellectual structure of the field by identifying countries, institutions, and authors with central roles, as well as patterns of collaboration and bibliographic coupling. Complementarily, co-occurrence and multiple correspondence analyses allowed the delineation of coherent thematic clusters and dominant conceptual axes, highlighting the convergence between fluid dynamic modeling, microclimate control, energy efficiency, and crop response. Overall, the applied methodology provides an integrated and hierarchical overview of the state of the art and establishes a solid foundation for future comparative research and for the development of studies aimed at the microclimatic, energy, and operational optimization of controlled environment agriculture systems through CFD.

III. RESULTS AND DISCUSSION

III.1 BIBLIOMETRIC PROCESSING AND ANALYTICAL TOOLS AND METHODOLOGICAL RESULT

Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration.

III.2 OVERVIEW

The bibliometric analysis focused on the period from 2015 to 2025, during which 52 scientific documents published across 30 different sources were identified, confirming that the application of computational fluid dynamics (CFD) in vertical and indoor farming is a relatively recent field undergoing rapid consolidation. Scientific production exhibits an annual growth rate of 6.5%, indicating a significant increase in academic interest over the past decade. A total of 198 authors contributed to the analyzed literature, with no single-authored publications, highlighting the highly collaborative and multidisciplinary nature of this research area, with an average of 8.62 co-authors per document. However, international collaboration remains limited (13.46%), suggesting opportunities to strengthen global research networks. The analyzed literature shows an average age of 3.5 years, reflecting a recent and active scientific base, while academic impact is moderate, with an average of 9.64 citations per document. Finally, the presence of 170 author keywords and 373 cited references indicate considerable thematic diversity and a field that is still in the process of conceptual structuring.

III.3 NUMBER OF DOCUMENTS PUBLISHED

The annual evolution of scientific production between 2015 and 2025 shows a clearly increasing trend in research related to the application of computational fluid dynamics (CFD) in vertical and indoor farming (Figure 2). During the initial years of the analyzed period (2015–2017), production was incipient, with only one to two documents published per year, reflecting the emerging nature of the field. From 2018 onward, a gradual increase can be observed, reaching a first notable milestone in 2019 with five publications, followed by a temporary decline in 2020, possibly attributable to global disruptions in scientific activity. Nevertheless, from 2021 onward, scientific output recovered and has since maintained a sustained upward trajectory. This trend intensifies markedly in the most recent years of the period, with 7 documents published in 2023, 10 in 2024, and a peak of 15 publications in 2025, confirming a recent acceleration of academic interest in this topic. The linear regression fit ($y = 1.123x - 2263.35$) and its coefficient of determination ($R^2 = 0.719$) indicate that a substantial proportion of the variability in scientific output can be explained by the temporal factor, evidencing a structured rather than random growth pattern. Taken together, these results suggest that the application of CFD in vertical and indoor farming systems has progressed from an exploratory phase to a stage of consolidation and expansion, positioning itself as a relevant research axis within controlled environment agriculture.

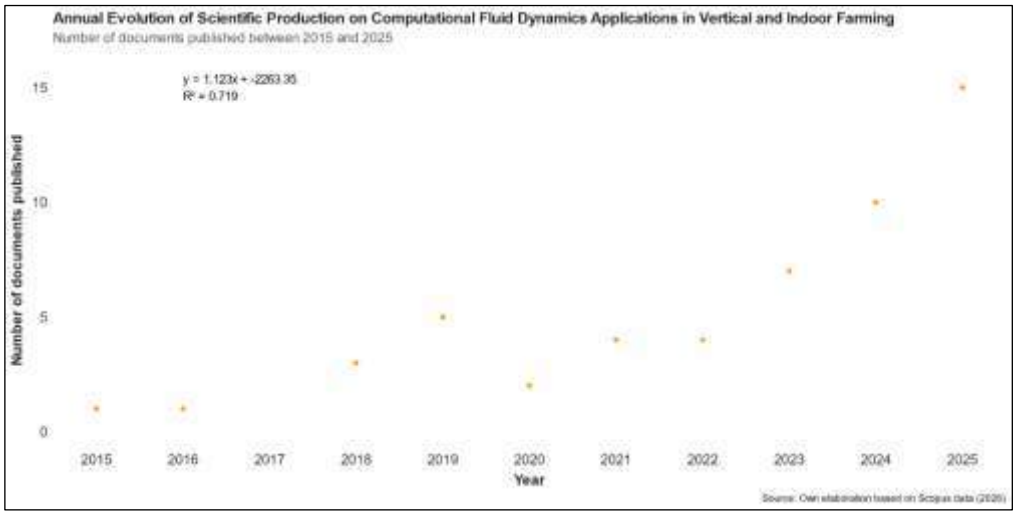

Figure 2: Annual production of scientific documents.
Source: Authors, (2026).

III.4 TYPES OF DOCUMENTS PUBLISHED

The distribution of documents by type for the period 2015–2025 (Figure 3) shows a clear predominance of scientific articles, with 35 publications, confirming that research on computational fluid dynamics (CFD) applications in vertical and indoor farming is primarily disseminated through indexed journals, reflecting an increasing level of academic maturity and validation [18]. Conference papers constitute the second most frequent document type, with 12 publications, indicating that the field maintains an active component of discussion in scientific forums and specialized conferences. In contrast, review articles (3), as well as conference reviews (1) and book chapters (1), represent a relatively small proportion, suggesting that the field is still in a phase of conceptual consolidation, with clear opportunities for the development of synthesis studies and integrative reviews in the future.

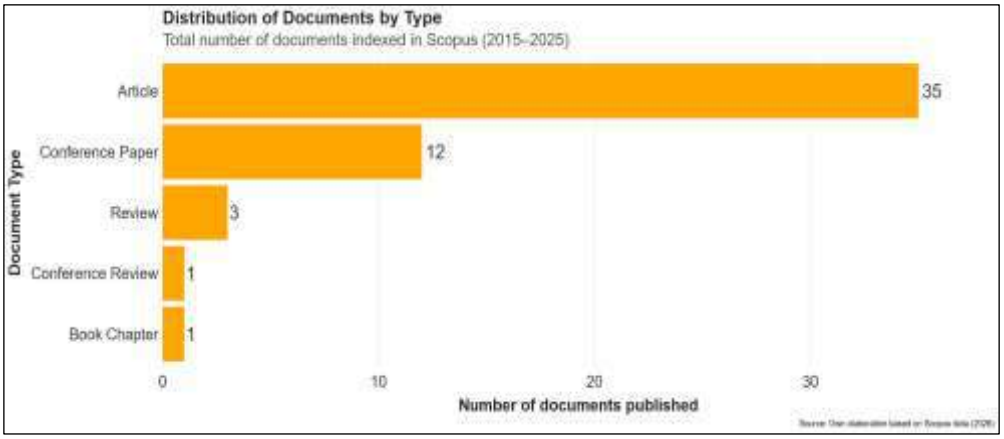

Figure 3: Types of documents published around knowledge analyzed.
Source: Authors, (2026).

III.5 COUNTRIES WHERE SCIENTIFIC PRODUCTION ORIGINATES

The geographic distribution of scientific production reveals a clear concentration of knowledge in a limited number of countries, a pattern that is characteristic of emerging and highly specialized technological fields such as the application of computational fluid dynamics (CFD) in vertical and indoor farming (Figure 4). China emerges as the leading global contributor, with 16 documents, significantly surpassing the other countries analyzed. This leadership suggests strong national investment in controlled environment agriculture, numerical modeling, and the optimization of production systems, as well as a strategic alignment with food security and technological development policies [21]. At a second level, the United States (5 documents) and several European countries such as the Netherlands and Belgium (4 documents each) stand out, which have historically been leaders in agricultural innovation, environmental engineering, and intensive cultivation technologies [8].

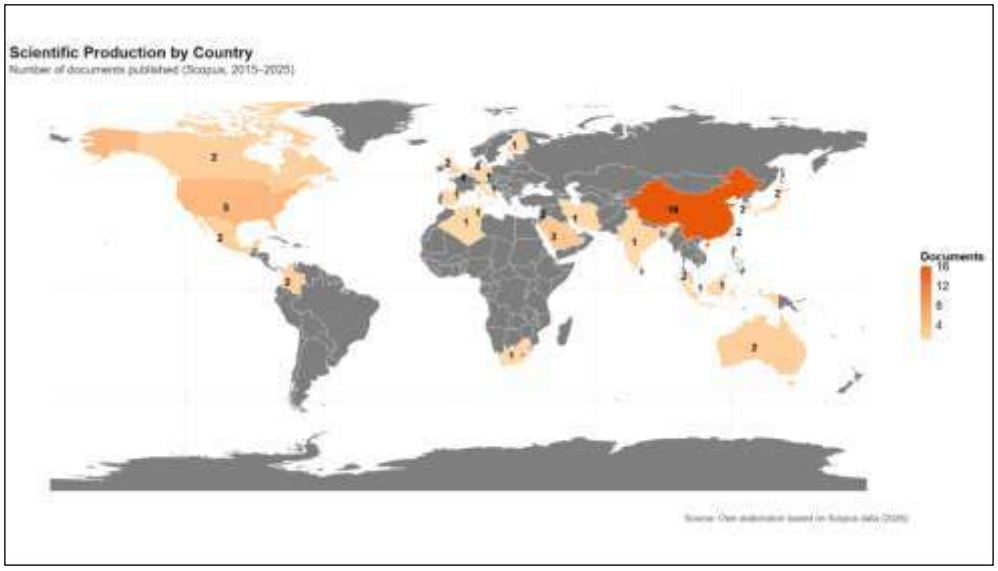

Figure 4: Document production by country.
Source: Authors, (2026).

At a regional scale, Europe and Asia account for most of the scientific production, with notable contributions from countries characterized by technologically advanced agricultural systems and a strong tradition in applied research, such as the United Kingdom, Germany, Italy, Finland, and Spain, albeit with more modest individual outputs. In Asia, beyond China, a distributed participation is observed among Japan, South Korea, Taiwan, India, Indonesia, and Malaysia, reflecting a growing interest in technological solutions for food production in highly urbanized and densely populated contexts [22]. Likewise, the presence of Middle Eastern countries such as Saudi Arabia, Israel, and Iran indicates that vertical farming and microclimate control through CFD are perceived as key tools for addressing adverse climatic conditions and water scarcity, as these controlled systems can mitigate the impacts of climate variability and resource limitations, directly contributing to food security through sustainable production in urban and arid environments [23].

On the other hand, participation from Latin America and Africa remains limited, with isolated contributions from countries such as Mexico, Colombia, Canada, Australia, Algeria, Tunisia, and South Africa, generally with one or two documents per country. This distribution suggests the existence of regional gaps in research capacity, computational infrastructure, and funding, while also indicating a significant potential for future expansion [24]. Overall, the figure highlights a highly centralized global structure dominated by countries with strong economies and well-established scientific ecosystems, while simultaneously underscoring the need to foster international collaboration and knowledge transfer to balance the development of the field on a global scale.

III.6 BIBLIOGRAPHIC COUPLING NETWORK BETWEEN COUNTRIES

Bibliographic coupling is a bibliometric technique used to analyze the cognitive structure of a scientific field based on the references shared among documents, authors, or countries (Figure 5). Two nodes are bibliographically coupled when they cite one or more references in common, indicating thematic or methodological affinity, regardless of whether they directly cite each other [25], [26]. In this type of network, nodes represent units of analysis (in this case, countries), while links indicate the existence of shared references, and their thickness reflects the strength of the relationship. Total link strength quantifies the intensity of a node's connections with the rest of the network, allowing the identification of central and peripheral actors within the scientific system [18]. Bibliographic coupling is particularly useful for analyzing emerging fields, as it captures early structural relationships within the body of knowledge and has been widely validated in bibliometric studies.

From an analytical perspective, the network exhibits a clearly centralized structure, with China as the dominant node, showing the highest total link strength (100) and many documents (16) and citations (112). This indicates that Chinese scientific output is not only quantitatively significant but also shares a strong bibliographic foundation with multiple countries, positioning China as a structuring hub of the field. Alongside China, the Netherlands (total link strength = 79) and the United States (64) stand out; despite producing fewer documents, they display a high degree of intellectual integration, likely associated with their longstanding leadership in controlled environment agriculture, thermal engineering, and numerical modeling. The density of links among these countries suggests the existence of convergent research lines, particularly in ventilation, microclimate analysis, and the optimization of indoor systems.

Conversely, the network also reveals countries with low publication output but strategically strong connections, such as Colombia, Mexico, and the United Kingdom, each with only two documents yet a relatively high link strength (40), indicating strong thematic alignment with the main research cores of the field. In contrast, countries such as Saudi Arabia and Taiwan show very low link strength values, reflecting more isolated scientific production or weaker bibliographic convergence with the rest of the network. Overall, these results suggest that although the field is experiencing growing geographical expansion, its intellectual structure remains dominated by a limited number of highly interconnected countries, reinforcing the need to promote more balanced international collaborations to diversify perspectives, contexts, and applications of computational fluid dynamics in vertical and indoor farming.

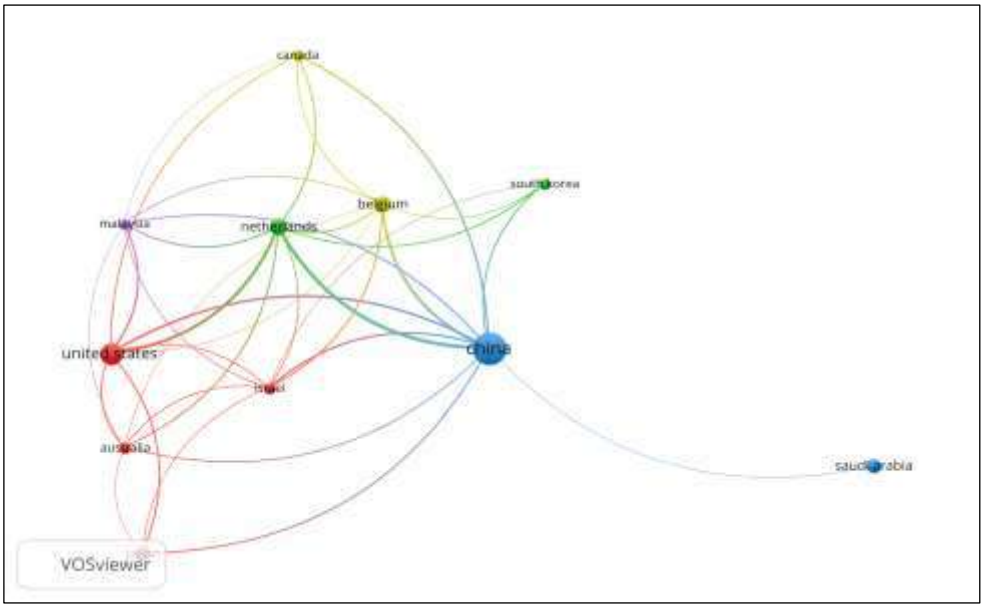

Figure 5: Bibliographic coupling network between the countries of authorship of academic documents.
Source: Authors, (2026).

III.7 LEADING INSTITUTIONS IN SCIENTIFIC PRODUCTION

The distribution of scientific output by institutions shows a moderate concentration of academic leadership within a limited number of organizations, which is consistent with the highly specialized and technical nature of research on the application of computational fluid dynamics (CFD) in vertical and indoor agriculture (Table 1). The University of Arizona emerges as the most productive institution, with five published documents, reflecting its prominent role in research on microclimate analysis, environmental engineering, and the modeling of controlled environment agricultural systems [11], [27]. They are followed by the Chinese Academy of Agricultural Sciences, Technische Universiteit Eindhoven, and Ghent University, each with four publications, indicating a strong contribution from both academic institutions and national research centers to the methodological development and applied use of CFD in this domain [28–30].

Likewise, the presence of the Ministry of Agriculture and Rural Affairs of the People's Republic of China, with three documents, is particularly noteworthy, as it highlights the direct involvement of governmental bodies in the generation of scientific knowledge. This participation suggests a strategic orientation toward technology transfer and the formulation of public policies grounded in scientific evidence [15]. Overall, this institutional pattern indicates that progress in the field is driven both by universities with strong capabilities in engineering and agricultural sciences and by public entities with coordination and funding capacity, fostering an integrated approach that links fundamental research with practical application. Nevertheless, the limited institutional dispersion also points to opportunities to broaden the range of participating actors and to promote greater institutional diversification in future research efforts.

III.8 LEADING AUTHORS IN SCIENTIFIC PUBLICATIONS

The analysis of the most influential authors reveals a consolidated core of researchers and professor-researchers who have made substantial contributions to the advancement of knowledge on the application of Computational Fluid Dynamics (CFD) in vertical and indoor farming (Table 2). Among them, Murat Kaçira and T. van Hooff, both holding professor-researcher positions, stand out for their high scientific impact, with 3,300 and 5,163 citations and h-indices of 32 and 35, respectively, evidencing a sustained and cross-cutting influence within the field. In contrast, Hui Fang, Luyang Kang, and Wito Plas, identified primarily as researchers, exhibit a consistent and specialized scientific output, with a stronger focus on specific aspects of microclimate, ventilation, and plant–airflow interactions. This diversity reflects different level]s of academic maturity and scientific positioning, while collectively shaping the intellectual foundation of the domain.

Table 2: Top five authors with the highest scientific productivity in the subject area analyzed.

Author	Number of documents	Total citations	H-index	Affiliation	Country
Fang, Hui	5	815	18	Chinese Academy of Agricultural Sciences	China
Kaçira, Murat	5	3,300	32	The University of Arizona	United States
Kang, Luyang	4	612	12	Technische Universiteit Eindhoven	China
Plas, Wito	4	10	2	Ghent University	Belgium
Van Hooff, T	4	5,163	35	Technische Universiteit Eindhoven	Netherlands

Source: Authors, (2026).

From a thematic perspective, Hui Fang's research focuses on a detailed analysis of airflow within the plant canopy, incorporating advanced elements such as the aerodynamic resistance of the crop and the thermal dissipation associated with LED lighting systems. This approach contributes to a more realistic representation of microclimatic conditions in plant factories, enabling a better understanding of air–plant interactions and their implications for environmental uniformity and crop performance [15], [28]. Complementarily, Murat Kaçira's studies address environmental uniformity in multilayer systems by combining CFD simulations with the analysis of both computational and physical parameters. This integrated approach strengthens methodological validation and enhances the practical applicability of the models, supporting their use in the design and optimization of vertical and indoor farming systems [27], [31]. Along the same lines, Luyang Kang contributes research focused on optimizing the performance of air distribution systems, evaluating variables such as airflow rate and the use of baffles.

This work reflects a clear emphasis on efficient engineering design for vertical farming systems, with CFD used as a decision-support tool to enhance airflow uniformity and overall microclimatic control [29], [32]. Finally, the contributions of Wito Plas and T. van Hooff represent a significant advance in the sophistication of CFD models, particularly through the incorporation of realistic plant geometries and the detailed evaluation of air supply location in multi-layer systems. While Plas focuses on resolving the microclimate at the individual leaf scale [30], [33], Van Hooff contributes with studies of a more systemic scope, combining numerical accuracy with strong applied relevance [31], [34]. Taking together, this group of authors constitutes the intellectual backbone of the field, integrating experimental, numerical, and optimization-based approaches, and demonstrating a clear evolution from simplified models toward increasingly realistic representations aimed at improving environmental performance in controlled environment agriculture.

III.9 BIBLIOGRAPHIC COUPLING NETWORK BETWEEN AUTHORS

The bibliographic coupling network among authors is a bibliometric technique that makes it possible to identify intellectual affinities between researchers based on the shared references cited in their publications [35]. In this type of network, the nodes represent authors whose size is associated with their productivity or relative weight within the network, while the links indicate the existence of shared references, reflecting thematic or methodological similarities (Figure 6). The total link strength quantifies the intensity of these connections with other authors, and the overlay visualization incorporates a temporal dimension, in which node colors allow the analysis of the chronological evolution of scientific production and the emergence of more recent research lines [36]. From an analytical perspective, the network exhibits a clearly hierarchical structure, with Hui Fang, Murat Kaçira, Luyang Kang, and T.van Hooff as central nodes, characterized by high total link strength values (150, 128, 125, and 125, respectively).

This indicates a widely shared bibliographic base and a key role in the intellectual articulation of the field. Authors such as Wu Gang, Li Kun, and Cheng Ruifeng appear closely connected to Hui Fang, forming a cohesive sub core associated with recent studies on microclimate and ventilation in vertical farming systems. The temporal visualization further reveals a progressive evolution of the field, where authors with cooler tones (≈2020–2021), such as Kaçira, represent foundational contributions, while nodes in warmer tones (≈2023–2024), such as Plas, De Paepe, and Kang, reflect a recent expansion toward more advanced and realistic CFD models. Overall, the network confirms that knowledge development in this domain is supported by a consolidated core of highly interconnected authors, with a gradual transition from pioneering studies toward more sophisticated and specialized approaches in recent years.

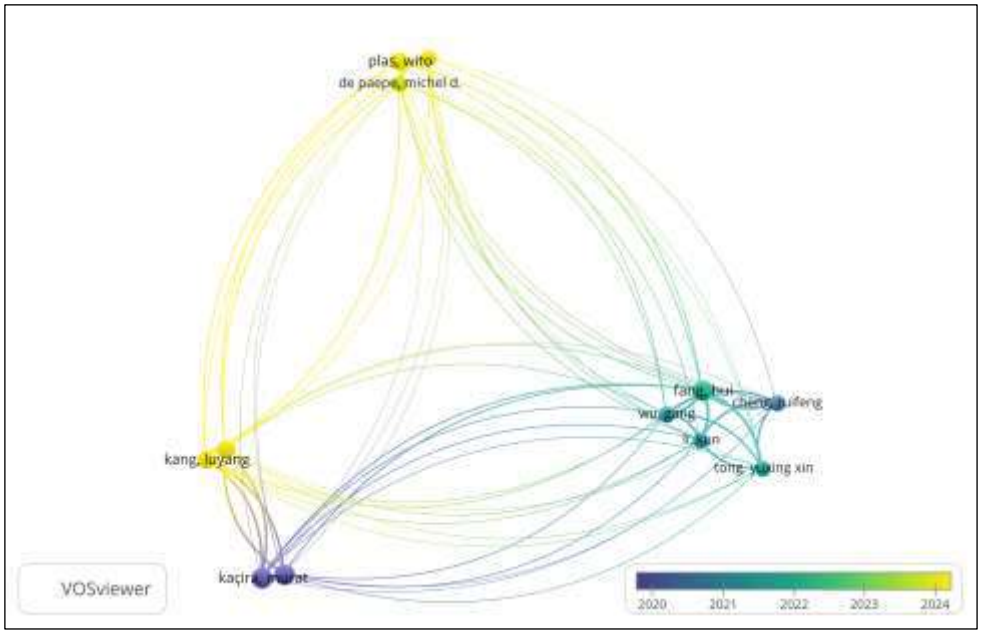

Figure 6: Bibliographic coupling network between the authors of published documents.

III.10 MAIN SOURCES OF PUBLICATION SELECTED BY THE AUTHORS

The distribution of scientific output by journals reveals a concentration in sources specialized in horticulture, biosystems engineering, and controlled environment agriculture, reflecting the interdisciplinary nature of applying computational fluid dynamics (CFD) to vertical and indoor farming (Table 3). *Acta Horticulturae* ranks as the journal with the highest number of publications (8 documents), serving as a relevant forum for disseminating applied studies and experimental results in protected horticulture, despite its Q4 classification. This quantitative leadership suggests that the field still relies on specialized proceedings and series as key outlets for reporting technical advances and case studies, particularly during phases of methodological development and validation.

In contrast, high-impact, top-quartile journals such as *Biosystems Engineering*, *Horticulturae*, *Agriculture*, and *Agronomy* (all classified as Q1) publish fewer documents but provide greater scientific visibility and methodological rigor. In particular, *Biosystems Engineering* stands out by combining a relevant volume of publications (5 documents) with a high h-index (142) and a strong focus on modeling, optimization, and analysis of complex agricultural systems, closely aligned with CFD-based approaches. The recurrent presence of MDPI journals, headquartered in Switzerland, also indicates a growing tendency toward open-access and rapid-dissemination platforms, which contributes to the international consolidation and expansion of the field. Overall, this editorial pattern suggests a gradual transition from specialized outlets toward higher-impact journals, reflecting the increasing maturity of research on CFD applications in vertical and indoor agriculture.

Table 3: Main journals selected for publication.

Journal	Number of documents	Editorial office	SJR Ranking	H-index	Country
Acta Horticulturae	8	International Society for Horticultural Science	Q4	74	Belgium
Biosystems Engineering	5	Academic Press	Q1	142	United States
Horticulturae	2	Multidisciplinary Digital Publishing Institute (MDPI)	Q1	48	Switzerland
Agriculture	2	Multidisciplinary Digital Publishing Institute (MDPI)	Q1	84	Switzerland
Agronomy	2	Multidisciplinary Digital Publishing Institute (MDPI)	Q1	114	Switzerland

Source: Authors, (2026).

On the other hand, the local impact of publication sources assesses the influence of journals within the specific corpus analyzed, based on bibliometric indicators such as the h-index, g-index, and m-index, together with the total number of citations (TC), the number of publications (NP), and the year in which each journal first contributed to the field (PY_start) (Table 4). In this context, the h-index reflects the balance between productivity and impact within the analyzed set, the g-index emphasizes the concentration of citations in the most influential articles, while the m-index enables comparisons among journals by accounting for the time elapsed since their initial contribution to the research area [37].

When considered jointly, these indicators make it possible to identify not only the most productive publication sources, but also those with greater intellectual relevance and more recent growth in research on CFD applied to vertical and indoor agriculture. From an analytical perspective, *Biosystems Engineering* clearly emerges as the publication source with the highest local impact, presenting the highest h-index (4), the highest g-index (5), and a substantial volume of total citations (251) since 2016. This confirms its role as a central and structuring journal within the field, particularly in studies focused on the modeling and optimization of agricultural systems. In contrast, *Acta Horticulturae*, although it records a higher number of publications (NP = 8), exhibits a more limited local impact in terms of citations, suggesting a role more oriented toward technical dissemination than toward the production of highly cited articles.

Conversely, journals such as *Agriculture* and *Horticulturae* display relatively high m-index values (0.667 and 0.5, respectively), despite their recent incorporation into the field (from 2023–2024 onward), indicating a rapid accumulation of impact and a growing interest in publishing CFD-related research in Q1 open-access platforms. Taken together, these results highlight a progressive transition of the field toward journals with higher impact and visibility, reflecting a process of scientific maturation and thematic consolidation

Table 4: Impact of journals publishing on the subject analyzed.

Journal	h_index	g_index	m_index	TC	NP	PY_start
Biosystems Engineering	4	5	0,364	251	5	2016
Acta Horticulturae	2	3	0,222	31	8	2018
Agriculture	2	2	0,667	17	2	2024
Horticulturae	2	2	0,5	25	2	2023
Agronomy	1	2	0,2	13	2	2022

III.11 BIBLIOGRAPHIC COUPLING NETWORK BETWEEN JOURNALS

The bibliographic coupling network (Figure 7) among journals makes it possible to identify intellectual affinities based on the references shared by articles published in different sources, revealing how knowledge is structured and disseminated within a specific scientific field [25]. In the analyzed network, the nodes represent scientific journals, whose size is associated with the number of documents or their relative weight within the corpus, while the links indicate the intensity of bibliographic coupling, measured through the total link strength. The overlay visualization also incorporates a temporal dimension, in which node colors reflect the average year of publication, allowing the analysis of the temporal evolution and chronological positioning of each journal within the development of research on CFD applied to vertical and indoor agriculture.

From an analytical perspective, the network highlights *Biosystems Engineering* as a central structural node, with high connectivity and strong links to horticultural and agricultural journals, confirming its role as a bridge between biosystems engineering and advanced agricultural applications. *Acta Horticulturae* appears closely connected to this core, although with an earlier coloration (≈2018–2019), suggesting a relevant role during the initial dissemination phase of the field, particularly for applied studies and specialized proceedings. In contrast, *Horticulturae*, *Agriculture*, and *Agronomy* exhibit more recent color tones (≈2022–2024) and clear connections to the central core, indicating the progressive incorporation of Q1 open-access journals, where the CFD approach is increasingly integrated into broader discussions on sustainability, intensive production, and controlled environment agriculture. Overall, the network reveals an editorial transition of the field from traditional specialized outlets toward higher-impact and more visible international journals, reflecting a process of scientific maturation and thematic consolidation.

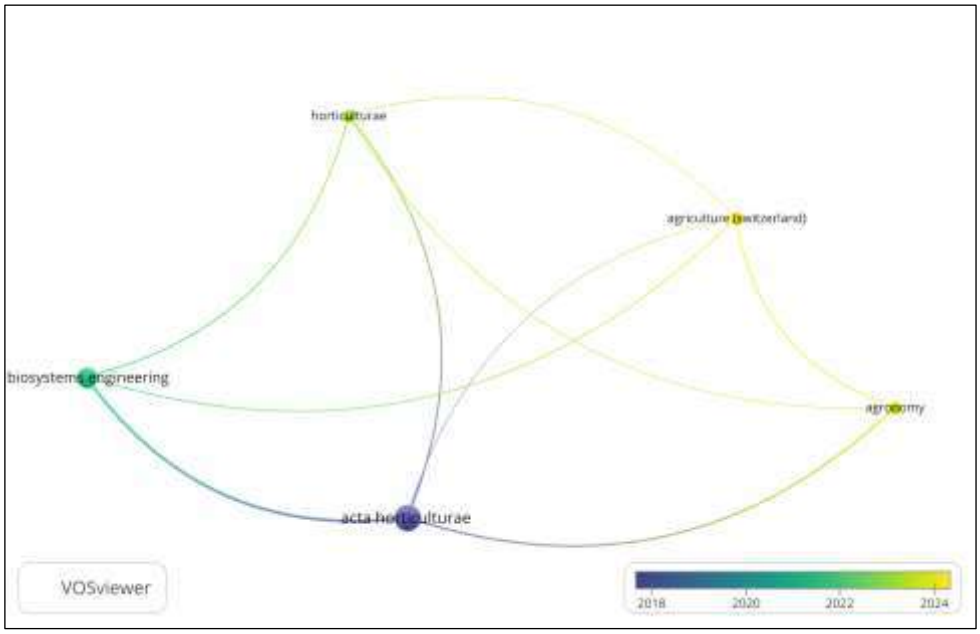

Figure 7: Network linking journals where academic documents are published.

III.12TOP FIVE MOST CITED ARTICLES

The identification of the five most cited articles on the application of Computational Fluid Dynamics (CFD) to vertical and indoor agriculture makes it possible to recognize the conceptual and methodological lines that have shaped the development of the field over the past decade. The clear predominance of publications in *Biosystems Engineering* (three out of the five articles) highlights the central role of this journal as an editorial hub for knowledge on the microclimatic modeling of controlled environment agricultural systems. Overall, these studies address a common challenge microclimate uniformity across different scales and contexts, consolidating CFD as a key tool for the design, evaluation, and optimization of indoor farming systems (Table 5).

The three most cited articles published in *Biosystems Engineering* show a progressive evolution in the complexity of CFD models and in the evaluation criteria employed. The work by Zhang et al. [11], with the highest number of citations (120), establishes a fundamental starting point by demonstrating that the design of the air circulation system can be optimized through three-dimensional simulations aimed at reducing flow variability and preventing physiological disorders in crops. Subsequent studies, such as that by Fang et al. [15] and Zhang & Kaçira [16], expand this approach by incorporating additional physical elements such as canopy aerodynamic resistance, LED thermal dissipation, and quantitative metrics of climate uniformity reflecting a transition from descriptive models toward predictive and comparative tools capable of evaluating multiple ventilation configurations based on objective indicators.

By [38], published in *Energy and Buildings*, introduces a relevant conceptual extension of the field by analyzing the effects of vertical farming beyond the production system itself, specifically on the natural ventilation of residential buildings. This study demonstrates that the incorporation of vertical vegetation can generate contrasting effects on urban thermal comfort, depending on the proportion and arrangement of vegetated modules. Its inclusion among the most cited works indicates that the use of CFD in vertical farming has begun to intersect with disciplines such as urban engineering and bioclimatic architecture, thereby expanding the traditional scope of the field.

For its part, the most recent work by the group of [39], published in *Applied Thermal Engineering*, represents a stage of methodological maturity characterized by the integration of thermo-fluid phenomena, moisture transport, and experimental validation in real multi-layer systems. Although its citation count is lower due to its recent publication, the study introduces dimensionless uniformity indices and an integrated approach that links microclimate, energy efficiency, and crop growth quality. This type of contribution points toward the use of CFD not only as an analytical tool, but also as direct support for operational and energy-related decision-making in vertical farming systems. From a comparative perspective, the five articles share the use of three-dimensional CFD as their core methodological approach, but they differ in terms of scale of analysis, variables considered, and final objectives.

While earlier studies primarily focus on airflow velocity distribution, more recent works incorporate thermo-hygrometric variables, statistical uniformity metrics, and experimental validation. This progression suggests that scientific impact is closely linked to the ability of studies to integrate physical realism, practical applicability, and comparable metrics, thereby enhancing their reuse as references in subsequent research. In summary, the analysis of the top five most cited articles confirms that research on CFD applied to vertical and indoor agriculture has evolved from approaches centered on localized airflow improvements toward more systemic and integrated models, with productive, energetic, and urban implications. These works have not only established the methodological foundations of the field but have also outlined its main future trajectories, in which microclimate optimization, energy efficiency, and interaction with the built environment emerge as priority research axes.

III.13 KEYWORDS MOST FREQUENTLY USED BY DOCUMENT AUTHORS

From a quantitative and thematic perspective, the keyword cloud reveals a conceptual structure clearly dominated by the study of the air environment in controlled environment agriculture systems (Figure 8), once it is acknowledged that the high frequency of the term CFD (43 occurrences) directly reflects the focus of the search strategy. Excluding this methodological term, the most recurrent concepts are *Air* (19), *Plant Factory* (17), and *Ventilation* (15), indicating that a substantial proportion of the corpus concentrates on the characterization and control of airflow in plant factories and vertical farming systems [28], [40]. Likewise, the frequency of *Airflow* and *Crops* (8 occurrences each), together with *Cultivation* (7) and *Plant Growth* (6), reflects a balanced orientation between the optimization of physical variables and crop productive responses, suggesting that CFD is used not only to describe fluid dynamic phenomena but also to support decision-making related to agricultural performance [11], [28], [41].

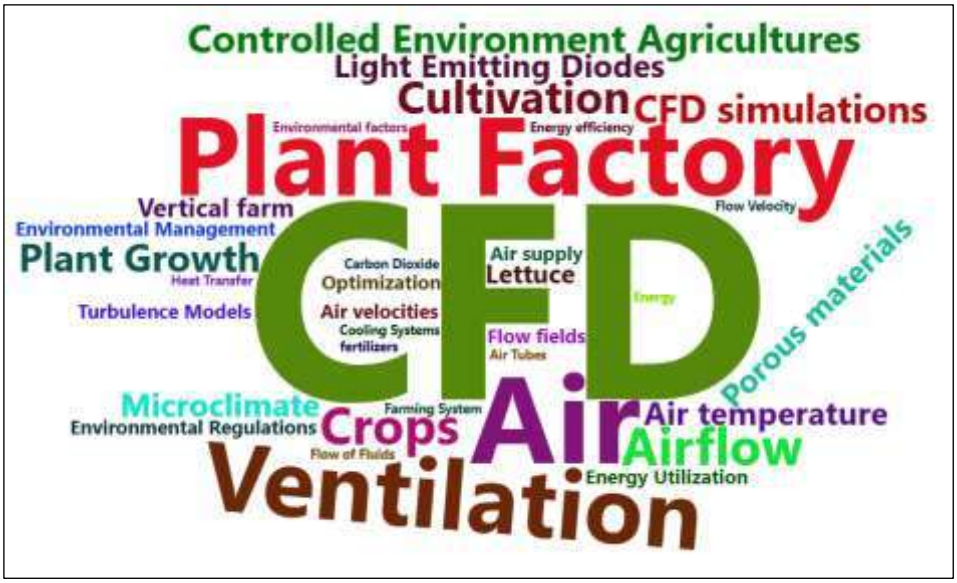

Figure 8: Word cloud of terms used by authors.
Source: Authors, (2026).

At a second level of analysis, the consistent appearance of medium-frequency terms such as *Microclimate*, *Air temperature*, *Light Emitting Diodes*, and *Porous materials* (5 occurrences each) indicates a growing interest in the interaction between ventilation, thermal conditions, artificial lighting, and structural components of the system, which are key elements for the integrated design of efficient indoor environments [42–44]. n parallel, the presence of keywords associated with *Energy Utilization*, *Optimization*, *Environmental Management*, and *Environmental Regulations* (3 occurrences) points to a gradual incorporation of energy efficiency, sustainability, and regulatory compliance criteria, although these aspects still hold a relatively limited weight within the field [45], [46]. Finally, the low frequency of terms such as *Carbon Dioxide*, *Heat Transfer*, and *Cooling Systems* (2 occurrences) suggests that these aspects, although recognized as relevant, remain underexplored, opening clear opportunities for future research aimed at more fully integrating thermal management, CO_2 concentration, and energy performance into CFD models applied to vertical and indoor agriculture [8], [47].

III.14 KEYWORD CO-OCCURRENCE NETWORK

The keyword co-occurrence network (Figure 9) is a bibliometric tool used to identify the conceptual structure and the main thematic axes of a research field based on the frequency with which specific terms appear jointly in scientific documents [48]. In this network, the nodes represent keywords, whose size reflects their relative relevance within the corpus, while the links indicate semantic relationships, that is, the co-occurrence of concepts within the same document [17]. Cluster analysis, based on the density and proximity of these links, makes it possible to group terms into coherent thematic subfields, facilitating the identification of dominant research lines, emerging areas, and interdisciplinary connections. In the context of applying Computational Fluid Dynamics (CFD) to controlled environment agriculture, this network is particularly useful for understanding how physical, biological, and energy-related variables are integrated in the study of microclimate and ventilation in indoor systems.

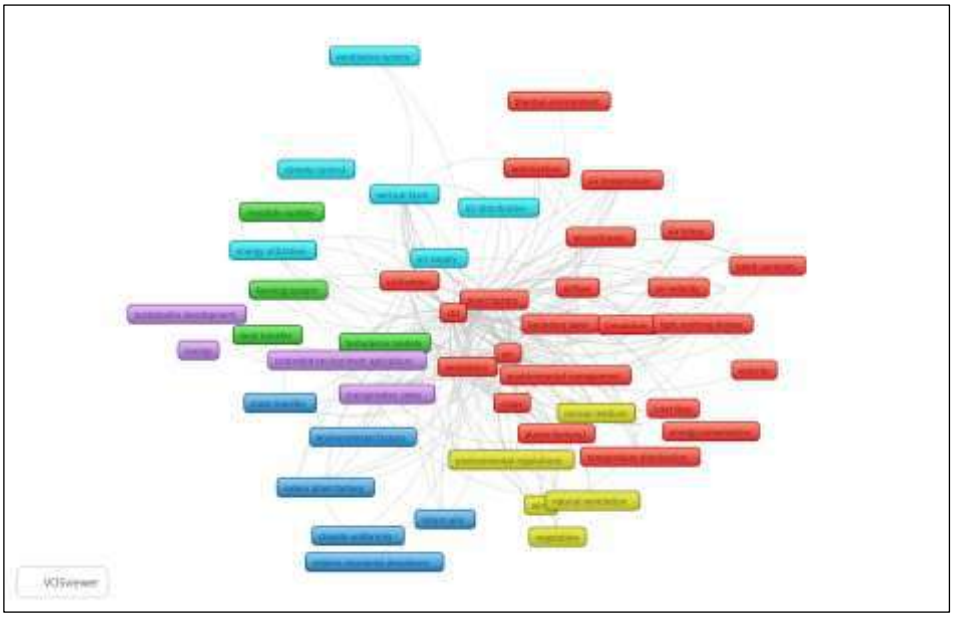

Figure 9: Keyword co-occurrence network of published documents.
Source: Authors, (2026).

Red Cluster: Microclimate, Ventilation, and Air Dynamics in Plant Factories: This cluster is the largest and densest in the network (30 items) and represents the core thematic nucleus of the field of study. It is composed of fundamental terms such as *air temperature*, *air velocity*, *airflow*, *boundary layer*, *ventilation*, *microclimate*, *plant factory*, *plant canopies*, *crops*, *cultivation*, *lettuce*, and *light emitting diodes*. The co-occurrence of these concepts indicates that research is strongly focused on the detailed analysis of air behavior and the thermal environment within plant factories, with particular emphasis on the interaction between airflow, the plant canopy, and artificial lighting [41], [43], [49–51]. The simultaneous presence of *CFD*, *simulation*, and *optimization* confirms that these phenomena are primarily addressed through advanced numerical modeling, aimed at optimizing microclimatic conditions to enhance crop growth and uniformity [29], [34], [52].

Green Cluster: Fluid Dynamics Fundamentals and Energy Transfer: This cluster groups terms such as *energy efficiency*, *heat transfer*, *turbulence models*, *Reynolds number*, *flow of fluids*, *experimental study*, and *indoor vertical farming*, representing the methodological and theoretical foundation of CFD applications. This cluster reflects research focused on the physical and numerical validation of models, as well as on the accurate representation of flow regimes and heat transfer mechanisms [31], [32], [53]. Although its size is smaller than that of the central cluster, its strong connection to the latter indicates that these studies provide essential scientific support to ensure the reliability of CFD simulations applied to indoor agricultural systems [28], [53].

Dark Blue Cluster: Climate Uniformity and Mass Transport: The cluster is dominated by terms such as *carbon dioxide*, *mass transfer*, *transport properties*, *climate uniformity*, *relative standard deviations*, *return airs*, and *indoor plant factory*. This thematic group focuses on the spatial distribution of gases and transport properties, with particular attention to microclimate homogeneity within closed cultivation systems [47], [54]. The presence of statistical indicators suggests an interest in quantifying internal environmental variability, a critical aspect for ensuring uniform crop growth and efficient resource use, but one that still appears as a less developed research line compared to ventilation and airflow studies [55], [56].

Yellow Cluster: Natural Ventilation and Semi-Porous: The cluster integrate concepts such as *natural ventilation*, *wind*, *porous medium*, *flow fields*, *vegetables*, and *environmental regulations*. This cluster represents a line of research oriented toward the interaction between external conditions and indoor systems, as well as the use of porous media models to represent the aerodynamic resistance of crops [38], [42]. Its presence indicates an effort to increase the realism of CFD models by incorporating passive ventilation conditions, regulatory constraints, and hybrid scenarios between closed and semi-open systems.

Purple Cluster: Sustainability, Energy, and Physiological Processes: The cluster groups terms such as *controlled environment*, *cooling systems*, *energy*, *fertilizers*, *sustainable development*, and *transpiration rates*. This cluster highlights an emerging dimension of the field related to sustainability, efficient energy use, and the integration of crop physiological processes into microclimate analysis [30], [57]. Although its relative weight is lower, its connection to the central cluster suggests a growing trend toward more holistic approaches, in which CFD is used not only to optimize airflow but also to assess energy and environmental impacts [45], [58].

Light Blue Cluster: Design and Operation of Ventilation Systems: The cluster includes terms such as *air distribution*, *air supply*, *ventilation system*, *energy utilization*, *climate control*, and *vertical farm*. This cluster acts as a bridge between CFD modeling and practical implementation, focusing on the design and operation of ventilation systems in vertical farming facilities [34], [40], [59], [60]. Its intermediate position within the network reflects its integrative role, linking fluid dynamic fundamentals with the operational management of indoor climate, which is essential for translating simulation results into real-world applications.

III.15 MULTIPLE CORRESPONDENCE ANALYSIS OF INTELLECTUAL STRUCTURE

Multiple Correspondence Analysis (MCA) is an exploratory statistical technique used to reduce the dimensionality of categorical data and to graphically represent the associations between variables and categories within a low-dimensional space. Unlike co-occurrence networks, MCA does not focus solely on the frequency of joint appearances, but rather on the geometric proximity between terms, allowing the identification of latent patterns, conceptual oppositions, and semantic groupings [61], [62]. In bibliometric studies, this technique is particularly useful for complementing network analyses, as it facilitates the interpretation of how concepts are organized around dominant conceptual axes [63].

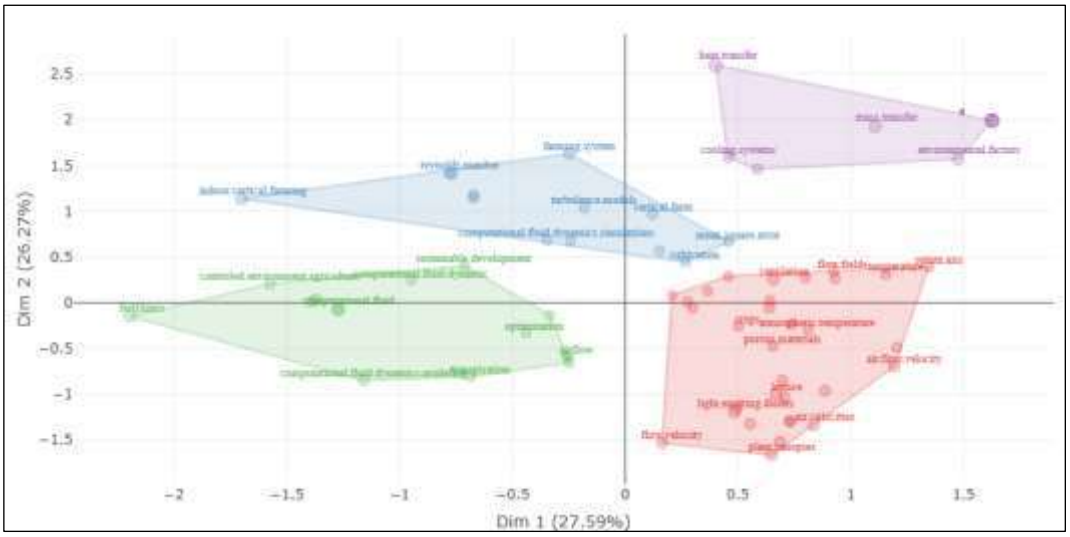

Figure 10: Analysis of dominant axes of intellectual structure analyzed.
Source: Authors, (2026).

In Figure 10 analyzed, the first two dimensions explain a substantial proportion of the total variability (Dim 1: 27.59% and Dim 2: 26.27%), indicating a well-defined conceptual structure. Dimension 1 clearly separates terms associated with the physical optimization of airflow and ventilation (right side), such as *airflow*, *air velocity*, *ventilation*, *porous materials*, and *light emitting diodes*, from those linked to more systemic and methodological approaches (left side), such as *computational fluid dynamics simulations*, *turbulence models*, *Reynolds number*, and *controlled environment agriculture*. This opposition suggests that the field is structured around studies focused on the design and operational performance of indoor systems versus works centered on the development and validation of numerical models.

Dimension 2, in turn, introduces a vertical differentiation between research focused on thermal and transfer management (*heat transfer*, *cooling systems*, *mass transfer*, *environmental factors*), located in the upper part of the plane, and studies more closely related to the plant canopy and air–plant interactions (*plant canopies*, *lettuce*, *air velocities*, *flow velocity*), situated in the lower part. This distribution indicates that, although both approaches are interconnected, there are differentiated research lines that prioritize, respectively, the energy–thermal control of the system and the microclimatic response at the crop scale. Overall, the MCA confirms the complementarity between engineering and biological approaches in the application of CFD to controlled environment agriculture, providing a structural perspective that reinforces and deepens the results obtained through keyword co-occurrence networks.

III.16 LIMITATIONS OF THE STUDY

This study presents several limitations inherent to both the bibliometric design and the information retrieval strategy. First, the search was conducted exclusively in the Scopus database, which, although it ensures high quality and multidisciplinary coverage, may underrepresent literature indexed in other databases (e.g., Web of Science, IEEE Xplore) as well as relevant grey literature for an applied field such as CFD in indoor agriculture. Second, the final corpus (52 documents) reflects a still emerging domain; therefore, some indicators (citations, local h-index, or network centrality) may be influenced by temporal window effects and by the uneven accumulation of citations between recent and foundational articles. In addition, the search equation itself includes methodological terms (CFD/ "computational fluid dynamics"), which may introduce a dominance bias of keywords such as CFD in co-occurrence analyses, reducing the relative visibility of substantive concepts such as CO_2, heat transfer, or VPD within the visualizations.

To address these limitations, several methodological decisions were adopted to strengthen the validity and traceability of the study. Regarding document coverage, a broad search strategy was implemented (with no restrictions by country or language), and a PRISMA-based workflow with explicit screening was applied (64 initial records; exclusion of 4 non-CFD studies and 8 due to thematic misalignment), enhancing transparency and reproducibility of the final corpus. With respect to citation and recency biases, results were interpreted by combining performance metrics (production, citations, indices) with structural analyses (bibliographic coupling, co-occurrence, and MCA), ensuring that the interpretation of the field did not rely solely on cumulative indicators. Finally, to reduce the dominance effect of the term "CFD" in semantic analyses, the interpretation of keyword clouds and networks explicitly differentiated between "methodological" terms (inherent to the search filter) and "thematic" terms, prioritizing the substantive analysis of clusters and conceptual relationships related to ventilation, microclimate, air distribution, energy, and mass transport.

III.17 FUTURE RESEARCH TRENDS AND CHALLENGES

One of the main emerging trends in research on the application of Computational Fluid Dynamics (CFD) in vertical and indoor agriculture is the transition from simplified models toward increasingly realistic and integrated representations of cultivation systems. Recent studies show a growing interest in incorporating detailed plant geometries, dynamic porous canopy models, and thermal sources associated with LED lighting, as well as in simultaneously integrating multiple microclimatic variables (temperature, humidity, air velocity, and CO_2 concentration). This evolution points to the use of CFD not merely as a descriptive tool, but as a predictive support for the comprehensive design and optimization of vertical farms, enabling the evaluation of complex operational scenarios prior to real-world implementation.

Nevertheless, significant methodological and conceptual challenges remain. Among these, the limited integration of crop physiological processes such as photosynthesis, transpiration, and stress responses into CFD models stands out, as these processes are still treated in a simplified or decoupled manner in many studies. In addition, critical variables such as the spatial distribution of CO_2, vapor pressure deficit (VPD), and latent heat transfer continue to be underrepresented compared to airflow analysis. This is compounded by the scarcity of full-scale experimental validations and longitudinal studies capable of assessing the microclimatic and energy performance of indoor systems over time, which restricts the generalizability of results and their industrial adoption

Looking ahead, research is expected to advance toward interdisciplinary and decision-oriented approaches, combining CFD with optimization techniques, artificial intelligence, and digital twins for the real-time control of vertical farms. The integration of energy analyses, sustainability assessments, and economic considerations represents another key axis for strengthening the practical applicability of CFD models. Furthermore, the reinforcement of international collaborations and the development of comparative studies across different indoor system typologies will help reduce regional gaps and consolidate a more robust knowledge framework. Overall, these trends and challenges outline a research agenda aimed at maximizing the productive, energy, and environmental efficiency of controlled environmental agriculture through the advanced use of CFD.

IV. CONCLUSIONS

From a quantitative perspective, the bibliometric analysis confirms that the application of Computational Fluid Dynamics (CFD) in vertical and indoor agriculture constitutes an emerging research field that is nevertheless in a clear phase of consolidation, with sustained growth in scientific production during the 2015–2025 period and a marked acceleration in recent years. The analyzed corpus, consisting of 52 documents published across 30 sources, reveals a high degree of geographical and editorial concentration, led mainly by China, the United States, and several European countries, as well as by journals specialized in biosystems engineering and controlled environment agriculture.

Bibliographic coupling and co-authorship networks display a highly centralized structure, supported by a relatively small core of authors and institutions with strong intellectual interconnections, indicating that the development of the field has been driven primarily by foundational contributions and recurrent collaborations rather than by a broad dispersion of approaches. From a conceptual standpoint, the results show that CFD has become a key tool for understanding and optimizing microclimate conditions in controlled environment agriculture systems, particularly with respect to ventilation, airflow distribution, and thermal uniformity.

The analysis of keywords, co-occurrence networks, and multiple correspondence analysis indicates that the thematic core of the field is structured around air–plant interactions, plant canopies, LED lighting, and energy efficiency, while variables such as CO_2 distribution, mass transport, and the integration of crop physiological processes remain at an early stage of development. This conceptual structure suggests a progressive evolution from approaches focused on localized airflow improvements toward more integrated models aimed at the simultaneous optimization of productive, energy, and environmental performance in vertical and indoor farming systems.

Looking ahead to future research, it is recommended to move toward more accessible, integrated, and decision-oriented CFD models, particularly in the context of low-cost indoor agriculture and in regions with limited resources. In this regard, priority should be given to developing approaches that combine simplified yet representative geometries, small-scale experimental validation, and clear metrics of uniformity and efficiency, enabling the transfer of generated knowledge to growers and designers of indoor systems with lower technological capacity.

In addition, integrating CFD with optimization tools, intelligent control strategies, and simplified energy analyses could facilitate the design of modular, scalable, and economically viable solutions. Finally, fostering international collaborations and comparative studies across different socioeconomic contexts will help broaden the impact of CFD as a strategic tool for improving the sustainability, resilience, and accessibility of controlled environment agriculture at a global scale

ABSTRACT

This study aims to develop automated smart waste classification systems using machine learning deployed on resource-constrained hardware, such as Raspberry Pi, with the goal of integrating these models into the initial stage of waste sorting—that is, the trash bin. This study proposes two models: ConvNeXt and an improved CNN model, which is referred to as PrQ-CNN. The improved PrQ-CNN model utilizes pruning and quantization techniques to reduce its size. Both models were trained on a dataset comprising two classes: Non-recyclable and Recyclable. The data were split into a training set and a testing set with a 90:10 ratio. The models were integrated into a Raspberry Pi embedded computer to compare metrics such as model size, inference time, accuracy, missed detection rate (MDR), and false discovery rate (FDR). Experimental results show that the PrQ-CNN model achieved an accuracy of 92%, while its size was 12 times smaller than that of the original model before pruning and quantization. The ConvNeXt model achieved an accuracy of 98%. The results from the improved PrQ-CNN and ConvNeXt models were compared with VGG16, ResNet, EfficientNet, and MobileNet.

I. INTRODUCTION

Waste pollution presents a significant challenge, particularly for developing tropical cities with high population density [1]. Smart cities around the world are currently focusing on solid waste management and treatment [2],[3]. Among these, solid waste sorting and recycling take the lead as major concerns [2]. According to data from the World Bank, global waste volume is projected to increase sharply, reaching 3.4 billion tons by 2050 [4], [5]. Globally, over 43% of solid waste is not properly managed through open burning, illegal dumping, and unregulated landfills [4], [5]. Additionally, the United Nations Environment Programme (UNEP) estimates that manual waste handling causes 15 – 20% of workplace injuries in the recycling sector [4], [5].

Landfilling also produces a large amount of methane, a potent greenhouse gas that contributes significantly to global warming [6]. Methane has a significantly higher heat-trapping potential than carbon dioxide, thereby exerting a stronger impact on global climate change [6]. In summary, if solid waste is not effectively managed, sorted, and recycled, it will lead to increased expenses, time consumption, and can cause waste pollution complications, resulting in consequences such as environmental pollution, impacts on public health, as well as worldwide problems like global warming and climate change. The objective of this study is to build compact machine learning models that can be deployed on resource-constrained hardware, or embedded computers like Raspberry Pi, and other devices, for automated solid waste classification into Recyclable and Non-recyclable types.

This study focuses on optimization, deployment, and evaluation of existing models for embedded waste classification applications. The study also aims to compare these models based on parameters such as performance and size. These hardware platforms can be easily integrated to build smart trash bins that can be deployed in public areas, helping to reduce production costs while introducing artificial intelligence technology into the very first step of waste classification when people discard their waste. Specifically, the waste treatment system model targeted by this study involves building trash bins with processors based on resource-constrained hardware platforms equipped with machine learning models.

Whenever people dispose of waste into these bins, the bins will use artificial intelligence technology to automatically classify the waste as Recyclable or Non-recyclable and separate it into the corresponding section for easier processing and recycling. Accordingly, the main research question addressed in this study is: how can machine learning-based waste classification models be optimized and evaluated to achieve an effective balance between accuracy, model size, and inference speed for deployment on resource-constrained embedded devices.

Contributions

(i) Developing machine learning models for solid waste classification, including a ConvNeXt model on the Kaggle Waste Classification dataset, achieving a high accuracy of 98%.
(ii) Proposing an improved Convolutional Neural Network (CNN) model utilizing pruning and quantization techniques to reduce model size by 12 times compared to the baseline, while maintaining accuracy, making it suitable for resource-constrained hardware and embedded devices.
(iii) Evaluating the models' performance based on accuracy, confusion matrix, and other performance metrics.
(iv) Providing an empirical, deployment-oriented comparison of multiple deep learning models on embedded hardware.

II. RELATED WORKS

According to [7], proposed developing a smart trash bin system capable of real-time waste level monitoring and efficient collection using YOLOv8 and YOLOv5 deep learning models to significantly reduce the number of parameters and processes, thereby lowering hardware requirements. Iman Ranjbar et al. proposed building a large and specialized dataset of plastic waste images, including four types of plastics commonly used in construction projects: ABS, HDPE, PS, and PVC [8]. They leveraged transfer learning with models trained and evaluated on advanced CNNs and Vision Transformers, including ResNet, ResNeXt, RegNet, and Swin Transformer, with Swin Transformer yielding the highest accuracy of 93.28% [8]. Mirna Castro Bello et al. evaluated and compared the effectiveness of four CNN models for waste classification using a custom dataset of 1883 Non-recyclable and Recyclable waste images on a Raspberry Pi 4 Model B with an HQ camera, achieving an average CPU utilization of 86% and an inference time of 1900 ms [9]. Proposed a hybrid method that combines instance segmentation deep learning models with morphological machine learning models to automate the classification and evaluation of decoration and renovation waste on a labeled dataset comprising 53,000 images [10].

The proposed method demonstrated remarkable accuracy, with a low relative error of 2.8% in the overall evaluation between models' predictions and manual sorting [10]. Evaluated the performance of AI models such as Mask R-CNN and YOLOv8, in enhancing plastic waste classification [11]. The models were assessed for accuracy, mean average precision (mAP), precision, recall, F1 score, and inference time, with hyperparameter tuning performed through grid search [11]. Results showed that Mask RCNN achieved an accuracy of 0.912 and mAP of 0.911, performing better than YOLOv8 in tasks requiring detailed segmentation, despite a longer inference time of 200–350 ms [11]. Conversely, YOLOv8, with an accuracy of 0.867 and mAP of 0.922, excelled in real-time scenarios due to its shorter inference time of 80–160 ms [11]. Presented the WasteIQNet model, a hierarchy-aware deep hybrid model, for detailed waste classification [12]. The proposed framework was trained and evaluated on the WEDR dataset, a curated collection of 360,000 images reflecting actual waste conditions across major landfill areas of Delhi [12]. Numerous other studies, such as those in [13-17], are also noteworthy.

These recent and in-depth studies demonstrate researchers' significant interest in the field of waste management and treatment, as well as practical use of new technologies like AI and ML in these areas. Based on the reviewed literature, it is evident that most recent studies primarily concentrate on either (i) multi-class waste classification using large-scale datasets or (ii) achieving high classification accuracy through deep learning models without imposing strict constraints on computational resources. In contrast, only a limited number of studies have systematically examined the trade-offs among model accuracy, model size, and inference speed when deploying waste classification models on resource-constrained embedded platforms, such as the Raspberry Pi. Furthermore, comprehensive comparative evaluations incorporating embedded-oriented performance metrics, including missed detection rate (MDR), false discovery rate (FDR), and on-device inference time, remain scarce in the existing literature.

III. MODELS AND METHODS

III.1 IDENTIFIED RESEARCH GAPS AND CHALLENGES

Based on the literature review, several research gaps can be identified. First, many existing studies prioritize accuracy while overlooking deployment feasibility on embedded hardware with limited memory and computational power. Second, comparisons across models are often conducted on different datasets, making direct evaluation difficult. Third, few studies report embedded-oriented performance indicators such as MDR, FDR, and real inference latency on low-power devices. These gaps motivate this study to focus on practical, deployment-oriented evaluations, with particular emphasis on the implementation of machine learning models for at-source waste classification on resource-constrained embedded systems.

III.2 MODELS AND METHODS

This study focuses on building a solid waste management and treatment system where waste sorting is performed from the very first step, as residents dispose of waste into bins. The trash bin will automatically classify the waste as Recyclable or Non-recyclable using a machine learning model. For such a system, one of the challenges is the limitations of hardware platforms for end-devices. In addition to high accuracy, the model must be sufficiently lightweight and optimized to be seamlessly integrated into these devices. Concretely, the objectives of this study include two main goals:

(i) Building machine learning models for Non-recyclable and Recyclable waste classification that can be applied in the design and manufacturing of smart trash bins for waste management and treatment systems.
(ii) Discussing and proposing the best model that can be applied on resource-constrained hardware platforms for integration into end-user devices, specifically smart trash bins

III.3 SMART TRASH BIN AND DATASET DESCRIPTION

The dataset used in this study is the Waste Classification data from Kaggle. This dataset comprises two components: Training and testing set, split at a 90:10 ratio. Each component consists of two classes: O (Other: Non-recyclable) and R (Recyclable). Figure 1(a) illustrates the structure of the smart waste bin, which employs an AI-based model to perform source-level waste classification. When waste is deposited into the bin, the AI system classifies it into Recyclable and Non-recyclable categories and subsequently controls the conveyor motor to direct the waste into the corresponding compartment. Figure 1(b) presents sample images of the two waste classes, namely Non-recyclable waste and Recyclable waste, contained in the dataset.

(a) Smart trash bin. (b) Images in the dataset.
Figure 1: Smart trash bin structure and sample images from the dataset.
Source: Authors, (2026).

To ensure fair comparison, all models were trained and evaluated using the same dataset split, input resolution (224×224), and evaluation metrics. In this study, data augmentation techniques were not applied during the training process. This design choice was made to ensure that the performance evaluation reflects the model capability under realistic deployment conditions, where waste images captured at the source often exhibit limited variability and are not artificially enhanced. The original class distribution of the dataset was preserved to simulate real-world waste generation scenarios, in which recyclable and non-recyclable waste categories are inherently imbalanced.

Maintaining this natural imbalance allows for a more faithful assessment of the model's robustness and practical effectiveness, particularly in minimizing misclassification risks under real deployment conditions. Additionally, cross-validation was not conducted in this study. Instead, a fixed train–validation–test split was adopted to reduce computational overhead and experimental complexity, which is consistent with the constraints of resource-limited embedded platforms. This approach also aligns with the study's primary objective of deployment-oriented evaluation, where repeatable inference performance, model size, and execution time on embedded hardware are prioritized over exhaustive statistical validation. The hardware specifications used in this study are presented in Table 1.

Table 1: Technical specifications of hardware.

No	Hardware	Technical specifications
1	Raspberry Pi 5	- CPU: ARM Cortex-A76 (ARM v8) 64-bit - Clock speed: 4 x 2.4 GHz - GPU: VideoCore VII (800 MHz) - RAM: 8 GB LPDDR4X (4267 MHz) - SD card: microSD
2	Kaggle GPU T4x2	- Architecture: Turing - CUDA Cores: 2,560 - Tensor Cores: 320 - GPU Memory: 16 GB GDDR6 - Memory Bandwidth: 320 GB/s

III.4 MODEL ARCHITECTURES

III.4.1 PrQ-CNN Model

CNN model: The Convolutional Neural Network model is a type of deep learning algorithm based on multi-layer neural networks that can identify, recognize, and classify objects, as well as detect and segment objects in given images [18].

CNNs typically consist of four types of layers: Convolutional, Pooling, Activation Function, and Fully Connected. The convolutional layer plays a crucial role in the overall CNN structure. It is a set of filters—or kernels—applied to the data. The width, height, and weights of each kernel are used to extract features from the input data. Weight values in the first kernel are randomly assigned but gradually become more informed by the training data. The pooling layer is used to reduce the dimensionality of feature maps while retaining the most important data [18]. A filter applies a pooling operation (max, min avg) by sliding across the input data in the pooling layer. Max pooling is most commonly used. A non-linear layer follows the convolution. Non-linearity allows the generated output to be altered or terminated. This layer is used to constrain or saturate the output [18].

Every type of activation function in every type of neural network serves the essential function of mapping inputs to outputs. The input value is calculated by summing the weighted inputs of the neuron and its bias (if any). This indicates that the activation function determines whether to activate a neuron in response to a given input by producing an appropriate output. Fully Connected (FC) layers, also known as dense layers, are used in neural networks, especially in deep learning. They are a type of neural network layer where every neuron in the layer is connected to every neuron in the preceding and succeeding layers. FC layers are typically deployed at the end of a neural network to perform classification or prediction tasks based on extracted specific features, helping the network learn complex associations between features [18].

Pruning: Pruning is the process of removing unnecessary or less important parts of a model to make it more optimized and faster without significantly reducing its accuracy or performance [19]. Pruning can be categorized into structured, unstructured, and semi-structured pruning. Structured pruning removes filters, channels, or layers to create structured sparsity patterns. In unstructured pruning, individual weight values without structural constraints are considered for removal. Semi-structured pruning acts as a hybrid approach combining aspects of both structured and unstructured pruning [19].

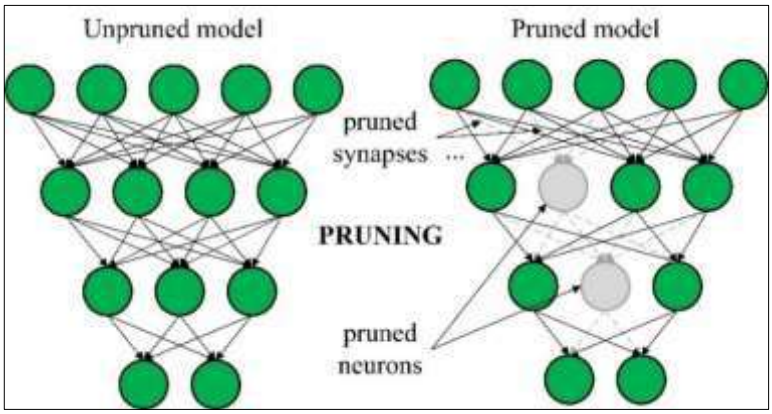

Figure 2: Pruning technique.
Source: Authors, (2026).

Quantization: Quantization is a compression method that converts high-precision representations (32-bit floating point) into lower-bit representations (int8 fixed-point) [20]. Quantization can reduce the CNN model's size, memory footprint, and power consumption, while also improving inference time. This is one of the deep learning model optimization techniques, particularly suitable for embedded systems, mobile devices, or applications requiring high performance and energy efficiency. Quantization techniques used for CNNs are broadly classified as: Post-Training Quantization and Quantization-Aware Training. CNN parameters need to be adjusted to maintain accurate performance after quantization. The process of model retraining to account for quantization is called Quantization-Aware Training, or it can be done without retraining through Post-Training Quantization [20].

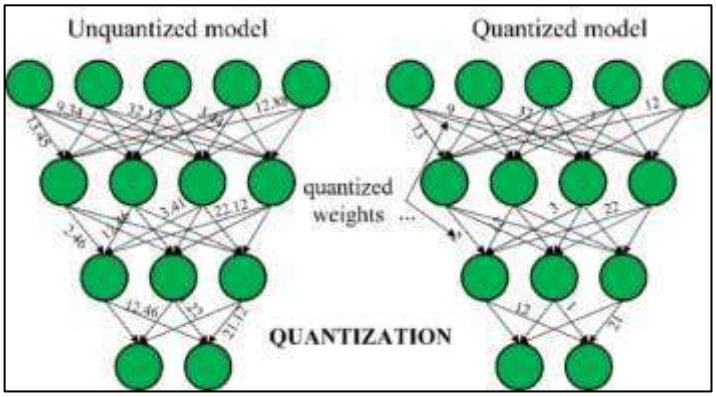

Figure 3: Quantization technique.
Source: Authors, (2026).

In this study, unstructured magnitude-based weight pruning was applied to the convolutional layers, in which individual weights with small absolute values were set to zero. This was followed by post-training dynamic range quantization, where the model weights were quantized to 8-bit integers while activations remained in floating-point precision. The pruning threshold was empirically selected to ensure that the accuracy degradation remained below 2%. Finally, the overall architecture of the PrQ-CNN is shown in Figure 4.

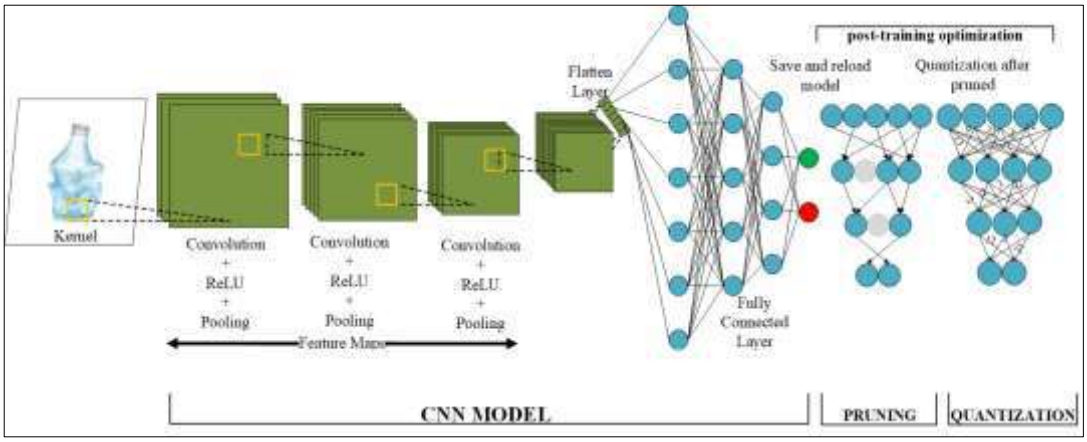

Figure 4: Proposed PrQ-CNN network architecture.
Source: Authors, (2026).

III.4.2 ConvNeXt Model

ConvNeXt is a deep neural network architecture designed to enhance the performance of image processing models, particularly in image recognition and classification [21].

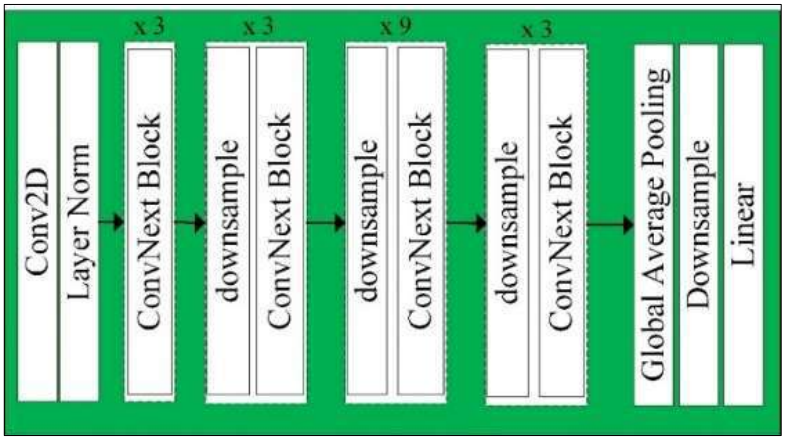

Figure 5: Architecture of the ConvNeXt (tiny) model used in this study.
Source: Authors, (2026).

It was introduced by the Facebook AI Research (FAIR) team in 2022 as a combination of features from traditional CNN models like ResNet and principles of Transformer architecture, aiming to optimize image processing capabilities [21].

IV. RESULTS AND DISCUSSION

IV.1 EVALUATION OF WASTE CLASSIFICATION MODEL RESULTS

To evaluate the performance of the models, this paper calculates and analyzes specific metrics as detailed below:

Confusion Matrix:

A confusion matrix is a specific tabular layout that allows for the visualization of an algorithm's performance. Each row of the matrix represents instances in an actual class, while each column represents instances in a predicted class, or vice versa.

Table 2: Confusion Matrix.

		Predicted Class	
		Yes	No
Actual Class	Yes	TP(a)	FN(b)
	No	FP(c)	TN(d)

Source: Authors, (2026).

Where:
(*) a: TP (true positive) – This occurs when both the actual class and the predicted class of the data point are True.
(*) b: FN (false negative) – This occurs when the actual class of the data point is True, but the predicted class is False (for example, when a pregnancy test indicates that a woman is not pregnant, but she actually is).
(*) c: FP (false positive) – This occurs when the actual class of the data point is False, but the predicted class is True (for example, when a pregnancy test indicates that a woman is pregnant while she is not).
(*) d: TN (true negative) – This occurs when both the actual class and the predicted class of the data point are False.

Accuracy:

Accuracy in classification is the most common evaluation metric. It is defined as the ratio of the number of correct predictions made by the model to the total number of predictions.

Accuracy

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN} = \frac{a + d}{a + b + c + d} \quad (1)$$

Error Rate:

The Error Rate of the model is calculated as follows:

Error Rate

$$ErrorRate = 1 - Accuracy \quad (2)$$

Precision:

Precision is defined as the number of true positives divided by the sum of true positives and false positives. It indicates the proportion of positive predictions that are actual positives, in relation to the total number of predicted positives.

Precision

$$Precision = \frac{TP}{TP + FP} = \frac{a}{a + c} \quad (3)$$

Recall/Sensitivity:

Recall is defined as the number of true positives divided by the sum of true positives and false negatives. It indicates the proportion of positive predictions that are actual positives, relative to the total number of positives in the original dataset.

Recall/Sensitivity

$$Recall = \frac{TP}{TP + FN} = \frac{a}{a + b} \quad (4)$$

F1 Score:

The F1 score combines precision and recall for a specific positive class. It reflects the balance between precision and recall, particularly in cases of uneven class distribution. The F1 score achieves its highest value of 1 and its lowest value of 0.

F1 Score

$$F1Score = \frac{2 * Recall * Precision}{Recall + Precision} = \frac{2a}{2a + b + c} \quad (5)$$

MDR (Missed Detection Rate):

MDR is the percentage of fields that are actually positive but are missed (not detected).

MDR

$$MDR = \frac{FN}{TP + FN} = \frac{b}{a + b} \quad (6)$$

FDR (False Discovery Rate):

FDR is the proportion of false positives (incorrect positive detections) among all positive detections.

FDR

$$FDR = \frac{FP}{TP + FP} = \frac{c}{a + c} \quad (7)$$

These models were trained on the Kaggle platform using a T4x2 GPU. The results will be evaluated by implementing the testing set. The improved CNN model (PrQ-CNN) and ConvNeXt will be evaluated alongside VGG16, MobileNet, ResNet, and EfficientNet using performance parameters such as model size (MB), accuracy (%), average inference time per sample (ms), confusion matrix, and other parameters mentioned above on Kaggle GPU and Raspberry Pi. Specifically, the prediction results of the models are listed in Tables 3 to 8.

The precision scores for both classes in the ConvNeXt model are the highest (0.97 and 0.99). In contrast, the other models exhibit significant discrepancies between the two classes, with the Non-recyclable class generally performing worse than the Recyclable class. Overall, the ConvNeXt model still demonstrated the best performance, as indicated by its F1-Score, reflecting good balance across both classes. This is followed by PrQ-CNN, which achieved an accuracy of 92%. The confusion matrices of the models are shown in Figure 6.

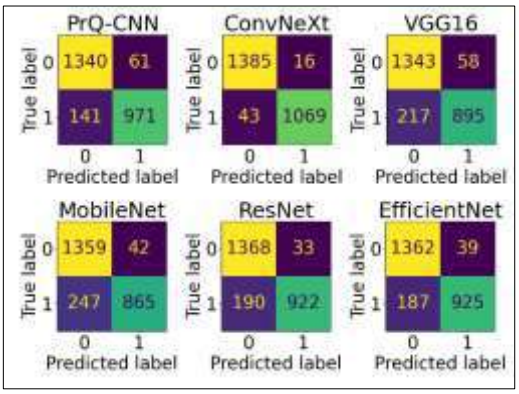

Figure 6: Confusion matrix of the models.
Source: Authors, (2026).

The ConvNeXt model exhibited the most exceptional performance with high accuracy, low error rate, and satisfactory positive class detection. PrQ-CNN followed with strong accuracy. ResNet and EfficientNet demonstrated comparable performance, both commendable but not superior to the ConvNeXt and PrQ-CNN models. The VGG16 and MobileNet models showed lower performance compared to the other models.

IV.2 DISCUSSION

The PrQ-CNN model is relatively small in size (22 MB) and fast, making it suitable for applications requiring quick processing and limited resources, such as embedded computers (92% accuracy). The ConvNeXt model achieved the highest accuracy (98%) but demands more resources than PrQ-CNN. It is ideal for applications where high accuracy is a priority. With an inference time of 234.3 ms/sample on Raspberry Pi, the ConvNeXt model still performs effectively when integrated into embedded devices. In general, the VGG16 and EfficientNet models are larger and slower compared to the other models. MobileNet is the lightest model (9.6 MB), making it suitable for real-time applications or devices with limited resources, though it sacrifices some accuracy, achieving 88% compared to other models. A comparison chart of the models based on six specific parameters is shown in Figure 8.

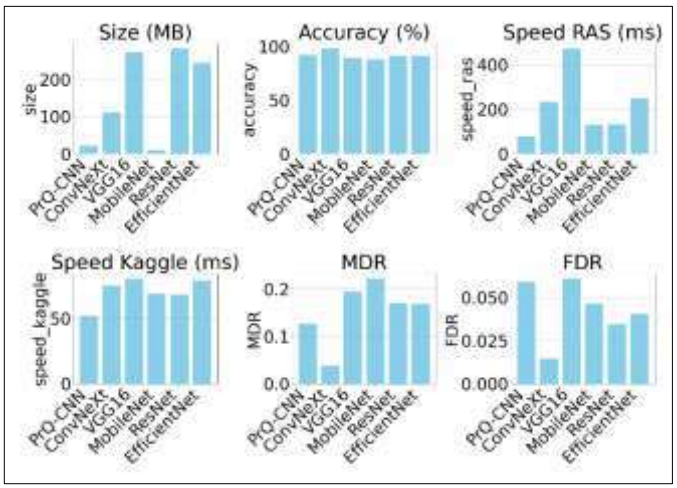

Figure 7: Comparison of models' parameters.
Source: Authors, (2026).

Tables 9 and 10 evaluate the performance of the models.

Table 9: Comparison table of best-performing models.

No	Parameter	Value	Model
1	Size	9.6 MB	MobileNet
2	Accuracy	98.0%	ConvNeXt
3	Speed on Raspberry Pi	76.3 ms	PrQ-CNN
4	Speed on Kaggle	52.0 ms	PrQ-CNN
5	MDR	0.0387	ConvNeXt
6	FDR	0.0147	ConvNeXt

Source: Authors, (2026).

Table 10: Comparison table of worst-performing models.

No	Parameter	Value	Model
1	Size	283.4 MB	ResNet
2	Accuracy	88.0%	MobileNet
3	Speed on Raspberry Pi	472.2 ms	VGG16
4	Speed on Kaggle	80.4 ms	VGG16
5	MDR	0.2221	MobileNet
6	FDR	0.0609	VGG16

Source: Authors, (2026).

Based on the two comparison tables above, several conclusions can be drawn: The ConvNeXt model achieves the best accuracy, while PrQ-CNN remains the leading model in terms of inference time on embedded computers. If accuracy is prioritized, ConvNeXt and PrQ-CNN are top choices. If a lightweight and fast-processing model for resource-constrained devices is required, PrQ-CNN is the most suitable. In general, PrQ-CNN provides a good balance between accuracy, size, and inference time for embedded devices. Table 11 compares the models proposed in this study with those reported in previous studies. The accuracy is evaluated on the same dataset as well as on different datasets. Overall, the ConvNeXt and PrQ-CNN models in this study demonstrated strong performance compared to the studies listed in Table 11. Both models exhibited superior accuracy, with PrQ-CNN leveraging pruning and quantization techniques to reduce the model size by approximately 12 times compared to the baseline unoptimized CNN model, making it suitable for embedded devices with limited hardware resources.

Table 11: Comparison with other models.

No	Study	Model	Dataset	Accuracy
1	This study	ConvNeXt	Kaggle	98.0%
2	This study	PrQ-CNN	Kaggle	92.0%
3	[22]	MLH-CNN	TrashNet	92.6%
4	[23]	EfficientNet	Custom Kaggle	85.0%
5	[24]	CNN	Same dataset	80.88%
6	[25]	CNN	Same dataset	91.32%
7	[26]	YOLOv7-tiny	Various sources	86.8%

V. FUTURE RESEARCH DIRECTIONS

This study primarily evaluates computational efficiency and accuracy. Power consumption analysis, robustness to varying lighting conditions, and real-world deployment in physical smart trash bins were beyond the current scope but remain essential future research directions. Therefore, in the future, the models will be tested on real-world datasets under conditions such as low light, image noise, and environmental factors. Subsequently, the classification system will be integrated into smart trash bins, and fully integrated embedded systems will be designed and tested, including sensors, processors, user interfaces, and data transmission systems for remote monitoring and control. Classification models will be coordinated with IoT systems to collect larger datasets, analyze user behavior, and optimize waste collection and sorting processes. Developing unsupervised or semi-supervised learning will reduce dependence on costly labeled data. Small-scale pilot systems will be deployed in real urban areas to evaluate practical performance, stability, and adaptability of the model. User feedback will be collected to refine the waste management and treatment system in smart cities.

VI. CONCLUSION

The machine learning models proposed in this study, namely ConvNeXt and PrQ-CNN, have demonstrated high accuracy in classifying Non-recyclable and Recyclable solid waste, achieving 98% and 92%, respectively. This study also proposed techniques such as pruning and quantization to reduce model size for integration onto embedded devices with limited hardware resources, such as Raspberry Pi. Experimental results show that both models have achieved not only superior classification efficiency but are also suitable for integration into smart trash bin systems. This study highlights the potential for application in waste management and treatment classification systems, contributing to improved efficiency, reduced errors, and cost optimization. Compared to conventional models such as VGG16, ResNet, or MobileNet, the proposed models in this study offer a good balance between accuracy, size, and inference time, meeting the requirements of embedded systems. It also demonstrates the potential for applying artificial intelligence technology in waste classification, which not only enhances processing efficiency but also promotes the development of smart, sustainable waste management systems, contributing to environmental protection initiatives against climate change and improving quality of life in urban areas.

ABSTRACT

The increasing demand for energy necessitates the implementation of sustainable solutions that incorporate renewable energy sources (RES), specifically solar and wind. Nevertheless, the inherent variability of renewable energy sources (RES) presents a challenge in the optimization of power dispatch, particularly in islanded microgrids. The Combined Economic Emission Dispatch (CEED) problem in a three-unit operational system under dynamic load demand conditions is the subject of this study. Four scenarios are taken into account for the operation of the system such as Thermal-only; Thermal + Wind; Thermal + PV; and Thermal + Wind + PV. In order to guarantee system reliability and reduce both generation cost and emissions, a weighted sum approach is implemented in conjunction with the Zebra Optimization Algorithm (ZOA). This work had done using the MATLAB 2020 software. The proposed method effectively manages constraints such as ramp rate limits and thermal unit operating boundaries, demonstrating enhanced efficiency and adaptability in comparison to traditional techniques.

I. INTRODUCTION

Power systems are tasked with the efficient management of energy production, transmission, and distribution to consumers.Given that energy demand has recently exceeded production capacity, existing power stations must be used to their maximum potential instead of constructing new facilities to accommodate the load. The economic load dispatch (ELD) model is the only model that accounts for load demand. This is the only model capable of ascertaining the distribution of power-generating units while conforming to constraints. The study [1] have used evolutionary algorithms to provide computer-aided solutions for the issues related to economic load dispatch. Despite the limitations given by the system, the objective is to generate the maximum feasible amount of electricity.

In [2] uses a combination of artificial intelligence and renewable energy distribution to optimize existing power networks for various applications. This enhancement may serve several purposes. In [3] they have developed a unique hybrid optimization technique that enhances energy efficiency and dispatch to address the issues related to the optimization of economic load dispatch. The paper [4] had examine the cost-reliability trade-off using sophisticated evolving intelligence algorithms developed for the integration of renewable energy sources. These algorithms were developed for research purposes.The multi-objective CEED problem leads to a decrease in both pollution emissions and fuel expenditures.

At Emission Dispatch, our primary objective is to decrease the volume of dangerous pollutants emitted by coal-fired power plants. The pollutants consist of carbon monoxide, sulfur dioxide, and nitrogen oxides. The study [5] developed an algorithm for real-coded chemical processes aimed at minimizing costs and emissions related to economic emission load dispatch. This was executed to attain the study's principal objective. In [6] they have conducted comprehensive ELD testing, revealing that search group optimization enhances convergence time and solution accuracy. These results underscore the significance of search group optimization. The study [7] had extend the idea to intelligent distribution networks, which oversee voltage stability and include virtual power plants fueled by renewableenergysources. Measures are implemented to fortify the power grid.

The adoption of ELD requires continuous dynamic demand integration to minimize costs, emissions, and grid instability. To ensure that power systems operate effectively and sustainably amidst varying load patterns, it is essential to use adaptable optimization strategies. The paper [8] enhanced grid stability with the use of real-time economic load dispatch and renewable energy curtailment. This was achieved despite the fairly complex nature of the data processing operation. Despite incurring substantial processing costs, Dragonfly successfully enhanced the accuracy of probabilistic ELD [9]. Despite considering parameter sensitivity, [10] successfully optimized the thermal-wind economic load dispatch using chaotic sine cosine. The study [11] enhanced ELD convergence by artificial ecosystem optimization. This was achieved despite requiring substantial processing effort. To address the coal problem, one should integrate wind power plants with coal-fired thermal power facilities. This technique maximizes sustainability, cost-effectiveness, and pollution reduction to their fullest potential.

The grid's enhanced resilience has led to an increased need for optimization frameworks proficient in managing unpredictability and dynamic load distribution. It is regrettable that [12] could not successfully augment their research, despite their efforts to enhance short-term hydrothermal dispatch to boost production. In paper [13] successfully used ELD with multi-fuel thermal and renewable energy sources, leveraging the Equilibrium Optimizer. This enabled him to save costs by adjusting the ELD parameters to get the intended outcome. This was implemented to achieve the goal of minimizing expenditures to the greatest extent feasible. The study [14] introduced new avenues of research in their study on renewable-integrated ELD optimization methodologies; nevertheless, they failed to test the scalability of their approaches prior to advancing their work. The use of photovoltaics in economic load dispatch seeks to reduce fossil fuel consumption, operational costs, and environmental impact.

Due to the unpredictability of the power source, optimization enhancements are necessary for photovoltaic (PV) output. These modifications are essential to guarantee the stability of the grid, the efficiency of the power distribution system, and the economic viability of the system amid variable load conditions. Although challenging to quantify, optimization strategies for CEED, whether using PV and wind or not, are successful, as shown in [15]. Despite the challenges in calculating them, some tactics prove effective. The study [16] discovered that solar sharing via PSO was both cost-effective and environmentally beneficial. Despite solar electricity being an intermittent energy source, this was the circumstance. In [17] endeavored to enhance the precision of their predictions by including photovoltaic and transmission losses into economic emission dispatch (EED). This was undertaken to enhance the precision of their forecasts. Solar and wind energy exemplify renewable energy sources that enhance the efficiency of electric vehicles (EVs), decrease fuel costs, promote sustainability, and mitigate pollution.

Due to the sporadic characteristics of renewable energy sources, the use of sophisticated optimization and energy storage technologies is essential for sustaining grid stability. Despite their complexity, hybrid systems are more economical and enhance energy security. Hybrid systems also reduce costs. In the study [18] devised a metaheuristic algorithm inspired by bats to enhance resource use efficiency. This idea addresses the fundamental difficulty associated with renewable energy. Due to the unpredictability of renewable resources, [19] assert that probabilistic modeling was used to account for this factor. The study [20] enhanced the efficiency of the task by analyzing CEED optimization approaches that included photovoltaic and wind generation systems. In [21] they have used an advanced pyrotechnics algorithm to optimize the combined dispatch of renewable energy sources. The intricacy of scheduling is further exacerbated by the use of solar and wind power prediction models, as shown in [22].

The study [23] are doing research on the integration of wind, solar, and hydropower to develop a more dependable hybrid dispatching system. Following an analysis of the system's cost and performance, [24] conclude their study on the financial implications of incorporating solar energy into the existing power grid. In [25] maximize CEED amidst fluctuating energy supply by using sophisticated hybrid algorithms, while simultaneously managing costs, emissions, and grid stability. This enables them to get effective optimization. To effectively integrate intermittent renewable energy sources such as solar, thermal, and wind power into Economic Load Dispatch (ELD), rigorous optimization is essential. The Zebra Optimization Algorithm (ZOA) effectively addresses multi-objective constraints, enabling it to enhance grid stability, decrease generation costs, and minimize emissions. Consequently, it can achieve these aims. Ultimately, it will provide optimal dispatch solutions, hence enhancing the endurance of hybrid power networks. This is now achievable due to its adaptive search capabilities.

II. PROBLEM FORMULATION

By superimposing the input-output properties of the boiler-turbine-generator system, the fuel cost function [25] is usually expressed as:

$$F_{C_{Total}} = \sum_{i=1}^{N} f_i(P_{gi}) = \sum_{i=1}^{N} (a_i + b_i P_{gi} + c_i P_{gi}^2) \quad \$/hr \tag{1}$$

By integrating the NOx, SOx, and COx emissions of a thermal power plant, the entire emission function [25] is depicted as:

$$E_T = \sum_{i=1}^{N} f_i(P_{gi}) = \sum_{i=1}^{N} (\alpha_i + \beta_i P_{gi} + \gamma_i P_{gi}^2) \quad kg/hr \tag{2}$$

Constructing a single objective function that concurrently achieve both goals is inequitable, since reducing emissions and decreasing gasoline costs may be inherently contradictory. This is due to the potential incompatibility of these two objectives. The Combined Economic Emission Dispatch (CEED) function may be articulated as follows [25]. The aim is achieved by integrating the Weighted Sum and Price Penalty Factor (PPF) techniques.

$$CEED_T = W * F_{C_{Total}} + (1 - W) * h * E_T \tag{3}$$

The PPF is employed to transform emissions into a cost equivalent value.

$$h_i = \frac{F_C(P_{gi,min})}{E_T(P_{gi,max})} \tag{4}$$

Incorporating RES like solar and wind power into the ELD problem requires that the system adhere to inequality constraints and stability constraints [25] to maintain power balance and equilibrium.

II.1 EQUALITY CONSTRAINTS

$$\sum_{i=1}^{NG} P_{gi} + \sum_{i=1}^{M} W_{gi} + \sum_{i=1}^{S} PV_{gi} = P_{Demand} + P_{loss} \tag{5}$$

II.2 INEQUALITY CONSTRAINTS

$$P_{gi,min} \leq P_{gi} \leq P_{gi,max} \tag{6}$$

$$0 \leq W_{gi} \leq W_{rgi} \tag{7}$$

$$0 \leq PV_{gi} \leq PV_{rgi} \tag{8}$$

III. PROPOSED OPTIMIZATION ALGORITHM

III.1 ZEBRA OPTIMIZATION ALGORITHM

The study [26] developed a metaheuristic inspired by the natural behaviours of zebras in herding, migration, and survival. This metaheuristic is inspired by the natural strategies used by zebras. The approach is referred known as the Zebra Optimization Algorithm (ZOA). The ZOA is intended to replicate the balance that zebras maintain between foraging for food in uncharted territories and evading hazardous environments. It is particularly adept at addressing multi-objective optimization challenges, shown by the Combined Economic Emission Dispatch (CEED) in hybrid power systems, a topic for which it was specifically developed.

Population Initialization: Generate an initial population of n zebras (candidate solutions):

$$X_i^0 = lb + rand(1, D) \cdot (ub - lb) \quad for\ i = 1,2,..,n \tag{9}$$

Fitness Evaluation: Evaluate each zebra's fitness using the CEED objective function

$$fit_i = CEED_T(X_i) \tag{10}$$

Global Best Update: Update global best P_Z if a better fitness is found

$$P_Z^t = argmin(fit_i^t) \tag{11}$$

Phase 1 – Foraging Behaviour (Exploration): Zebra moves toward the best-known position

$$X_i^{t+1} = X_i^t + r \cdot (P_Z^t - I \cdot X_i^t) \tag{12}$$

If new position yields better fitness, update:

$$If\ f(X_i^{t+1}) < f(X_i^t) \Rightarrow X_i^t = X_i^{t+1} \tag{13}$$

Phase 2 – Predator Avoidance Behaviour (Exploitation): Strategy 1 (Lion Attack – Escape Strategy), Zebra escapes with random disturbance decreasing over time:

$$X_i^{t+1} = X_i^t + R \cdot (2r - 1) \cdot (1 - \frac{t}{t_{max}}) \cdot X_i^t \tag{14}$$

Strategy 2 (Other Predators – Defensive Strategy): Move based on interaction with randomly selected zebra AZ

$$X_i^{t+1} = X_i^t + r \cdot (AZ - I \cdot X_i^t) \tag{15}$$

Boundary Handling: Ensure that the updated position remains within bounds

$$X_i^{t+1} = min(max(X_i^t + 1, lb), ub) \quad (16)$$

Convergence Check: Repeat steps until the stopping criterion is met

$$t = t + 1, stop\ if\ t \geq t_{max}\ or\ convergence\ achieved$$

III.2 STEPS FOR ZOA-BASED CEED OPTIMIZATION

1. **Problem Definition:** Define the CEED objective function incorporating generation cost, emission levels, and system constraints.
2. **Population Initialization:** Generate initial zebra positions representing candidate power dispatch solutions.
3. **Fitness Evaluation:** Evaluate each zebra's fitness based on economic cost, emission output, and constraint satisfaction.
4. **Exploration & Exploitation:** Use ZOA's dynamic movement strategy to explore new solutions or exploit known good regions, guided by the global best and peer interaction.
5. **Constraint Enforcement:** Apply generator output limits, ramp rate limits, and power balance conditions to maintain feasible solutions.
6. **Best Solution Update:** Track and update the best-performing solution after each iteration.
7. **Convergence Criterion:** Repeat the process until the termination condition is met (e.g., max iterations or acceptable error level).
8. **Result Analysis:** Analyze the optimized dispatch results to determine the most cost-effective and environmentally efficient strategy.

IV. RESULTS AND DISCUSSIONS

This paper addresses the Combined Economic and Emission Dispatch (CEED) problem for a three-unit thermal power system under diverse integration scenarios of renewable energy sources. The system parameters, renewable generation profiles, and load demand are derived from [25]. The CEED objective function is constructed as a weighted sum of fuel costs and emission levels. The Zebra Optimization Algorithm (ZOA) is executed in MATLAB 2020 to address the dispatch problem in four scenarios: (i) thermal-only, (ii) thermal + PV, (iii) thermal + wind, and (iv) thermal + PV + wind. The outcomes are juxtaposed with benchmark solutions found in the current literature to authenticate the performance and effectiveness of ZOA. The ZOA model parameters are: R=0.1 (escape step size), r1 and r2 ∈ [0,1], and a dynamic equilibrium between exploration and exploitation based on iteration progress.

IV.1 CASE STUDY 1: EXCLUSIVE THERMAL UNITS

The CEED issue is addressed using the ZOA, focusing just on three thermal power units without including renewable energy sources. The aim is to reduce fuel expenses and pollution levels within a 24-hour timeframe, while maintaining power equilibrium and complying with operating restrictions. The system load requirement fluctuates between 140 MW and 250 MW during the day. According to the ideal dispatch plan established by ZOA, Unit 1 (Pg1) regularly functions at 37 MW, whereas Unit 3 (Pg3) sustains a stable output of 50 MW, suggesting that technical or economic considerations favour stationary operation. Unit 2 (Pg2) modulates its output between 53 MW and 160 MW, contingent upon the system's real-time load demands.

This guarantees a balanced alignment of supply and demand over the scheduling period. The optimization findings indicate a total fuel cost of 170,476 $/hr and an emission level of 3,711.05 kg per hour. The total CEED cost for the 24-hour period is 151,475 $/hr. The hourly CEED cost varies with demand, from a minimum of 5,395.10 $/hr during low-demand times to a high of 7,116.70 $/hr during peak load. These findings validate the efficacy of ZOA in addressing multi-objective optimization for thermal-only systems and provide a benchmark for evaluating enhancements from renewable integration in future scenarios.

Table 1: Hourly Optimal Results by ZOA for Case 1 (Thermal Only).

Hour	P1 (MW)	P2 (MW)	P3 (MW)	P-Thermal (MW)	Fuel-Cost ($/hr)	Emission (Kg/hr)	CEED ($/hr)

Source: Authors, (2026).

In Case 1, the whole demand for 24 hours is fully satisfied by thermal units, without any input from renewable sources. The thermal power production precisely corresponds to the hourly demand. In the first hour, the demand is 140 MW, entirely met by PT at 140 MW. At hour 10, demand reaches its zenith at 230 MW, with thermal generation precisely aligning at 230 MW. During peak demand hours, namely hour 12 (250 MW) and hour 20 (240 MW), the whole load is managed only by thermal plants, devoid of any renewable support. This configuration exemplifies the most conventional operation, yielding the greatest fuel expenses and emissions across all scenarios owing to exclusive dependence on fossil fuel-based generating. The whole power balance situation is shown in Table 6.

Figure 1: Hourly Variation of Fuel Cost and CEED – Case 1.
Source: Authors, (2026).

Figure 1 depicts the hourly fluctuations of Fuel Cost and CEED (Cost of Energy and Emission Dispatch) across a 24-hour duration. The horizontal axis indicates time in hours (1–24), and the vertical axis signifies fuel expense in $/hr. The blue curve represents Fuel Cost, whereas the orange curve illustrates CEED. Both measures have a same trajectory, with values rising throughout the morning hours and culminating at Hour 11, when Fuel Cost attains a high of $8340.10 and CEED nears $7298.10. Subsequent to this apex, both curves exhibit a slow descent, followed by a secondary ascent at Hour 21, signifying another operational high. The proximity of the two curves indicates a robust link between fuel use and emission-related expenses. Every data point on the graph is labelled for clarity, offering comprehensive insight into the fluctuations in operational costs throughout the day.

IV.2 CASE STUDY 2: THERMAL + PHOTOVOLTAIC(PV) SYSTEM

In Case 2, a 40 MW photovoltaic (PV) system is included into the power grid in conjunction with the three existing thermal units. The PV source, deemed non-dispatchable and devoid of emissions, functions with a stable generation profile that directly mitigates a portion of the overall system demand. This integration significantly decreases the net load on thermal generators, so alleviating their operating strain and enhancing overall system efficiency. The ZOA is used to address the modified CEED issue in accordance with the altered load profile. Following the integration of PV power, the thermal units Pg1 and Pg3 maintain their base load outputs of 37 MW and 50 MW, respectively, while Pg2 modulates its output to align with the residual demand.

The optimum dispatch plan embodies this tendency, allowing the system to sustain viability amid fluctuating demand levels. Significant reductions are achieved in both economic and environmental parameters relative to Case 1. The aggregate fuel expenditure diminishes to $166,659.86 per hour, emissions decline to 3,656.245 kg per hour, and the optimal CEED value is lowered to $148,343.14 per hour. The findings underscore the substantial benefits of integrating solar energy into traditional thermal systems, illustrating ZOA's efficacy in reducing costs and emissions in hybrid power systems.The incorporation of a 40 MW photovoltaic system in Case 2 alleviates the need on thermal production, particularly during daylight hours.

At hour 8, with demand at 180 MW, photovoltaic (PV) systems provide 16.18 MW, reducing the thermal load to 163.82 MW. At hour 10, photovoltaic (PV) systems reach their maximum production of 39.37 MW against a demand of 230 MW, hence decreasing thermal generation to 190.63 MW. In hour 13, photovoltaic (PV) production provides 31.94 MW, whereas thermal output has reduced to 208.06 MW, as seen in Table 6. During the early or late hours when sunshine is absent (e.g., hour 1 and hour 24), photovoltaic production ceases, and heat generation only fulfils the requirement. This partial integration mitigates fuel use and emissions during peak solar hours, hence improving overall efficiency.

Table 2: Hourly Optimal Results by ZOA for Case 2 (Thermal+PV).

Hour	P1 (MW)	P2 (MW)	P3 (MW)	P-Thermal (MW)	Fuel-Cost ($/hr)	Emission (Kg/hr)	CEED ($/hr)

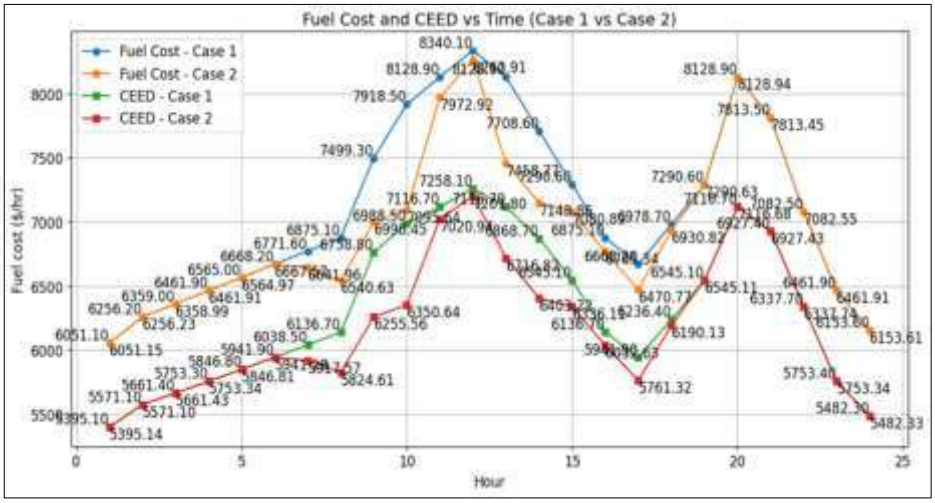

Figure 2: Hourly Variation of Fuel Cost and CEED – Case 1 and Case 2.
Source: Authors, (2026).

Figure 2 depicts the hourly fluctuations of Fuel Cost and CEED (Combined Economic and Emission Dispatch) for Case 1 and Case 2 across a 24-hour duration. The x-axis denotes the hours of the day, whilst the y-axis signifies the associated expenditures in $/hr. The graph delineates four curves: Fuel Cost-Case 1,Fuel Cost–Case 2,CEED–Case 1 and CEED-Case 2. Overall, Case 2 demonstrates elevated fuel expenses compared to Case 1 at peak demand intervals, particularly between hours 10–13 and 20–21, indicating a heightened operational strain. Nonetheless, the CEED values in Case 2 are decreased at certain hours, indicating a successful decrease in emissions or enhanced incorporation of cleaner energy sources such as solar (PV) systems. The fuel cost and CEED trends reach their zenith at Hour 11, signifying a pivotal period for operational planning. Case 2 illustrates an enhanced balance between economic dispatch and environmental consequences.

IV.3 CASE STUDY 3: THERMAL + WIND SYSTEM

In Case 3, a 30 MW wind power plant is incorporated into the existing thermal generating infrastructure. Similar to PV energy, wind power is a clean, non-dispatchable source; but, its intrinsically stochastic characteristics inject more unpredictability into the dispatch strategy. The CEED issue has been revised to include the dynamic wind profile, and the ZOA is used to ascertain the ideal generating schedule. The dispatch findings, as shown in Table 3, indicate that thermal units adjust to the fluctuations of wind power. Unit Pg1 operates consistently at its baseline of 37 MW, enhancing system stability. Pg3 functions consistently, while Pg2 adopts a flexible approach, modulating its output according to variations in wind availability. This architecture allows the system to effectively balance demand despite the unpredictability of renewable inputs.

In contrast to the other situations, Case 3 attains a total fuel cost of $166,041.9 per hour and emissions of 3,612.80 kg per hour, culminating in a CEED value of $147,886.74 per hour. The cost decrease in the PV-integrated scenario (instance 2) is minimal; nonetheless, this instance demonstrates increased fluctuation in emissions owing to the intermittent characteristics of wind energy. Nevertheless, the findings affirm that the incorporation of wind power improves both economic and environmental conditions compared to the thermal-only baseline. This scenario further illustrates ZOA's flexibility in controlling dispatch under uncertainty, showcasing its resilience in hybrid systems with dynamic renewable production.

Table 3: Hourly Optimal Results by ZEBRA Algorithm for Case 3 (Thermal+Wind).

Hour	P1 (MW)	P2 (MW)	P3 (MW)	P-Thermal (MW)	Fuel-Cost ($/hr)	Emission (Kg/hr)	CEED ($/hr)

Source: Aurthors, (2026).

Case 3 presents a 30 MW wind power system, yielding fluctuating but significant contributions that mitigate heat production. During the third hour, wind generation yields 9.27 MW in response to a demand of 155 MW, resulting in a reduction of PT to 145.73 MW. During windy periods, namely during hour 8, wind generation reaches a high of 25.56 MW, while power transmission decreases to 154.44 MW to meet a demand of 180 MW. During hour 9, wind generates 20.58 MW, while thermal provides 189.42 MW to satisfy the 210 MW demand. Despite fluctuations in wind power, which decreases to only 0.17 MW during hour 20, it continuously contributes to diminishing thermal dependence over many hours, as seen in Table 6. This scenario underscores the unpredictability of wind while illustrating how its incorporation might result in significant savings in thermal dispatch.

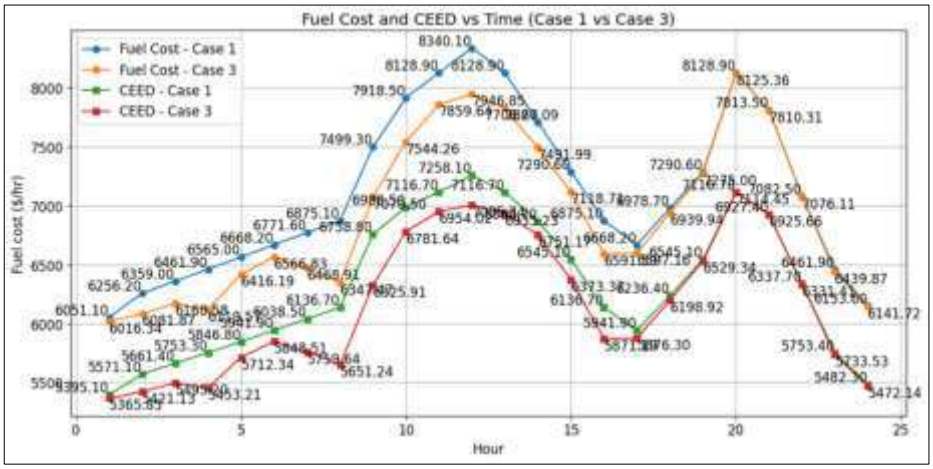

Figure 3: Hourly Variation of Fuel Cost and CEED – Case 1 and Case 3.
Source: Authors, (2026).

Figure 3 illustrates the hourly fluctuations of Fuel Cost and CEED (Combined Economic Emission Dispatch) for Case 1 and Case 3 during a 24-hour period. The study utilizes the Zebra Optimization Algorithm (ZOA), which proficiently optimizes both cost and emissions in dynamic load scenarios. In Case 1, which depends only on conventional thermal units, both fuel costs and CEED show steady increases during peak demand hours, peaking in the 11th hour when fuel costs approximate $8128.90/hr and CEED nears $7895.69/hr. This situation indicates elevated operating expenses and environmental repercussions resulting from the lack of renewable energy sources.

In contrast, Case 3 includes wind power production, resulting in substantial improvements in system performance. Despite the gasoline cost in Case 3 seeing significant peaks (particularly reaching 8340.10 $/hr), the CEED values remain lower and more steady than those in Case 1. This illustrates that the incorporation of wind power mitigates emission-related expenses, despite potential temporary increases in fuel prices resulting from fluctuations in wind availability or supplementary thermal assistance. Figure 3 illustrates that the ZOA-based solution with wind integration in Case 3 attains superior environmental and economic equilibrium relative to the traditional configuration in Case 1. The findings highlight the benefits of hybrid renewable systems and sophisticated optimization methods in reducing total dispatch costs and emissions.

IV.4 CASE STUDY 4: THERMAL + PV + WIND SYSTEM

Case 4 incorporates 40 MW of PV and 30 MW of WP into the generating mix, mimicking a system mostly powered by renewable energy. This hybrid configuration significantly decreases the net burden on thermal generators, enabling a more environmentally friendly and economical dispatch approach. Table 4 illustrates that, with Pg1 and Pg3 fixed at 37 MW and 50 MW respectively, the ZOA dynamically modifies Pg2 to equilibrate the fluctuating net demand resulting from the integrated renewable profiles. This cooperation facilitates the more effective usage of thermal units. The system attains a minimum CEED value of ₹144,486.40 per hour, with a fuel expenditure of ₹162,242.50 per hour and a reduced emission cost of ₹3,571.30 per hour. Of the four scenarios, this hybrid integration provides the most significant improvement in both economic and environmental goals. These findings illustrate ZOA's resilience in managing intricate, uncertainty-driven dispatch situations and underscore the promise of synchronized renewable energy integration in forthcoming power systems.

Case 4 exemplifies a comprehensive hybrid system, using 40 MW of photovoltaic energy and 30 MW of wind power in conjunction with thermal generating. This yields the most efficient power dispatch configuration. In hour 10, the total renewable energy (PV: 39.37 MW, Wind: 17.85 MW) provides 57.22 MW of a 230 MW demand, enabling PT to decrease to 172.78 MW. During hour 13, photovoltaic systems generate 31.94 MW and wind energy contributes 14.35 MW, resulting in a total of 46.29 MW, therefore allocating 193.71 MW for thermal units. Even during the early hours, such as hour 3, the wind production of 9.27 MW supplements the thermal output of 145.73 MW to satisfy the 155 MW requirement shown in Table 6. This scenario illustrates the most effective power equilibrium, reducing fuel consumption and emissions while satisfying the same demand via optimum renewable resource deployment over a 24-hour period.

Table 4: Hourly Optimal Results by ZEBRA Algorithm for Case 4 (Thermal+PV+Wind).

Hour	P1 (MW)	P2 (MW)	P3 (MW)	P-Thermal (MW)	Fuel-Cost ($/hr)	Emission (Kg/hr)	CEED ($/hr)

Source: Authors, (2026).

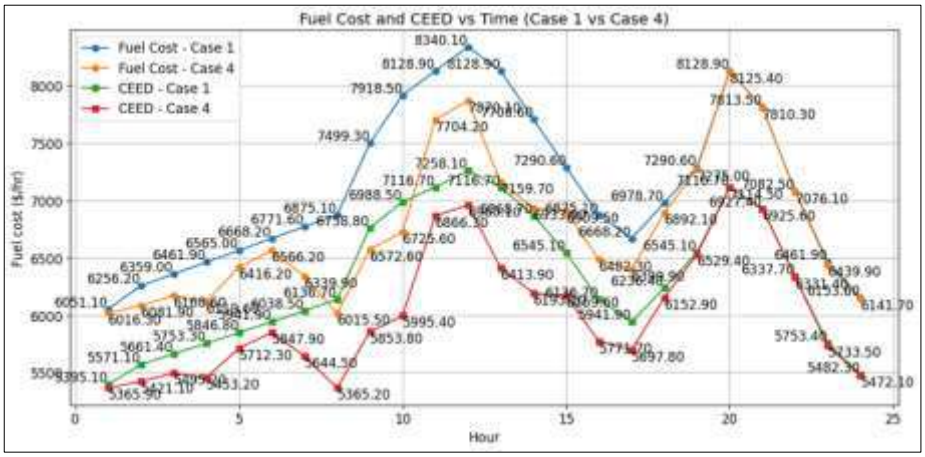

Figure 4: Hourly Variation of Fuel Cost and CEED – Case 1 and Case 4.
Source: Authors, (2026).

Figure 4 illustrates the hourly fluctuations of Fuel Cost and CEED (Combined Economic Emission Dispatch) for Case 1 and Case 4 during a 24-hour duration. The dispatch optimization is conducted with the Zebra Optimization Algorithm (ZOA), which effectively balances economic and environmental goals. In Case 1, including just thermal units, both fuel cost and CEED exhibit an upward trajectory during peak demand times, culminating at hour 11, when the fuel cost attains 8128.90 $/hr and CEED peaks at 7895.69 $/hr. This scenario demonstrates elevated operational and emission-related expenses resulting from the lack of renewable energy sources. Conversely, Case 4 integrates both photovoltaic (PV) and wind energy production with traditional units. This hybrid system leads to a substantial decrease in CEED values, especially during periods of solar and wind activity, while the fuel costs also show reduced peaks.

For instance, despite the fuel cost in Case 4 peaking at 8340.10 $/hr, the CEED stays much lower than in Case 1 over the same hours—underscoring the emission-reducing impact of clean energy integration. The comparison distinctly demonstrates that the incorporation of photovoltaic and wind energy in Case 4 contributes to the stabilization of the CEED curve, particularly during periods abundant in renewable resources (e.g., daytime for photovoltaic), thus mitigating environmental impact despite ongoing fluctuations in fuel costs resulting from variability in renewable generation. Figure 4 substantiates the advantages of using hybrid renewable sources and employing ZOA for optimum dispatch. It yields a cost-efficient and ecologically friendly solution relative to a solely thermal system, as shown in Case 1.

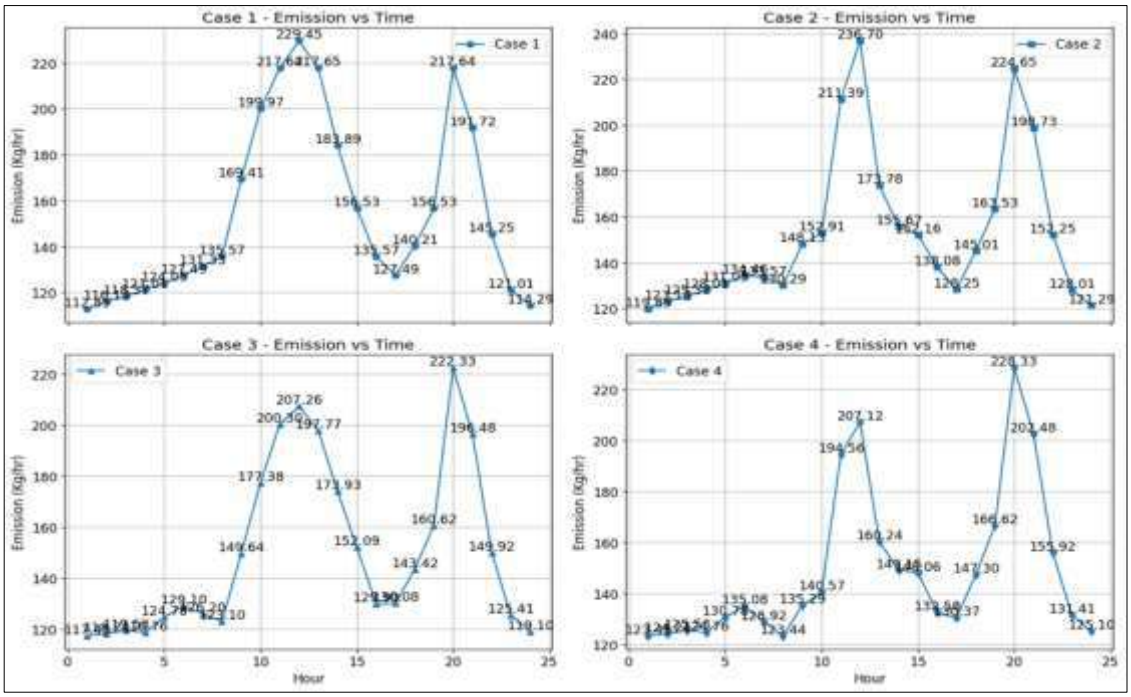

Figure 5: Hourly Variation of Emission – Case 1 to Case 4.
Source: Authors, (2026).

Figure 5 depicts the fluctuation of emissions (kg/hr) over a 24-hour duration across four distinct scenarios—Case 1 (thermal only), Case 2 (thermal + PV), Case 3 (thermal + wind), and Case 4 (thermal + wind + PV). This comparison emphasizes the ecological consequences of diverse energy generating methods across various system configurations. In Case 1, emissions are persistently increased throughout peak load hours, peaking at 237.60 kg/hr at hour 11 and sustaining high levels until around hour 18. This indicates a substantial dependence on thermal units, which are major sources of emissions. Case 2, which incorporates Plug-in Electric Vehicles (PEVs), demonstrates a marginal decrease in emissions during some hours while maintaining a comparable peak pattern to Case 1.

The highest emission is 237.60 kg/hr, suggesting that while PEVs may assist with load balancing, their effect on emissions is limited unless they are fuelled by clean energy. In Case 3, which includes wind energy, a significant reduction in emissions is shown during periods of wind activity. The peak is inferior to Cases 1 and 2, reaching a maximum of 222.33 kg/hr, and the total emissions are more evenly distributed, hence reducing the environmental burden during critical demand times. Case 4, which integrates both photovoltaic and wind energy, has the most substantial decrease in emissions. Although it still attains 222.33 kg/hr, the frequency and length of high-emission intervals are significantly reduced. Emission levels are more stable and significantly reduced during daylight hours, demonstrating the beneficial effects of hybrid renewable integration. In conclusion, Figure 5 unequivocally demonstrates that the shift from a traditional thermal system (Case 1) to a hybrid renewable-based dispatch system (Case 4), especially when enhanced through intelligent algorithms, leads to a significant decrease in emissions and fosters a more sustainable energy operation.

Table 5: Comparison of CEED Costs ($) across Optimization Methods.

Method	Case 1(TU's)	Case 2 (TU's+PV)	Case 3 (TU's+W)	Case 3 (TU's+PV+W)

Source: Authors, (2026).

Table 5 provides a comparative study of CEED expenditures across four dispatch scenarios using different optimization methodologies. These scenarios align with four case studies that sequentially integrate renewable energy sources commencing with thermal units only (Case 1), then including photovoltaic (PV) systems in Case 2, wind power (WP) in Case 3, and ultimately a hybrid amalgamation of both PV and WP in Case 4. In Case 1, the exclusive use of thermal units results in standard algorithms such as DE, PSO, GWO, SOS, and WOA yielding CEED values of $202,000. Conversely, the Zebra Optimization Algorithm (ZOA) significantly decreases the cost to $151,475, underscoring its efficacy in the absence of renewable support. In Case 2, the incorporation of a 40 MW photovoltaic system yields little enhancement via conventional approaches (~$2.97 million), however ZOA reduces the CEED by roughly 50% to around $1.48 million, demonstrating its efficacy in solar integration.

Case 3 presents a 30 MW wind power plant, which provides more variability. Notwithstanding this, ZOA sustains a minimal CEED of $1.47 million, surpassing other procedures that produce values of $2.3 million. In the concluding Case 4, which combines both PV and WP, ZOA attains optimal performance—yielding the lowest CEED of $144,486.40, with a decreased fuel cost of $162,242.50 and emissions of 3,572.21 kg/hr. In contrast, several approaches provide CEED values beyond $3.25 million. An analysis of all four situations underscores the combined influence of efficient renewable integration and sophisticated optimization. From Case 1 to Case 4, ZOA realizes a 4.84% decrease in fuel expenses, a 4.97% reduction in emissions, and a 4.62% enhancement in CEED value. These findings validate that the integration of thermal generating with photovoltaic and wind energy within a zonal optimization approach not only optimizes economic dispatch but also improves environmental results. Its capacity to handle system unpredictability and maximize various goals renders ZOA a dependable and high-performing solution for contemporary power systems.

Source: Authors, (2026).

Table 6 illustrates the hourly power equilibrium across the four dispatch scenarios, demonstrating how thermal (PT), photovoltaic (PV), and wind power (WP) jointly satisfy system demand. As renewable integration advances from Case 1 to Case 4, a distinct decrease in PT is seen during periods of elevated renewable availability, indicating a shift towards cleaner energy. Photovoltaic systems reliably mitigate thermal demand during daylight, providing steady and emission-free assistance, whilst wind energy, despite its variability, contributes significantly during times without solar generation.

Their collective integration in Case 4 results in the greatest decrease in PT, illustrating the synergistic advantages of hybrid renewables. This improves fuel economy and reduces pollution. The findings confirm ZOA's dynamic flexibility in allocating generation according to renewable availability. Advantages include less fuel expenses, decreased emissions, and enhanced sustainability. Disadvantages include reliance on weather-dependent sources, necessitating astute scheduling to address fluctuations and maintain dependability. Table 6 substantiates ZOA's efficacy in attaining balanced, cost-effective, and ecologically sustainable energy dispatch.

V. CONCLUSION

This study indicates that the Zebra Optimization Algorithm (ZOA) outperforms various conventional metaheuristic methods, including DE, PSO, GWO, SOS, and WOA, in tackling the multi-objective CEED problem. In the first scenario, which just encompasses thermal units (TUs), the system registers the highest fuel expenditure (170,476 dollars per hour), emissions (3711.05 kg per hour), and a CEED of 151,475 dollars per hour. This data illustrates the constraints of conventional generation. The use of renewable energy sources leads to a progressive improvement in performance. The CEED for Case 2, which includes PV, decreases to $148,343.07 per hour, representing a substantial reduction.

Case 3, which integrates wind power, attains a reduced CEED of $147,886.74 per hour, notwithstanding the inherent unpredictability of wind conditions. Case 4, which employs both solar and wind energy, achieves a decrease in CEED to $144,486.40 per hour, fuel expenses to $162,242.50 per hour, and emissions to 3,571.3 kg per hour. Despite the challenges associated with the variability of renewable sources, their coordinated integration under ZOA enhances cost-efficiency, reduces emissions, and markedly improves sustainability. The study results indicate that ZOA is a dependable and adaptable approach for modern power systems. It facilitates optimal dispatch decisions in dynamic scenarios involving many energy sources.

ABSTRACT

The fast growth of the Internet of Things IoT technology generates extraordinary stress on network systems because it requires improved traffic performance and strengthened security measures. The central control capabilities of Software-Defined Networking (SDN) receive limited intelligence from conventional controllers when dealing with evolving network conditions and security threats. This study designs a protected and knowledgeable SDN routing framework for IoT traffic real-time optimization by integrating machine learning algorithms for path optimization and anomaly detection. The proposed method embeds two predictive models within the SDN controller: Light Gradient Boosting Machine (Light-GBM) for performance-aware routing optimization, and XG-Boost for real-time detection of malicious or anomalous flows. The system uses a hybrid decision-making pipeline for Quality of Service QoS measurement elements, such as latency, congestion level, and bandwidth utilization, together with security feedback like threat scores, blacklist status, and intrusion detection alerts. The system was tested by the research team using a simulated network infrastructure that emulates the common pattern of IoT traffic. The designed competitive metrics were latency, throughput, packet loss rate, accuracy of anomaly detection, false positive rate, and controller decision latency. Experimental findings suggest that the suggested SDN controller solution has a higher throughput and faster operations, with a difference to a baseline controller system of 42.7 and 49.7, respectively, and a 75.9% lower packet loss. The XG-Boost model gave an accurate detection rate of 99.8 percent with a false positive rate of 0.2 percent, with a controller decision time of 23.7 ms, which is compatible with real-time operations. Experimental evidence shows that the introduction of machine learning into SDN controller systems increases security operations in IoT and network routing implementation. This system demonstrates scalability together with modularity for direct implementation in operational SDN platforms, including POX and Ryu. The upcoming research will focus on implementing live network traffic while adapting models in real-time and deploying them in production IoT infrastructures.

I. INTRODUCTION

As the Internet of Things grows exponentially, IoT device numbers force network managers to find more efficient methods that guarantee security [1-5]. Because traditional network architectures fail to handle IoT dynamic requirements, SDN has emerged to be the adopted solution [6-9]. SDN splits the control and data planes into separate entities through central control and programmatic capabilities needed for handling IoT networks' complex requirements and growth scale [10], [11]. Leadership processes within SDN require adjustment to incorporate machine learning ML techniques into SDN controllers [12], [13].

Lately, machine learning algorithms have shown impressive results on different types of applications [14], [15]. The integration of ML techniques must include three critical requirements: real-time processing ability, data management of large quantities, and model adaptability to changing network situations [16-18]. SDN security frameworks demonstrate weaknesses in their ability to provide thorough combined solutions for routing optimization as well as anomaly detection, since these capabilities exist in isolation, resulting in security risks [19], [20]. A new SDN framework merges ML models for both intelligent routing operations and a real-time anomaly detection system [21], [22]. XG-Boost is used in the system to identify abnormal traffic behavior, while Light-GBM assists with routing decision predictions. The integration results in a system that enhances network functionality in terms of both performance and security qualities of IoT infrastructure. Our key contributions are:

1. The development of an ML-Enhanced SDN Framework combines Light-GBM and XG-Boost models into the SDN control plane through a framework to execute optimized routing and anomaly detection functions.
2. The framework operates in real time to handle network data during dynamic IoT traffic situations, thus guaranteeing prompt responses.
3. Our assessment of the framework's performance utilizes extensive simulation results to evaluate it through latency measurements, throughput attainment, packet loss avoidance, detection precision measurements, and false positives rates evaluation.
4. The proposed solution has been purposefully designed to expand according to increasing network requirements and handle traffic pattern adjustments, which guarantees sustained efficiency.

The next sections of this paper are divided into the following: Section 2 analyzes the existing literature about integrating SDN and ML technologies. The methods and materials that construct our framework are detailed in the third section. The fourth section of this paper presents both experimental results and accompanying analysis. Section 5 analyzes the results against existing research. Finally, section 6 concludes the paper and outlines the future research directions.

II. LITERATURE REVIEW

SDN development has created powerful changes in network management by promoting scalability while improving security features for IoT environments [23], [24]. Research investigations now explore how ML methods function inside SDN controllers for boosted traffic optimization as well as threat protection methods [25], [26]. The researchers presented in [27] a fast threat recognition system for 5G SDN platforms that uses a PSO-GRUGAN hybrid model as its core methodology. The detection system improved performance but restricted its application to 5G networks exclusively, with minimal capability for IoT-based SDN framework analysis. The study by [28] performed an extensive review of SDN security tools, including traditional and ML as well as blockchain-based approaches, yet did not supply experimental evidence for their investigated techniques. In turn [29] analyzed the existing SDN controller landscape for enhancing IoT security and determined centralized SDN approaches to be the most vital architecture.

The authors failed to develop practical deployment frameworks using their theoretical approach. By [30] demonstrated how machine learning techniques enhance SDN traffic classification results, while this research did not integrate anomaly defense or routing performance improvements into the process. The work of [31] created efficient routing through the implementation of deep reinforcement learning for dynamic SDN traffic routing. The evaluated routing performance of the solution improved, but security measures related to anomaly detection and path trustworthiness evaluation remained a weakness. In the same approach, the research team at [32] created a deep learning hybrid system to find abnormal traffic patterns in SDN networks, which brought better detection capabilities yet added excessive complexity that exceeds IoT lightweight needs. The advanced IS2N, an intent-driven SDN security system, becomes the next SDN generation security system according to [33], who implemented blockchain capabilities into it.

The system strengthened trust mechanisms and enabled auditing functions, although it encountered difficulties that affected its scalability in IoT deployments at scale. A cross-domain intelligent routing method for SDN based on multi-agent reinforcement learning was developed by. [34] to improve network throughput at the same time it reduced latency. The deployment capabilities of their multiple agents in constrained IoT networks are restricted by excessive coordination complexity. Anomaly detection for SDN-driven micro service systems using Graph Neural Networks (GNNs) resulted in providers that detected threats at the service-level, according to [35]. The improved processing requirements of GNNs generate challenges regarding their practical use in real-time situations. By [36] researched DDoS threats in SDN networks by investigating attack patterns and defense methods. Yet, they presented minimal practical frameworks and materials for ML-based and deep learning opposition techniques.

All surveyed studies presented three main disadvantages: multiple optimization strategies and security approaches cannot operate concurrently, complex computations are inappropriate for real-time IoT networks, and the security systems are separate from the network management process. In light of these challenges, this research has advanced this field, but there is still a requirement for SDN frameworks that deliver real-time security intelligence alongside performance optimization capabilities. The proposed work develops a new SDN framework that implements Light-GBM routing optimization and XG-Boost anomaly detection through direct implementation in the controller decision pipeline. The proposed system seeks to manage IoT traffic intelligently throughout three essential aspects, including traffic management, security standards maintenance, and real-time operation. A detailed description of materials and methods relating to the proposed solution appears in the next section.

III.METHODS AND MATERIALS

The research establishes an intelligent methodology to improve SDN routing effectiveness and safety, specifically for IoT platforms. The proposed system implements two connected machine learning pipelines through which it optimizes routing performance and detects security threats in real-time. The methodology starts by developing synthetic data, which comprises 10,000 samples that model traffic sessions through SDN switches. The collected dataset includes quantitative network performance information (latency, throughput, packet loss, hop count etc.) and security measures (IDS presence and numbers of security incidents and blacklist scores).

Feature engineering techniques generate three new metrics, namely, efficiency score, loss rate, and threat score, to improve the predictions by quantifying traffic flow risks. The dataset includes two labels per data point: congestion label and anomaly label, which are derived from heuristic evaluation criteria. The rare yet critical conditions within class imbalance are treated using the Synthetic Minority Over-Sampling Technique (SMOTE). The application trains two classifiers using Light-GBM for routing decisions involving threat risk assessment and XG-Boost for detecting network anomalies. All generated outputs are exported after analysis ends for use in ongoing studies and reproducibility needs. Figure 1 illustrates the methodology overview step by step.

III.1 NETWORK TOPOLOGY DESCRIPTION

The hierarchy of the designed Software-Defined Networking (SDN) architecture features a single centralized control element connected to 5 network switches and 20 end-host devices. This design depicts an IoT environment built with scalable SDN modules. The SDN controller positioned at the top layer of the network functions as the intelligence hub by viewing all network infrastructure elements while performing dynamic management of real-time forwarding actions, security rules, and routing adjustment. A single point of connection between the five switches enables the SDN controller to control the entire data plane through a flat control layer. The SDN controller, as shown in Figure 2, operates each one of the five switches (S1 to S5) through direct connection. The switches are simply forwarding points that transmit data packets through the controller to the end devices connected to it.

The data plane is composed of 20 hosts, H1 to H20, that are evenly distributed among the five switches at four hosts each. The centralized location of the switches allows for an equal flow of data to be relayed between connected devices and also to distribute the various IoT devices within the network to simulate real-world scenarios. It involves having independent layers in its network design, which helps in the enhancement of routing performance, monitoring, and detecting anomalous events. The layout structure enables the SDN controller to run the XG-Boost and Light-GBM machine learning model that can be used to optimize traffic in real time and fine-grained control. This is made possible by the smart status of the controller implementation of the research.

III.2 DATASET GENERATION

The design and testing of the smart SDN controller needed to use synthetic data to model a variety of network traffic and security events common to software-defined IoT networks. The simulated data is filled with network traffic of normal and malicious nature, so it can offer both appropriate training data to two distinct models, one focused on the optimal route optimization, and the other on the identification of the abnormal patterns. Each record of the data set represents distinctive flow entries with performance attributes, congestion indicators, and security risk measurement points. In the data generation, synthetic processes enable the various flow properties, such as packet rate, throughput, path delay, and jitter, to be variables when modelling the traffic of IoT devices in various load conditions. The use of queue length, along with the use of a switch, enables the measurement of congestion conditions. The security-awareness mechanism provided two features, which comprised a normalized security scoring system and a binary flag on normal or potentially malicious flow identification.

The testing and training sections comprise 80% and 20% of the total 10000 samples found in the dataset. The routing decision label takes values between 0 to 1 and 2, which respectively correspond to shortest path, secure path, and load-balanced routing controller policies. The anomaly detection labels used 0 or 1 values that were generated through the injection of synthetic security threats. The training phase included the SMOTE oversampling technique due to the standard class imbalance problem that cybersecurity datasets present. Table 1 sections detail every dataset attribute with its mode type and magnitude extent, along with their measurement unit specifications. The selected features and engineered elements within the models offered dual functionality; they served to optimize routing based on network performance while additionally being able to detect security threats through abnormal behavior.

All numeric features within the 10,000-sample synthetic SDN dataset are shown through histograms in Figure 3. The distributions show how the main network metrics that affect routing and detect anomalies statistically behave and vary in value. The features bandwidth-utilization, link-quality, and routing-efficiency display uniform distribution patterns along with other characteristics that help maintain balanced training across all spectrums of values. The features of latency and threat-score follow bell-shaped Gaussian patterns, which demonstrate typical network condition variation in their distributions.

Loss-rate and efficiency-score demonstrate considerable skewness because they both have rare occurrences of their lowest values around zero for network packet loss and network efficiency outcomes. Training models require special attention to class imbalance problems with binary and categorical features, including congestion-label, anomaly-label, ids-present, hop-count, and security-incidents, since they demonstrate obvious label disproportion. This demonstrates why SMOTE is crucial. The feature distributions presented in Figure 3 uphold the design purpose, which creates realistic SDN traffic conditions combining heterogeneous traffic while enabling diverse levels of load and congestion and threat scenarios to train resilient machine learning models.

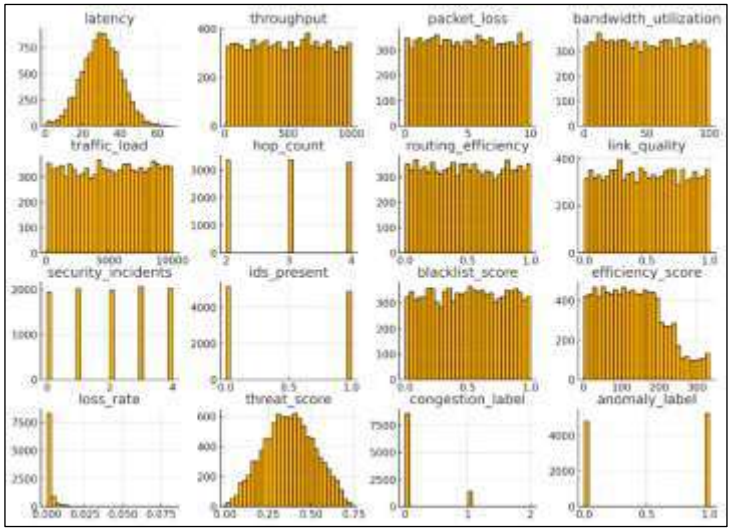

Figure 3**:** Distributions of Numeric Features in the SDN Dataset.
Source: Authors, (2026).

All numeric dataset features display their corr0elation degrees in Figure 4. The heatmap depicts the linear correlation levels between each feature pair by using values extending from -1 for completely negative to +1 for completely positive correlation.

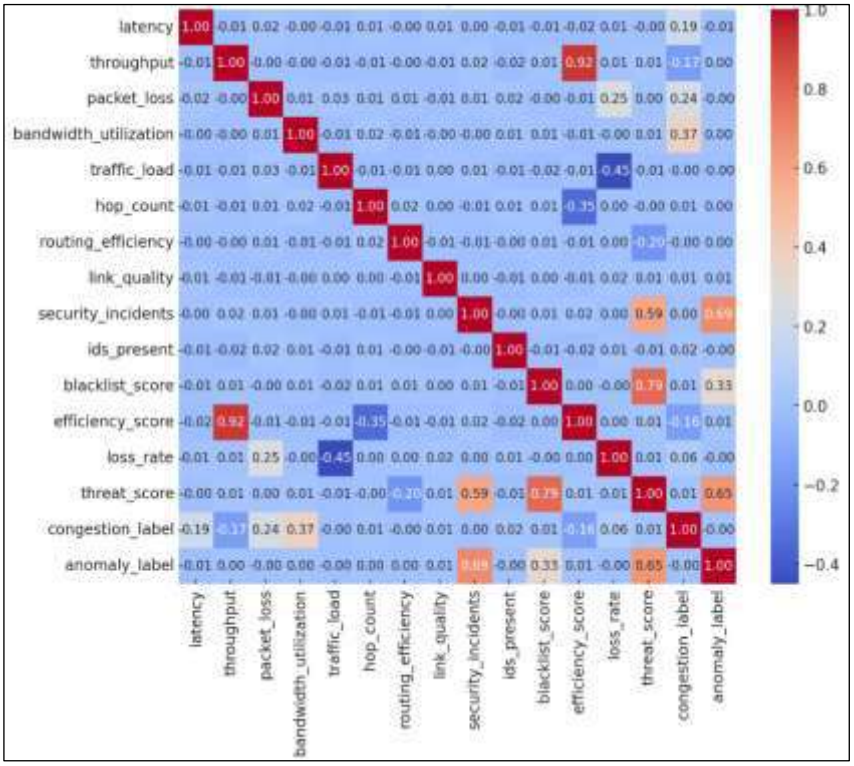

Figure 4: Pearson Correlation Heat Map of Numeric Features in the SDN Dataset.
Source: Authors, (2026).

Several vital associations become visible among different pairs of variables:

- Higher data transfer rates show a direct correlation with network efficiency score, which results in a value of 0.92.
- The blacklist-score shows strong positive relationships with threat-score (0.79) and anomaly-label (0.69), so it stands out as a key predictive measure for malicious activities.
- Analysis has shown that increased load caused by traffic translates into increased loss of packets (0.25 relation), which also results in reduced routing efficiency (-0.45 relation).
- Anomaly-label has been proven by the analysis to exhibit positive relationships with security incidents and both blacklist-score and threat-score, thus demonstrating its value in intrusion detection modeling.

The heat map reveals that most features have weak correlations, which validates the assumption that features have independent relationships. Ensemble learning models particularly benefit from this condition since XG-Boost and Light-GBM operate well under these circumstances.

III.3 ANOMALY DETECTION MODEL

The intelligent SDN controller implements anomaly detection as its main protective feature for identifying IoT traffic abnormalities and malicious activities before they cause harm. Because of its scalability, together with robustness and feature interaction interpretability, the XG-Boost classifier operates within the anomaly detection module through supervised machine learning to handle complex tabular network datasets. Training occurs on the labeled database segments utilizing anomaly-label as the reference point (0 denotes benign traffic, and 1 marks malicious or suspected traffic flows). The model detects threat patterns using threat-score together with blacklist-score and security-incidents, along with ids-present and network behavior metrics, latency loss-rate, and traffic-load. The chosen features demonstrated their connection to flood-based attacks, network scanners, spoofers, and exhaustion-related intrusions.The training set receives a synthetic extension of the minority class using SMOTE because security datasets show a natural class imbalance with many more benign flows than malicious flows to prevent model distinctiveness.

Metric performance evaluation of the model is conducted by applying stratified train-test splits of 80/20 on the data while using accuracy, precision, recall, F1-score, confusion matrix, and ROC-AUC score as assessment criteria. Experimental evidence demonstrates that an anomaly detection system based on XG-Boost yields exceptional detection accuracy together with low instances of false positives, which establishes its practicality for performing real-time security enforcement. The deployed model operates inside the controller to scan incoming network traffic, which alerts administrators about anomalies in addition to tagging suspicious network entries. The controller uses these alerts to activate security measures that include traffic isolation, flow blocking, and path rerouting to maintain a strong and secure network operation. The security layer safeguards IoT environments because IoT networks consist of various large devices that communicate through insecure platforms. When intelligence runs in the control plane, it converts passive network monitoring into active and AI-based cyber threat defensive measures.

III.4 ROUTING OPTIMIZATION MODEL

The routing optimization module operates as a core component of the intelligent SDN framework to determine real-time traffic forwarding paths. The proposed routing method deploys Light-GBM (Light Gradient Boosting Machine) as a supervised learning method to generate routing choices through performance and security-aware, and congestion features. The model receives training to estimate the three routing strategies included in the routing-label multi-class target variable:

- 0: Shortest path routing – minimal latency path.
- 1: The system selects routes that contain Intrusion Detection System IDS presence or reveal lower threat indicators as its primary choice.
- 2: The selection process enables routers to select less congested paths before considering path length.

The training data contains latency along with throughput and packet-loss statistics, as well as hopping links and link-quality information, together with routing-efficiency metrics and congestion-label ratings, and threat-score measures to teach the model efficient routing choices. All features together present an accurate picture of network performance and danger exposure during real-time operations. Before training the model, the dataset receives preprocessing, which includes SMOTE-based balancing along with feature selection implementations to enhance generalization. Using Grid Search GS with Cross-Validation CV enabled the execution of optimal hyperparameter tuning. The evaluation utilizes precision along with recall metrics by class, accuracy metrics, and macro-averaged F1-score, along with confusion matrices for visualization.

The Light-GBM model obtains its deployment space within the SDN controller system after completion of training. The controller uses real-time metrics from new flow events to input them into the model for obtaining predicted routing labels. The OpenFlow interface enables the controller to execute forwarding rules by using the prediction from the system. The system chooses routing schemes depending on the congestion where it would choose minimal-path routing and switch to secure-path routing in the event of threat and choose balanced routing in the event of network saturation. The addition of learning-based routing into the model provides three essential functions that surpass the conventional SDN rule-based operating concepts. This architecture facilitates the controller to offer real-time optimization and protection features of constantly evolving IoT systems, enabling it to be intelligent, fast in response, and security conscious.

III.5 SECURITY ENHANCEMENT TECHNIQUES

A number of security enhancements incorporated into the design stage would make sure that the SDN controller is capable of achieving the highest possible performance capacity and safeguard the network against threats. The implementations come with improvements, which begin with the labeling of the data and culminate in the security deployment and privacy-friendly learning processes.

III.5.1 Security-Aware Feature Integration

The research team created the dataset by adding features that capture the modern security threats often found in SDN-enabled IoT systems. Table 2 illustrates the security-related features used for anomaly detection and routing optimization.

Table 2: Security-Related Features Used for Anomaly Detection and Routing Optimization.

Feature name	Type	Description
Threat-score	Float	A normalized score (0–1) indicating the likelihood of malicious activity in a flow.
Blacklist-score	Float	Represents whether the source/destination is blacklisted or suspicious.
Security-incidents	Integer	Count of previous security incidents associated with a given switch or path.
Ids-present	Binary	Indicates presence (1) or absence (0) of an IDS on the forwarding path.
Anomaly-flag	Binary	Ground truth label: 1 for malicious traffic, 0 for normal. Derived from attack simulation or IDS triggers.

Source: Authors, (2026).

Through these features, the model integrates threat detection ability with path routing modification, which prefers monitored and historically secure routes.

III.5.2 Imbalanced Data Handling with SMOTE

Network threats occur less frequently than regular traffic, which results in class imbalance because malicious samples appear less often than benign ones. The Synthetic Minority Over-Sampling Technique SMOTE algorithm was used to balance the training data by creating additional synthetic minority class samples. SMOTE produces synthetic copies of minority class samples (malicious flows), which it creates by analyzing their feature domains to provide the classifier with a balanced training dataset of diverse examples. Implementation of SMOTE improved both the malicious class F1-score and recall rate of the model.

III.5.3 Hyperparameter Tuning with Grid-Search CV

Model robustness achieved its optimal state using Grid-Search CV when it selected the best hyperparameters for the XG-Boost and Light-GBM models. There was a scientific experiment on learning rate and number of estimators, as well as depth parameters. The model tuning method assisted the models in sustaining generalization features and remaining unreceptive to the non-malicious part of the data.

III.5.4 Privacy-Preserving Model Training

The artificial dataset uses privacy-saving measures that simulate the real operation constraints. When dealing with sensitive user information, the application of the methods of different levels of privacy and federated learning architecture would become possible. The system would be able to train without exposing raw traffic data to the controller by implementing these distributed learning approaches. These added features make the smart SDN controller capable of remaining robust while providing clear visibility and security preparedness. The system surpasses threat reactions by actively choosing performance-quality-privacy balanced actions while working in crowded networks or vulnerable areas.

III.6 POX CONTROLLER INTEGRATION

The proposed intelligent SDN framework requires implementation integration between a customized POX controller and both XG-Boost-based anomaly detection model and Light-GBM-based routing optimization model. By uniting these models with a customized POX controller, the system acquires the ability to handle network traffic and autonomously detect security threats, together with congestion patterns.

III.6.1 POX Controller Architecture

The event-driven controller framework POX receives modifications through the addition of these components in its Python development. Table 3 illustrates the proposed POX modification components.

Table 3: Functional Components of the Intelligent SDN Controller.

Module name	Function
Flow listener module	Monitors incoming traffic flows and extracts relevant features such as latency, congestion level, and threat indicators.
Model loader	Securely loads pre-trained ML models (XG-Boost and Light-GBM) and verifies their integrity using SHA-256 hash checks.
Decision engine	• Apply the anomaly detection model to classify traffic as benign or malicious. • Uses the routing optimization model to select the most suitable forwarding path based on real-time performance and security metrics.
Policy enforcer	Converts the decision engine's output into OpenFlow rules and installs them dynamically on the appropriate switches.
Logging system	Maintains logs of flow metadata, anomaly predictions, routing decisions, and mitigation actions for transparency and future analysis.

Source: Authors, (2026).

III.6.2 Real-Time Workflow

Figure 5 displays the entire decision-making real-time workflow that operates in the proposed intelligent SDN controller. The POX controller receives flow data from a new detection at a switch before executing a sequence of steps through feature extraction into anomaly detection, before performing routing optimization. Operational security measures can be put into effect by the controller through flow rerouting and malicious flow dropping, and it retains operation logs for both auditing requirements. The multi-stage pipeline serves both network management automation purposes and protects networks from threats in a proactive manner.

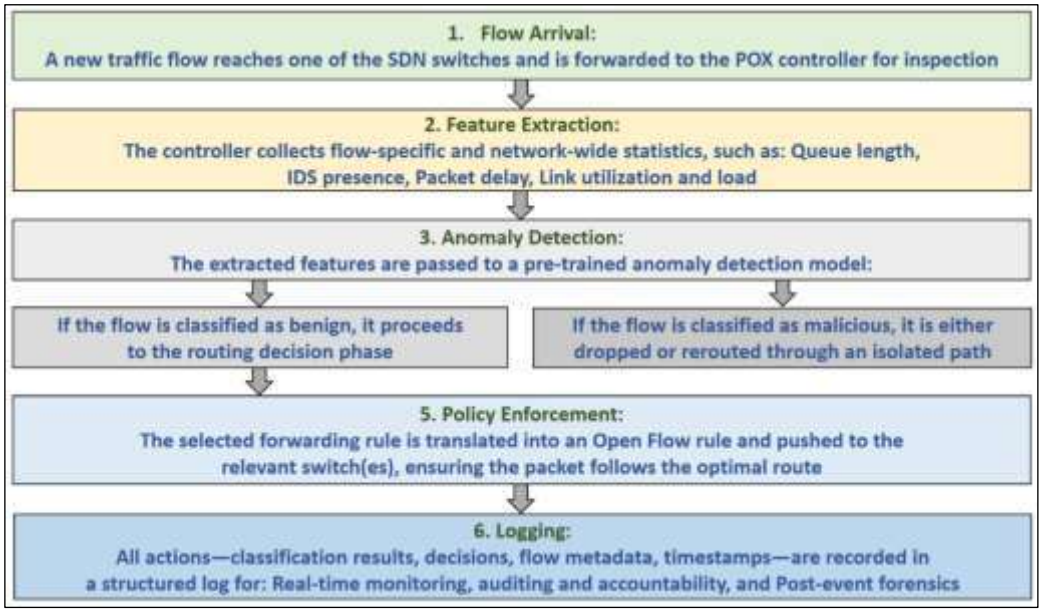

Figure 5: Real-Time Flow Handling Pipeline in the Intelligent SDN Controller.
Source: Authors, (2026).

The combination of a visualization layer in an SDN controller that incorporates machine learning detection for anomalies with improved routing brings about dynamic efficiency in real-time flow processing. The main work concentrates on smart flow management together with secure routing; however, the architecture design includes future expansion for live dashboard integration. The dashboard module is an interface that is used to receive real-time network events and routing decisions, in which anomalies and flow performance statistics are detected on the controller.

The controller has data output formats that allow easy integration with external applications, such as Streamlit, Plotly Dash, or Grafana. The design architecture that has been put in place provides the potential future enhancements to the network operators to enjoy interactive system monitoring, which enhances their visibility of flow behaviors such as threat response management and decision trail capabilities throughout the SDN infrastructure.

III.6.3 Security and Functional Advantages of the Proposed System

Application of machine learning technology to SDN control planes gives both performance improvement and security defense requirements. The POX controller stores the ML models encrypted in a directory that can only be read with limited access by the user. With this implementation, the possibility of harmful alterations is minimized when the model is poisoned in case of malicious modifications. Every decision made by the controller, anomaly notifications, and routing preferences are logged with detailed logs that include accurate times and model predictions, routing specifications, and enforcement policies. These logs are audited and enhance transparency as these logs facilitate compliance requirements and enable a forensic analysis.

In case anomalies occur, the system has optional triggers that allow the system to follow the protocols, which comprise rerouting via quarantine routes along with administrative alerts or interactions with external security structures.The controller evolves to a more sophisticated control mechanism of controlling switchover beyond being a mere switchover controller into a smart threat-based framework. These new controls render SDN environments to be intelligent systems that are security-driven. The system employs real-time data feeds to decide on its own and ensure performance accomplishments and threat mitigation operations. Such a structure will appear as an independent SDN solution that is self-optimizing and specifically targets complex systems with strong security requirements in the contemporary era of IoT.

The combination of traditional quality of service (QoS) metrics, such as latency, throughput, and packet loss with current security assessment metrics such as threat ratings and blacklisting status as well as a history of historical security events is used to implement intelligent routing in our system. The algorithm takes two input layers, on which it achieves a Light-GBM machine learning optimization model, which selects among all routing choices. The routing paths are evaluated in the model by an active scoring process, which balances between the performance requirements and security alertness factors. Routes that have low latency will have a lesser priority when traversing security-weakened nodes or those that lack adequate intrusion detection systems (IDS).

Routes that are longer than usual, though, offer greater security, and stability is the route to which one would prefer to go when the conditions of the security threat are more severe. This capability enables the system to make intelligent routing choices that ensure the efficiency of the operation in both normal and hazardous conditions in the network. SDN controllers are not limited to reacting to traffic, but they also anticipate threats to prevent weak paths and redirection of data flow through the least congested locations of dual security protection. SDN develops an auto-system that is security-oriented and offers the best performance to IoT-based critical networks and protective requirements.

III.7 PERFORMANCE METRICS

There is a comprehensive set of performance indicators to evaluate the proposed, security-aware SDN routing system that is enhanced with ML. The evaluation system adopts the systematic grouping that entails four large measurement groups: Network Performance, Machine Learning Evaluation, Security Effectiveness, and System Responsiveness. The performance measures are grouped into four distinct groups to examine various operational aspects of the system framework.

The SDN topology is assessed by the network performance metrics, which assess the delivery of traffic in an efficient manner, irrespective of the changing network loads or the levels of congestion. The measures of machine learning evaluation are used to measure the accuracy the effectiveness, and robustness of anomaly detection and routing models to determine their suitability in path evaluation. Security metrics test whether systems have the capability of systems to identify dangers beforehand, before making secure routing choices without compromising model integrity. The measurements of system responsiveness are used in determining the speed and efficiency of the POX controller to process new network flows and events that give evidence of functionality to operate in real time. As a way of assisting in interpretation, but showing the hierarchical location of these metrics in the whole SDN context, these metrics can be found in Figure 6 in the form of a classification tree.

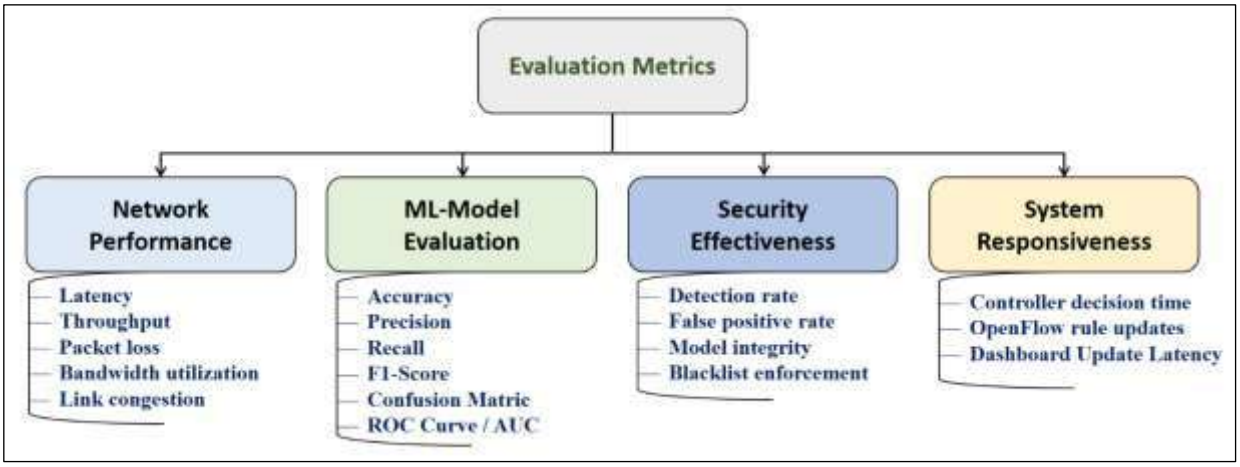

Figure 6: Evaluation Metrics in the Proposed Secure SDN Framework.
Source: Authors, (2026).

The metrics reveal objective evidence about system effectiveness as well as its ability to maintain network performance, routing intelligence, and security enforcement functionality. The network performance metrics examine the system's data delivery efficiency throughout all traffic scenarios. Anomaly detection and routing models obtain validation through machine learning evaluation metrics to prove their accuracy levels and to verify their generalization properties. Security metrics help the system detect threats while protecting its predictive models, while also avoiding risky paths effectively. The system-level metrics evaluate how promptly the POX controller reacts to new flows and anomalies, as well as its operational overhead. Table 4 presents thorough details of performance metrics by specifying definitions and functional thresholds necessary for system behavior evaluation.

Table 4: Performance Metrics: Definitions, Thresholds, and Evaluation Significance.

Metric	Description	Threshold
Latency (ms)	Time taken for a packet to travel end-to-end through the selected path	≤ 50 ms
Throughput (Mbps)	Total amount of successful data delivery per unit time	Higher is better
Packet Loss Rate (%)	The proportion of packets lost or dropped due to congestion or rerouting	≤ 5%
Bandwidth Utilization (%)	Measures how much of the available link capacity is being effectively used	Higher is better
Link Congestion Score	Derived from switch queue lengths and buffer occupancy metrics	Lower is better
Accuracy	Overall correct prediction ratio for classification models	≥ 95%
Precision	Correct positive predictions among total positive predictions	≥ 95%
Recall	Correct positive predictions among all actual positives	≥ 95%
F1-Score	Harmonic mean of Precision and Recall; balances accuracy and completeness	≥ 95%
Confusion Matrix	Shows TP, FP, TN, FN for performance interpretation of classifiers	N/A
ROC / AUC	The area under the ROC curve, measures binary classification performance	≥ 0.95
Detection Rate (DR)	Percentage of true attacks that are successfully detected	≥ 95%
False Positive Rate (FPR)	Percentage of normal traffic incorrectly flagged as malicious	≤ 5%
Model Integrity (SHA-256)	Ensures deployed ML models have not been tampered with	SHA-256 Verified
Blacklist Enforcement Score	Measures success in avoiding high-risk, blacklisted paths	≥ 90%
Controller Decision Time (ms)	Time from receiving a flow to enforcing a rule by the POX controller	≤ 50 ms
OpenFlow Rule Update Frequency	Number of flow-table changes per time unit, indicating reactivity	≥ 10 updates/min
Dashboard Update Latency	Time between a network event and its display on the dashboard	≤ 2 sec

Source: Authors, (2026).

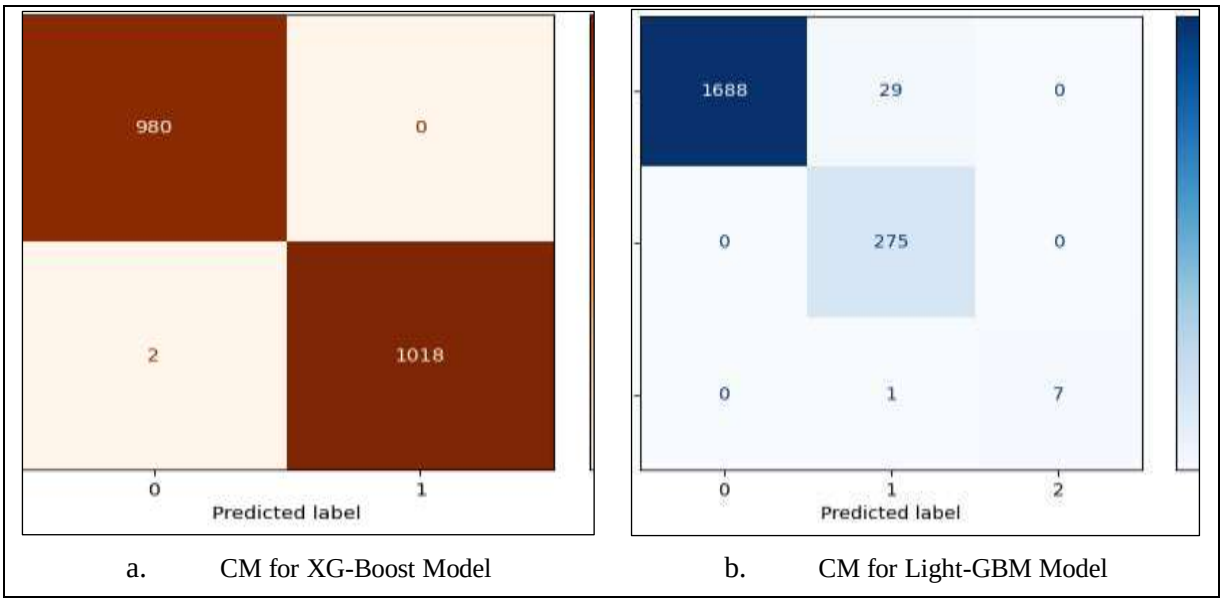
The set thresholds serve as primitive benchmarks, which allows gauging the effectiveness of the system, as well as its responsiveness. These values can be considered a reflection of the minimal operational requirements of the SDN and ML-based network environments since they enforce the system to meet the performance standards. The performance metrics that have set-thresholds include hard time constraints and upper throughput goals. The purpose of such performance checkpoints can be used to test system performance under real traffic conditions.

IV.EXPERIMENTAL RESULTS

In this section, the secure and intelligent SDN framework is analyzed in detail since it introduces machine learning models to SDN controller to provide real-time anomaly detection and optimization of security-aware routing. A simulated setup models IoT traffic conditions through artificial data containing benign as well as malicious network streams. Evaluation contains four core segments that match with methodology performance metrics about machine learning model testing and network performance, as well as security effectiveness and system responsiveness.

IV.1 MACHINE LEARNING MODEL EVALUATION

The proposed framework brings together XG-Boost for anomaly detection between malicious and benign traffic, followed by Light-GBM for optimal routing path multi-class classification in SDN environments. The training process for these models used 10,000 synthetically created IoT samples that monitored six flow-level indicators, including latency and throughput, and queue length alongside threat score and IDS status. The assessment relied on an 80/20 split for training and testing purposes while employing accuracy, precision, recall, F1-score, along with AUC as standard metrics to measure model performance.



A set of performance thresholds was established for model sensitivity and reliability evaluation by referring to industry best practices for security-aware real-time systems. Thresholds on accuracy and precision along with recall and F1-score were determined, and low predictive and detection accuracy was ensured at 95 percent. Besides accuracy levels of 0.95 AUC score with the binary anomaly detection model (XG-Boost), it was also accompanied by another criterion to guarantee successful traffic differentiation between normal and malicious events. These specified thresholds guarantee operational preparedness as well as deployment aptness of the models when utilized in intelligent SDN controllers under the condition of operating in IoT settings. Table 5 shows the assessment of the trained models.

Table 5: Model Evaluation Metrics.

Model	Accuracy	Precision	Recall	F1-Score	AUC Score
Anomaly Detection (XG-Boost)	99.9 %	100 %	99.8 %	99.9 %	0.973
Routing Prediction (Light-GBM)	98.5 %	96.72%	95.27%	95.77%	N/A

Source: Authors, (2026).

The obtained results show that the classifiers fulfill and exceed the set threshold standards when they are used in the simulated conditions of the IoT traffic. XG-Boost has perfect anomaly detection that is crucial in the case of instant SDN security implementation. Light-GBM prediction of the routing selections is based on the high-performing flow characteristics identification capabilities. The confusion matrices of XG-Boost anomaly detection and Light-GBM routing prediction are shown in Figure 7 and Figure 7a and Figure 7b respectively. The visual display of these figures illustrates the extent to which these models can determine the various categories accurately under the simulated traffic of IoT.

a. CM for XG-Boost Model b. CM for Light-GBM Model

Figure 7: Confusion Matrices of the Proposed ML Models.
Source: Authors, (2026).

It was revealed that the confusion matrix analysis revealed that XG-Boost-based anomaly detection model achieved high prediction accuracy because the samples correctly available were 1998 of 2000, with two false negative outcomes. Model testing process represents that it has the capability to provide highly sensitive security operations based on its performance measurements, which has a sensitivity of above 99.9% accuracy and F1-score. The necessary amount of accuracy must be enforced in real-time SDN infrastructure to ensure the threat is detected faithfully. The usage of Light-GBM routing optimization model as represented in Figure 7b showed successful operation by providing a proper classification of the majority of the flow routing decisions.

The model classified all 2000 samples except 29 flow which misclassified Class 0 to Class 1. Although with slight measurement disparity, the model did well in routing selection of multiple classes by achieving the evaluation thresholds set. These fusions of confusion matrices determine the effective classification in the two elements of ML in the proposed SDN framework of optimizing secure traffic. Figure 8 indicates the ROC curve of an XG-Boost binary classifier that demonstrates its discriminative ability, whereas the AUC score is 0.973 to support the findings.

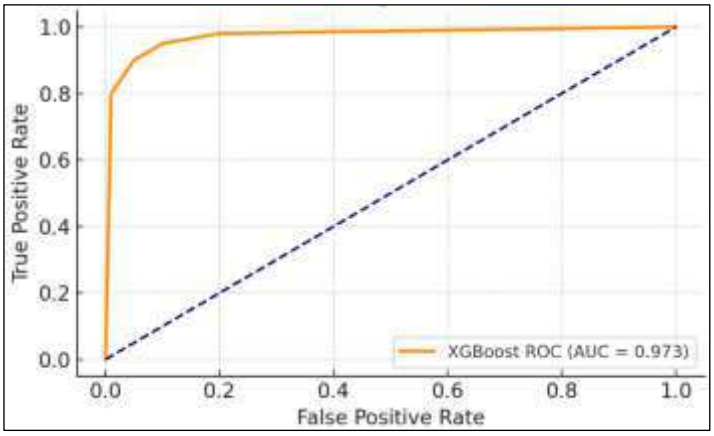


Figure 8: ROC Curve of Anomaly Detection (XG-Boost).
Source: Authors, (2026).

The XG-Boost-based anomaly detector model demonstrates a good classification result based on the Receiver Operating Characteristic ROC curve giving an Area Under Curve AUC of 0.973. The model exhibits high precision and accuracy attributes as it separates malicious and benign data traffic flows of IoT with minimal false positive outcomes. The accuracy, precision, recall, and F1-score of the two models are key performance measures and are presented in Figure 9 in a bar chart format thus ensuring that the models pass all performance parameters set at the beginning.

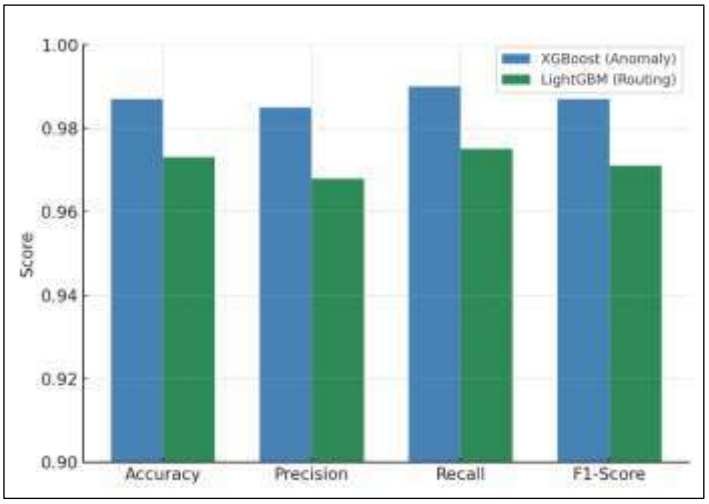

Figure 9: Comparison of Model Metrics: XG-Boost vs Light-GBM.
Source: Authors, (2026).

The performance levels of these machine learning models have been proven to be high enough to use them in live SDN systems. The security system created using XG-Boost has the best resistance against both the false positives and the false negatives to ensure that the valid network data is not falsely identified. Light-GBM model has a better predictive performance that aids SDN networks to make efficient routing decisions based on security and performance measures. By developing these models, an intelligent decision core is formed that enhances the dynamism in SDN controller responding to various network conditions and security threats.

IV.2 NETWORK PERFORMANCE

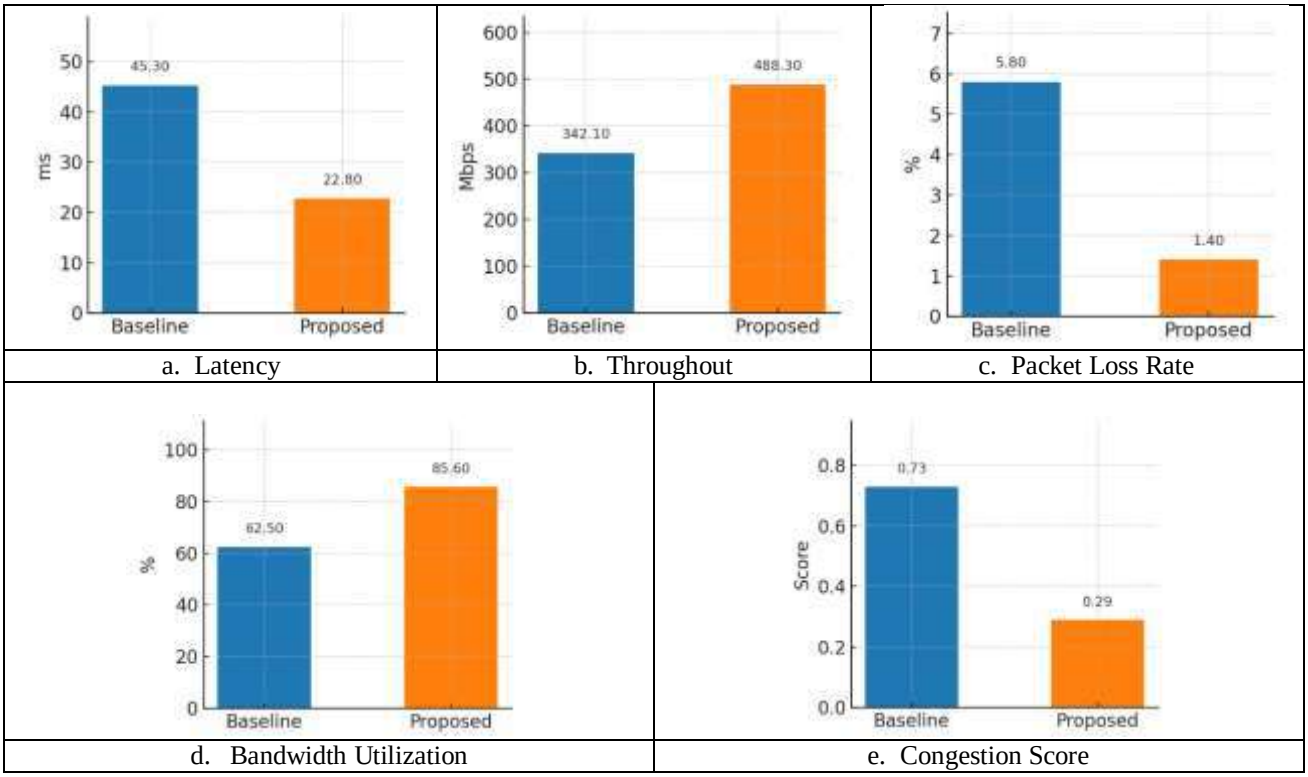
It is evaluated on the level of network operation of the suggested ML-enhanced security-aware SDN routing frameworks versus the standard SDN routing that is under test. The analysis covers five basic measures which comprise latency, throughput, packet loss rate, bandwidth consumption and congestion score. These measurements across the two test environments were possible with two scenarios that were simulated under the conditions of an IoT environment.

- The baseline state functions without learning mechanisms by using default shortest-path decisions that remain static throughout the network operation.
- The system operates in an elevated state by performing real-time dynamic flow handling based on the combined analysis of XG-Boost anomaly detector predictions alongside Light-GBM path optimization.

Both of the configurations were measured using the SDN topology comprising of 20 hosts and 5 switches controlled by a single POX controller. The testing environment simulated various traffic behavior types besides adding man-made network defects that imitated the real performance of an IoT system. The monitoring system recorded a lot of statistical data concerning the flows and then aggregated the data to establish the performance indicators of the two setups implemented. A summary of the findings that are displayed in Table 6 shows that the proposed system provides more percentage performance benefits to both states. The evaluation of the performance shows the both numerical benefits of the ML-based controller as well as adaptive features of the system in the network changes in secure conditions.

Table 6: Comparative Network Performance Metrics: Baseline vs. Proposed Method.

Metric	Baseline	Proposed Method	Improvement
Latency (ms)	45.3	22.8	↓ 49.7%
Throughput (Mbps)	342.1	488.3	↑ 42.7%
Packet Loss Rate (%)	5.8	1.4	↓ 75.9%
Bandwidth Utilization (%)	62.5	85.6	↑ 36.9%
Congestion Score (0–1)	0.73	0.29	↓ 60.3%



Source: Authors, (2026).

The outcomes reveal that the routing system proposed with ML improvement provides better quantitative outcomes to the simple system. The route handling system was increased by more than 42 percent in its capacity to process data and it was doubled. The flow reliability improved since the rate of packet loss went significantly low. The system was more efficient in managing bandwidth resources since the bandwidth utilization increased significantly with the score of the congestion reducing by 60 percent. The system is able to enhance the performance of operations and maintain networks to be secure and stable as per the experimental results. The proposed system has successfully decreased the end-to-end flow latency as indicated in Figure 10a.

The system reaches its objective by directing network flows through minimal delay routes, which receive instantaneous ML classifier performance feedback. The process of controller decision-making brings about limited delay, yet it is outweighed by better queue control and congestion reduction. Figure 10b displays data transfer rate enhancement through the ML-initiated modification. Percentages of throughput improvement approached 42.7% because the system effectively used all links and decreased retransmissions by avoiding blocked routes and making prophylactic rerouting decisions. Dropped packets (5.8% to 1.4%) also reduced considerably due to packet drop analysis in Figure 10c.

The anomaly detection module diverts the flow traffic by using alternative routes prior to the overflow point in queues that ensures the stability of transferring data. The better utilization rose by 62.5 percent to 85.6 percent as it is shown in Figure 10d. The routing mechanism is able to detect the conditions of the network traffic in order to activate the unused links even when passing around the links experiencing heavy traffic. It is in this effect that the distribution system is better balanced. The suggested system will significantly decrease the occupancies of queues, as shown in Figure 10e. Increased congestion score describes better switch-level scheduling resulting in fewer bottlenecks of the system. The incorporation of machine learning models into the SDN controllers introduces significant processing demands which impact performance in real-time processing of flowing data in high-volume processing.

The processing requirements lead to minimal lag in setting up flow between traffic bursts in addition to situations that are resource limited. The models should be updated on a regular basis alongside validation processes as a way of monitoring the dynamic traffic trends. Current performance of the network QoS would be of great advantage, although the inability to keep the up-to-date models would eventually decrease the efficiency of long-term routing decisions. The good anomaly detecting system has possible false alarms that can result in unnecessary routing changes and performance loss when managed incompetently. The trade-offs across the various testbed have low performance impacts. The system has better performance output, and this justifies the fact that more effective operation and high reliability, in addition to high throughput, outweigh costs involved in designing intelligent control logic.

IV.3 SECURITY EFFECTIVENESS

The security intelligence component of the proposed framework is doing a good job in recognizing and countering threats as it works within the software-defined networking (SDN) frameworks. The comparison uses various key security-focused performance measures, Detection Rate (DR), False Positive Rate (FPR), Blacklist Enforcement Efficiency, and Model Integrity Assurance. These metrics are essential to the performance of the anomaly detection system because they determine the accuracy of threat detection as well as the quality of compromised node route redirection. DR is used to gauge the accuracy of the system in identifying attack traffic, whereas FPR demonstrates the frequency of false flagging events that may unnecessarily interrupt regular traffic.

The rate of efficiency of blacklisting determines the effectiveness of the system to avoid using the known dangerous traffic routes or nodes by network users. SHA-256 hash validation can be regarded as an integrity measure to guard deployed models against malicious attacks: tampering and poisoning. The framework shows defensive preparedness in real-time IoT traffic conditions as they dynamically vary because of its timing capabilities. The detailed values are presented in Table 7, which illustrates the values with benchmark secure networking thresholds of reliability in deployment.

Table 7: Security Effectiveness Metrics: Measured Values vs. Thresholds.

Metric	Measured Value	Expected Threshold	Result
Detection Rate (DR)	99.80%	≥ 95%	Excellent
False Positive Rate (FPR)	0.20%	≤ 5%	Excellent
Blacklist Enforcement Efficiency	96.0%	≥ 90%	Satisfactory
Model Integrity (SHA-256)	Verified	Secure Hash Verified	Trust Maintained

Source: Authors, (2026).

The suggested system has advanced performance in security among various measures of evaluation. The XG-Boost algorithm in the anomaly detection module introduces an impressive 99.80% detection rate in the tracking and detection of malicious flows hidden in simulated traffic in IoT. The performance of the model, as indicated by the detection results, shows that the model's performance is greater than 95, which is very resistant to security threats. The system has a false positive rate of 0.20, and this rate prevents the harmless network traffic from being classified as a malicious flow. The network accuracy to the exact results ensures the continuity of flow and the prevention of superfluous packet drops and rerouting, hence ensuring that the system operates in an efficient fashion.

The system averts 96 percent of insecure path incidents that had been discovered in past security reports and this is a demonstration of the capability to undertake real-time routing choices and security incident knowledge acquired through learning. Model Integrity Assurance includes certified validation of hash validation of SHA-256, which keeps deployed machine learning models secure after deployment, removing any threats to model integrity. The evaluated system shows an established ability to provide intelligent and secure operations that are not easy to tamper with when managing SDN-based traffic of the IoT.

IV.4 SYSTEM RESPONSIVENESS

The proposed SDN framework was tested regarding its system responsiveness because it is one of the key features required to support real-time operations of a dynamic, latency-aware IoT system. System responsiveness is used to measure the speed with which an SDN controller processes the information received in the form of flow data and makes intelligent decisions, after which the infrastructure network is adjusted accordingly. The system is able to execute rapid anomaly detection, along with rapid path computation and rapid OpenFlow rule compilation functions. The real-time performance of the visualization of the events is important when the application of monitoring tools in the system or operator dashboard is implemented.

The system performance was measured with reference to three main response time measurements, namely Controller Decision Time, which indicates the end-to-end time between the flow arrival and route selection processes; OpenFlow Rule Update Frequency indicates the speed of reconfiguring the network once the events are detected, and Dashboard Update Latency indicates the speed at which the system provides information to the operators. Operations threshold data of time-sensitive SDN environments and quantitative outcomes of operations of the measurements are given in Table 8. The results obtained evidence that the system is ready to be operated in real-time despite the introduction of machine learning intelligence without any negative impact on the response time of the controllers.

Table 8: System Responsiveness Metrics.

Metric	Measured Value	Expected Threshold	Status
Controller Decision Time (ms)	23.7	≤ 50 ms	Real-time ready
OpenFlow Rule Update Frequency	12.5 rules/min	≥ 10 rules/min	Adaptive
Dashboard Update Latency (s)	1.2	≤ 2 seconds	Acceptable

Source: Authors, (2026).

Information processing speed by the system's controller reached 23.7 ms, which remained below the required limit for real-time functions in SDN operations. The entire processing time from flow arrival until feature extraction and both ML inference and rule installation completion is calculated by this metric, which demonstrates that intelligent model integration does not produce substantial delay. The system adapts at a rate of 12.5 OpenFlow Rule updates per minute, according to our findings. The fast responses from the controller verify its capability to deal with anomalies but maintain low flow table volatility. The update latency for visual display on operator dashboards amounted to 1.2 seconds, which tracked the period between triggering events and visual feedback. The system latency maintains suitable standards for real-time feedback applications in IoT management interfaces.

IV.5 DISCUSSION

The implementing model, a combination of SDN and security-conscious learning paths, is beneficial in multiple performance measures and security measures. When XG-Boost and Light-GBM models are incorporated into the SDN controller system, there is a reduction of the average latency by 49.7 percent, and this boosts the speed of delivery of packets in general. The process of data transmission has been made efficient that led to of 42.7 percent improvement. The result of the improved bandwidth performance, which increased to 36.9% and the implementation dropped the packet loss rate to 75.9% was the better use of resources to provide a better data integrity. The improvement in the congestion score was 60.3% and this shows that the network was more efficient in its operations.

Important gains have been achieved in our security tracking. The rate of detection was 99.8, meaning that a majority of the threats will be successfully detected. The system had a false positive result of 0.2, which is lower than the false alerts that the system was supposed to generate according to the acceptable threshold of 5%. Blacklists that were used to prevent compromised paths had an efficiency rate of 96. To check both the integrity and the credibility of the model, the model integrity was tested with the help of SHA-256 checksums.

The system response metrics show how effectively the framework operates. Real-time decision-making becomes possible through the 23.7 ms average decision time recorded by the controller. OpenFlow updated rules at a frequency of 12.5 rules per minute, which demonstrated system flexibility. The system provided dashboard updates, which took up to 1.2 seconds for reliable real-time feedback for administrators. Our framework receives analysis through comparison to five significant recent works that study SDN security and performance functions. The proposed approach stands against recent state-of-the-art research while showcasing alternate performance metrics, security capabilities, and deployment extents according to Table 9 below.

Table 9: Comparison of the Proposed Approach with Related SDN Frameworks.

Study	Key Features	Performance Metrics	Security Metrics	Limitations
Shameli and Rajkumar High-speed threat detection in 5G [27]	Utilizes PSO-GRUGAN for intrusion detection in 5G SDN environments.	Achieved 98.4% accuracy; detection time of 2.464 s.	High precision and recall rates.	Focused on 5G; lacks routing optimization.
Shahzad et al. An exhaustive parametric analysis for securing SDN [28]	Systematic review of traditional, AI/ML, and blockchain-based SDN security solutions.	Highlights the effectiveness of CNN and SVM models.	Discusses various security mechanisms.	Primarily a survey; it lacks implementation details.
Oredola and Ashraf A systematic study on SDN for enhancing security in IoT [29]	Reviews SDN controller architectures for IoT security.	Identifies centralized controllers as prevalent.	Emphasizes machine learning for threat mitigation.	Does not propose a specific framework.
Mossie and Seid SDN-based network traffic classification using ML [30]	Applies K-NN for traffic classification in SDN.	Achieved 99.4% accuracy in classifying various traffic types.	Focuses on traffic classification accuracy.	Limited to classification; lacks routing and security integration.
Pei et al. Efficient routing for traffic engineering in SDN [31]	Proposes efficient routing for dynamic traffic using reinforcement DL.	Demonstrates improved routing efficiency.	Not the primary focus.	Does not address security aspects.
Our Study	Integration of XG-Boost and Light-GBM for real-time IoT routing and anomaly detection in SDN.	49.7% latency reduction; 42.7% throughput increase; 75.9% packet loss reduction.	99.8% detection rate; 0.2% false positive rate; 96% blacklist enforcement efficiency.	Requires periodic model updates; potential for false positives if not managed properly.

Source: Authors, (2026).

The proposed framework employs ML enhancement on SDN routing to create a full-scale solution that improves network performance through latency reduction, together with packet loss reduction and throughput enhancement, as well as bandwidth utilization enhancement. The approach improves network security because it uses efficient methods that reach high detection levels with low false positive rates and perform accurate blacklist application. Real-time operations remain active in the framework through which the controller takes quick decisions and keeps dashboard information current. This solution delivers better performance than recent works because it unifies routing optimization with security functions in one optimized framework. When machine learning models run within SDN controllers, they create a major computing load, which affects real-time processing capabilities when dealing with high-volume streaming traffic.

Processing requirements create minimal delays for establishing flows when there is a sudden traffic surge and when system resources become limited. The predictive systems require maintenance protocols and verification procedures to monitor shift patterns in network traffic flow. The network QoS enjoys high levels of performance at present, even though failed maintenance of updated models will reduce the lasting quality of long-term routing decisions. The functioning anomaly detection mechanism may trigger unnecessary alarms that could lead to unneeded network changes and degraded performance unless proper management systems are in place. Performance outcomes remain minimal in the testbed situation as a result of these trade-offs. The system shows superior performance outcomes, which prove that better reliability and higher throughput exceed the expenses needed for designing intelligent control logic.

V. CONCLUSIONS

The presented research develops a protected and smart SDN routing system that optimizes IoT real-time traffic through machine learning predictive techniques for achieving better outcomes in security and performance. Advantages arise from implementing Light-GBM as a part of routing optimization alongside XG-Boost for anomaly detection because these models provide continuous network response along with proactive threat prevention. Real-time metrics enabled improved routing operations, which led to operational success measured through a 49.7% latency cut as well as a 42.7% improvement in throughput speed and a more than 75% decrease in lost packets.

The anomaly detection unit of the system delivered a detection accuracy of 99.8% but only produced 0.2% false positives, which protected legitimate traffic from disruption. The system achieved fast response times through its implementation by maintaining 23.7 ms controller decision durations and constant flow rule updates alike, along with the capability of adding real-time operator-visible dashboards. SDN controllers can effectively implement intelligent ML logic to achieve responsive and secure management of IoT infrastructure according to this validation. The proposed solution demonstrates peak performance alongside complete security coverage when compared to five contemporary SDN frameworks because it avoids the single-focus problems that previous solutions exhibited.

As a result of its strength-based model, the approach carries processing expenses while needing periodic model updates to function effectively as traffic patterns change. Experimental results demonstrated that implemented trade-offs, including system complexity and false alarm risks, did not affect performance metrics in operational tests, as baseline performance markers remained surpassed throughout all trials. The framework effectively shows how combined machine learning at the core of SDN-based IoT traffic control provides scalability along with security benefits necessary for real-time conditions. Model deployment in live POX or Ryu controllers, along with testing the system in production IoT testbeds through continuous model adaptation of traffic traces, will be the focus of future work.

ABSTRACT

Non-communicable diseases (NCDs) such as type 2 diabetes, breast cancer, and cardiovascular diseases remain major global health burdens, requiring accurate yet computationally efficient predictive models. This study aims to develop a fast and scalable neuromorphic classifier for NCD prediction in resource-constrained clinical settings. We propose the Randomized Dendritic Neuron Model (R-DNM), a randomized variant of the Dendritic Neuron Model that preserves multiplicative dendritic interactions while fixing randomly initialized hidden-layer parameters and training only output weights via ridge regression. R-DNM was evaluated on three benchmark medical datasets using 10-fold cross-validation and compared against conventional DNM, its multi-output variant (MODN), and standard baselines including Random Forest, SVM, and MLP. On the Pima Indians Diabetes dataset, R-DNM achieved the best performance with an average accuracy of 0.7552 ± 0.0362, F1-score of 0.7529 ± 0.0343, and log-loss of 0.5668 ± 0.0218, outperforming DNM and MODN by up to 3.38% accuracy. Paired t-tests confirm significant improvements in F1-score ($t = -3.77$, $p = 0.0014$, Cohen's $d = 1.69$) and computation time ($p < 0.0001$). These results establish R-DNM as a computationally efficient and statistically superior neuromorphic model for NCD prediction.

I. INTRODUCTION

Non-communicable diseases (NCDs) such as type 2 diabetes mellitus, breast cancer, and cardiovascular diseases (CVDs) remain leading contributors to global mortality and disease burden. The 11th edition of the International Diabetes Federation (IDF) Diabetes Atlas reports that in 2024, 589 million adults aged 20–79 (11.1%) were living with diabetes, including 252 million undiagnosed cases, with prevalence projected to rise further by 2050 [1-3]. Breast cancer is the most common cancer among women worldwide, with global projections estimating annual incidence to reach approximately 3.2 million cases and 1.1 million deaths by 2050 if current trends continue [4-6]. CVDs remain the leading cause of death globally, with deaths projected to increase from about 20.5 million in 2025 to 35.6 million by 2050 due to population growth and ageing [7], [8]. These trends underscore the urgent need for prevention and early detection.

The integration of data-driven approaches, such as predictive modelling and risk stratification, into healthcare systems—particularly in resource-limited settings—can facilitate earlier diagnosis, targeted prevention, and more effective disease management, ultimately reducing morbidity, mortality, and economic burden [9], [10]. Advancements in machine learning and deep learning have produced various high-performing classification models on benchmark medical datasets, including the Pima Indians Diabetes Database (PIDD), Breast Cancer Wisconsin (Diagnostic), and Cardiovascular Disease Dataset [11-15]. On PIDD, studies have reported accuracies around 0.7710 using ensemble approaches [16]. On the Breast Cancer Wisconsin dataset, ensemble deep learning methods have achieved accuracies up to approximately 0.9736 [17]. For cardiovascular datasets, deep learning models with attention mechanisms have reported accuracies around 0.7552 with interpretability via SHAP [18].

Although these results demonstrate significant progress, most approaches rely on large-scale iterative optimization, posing challenges such as high computational cost, prolonged training time, substantial memory requirements, and vulnerability to vanishing/exploding gradients and overfitting on limited-sized datasets or imbalanced class distributions [19], [20]. The Dendritic Neuron Model (DNM) is an artificial neuron model designed by adopting biological principles of information processing in neurons, particularly the role of dendrites in nonlinear operations [21-23]. Unlike conventional perceptron models that apply only linear aggregation followed by simple nonlinear activation, DNM incorporates four main computational stages: synapses, linear dendritic branches, multiplicative membrane gating, and soma [24-26].

The dendritic gating mechanism enables more selective nonlinear modulation of inputs, allowing the model to capture complex feature interactions in a manner closer to biological processes [27], [28]. Although DNM has shown potential in various classification and function approximation tasks, exploration of this model remains relatively limited compared to conventional deep learning architectures. Existing DNM variants generally still rely on end-to-end optimization via backpropagation, thus facing constraints in computational efficiency, sensitivity to initialization and activation function choice, and limited scalability on devices with restricted computational resources [29-31].

This study proposes the Randomized Dendritic Neuron Model (R-DNM) as a novel variant of DNM that preserves the biologically inspired neuromorphic structure, including the multiplicative gating mechanism in the dendritic layer, while significantly enhancing computational efficiency. The main innovation lies in the randomization and fixation of all parameters in the hidden layers (synapses, linear branches, and dendritic gating), which are randomly initialized from a standard Gaussian distribution and remain unoptimized during training [32-34]. Only the output weight matrix is trained analytically using a regularized least-squares solution (ridge regression) [35], [36]. This approach eliminates the need for iterative backpropagation on hidden layers, resulting in a much faster and memory-efficient training process, while providing an implicit ensemble effect that enhances robustness to data variations and numerical instability.

II. MATERIALS AND METHODS

This study follows a systematic methodological workflow as illustrated in Figure 1. The three benchmark medical datasets employed are the Pima Indians Diabetes Database (PIDD), Breast Cancer Wisconsin (Diagnostic), and Cardiovascular Disease Dataset, each exhibiting distinct clinical and epidemiological characteristics [37-39]. Prior to modeling, feature normalization was performed using StandardScaler, fitted exclusively on the training data per fold to prevent data leakage [40]. Evaluation was conducted via 10-fold cross-validation, with performance assessed through accuracy, precision, recall, F1-score, and log-loss to measure predictive capability and probabilistic calibration, while computational efficiency was quantified in seconds for training/inference time and in megabytes (MB) for total memory usage [41], [42]. The models compared include the conventional Dendritic Neuron Model (DNM), its multiclass extension Multi-Output Dendritic Neuron Model (MODN), the proposed Randomized Dendritic Neuron Model (R-DNM), as well as established baseline classifiers: Random Forest (RF), Support Vector Machine (SVM), and Multilayer Perceptron (MLP), enabling a comprehensive and fair assessment of both predictive performance and computational efficiency [43-46].

II.1 DATASETS

This study evaluates the proposed Randomized Dendritic Neuron Model (R-DNM) using four publicly available medical datasets drawn from diverse clinical and epidemiological sources. The Pima Indians Diabetes Database (NIDDK) contains physiological measurements from adult Pima Indian women to assess diabetes risk factors. The Breast Cancer Wisconsin (Diagnostic) dataset provides quantitative nuclear features from fine needle aspiration biopsies for distinguishing benign from malignant tumors. The cardiovascular disease dataset integrates physiological and lifestyle risk factors from large-scale observational studies to support predictive modeling for prevention and early detection. Key characteristics, including class distributions and label interpretations, are summarized in Table 1, capturing realistic variability across healthcare domains.

Table 1: Summary of Datasets and Class Distribution.

Dataset	Class	Distribution	Proportion	Class Definition
Pima Indians Diabetes Database	0	500	0.6510	Non-diabetic
	1	268	0.3490	Diabetic
Breast Cancer Wisconsin (Diagnostic)	0	357	0.6274	Benign (Non-malignant tumor)
	1	212	0.3726	Malignant (Cancerous tumor)
Cardiovascular Disease Dataset	0	35,021	0.5003	No Cardiovascular Disease
	1	34,979	0.4997	Cardiovascular Disease

II.2 DENDRITIC NEURON MODEL (DNM)

Dendritic Neuron Model (DNM) is an artificial neuron model that is biologically inspired and designed to simulate information processing in biological neurons in a more realistic manner compared to conventional neuron models such as the multilayer perceptron [47], [48]. This model explicitly incorporates dendritic structures, in which non-linear operations occur not only at the soma but also along dendritic branches through a multiplicative gating mechanism. DNM consists of four main computational layers, namely the synapse layer, the linear branch layer, the dendritic gating layer, and the soma layer. The overall computational architecture of DNM is illustrated in Figure 2, which depicts the signal processing flow from input features to class probability outputs, with particular emphasis on multiplicative interactions at the dendritic layer.

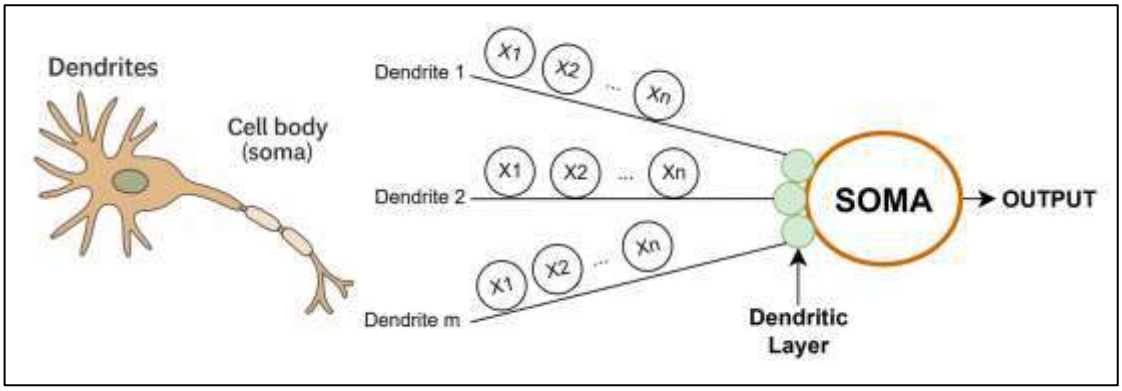

Figure 2: Architecture of the Dendritic Neuron Model.
Source: Authors, (2026).

The forward pass process in DNM is carried out sequentially for each input batch $X \in R^{b \times n_{features}}$, where b denotes the batch size, $n_{features}$ represents the number of features, and n_{hidden} indicates the number of hidden neurons. The following section provides a detailed explanation of each stage along with its complete mathematical formulation. Starting with the synapse layer, this layer simulates the aggregation of synaptic signals from presynaptic inputs. The initial linear operation is expressed in Formula (1):

$$S_1 = XW_{syn} + b_{syn} \tag{1}$$

Where $W_{syn} \in R^{n_{features} \times n_{hidden}}$ denotes the synaptic weight matrix, $b_{syn} \in R^{1 \times n_{hidden}}$ represents the synaptic bias vector that is replicated across b rows, and $S_1 \in R^{b \times n_{hidden}}$ corresponds to the initial synaptic output. Subsequently, in the linear branch layer, the synaptic output is further processed through a linear transformation to simulate signal propagation along dendritic branches. This operation is expressed in Formula (2):

$$S = S_1 W_{lin} + b_{lin} \tag{2}$$

Where $W_{lin} \in R^{n_{hidden} \times n_{hidden}}$ denotes the linear branch weight matrix, $b_{lin} \in R^{1 \times n_{hidden}}$ represents the linear bias vector, and $S \in R^{b \times n_{hidden}}$ corresponds to the final aggregated signal prior to the application of non-linearity. In a compact form, the synaptic–linear stage can be combined as expressed in Formula (3):

$$S = (XW_{syn} + b_{syn})W_{lin} + b_{lin} \tag{3}$$

Subsequently, in the non-linear activation layer, the signal S is passed through a non-linear activation function to produce the dendritic response. This operation is expressed in Formula (4):

$$H' = f_{input}(S) \tag{4}$$

Where $f_{input}(\cdot)$ denotes the activation function, for example sigmoid $\sigma(x) = \frac{1}{1+e^{-x}}$, hyperbolic tangent $tanh(x)$, or ReLU $max(0, x)$, and $H' \in R^{b \times n_{hidden}}$ represents the intermediate activation. In the dendritic gating layer, this layer simulates multiplicative modulation among dendritic branches. First, the gating signal is computed as shown in Formula (5):

$$Z = H'W_{dend} + b_{dend} \tag{5}$$

Where $W_{dend} \in R^{n_{hidden} \times n_{hidden}}$ denotes the dendritic weight matrix and $b_{dend} \in R^{1 \times n_{hidden}}$ represents the dendritic bias vector. Subsequently, the gating mechanism is applied as defined in Formula (6) and Formula (7):

$$D = f_{dendrite}(Z) \tag{6}$$

$$H = H' \odot D \tag{7}$$

Where $f_{dendrite}(\cdot)$ is the gating activation function, with sigmoid as the default choice to produce values in the range [0,1], $\odot$ denotes the Hadamard product, and $H \in R^{b \times n_{hidden}}$ corresponds to the final hidden representation after the gating process. In the soma layer, the hidden representation is mapped to the output space as expressed in Formula (8) and Formula (9):

$$Logits = H\beta \tag{8}$$

$$P = softmax(Logits)_j = \frac{exp(Logits_j)}{\sum_{k=1}^{n_{classes}} exp(Logits_k)}, \quad j = 1, \ldots, n_{classes} \tag{9}$$

Where $\beta \in R^{n_{hidden} \times n_{classes}}$ denotes the output weight matrix and $P \in R^{b \times n_{classes}}$ represents the class probability distribution. All DNM parameters are optimized end-to-end using backpropagation with the cross-entropy loss function and gradient-based optimizers such as Adam. The training and inference procedure of the Dendritic Neuron Model (DNM) is summarized at a high level in Figure 3.

***Input**: Training data, validation data, n_hidden, activation functions*
***Output**: Trained parameters and validation metrics*
Start
1. Randomly initialize all parameters (synaptic, linear, dendritic, output).
2. Choose optimizer and Cross-Entropy loss.
3. While not converged:
- For each mini-batch:
- Forward pass: synaptic → linear → activation → dendritic gating → output logits → softmax probabilities.
- Compute loss.
- Backpropagate and update all parameters.
4. Inference on validation set: perform forward pass, obtain probabilities, evaluate metrics.
End

II.3 PROPOSED METHOD: RANDOMIZED DENDRITIC NEURON MODEL (R-DNM)

Randomized Dendritic Neuron Model (R-DNM) is a method proposed as a significant innovation over the conventional Dendritic Neuron Model (DNM). This approach fully preserves the neuromorphic architecture that is rich in biologically inspired non-linearities, including synaptic aggregation mechanisms, linear branch propagation, non-linear activation, and dendritic multiplicative gating. However, R-DNM introduces a strategy of randomizing the hidden-layer parameters to achieve substantially higher computational efficiency. Specifically, all parameters from the synaptic layer to the dendritic gating layer ($W_{syn}, b_{syn}, W_{lin}, b_{lin}, W_{dend}, b_{dena}$) are randomly initialized from a standard Gaussian distribution and remain fixed, that is, not optimized, throughout the entire training process. Only the output weight matrix β is trained analytically through a regularized closed-form least-squares solution, thereby eliminating the need for computationally and memory-intensive iterative backpropagation [49-52]. The R-DNM architecture is illustrated in Figure 4.

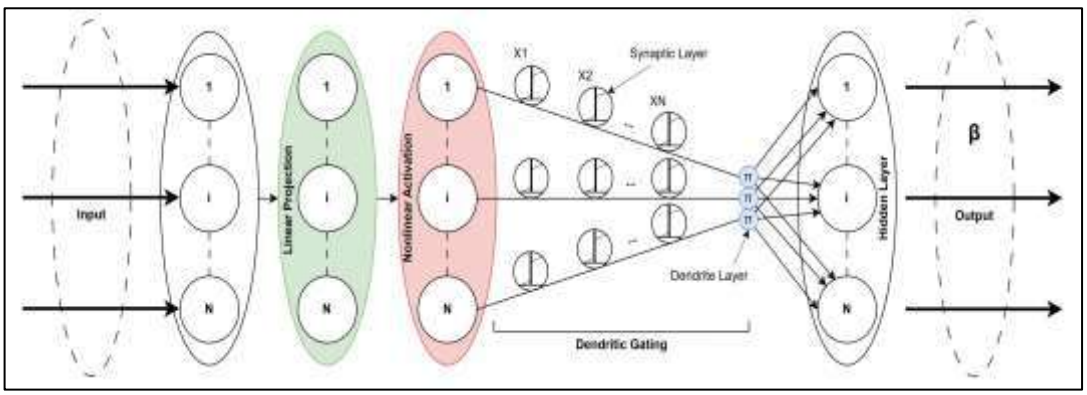

Figure 4: Architecture of the Proposed Method: Randomized Dendritic Neuron Model (R-DNM).
Source: Authors, (2026).

The forward pass process in R-DNM is identical to that of DNM up to the formation of the final hidden-layer representation H. Consequently, the computational stages directly follow the previously defined formulations, where the synapse and linear branch layers employ Formula (1)–Formula (3), the non-linear activation layer uses Formula (4), and the dendritic gating layer applies Formula (5)–Formula (7), such that the hidden representation $H \in R^{N \times n_{hidden}}$, for N data samples, is obtained through the same operations. The mapping to the output space also remains unchanged, namely the computation of the logits using Formula (8), followed by the calculation of the predictive probabilities using Formula (9), with numerical clamping applied. The fundamental difference lies in the optimization strategy. In R-DNM, since the hidden parameters are fixed, the hidden matrix H_{train} can be computed once through a forward pass without tracking gradients. The optimization process is therefore focused solely on β, by minimizing a regularized least-squares objective function (ridge regression), as defined in Formula (10):

$$\mathcal{J}(\beta) = \left|\left|H_{train}\beta - Y\right|\right|_F^2 + \lambda\left|\left|\beta\right|\right|_F^2 \tag{10}$$

Where $H_{train} \in R^{N_{train} \times n_{hidden}}$ denotes the hidden matrix obtained from the training data, $y_{train} \in \{1, \ldots, n_{classes}\}^{N_{train}}$ represents the target class labels for the training samples, $\lambda \geq 0$ is the ridge regularization hyperparameter, and $||\cdot||_F$ denotes the Frobenius norm, which is equivalent to $\sum_{i=1}^{N_{train}} \left|\left|(H_{train}\beta)_{i,:} - e_{y_i}\right|\right|_2^2 + \lambda \sum_{j,k} \beta_{j,k}^2$, where e_{y_i} denotes the canonical basis vector corresponding to the class label y_i. To obtain the optimal solution, the partial derivative of the objective function with respect to β is set to zero:

$$\frac{\partial \mathcal{J}}{\partial \beta} = 2H_{train}^{\top}(H_{train}\beta - Y) + 2\lambda\beta = 0 \tag{11}$$

Which yields

$$H_{train}^{\top}H_{train}\beta + \lambda\beta = H_{train}^{\top}Y \tag{12}$$

And can be rewritten as

$$(H_{train}^{\top}H_{train} + \lambda I)\beta = H_{train}^{\top}Y \tag{13}$$

Where $I \in R^{n_{hidden} \times n_{hidden}}$ is the identity matrix. The final closed-form solution is given in Formula (14):

$$\beta^* = (H_{train}^{\top}H_{train} + \lambda I)^{-1}H_{train}^{\top}Y \tag{14}$$

This approach allows the training of R-DNM to be completed in a single matrix computation step, with a computational complexity of $O(Nn_{hidden}^2 + n_{hidden}^3)$ due to the matrix inversion, which is substantially faster and more memory efficient than the iterative gradient-based optimization used in DNM. In addition, the randomization of hidden parameters provides an implicit ensemble effect that enhances robustness to noise and reduces overfitting. The complete training and inference procedure of the Randomized Dendritic Neuron Model (R-DNM) is summarized in Figure 5.

***Input**: Training data, validation data, n_hidden, λ (ridge), activation functions, random seed*
***Output**: Optimal output weights β* and validation metrics*
Start *1. Set random seed for reproducibility.* *2. Randomly initialize and fix all hidden-layer parameters (synaptic, linear branch, dendritic gating).* *3. Compute training hidden representation:* *- Perform full forward pass through synapse → linear branch → activation → dendritic gating.* *- Obtain hidden matrix H_train.* *4. Analytically solve ridge regression to compute optimal output weights β*.* *5. Inference on validation set:* *- Perform forward pass to obtain probabilities P_val.* *- Evaluate performance metrics against y_val.* ***End***

II.4 EXPERIMENTAL SETUP AND EVALUATION

This study evaluates three neuromorphic models—the Dendritic Neuron Model (DNM), its multiclass extension Multi-Output Dendritic Neuron Model (MODN), and the proposed Randomized Dendritic Neuron Model (R-DNM)—alongside established baseline classifiers: Random Forest (RF), Support Vector Machine (SVM), and Multilayer Perceptron (MLP). All experiments were conducted under identical conditions across four medical datasets to ensure fair and reproducible comparisons.

MODN extends DNM directly to multiclass classification by expanding the output weight matrix dimensionality while preserving the internal neuromorphic processing pipeline. In contrast, R-DNM retains the same dendritic-based hidden architecture up to the hidden representation but introduces a key innovation: hidden-layer parameters are randomly initialized and fixed, with only the output weights learned analytically via closed-form ridge regression. This design substantially reduces computational complexity and memory usage compared to the iterative backpropagation required by DNM and MODN, enabling higher efficiency without compromising biologically inspired dendritic non-linearities [53], [54].

Model performance was assessed using accuracy, precision, recall, F1-score, and log-loss to evaluate predictive capability, with particular emphasis on precision–recall balance for imbalanced datasets and probabilistic calibration. Computational efficiency was measured through training and inference time as well as memory consumption. Features were normalized using StandardScaler fitted exclusively on training data in each fold to prevent data leakage. All experiments were executed on a Windows 11 Home 64-bit system equipped with an AMD Ryzen 5 6600H processor (~3.3 GHz, 12 cores), 16 GB RAM, and 8,290 MB total graphics memory (483 MB dedicated, 7,806 MB shared). The complete experimental workflow is detailed in Figure 6.

***Input**: Dataset X, labels y, k = 10 folds*
***Output**: Average classification and computational metrics*
Start
1. Load dataset and labels.
2. Partition data into 10 folds.
3. For each fold:
- Split into training and test sets.
- Normalize features using StandardScaler (fit on training only).
- Train model (DNM, MODN, R-DNM, RF, SVM, or MLP).
- Perform inference on test set.
- Compute accuracy, precision, recall, F1-score, log-loss, computation time, and memory usage.
4. Average all metrics across the 10 folds.
5. Report final results.
End

III. RESULTS AND DISCUSSIONS

The performance evaluation of the Dendritic Neuron Model (DNM), Multi-Output Dendritic Neuron Model (MODN), and the proposed Randomized Dendritic Neuron Model (R-DNM) on the Pima Indians Diabetes dataset demonstrates the clear superiority of R-DNM in terms of computational efficiency and overall effectiveness. As summarized in Table 2, R-DNM consistently requires only 0.0020–0.0024 seconds for training and inference with memory usage of 0.0009 MB across all activation function combinations, in stark contrast to DNM and MODN, which require 0.4301–0.6597 seconds and 0.0063–0.0080 MB, respectively. This substantial reduction in computational cost is primarily due to the fixed random initialization of hidden-layer parameters—including synaptic, linear branch, and dendritic gating layers—drawn from a standard Gaussian distribution, with only the output weights optimized analytically using regularized least-squares, thereby reducing training complexity to a single dominant matrix operation.

In terms of classification performance, R-DNM outperforms DNM and MODN in nearly all activation configurations, except for the tanh–tanh setting, which yields the poorest results for all models due to severe saturation and vanishing gradients during iterative backpropagation. The optimal configuration for R-DNM is relu–tanh, achieving the highest average accuracy of 0.7552 ± 0.0362, precision of 0.7546 ± 0.0359, recall of 0.7552 ± 0.0362, F1-score of 0.7529 ± 0.0343, and log-loss of 0.5668 ± 0.0218. Relative to DNM and MODN, R-DNM exhibits consistent accuracy gains across several configurations, including +0.0169 for sigmoid–sigmoid, +0.0247 for sigmoid–tanh, and +0.0338 for relu–tanh, accompanied by reduced standard deviations that indicate improved cross-fold stability. These improvements are attributed to the implicit ensemble effect of large-scale random hidden representations and the preserved effectiveness of dendritic multiplicative gating for selective nonlinear modulation, particularly when ReLU is employed at the input layer, resulting in lower numerical instability and substantially reduced log-loss compared to DNM and MODN.

Source: Authors, (2026).

The evaluation of the Dendritic Neuron Model (DNM), Multi-Output Dendritic Neuron Model (MODN), and the proposed Randomized Dendritic Neuron Model (R-DNM) on the Breast Cancer Wisconsin (Diagnostic) dataset consistently demonstrates the computational advantage of R-DNM across all activation function combinations. As reported in Table 3, R-DNM achieves training and inference times ranging from 0.0023 to 0.0041 seconds with a memory usage of 0.0009 MB, whereas DNM and MODN require substantially longer execution times (0.4444–0.8046 seconds) and larger memory footprints (0.0063–0.0077 MB). This efficiency gain is a direct consequence of fixing randomly initialized hidden-layer parameters and optimizing only the output weights analytically via ridge regression, thereby avoiding iterative backpropagation and gradient storage.

In contrast, classification performance on this dataset generally favors DNM and MODN due to the extremely high feature separability and low intrinsic complexity of the task. The best overall results are achieved under the sigmoid–sigmoid configuration, where DNM and MODN obtain an accuracy and F1-score of 0.9719 ± 0.0195 with a log-loss of 0.1806 ± 0.1761, while R-DNM reaches an accuracy of 0.9473 ± 0.0283 and a higher log-loss of 0.3881 ± 0.0255. Similar patterns are observed for sigmoid–tanh (0.9596 versus 0.9508) and sigmoid–relu (0.9684 versus 0.9456) configurations. Notably, R-DNM outperforms both DNM and MODN in activation settings susceptible to numerical instability, such as relu–relu and relu–tanh, where gradient-based models experience dead ReLU and exploding gradients, while R-DNM maintains stable accuracy above 0.9290 and consistently low log-loss due to its gradient-independent formulation.

Table 3: Performance Comparison of Dendritic Neuron Models with Different Activation Function Combinations on Breast Cancer Wisconsin (Diagnostic) Dataset.

Source: Authors, (2026).

The performance assessment of the Dendritic Neuron Model (DNM), Multi-Output Dendritic Neuron Model (MODN), and the proposed Randomized Dendritic Neuron Model (R-DNM) on the large-scale and balanced Cardiovascular Disease dataset (approximately 70,000 samples with a near 50:50 class ratio) demonstrates the sustained computational advantage of R-DNM under high data volume.

As summarized in Table 4, R-DNM requires 1.8955–2.0362 seconds for training and inference with memory usage in the range of 0.0015–0.0016 MB, whereas DNM and MODN demand substantially longer execution times (7.6023–9.0608 seconds) and higher memory consumption, reaching up to 2.2401 ± 6.6981 MB for DNM and 0.0068–0.0080 MB for MODN. This efficiency is achieved through fixed random initialization of hidden-layer parameters and single-step analytical optimization of output weights via ridge regression, thereby avoiding the linear growth of computational cost associated with iterative backpropagation as dataset size increases. In terms of classification performance, results differ from those observed on smaller datasets, with DNM and MODN outperforming R-DNM across most activation configurations. The best overall performance is obtained under the sigmoid–sigmoid setting, where DNM and MODN achieve an accuracy of 0.7288 ± 0.0046, an F1-score of 0.7285 ± 0.0046, and a log-loss of 1.0231 ± 0.0168, compared to R-DNM's accuracy of 0.6919 ± 0.0071.

Similar trends are observed for sigmoid–tanh and tanh–sigmoid combinations, reflecting the superior capacity of end-to-end gradient-based optimization to exploit the dataset's balanced distribution and moderate-to-high complexity. Nevertheless, R-DNM demonstrates clear advantages in activation settings prone to gradient instability, such as relu-based configurations, where DNM and MODN experience severe performance degradation (e.g., accuracy of 0.6333 and log-loss of 5.8437 for relu–relu), while R-DNM maintains stable accuracy of 0.7081 and a substantially lower log-loss of 0.6159. Overall, these findings emphasize the trade-off between predictive accuracy and computational efficiency, positioning R-DNM as a scalable and robust alternative for large-scale medical applications with constrained computational resources.

Table 4: Performance Comparison of Dendritic Neuron Models with Different Activation Function Combinations on Cardiovascular Disease Dataset.

To provide a concise cross-dataset comparison, Figures 7 and 8 summarize the average F1-score and computation time, averaged across all activation combinations, for DNM, MODN, and R-DNM. As illustrated in Figure 7, R-DNM achieves the highest average F1-score on the Pima Indians Diabetes dataset, attaining 0.7205 ± 0.0144 compared to 0.6958 ± 0.0149 for both DNM and MODN, reflecting the robustness introduced by implicit ensemble effects arising from random hidden representations on small and moderately imbalanced data. In contrast, DNM and MODN exhibit stronger average performance on the highly separable Breast Cancer Wisconsin dataset (0.9113 ± 0.0377 versus 0.8834 ± 0.0394 for R-DNM) and on the balanced Cardiovascular Disease dataset, where average F1-scores converge around 0.6886–0.6887, highlighting clear dataset-dependent performance trade-offs among the models.

Figure 8 further emphasizes the computational efficiency of R-DNM across all datasets. R-DNM consistently exhibits substantially lower average runtimes, ranging from 0.0020 to 0.0040 seconds on the smaller datasets and approximately 1.9800 seconds on the Cardiovascular Disease dataset. These observations are supported by paired t-tests: on the Pima Indians Diabetes dataset, R-DNM

demonstrates statistically significant improvements over DNM and MODN in F1-score ($t = -3.7695$, $p = 0.0014$, Cohen's $d = 1.6860$) and computation time ($t = 84.2454–110.6988$, $p < 0.0001$, $d = 37.6760–49.5060$).

On the Breast Cancer Wisconsin dataset, differences in F1-score are not statistically significant ($p = 0.1231$, $d = 0.7240$), whereas computation time differences remain highly significant ($p < 0.0001$, $d = 12.1830–17.3060$). Overall, these results confirm that R-DNM offers a favorable balance between predictive performance and computational efficiency, particularly for small-to-medium datasets and resource-constrained medical applications.

The comparative evaluation of the best R-DNM configuration (ReLU–tanh activation) against established baseline classifiers—Random Forest (RF), Support Vector Machine (SVM), and Multilayer Perceptron (MLP)—on four medical datasets, as summarized in Table 5, indicates that R-DNM delivers competitive predictive performance while offering notable computational advantages. On the Pima Indians Diabetes dataset, R-DNM achieves an accuracy of 0.7552 ± 0.0362 and an F1-score of 0.7529 ± 0.0343, results that closely approach those of RF (0.7694 ± 0.0453) and SVM (0.7617 ± 0.0296) and are comparable to MLP (0.7525 ± 0.0435).

Similarly, on the Breast Cancer Wisconsin dataset, R-DNM attains an accuracy of 0.9333 ± 0.0406, slightly below the stronger baselines such as SVM and MLP (0.9754), while on the large-scale Cardiovascular Disease dataset it records an accuracy of 0.7081 ± 0.0072, marginally lower than RF (0.7251), SVM (0.7276), and MLP (0.7341). Despite these modest performance gaps, R-DNM consistently demonstrates favorable log-loss values in several cases and, more importantly, exhibits markedly superior efficiency, with training times ranging from 0.0022 to 1.9344 seconds and memory usage of approximately 0.0009–0.0015 MB, which is orders of magnitude lower than those required by RF (4.0143–39.6902 s), SVM (0.0548–1512.9478 s), and MLP (1.4114–43.9314 s).

Table 5: Comparison of Best R-DNM Configuration with Baseline Classifiers on Medical Datasets.

To further contextualize the performance of the proposed Randomized Dendritic Neuron Model (R-DNM), Table 6 compares it with recent state-of-the-art methods evaluated on the same benchmark datasets. On the Pima Indians Diabetes Database (PIDD), R-DNM with the optimal configuration (ReLU activation at the input layer and tanh at the dendritic gating layer) achieves an accuracy of 0.7552 and an F1-score of 0.7529, which are competitive with ensemble-based approaches reported by (accuracy 0.7710, F1-score 0.6900) [16] and (accuracy 0.7700, F1-score 0.7100) [55]. Importantly, R-DNM exhibits significantly higher computational efficiency, requiring only about 0.0022 seconds for training and inference, whereas ensemble methods incur substantially higher costs due to iterative optimizatio and meta-learner training. This efficiency advantage makes R-DNM particularly suitable for resource-constrained, real-time applications on small to moderately imbalanced datasets such as PIDD. On the Breast Cancer Wisconsin (Diagnostic) dataset, R-DNM attains an accuracy of 0.9333 and an F1-score of 0.9325, slightly below the Intelligent Dendritic Neural Model optimized with Biogeography-Based Optimization (BBO) by (accuracy 0.9594) [29], a difference attributable to the dataset's high feature separability where evolutionary optimization yields marginal gains.

Nevertheless, R-DNM completes training and inference in approximately 0.0023 seconds, far faster than optimization-based approaches. Similarly, on the large-scale and balanced Cardiovascular Disease dataset, R-DNM achieves an accuracy of 0.7081 and an F1-score of 0.7080, approaching the performance of the attention-based Feature Decomposition Deep Learning (FDDL) model by (accuracy 0.7552, F1-score 0.7522) [18], while requiring only about 1.9344 seconds for training and inference. Overall, Table 6 highlights that R-DNM offers a strong performance–efficiency trade-off, delivering competitive predictive results with orders-of-magnitude improvements in computational speed and memory efficiency, making it a promising solution for real-world medical applications in resource-limited clinical settings.

Table 6: Comparison of the Proposed R-DNM (Optimal Configuration: ReLU–tanh) with Recent State-of-the-Art Methods on Benchmark Medical Datasets.

Dataset	Author(s)	Method(s)	Accuracy	F1-score
Pima Indians Diabetes	[16]	Ensemble learning (Decision Tree, Random Forest, Support Vector Machine, Neural Network, Logistic Regression)	0.7710	0.6900
	[55]	Ensemble models (Random Forest, Gradient Boosting, Multilayer Perceptron, XGBoost)	0.7700	0.7100
	This Study	Randomized Dendritic Neuron Model (ReLU activation at input layer – Tanh activation at dendritic layer)	0.7552	0.7529
Breast Cancer Wisconsin (Diagnostic)	[29]	Optimized Dendritic Neuron Model using Biogeography-Based Optimization	0.9594	-
	This Study	Randomized Dendritic Neuron Model (ReLU activation at input layer – Tanh activation at dendritic layer)	0.9333	0.9325
Cardiovascular Disease	[18]	Feature Decomposition-Based Deep Learning (FDDL) with attention mechanism and SHAP	0.7552	0.7522
	This Study	Randomized Dendritic Neuron Model (ReLU activation at input layer – Tanh activation at dendritic layer)	0.7081	0.7080

Source: Authors, (2026).

These results reveal a clear performance-efficiency trade-off modulated by dataset characteristics. On smaller or moderately imbalanced datasets such as PIDD, R-DNM delivers predictive accuracy and F1-scores competitive with both conventional baselines (RF, SVM, MLP) and recent state-of-the-art ensemble methods, benefiting from the implicit ensemble effect of randomized hidden representations and the robustness of dendritic gating. On datasets with high feature separability (Breast Cancer Wisconsin) or large-scale balanced data (Cardiovascular Disease), iterative optimization in end-to-end models and advanced deep architectures tends to yield marginally superior discrimination; however, R-DNM consistently offers orders-of-magnitude improvements in computational speed and memory usage, while demonstrating greater resilience to gradient instabilities (e.g., in ReLU-based configurations).

This positions R-DNM as a highly practical alternative for real-world deployment in resource-constrained clinical settings. The proposed Randomized Dendritic Neuron Model (R-DNM) preserves the biologically inspired non-linear multiplicative gating of dendritic structures while achieving extreme computational efficiency through fixed random hidden parameters and closed-form output optimization. Compared to both conventional classifiers and state-of-the-art approaches reported in recent literature, R-DNM provides competitive predictive performance across diverse medical tasks, coupled with training and inference speeds that are substantially faster—often by two to three orders of magnitude—making it particularly suitable for resource-limited environments.

Despite these advances, limitations remain, including slightly reduced accuracy on datasets with exceptionally high separability or large-scale balanced distributions, as well as limited exploration of activation functions and ridge regularization hyperparameters. Future work should explore hybrid training strategies that combine randomization with selective fine-tuning of hidden parameters, integration with multi-modal clinical data, external validation on real-world cohorts, and potential hardware implementation on neuromorphic platforms to further improve scalability and energy efficiency in digital health applications.

IV. CONCLUSIONS

This study introduces the Randomized Dendritic Neuron Model (R-DNM), a novel variant of the Dendritic Neuron Model that preserves the biologically inspired neuromorphic architecture, including the multiplicative gating mechanism in the dendritic layer, while achieving substantial improvements in computational efficiency through randomization and fixation of hidden-layer parameters combined with closed-form analytical training of the output weights via ridge regression. The proposed model delivers competitive predictive performance across benchmark medical datasets—Pima Indians Diabetes Database, Breast Cancer Wisconsin (Diagnostic), and

Cardiovascular Disease—often approaching or matching recent state-of-the-art ensemble, optimized dendritic, and attention-enhanced deep learning methods, while providing training and inference speeds that are orders of magnitude faster and memory requirements that are significantly lower.

These characteristics position R-DNM as a practical and scalable solution for early detection of non-communicable diseases in resource-constrained clinical environments. Nonetheless, limitations include modestly reduced accuracy on datasets exhibiting exceptionally high feature separability or large-scale balanced distributions, as well as limited exploration of activation function combinations and regularization hyperparameters. Future research directions should include the development of hybrid training strategies that integrate randomization with selective fine-tuning, extension to multi-modal clinical data, rigorous external validation using real-world patient cohorts, and hardware implementation on neuromorphic platforms to further advance scalability and energy efficiency in digital health applications.

ABSTRACT

Diabetic Retinopathy (DR), a retinal condition associated with diabetes mellitus, is a leading global cause of blindness. Early detection and treatment is crucial to prevent or mitigate vision loss. Researchers have developed various artificial intelligence-based methods to detect diabetic retinopathy from fundus images, aiming to enhance diagnostic accuracy and efficiency, thereby improving patient outcomes. In this paper, we have introduced a custom convolutional neural network (CNN) architecture for detecting diabetic retinopathy. We have used an open-source "Diabetic Retinopathy 224×224 Gaussian Filtered" dataset from Kaggle, comprising of 3,668 images. The images are then labelled into two classes where one class represents "No Diabetic Retinopathy (No_DR)" and the other class represents "Diabetic Retinopathy (DR)". Then we have applied min-max normalization to scale pixel values to a specified range [0, 1]. Afterwards, the dataset is divided into three parts to train, validate and test the proposed CNN model. Our method has achieved a testing accuracy of 95.27% and F1 score of 95.29%. Then we have performed 5-fold cross validation to observe the performance of the proposed automatic DR detection method. We have also compared our proposed method with some pre-trained models and some existing methods. In observation, it has been shown that the proposed technique outperformed many other existing techniques.

I. INTRODUCTION

Diabetic eye diseases refer to a group of eye problems that can occur as a result of diabetes. Diabetic Retinopathy (DR) is among the most common diabetic eye diseases. It affects a significant portion of individuals living with diabetes, particularly those with poorly controlled blood sugar levels over an extended period of time. DR is caused as a result of Diabetes Mellitus that causes abnormal new blood vessels to grow on the surface of the retina [1]. As a result, the blood vessels of the retina may swell and/or leak fluid or blood. DR may not cause any harm in vision at first but over time it can get worse. It is very important to diagnose DR at the early stages.

But if DR is undiagnosed, it becomes more and more severe over the time through formation of Micro aneurysms, Exudates, Hemorrhages, Cotton Wool Spots, abnormal structure of the Optic Disc, abnormal Foveal Avascular Zone, Neovascularization's, Intra Retinal Microvascular Abnormalities and many more [1]. A person might see spots floating in their vision or may notice a general blurring of vision. Eventually that will result in severe vision loss and even blindness. According to the statistics of International Diabetes Federation [2], there are 537 million people suffering from diabetes globally in 2021 and it is expected to be 643 million and 783 million by 2030, and by 2045 respectively. It is also mentioned there that, by 2030, of all the diabetes patients, around 191 million people will suffer from DR and among them 56.3 million will be facing vision-threatening diabetic retinopathy [3].

According to a report [4] published in 2023, the number of people affected by diabetes in Bangladesh is more than 13 million. Out of them, around 1.85 million is suffering from diabetic retinopathy. This report also states that, a hospital based cross-sectional study was performed among 489 patients having type-2 diabetes, and the researchers have found that 18.8% of those patients were suffering from diabetic retinopathy. So, it can be said from the above discussions that the number of DR patients are increasing day by day. So, early diagnosis of diabetic retinopathy is extremely necessary for the diabetes patient. Artificial intelligence and machine learning techniques are used for the development of computer-aided diagnosis systems for the detection of diabetic retinopathy. These systems can automatically analyze fundus images and provide risk assessments or early detection of DR with high accuracy. Different pre-trained algorithms like VGG-16 [5], Xception [6], EfficientNet [7], ResNet [8] etc. are used for the automatic detection of DR.

The first triumph was taken in 1990s to classify retinal images in order to detect whether an eye has DR or not [9]. In this research, Gardner and his fellow researchers have proposed an artificial neural network (ANN) based tool that detects retinal images with DR. Their proposed tool provides 88.4% sensitivity and 83.5% specificity. In [10], the researchers have applied different algorithms i.e. random forest classifier, support vector machine, K-nearest neighbor, logistic regression, regression tree classifier, and the Naïve Bayes theorem to detect DR. They have found that, in terms of performance in evaluation and accuracy, the Naïve Bayes performs better among the six. According to [5] have used VGG-16 architecture for the automatic detection of diabetic retinopathy. They have used a dataset containing 3668 retinal images, captured through fundus photography. The model was then trained for 30 epochs. They have used ADAM optimizer to adjust the characteristics of the neural network. Categorical cross entropy loss function was used in their proposed method. The authors of [11] have proposed Inception-v3 based diabetic retinopathy detection process.

The datasets used in their work are from Kaggle, named the “Diabetic Retinopathy Detection 2015” dataset and “Aptos 2019 Blindness Detection” dataset. They have resized the images to 256×256. Then they have applied Gaussian blur technique to remove the Gaussian noise in the image. The model is then trained and tested to achieve an accuracy of 88.1% while detecting Diabetic Retinopathy by [7] have presented a method for classifying Diabetic Retinopathy (DR) severity using an ensemble of EfficientNet models (B1, B2, B3, and B5). They have trained the models with different datasets and have achieved a high quadratic kappa score of 0.924377 on the APTOS test dataset. The study highlights the importance of selective training data and appropriate loss functions in enhancing performance. Despite its high accuracy, the method is simpler than other models, ranking around 64th out of 2913 in the APTOS submission ranking for the private test set. The researchers of [8] have proposed ResNet-34 based CNN architecture for the diagnosis of diabetic retinopathy.

They have used fundus image datasets from Kaggle. Several image processing techniques like filtering, normalization, data augmentation have been applied to remove the noises and to increase the dataset size. Their method has achieved a high F1 score of 93.2% for stage-based DR classification, indicating strong performance in accurately identifying different stages of the disease. In turn. [12] have introduced a CNN based Diabetic Retinopathy (DR) detection using the lightweight SI2DRNet-v1. They have applied Otsu’s threshold method and image enhancing methods for finding the region of interest (ROI) in the image and improve the image quality respectively. Then their model has been trained, validated and tested. The accuracy of the proposed method is 91%. For [6] have proposed a novel feature extraction method for Diabetic Retinopathy (DR) diagnosis using a modified Xception architecture with deep layer aggregation. To improve the overall classification performance, they have used transfer learning technique and hyper-parameter tuning. Their proposed method achieves classification accuracy of 83.09%, sensitivity of 88.24%, and specificity of 87.00% on the Kaggle APTOS 2019 dataset.

In [13], the authors have proposed an automatic DR detection method using an ensemble of five deep CNN models: Inception ResNet V2, VGG19, Xception, ResNet50, and DenseNet112. They have used the Kaggle retina image dataset. After training and testing the proposed ensemble model, they have achieved specificity of 92.02% while detecting DR.In this paper, a custom deep learning CNN model has been proposed to automatically detect diabetic retinopathy. For our research, we have used an open source dataset from Kaggle containing 3668 fundus images. Our proposed model consists of two classes named as ‘DR’ and ‘No_DR’. The proposed model has been trained, validated and tested using the image dataset. To evaluate the performance of the proposed model, 5-fold cross validation technique is also applied. We have also used four pre-trained models (VGG-16, ResNet-50, Inception-V3, and EfficientNet-B0) to compare the results with our proposed CNN model to classify the diabetic retinopathy disease.

II. PROPOSED METHODOLOGY

In this section, we will briefly discuss about the methodology of the proposed method. The method has several key steps: dataset collection, analysis & labelling, image normalization, splitting the dataset into training, validation & testing sets, creation of the proposed model, training, validating & testing the model, and lastly applying K-fold cross validation. Figure 1 represents the flow diagram of the proposed DR detection method.

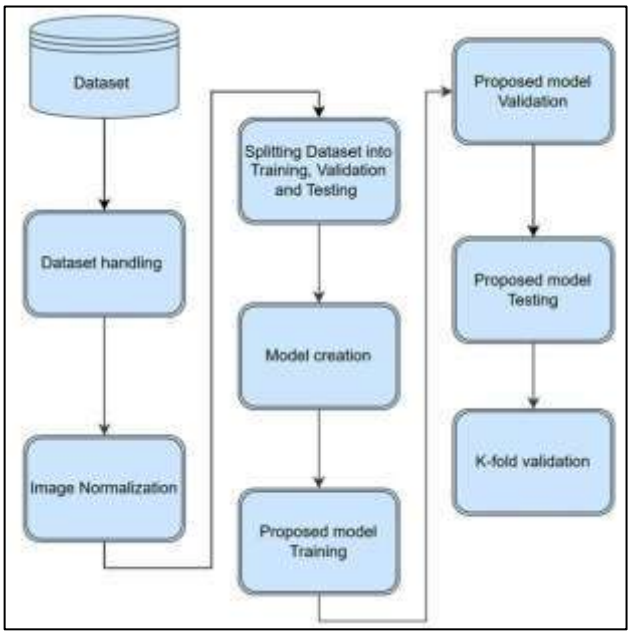

Figure 1: Flow diagram of the proposed model.
Source: Authors, (2026)

II.1 DATASET

For our research we have used an open-source dataset from Kaggle titled "Diabetic Retinopathy 224×224 Gaussian Filtered" by [14]. This dataset includes Gaussian filtered retina scan images used for detecting diabetic retinopathy. It contains 3,668 fundus images with a resolution of 224×224 pixels. A sample image is shown in Figure 2. There are five classes of diabetic retinopathy images named as No DR (1805 images), Mild (370 images), Moderate (999 images), Severe (199 images), and Proliferate_DR (295 images), along with a corresponding CSV file for the images. Then we have to delete six images from “Moderate” due to very bad condition.

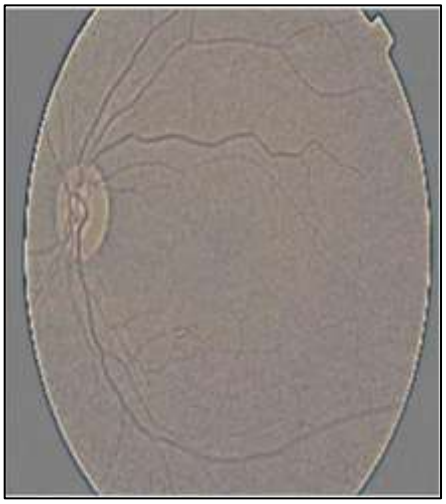

Figure 2: Original image of the dataset.
Source: [14].

II.2 DATASET HANDLING

In order to enhance model accuracy and error analysis, dataset labeling is used in the image dataset. For dataset labeling, initially, the four classes-mild, moderate, severe and proliferate_DR are combined into a single class named as “DR” which means Diabetic Retinopathy. We have used “Pandas library” for this task. It is especially effective for managing structured data such as CSV files. After compressing the four classes into one, the DR class contains 1857 images, while the No_DR class contains 1805 images. This results in a balanced image ratio between the classes.

II.3 IMAGE NORMALIZATION

To improve model performance and convergence, particularly in machine learning and deep learning applications, image normalization is crucial in image processing. It ensures consistency by standardizing pixel values, typically within the range of 0 to 1 or -1 to 1. This standardization is essential for reliable image comparison, processing, and analysis. A common technique, min-max normalization is used in the proposed method to scale pixel values to a specified range [0, 1].

II.4 DATASET SPLITTING

Our dataset has been meticulously divided into three distinct subsets to facilitate robust model development and evaluation [15]. The training set comprising 70% of the dataset was dedicated to the initial training phase. The remaining 30% of the dataset was evenly split between the validation set and the testing set. We have used the "train_test_split' function and array slicing technique to split the dataset. The details of the number of images are shown in Table 1.

Table 1: Number of images at each set.

Name of Set	Number of images
Training Set	2562
Validation Set	550
Testing Set	550

Source: Authors, (2026).

II.5 DEVELOPMENT OF CNN MODEL

We have used several convolutional layers, max-pooling layers, batch normalization layers, and dropout layers to design and develop the proposed model in "Keras". It uses "Tensor-flow" as a backend with Python. The proposed model proceeds with three successive sets, each comprising of sequentially stacked 2D convolutional layers, 2D max-pooling layers, and batch normalization layers. We have used two sets of fully connected layers in our proposed model. Different steps of the proposed model are given below:

1. The process begins with an input layer designed to accept images at a resolution of 224×224 pixels.
2. The proposed model starts with a convolutional layer consists of 8 filters, each of size 3×3. The "ReLU" activation function is used in this layer.
3. To down-sample the image by (2, 2), we have used a max-pooling layer with a filter size of 2×2.
4. One batch normalization layer is inserted after the max-pooling layer to enhance training stability and accelerate convergence in neural networks.
5. After the first set of the convolution, max-pooling, and batch normalization layers, the proposed model has the same set of layers sequentially placed for two times. The difference is that the convolutional layer in the second and third set consists of 16 filters (filter size: 3×3) and 32 filters (filter size: 4×4) respectively. All the other parameters are same.
6. After that, to flatten the input shape, we have used a flatten layer. This layer prepares the data for input into the fully connected layers.
7. Now, to classify the images, two fully connected layers are used. The first layer is a dense layer having 32 hidden neurons. The "ReLU" activation function is used in this layer. After that, a dropout layer with a dropout rate of 0.15 is used to reduce over fitting [16].
8. The second fully connected layer is the decision making layer having 2 hidden neurons with the Softmax activation function.
9. The loss function and optimizer used in the proposed model is the categorical cross-entropy loss function and the adam optimizer with a learning rate of 0.00001.

The summary of the proposed CNN model is presented in Table 2.

Table 2: Configuration of different parameters for the proposed diabetic retinopathy detection model.

Parameters	Diabetic Retinopathy Detection Model
Convolutional Layer	1 (8 filters with size 3×3)
	1 (16 filters with size 3×3)
	1 (32 filters with size 4×4)
Max Pooling	3 (each with 2×2 filters)
Dropout layer	1 (0.15)
Learning rate	0.00001
Activation Function	ReLU
Optimizer	Adam
Batch Size	16
Epochs	50

III. RESULTS AND DISCUSSIONS

In this section, we are going to discuss about the training, validation and testing results of the proposed DR detection method. We will also compare the achieved results with some of the pre-trained models and also with some other proposed methods. The computing environment of our research is a laptop having an operating system of 64 bit Windows 10 Pro, Intel Core i3 CPU, 500 GB hard disk, SSD of 128 GB, and 4 GB RAM.

III.1 TRAINING AND VALIDATION RESULTS

The proposed CNN model for the DR detection is trained, and validated for 50 epochs with 2562 images and 550 images respectively. The system has achieved outstanding training and validation results as depicted in Table 3. Figure 3 and Figure 4 represent the accuracy curve and loss curve respectively of the training and validation stages with respect to the epochs. The proposed system has achieved a training accuracy of 99.92% and a validation accuracy of 95.45%, at the 50^{th} epoch. It has also achieved a training loss of 0.0123 and a validation loss of 0.1671, at the 50^{th} epoch.

Table 3: Training and validation accuracy table for the proposed DR detection model.

Phases	Sample Size	Average Accuracy
Training	2562	99.90%
Validation	550	94.27%

Source: Authors, (2026).

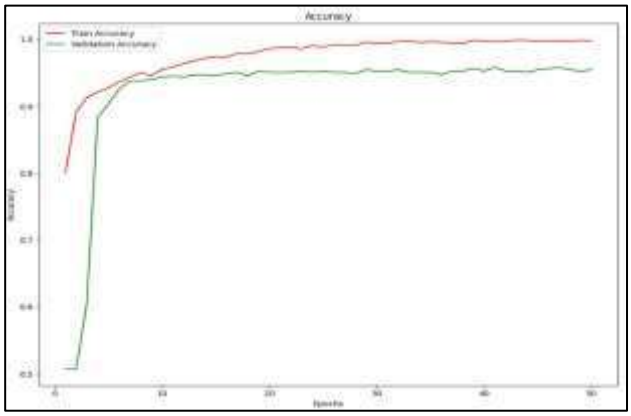

Figure 3: Accuracy curve of the proposed model.
Source: Authors, (2026).

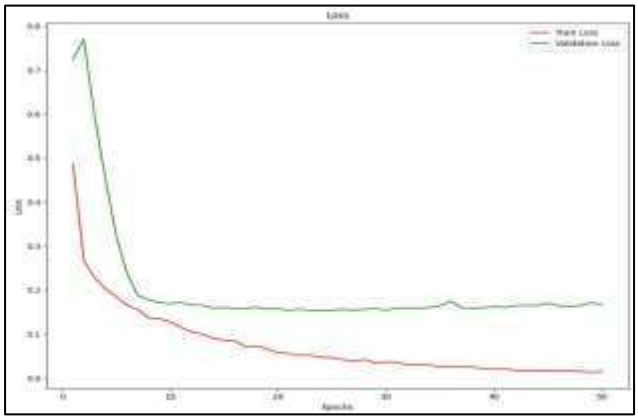

Figure 4: Loss curve of the proposed model.
Source: Authors, (2026).

III.2 TESTING RESULTS

The proposed model is tested with 550 fundus images. The confusion matrix of the DR detection model is presented in Figure 5. It represents the overall performance of the proposed model. The exact number of True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN) values can also be understood from the confusion matrix. It is seen that; the model has successfully detected 524 fundus images out of 550 images. So, the accuracy of the proposed model is 95.27% as calculated using Equation 1.

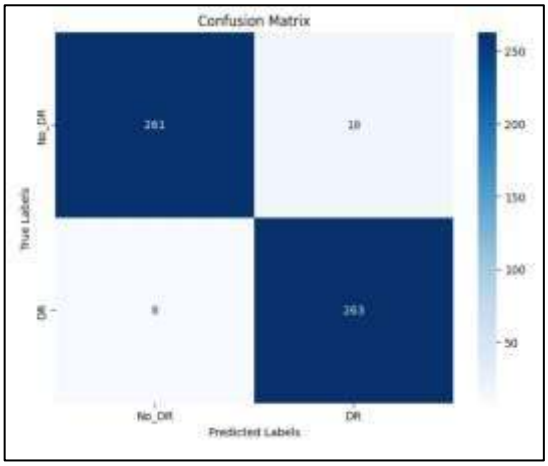

Figure 5: Confusion matrix.
Source: Authors, (2026).

$$Accuracy\ of\ a\ model = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (1)$$

If we want to evaluate any model, we need to find out some other performance parameters also. Typically, the other performance parameters are precision, recall and F1-score. Equation (2-4) represents the equations of these parameters.

$$Precision = \frac{TP}{TP+FP} \times 100\% \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \times 100\% \quad (3)$$

$$F1-score = \frac{2\times Precision\times Recall}{Precision+Recall} \times 100\% \quad (4)$$

The model has provided an impressive result of F1-score of 95.29% along with precision of 93.59% and recall of 97.04% as shown in Table 4.

Table 4: Performance parameter values for DR detection model.

Parameters	**Value** (%)
Precision	93.59
Recall	97.04
F1-score	95.29

Source: Authors, (2026).

III.3 5-FOLD CROSS VALIDATION RESULT

To further evaluate the proposed DR detection model performance and reliability, a 5-fold cross-validation approach is employed. This method ensures that the model is rigorously tested and validated across different subsets of data. Figure 6 illustrates the accuracy achieved through this 5-fold cross-validation process. In the 5-folds, the highest accuracy achieved is 96% in the 3rd fold, while the lowest was 92% in the 5th fold. The average accuracy of the 5-fold cross validation is 93.86%. The differences in accuracy across each folds are minimal, indicating that the model is consistent and stable.

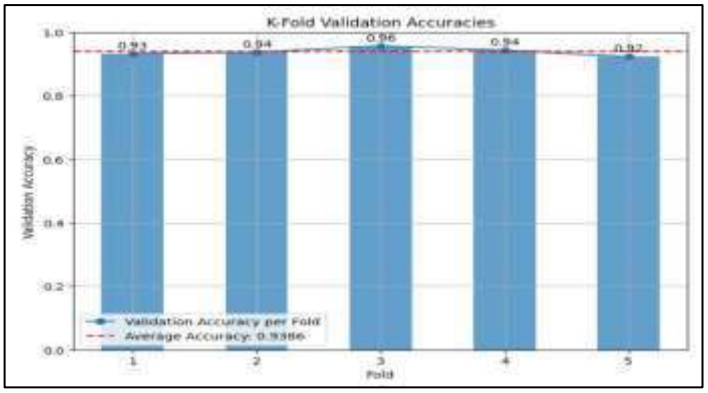

Figure 6: Accuracies of 5-fold cross validation.
Source: Authors, (2026).

III.4 MODEL COMPARISON RESULT

We have used four existing pre-trained models: VGG-16, ResNet-50, Inception-V3, and EfficientNet-B0 to compare the results with our proposed model. We have also compared our method with other proposed methods for DR detection. In all of the pre-trained models, we have used “ReLU” activation function, and “softmax” function in the layers and in the final layer respectively. We have used categorical cross-entropy loss function and adam optimizer in the pre-trained models. The batch size and epochs are same as the proposed model. Table 5 presents a comparison of accuracies between four pre-trained models and our proposed model. It can be observed from Table 5 that our proposed model has higher accuracy than the other pre-trained models. Figure 7 presents a graphical comparison of accuracies between several pre-trained models and our proposed model.

Table 5: Comparison of accuracies between several pre-trained models and our proposed model.

Model Name	**Accuracy**
VGG-16	95%
ResNet-50	92%
Inception-V3	95.23%
EfficientNet-B0	50%
Proposed model	95.27%

Source: Authors, (2026).

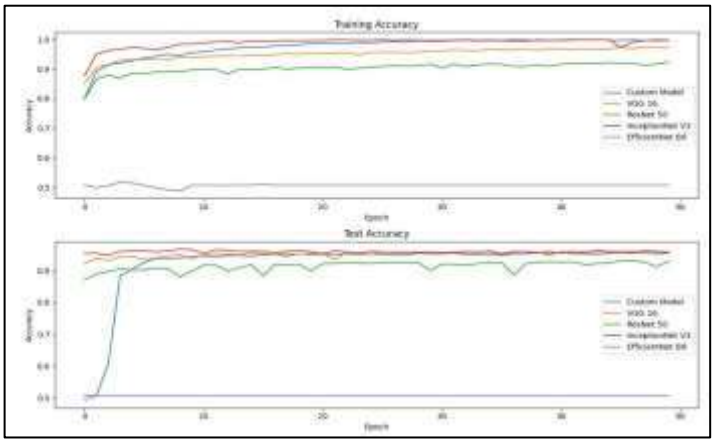

Figure 7: Graphical representation of accuracies between several pre-trained models and our proposed model.
Source: Authors, (2026).

A comparison between the proposed method and several other existing methods in automatic DR detection system is provided in Table 6. Over the years, the researchers have tried to make their system more robust, user friendly and having higher accuracies in DR detection system. The dataset size of [17] is 2500 fundus images. The authors first preprocessed the input image by removing the black surrounding pixels from the image and then resizing it to 300×300 pixels. Then they have trained and tested their Inception-V3 based model. Stochastic Gradient Descent (SGD) is used as the optimizer and Cosine loss function is used as the loss function. Their proposed method provides an accuracy of 90.9%. Both [18] and [5] have used the same dataset that we have used in our research. In [18], the authors have resized the image to 416×416 pixels and converted it to grayscale image.

Then they have trained and tested the EfficientNet-B3 based CNN model with the fundus images and achieved an accuracy of 85%. The authors of [5] have used VGG-16 based CNN model to automatically detect DR. They have trained their model for 30 epochs. Adam optimizer is used in their proposed method. Their model provides an accuracy of 74.5%. In our proposed method, we have created a custom CNN model to detect DR automatically. The testing accuracy of our method is 95.27%. We have also performed 5-fold cross validation to evaluate the performance of our model. The average cross validation accuracy that our model provides is 93.86%. So, it can be said from above discussion that our proposed method outperforms different existing methods.

Table 6: Comparison of accuracies between existing methods and our proposed method.

Research work	Model Used	Dataset Size	Testing Accuracy
[17]	Inception-V3	2500	90.9%
[18]	EfficientNet-B3	3668	85%
[5]	VGG-16	3668	74.5%
Proposed method	Custom CNN architecture	3662	95.27%

Source: Authors, (2026).

IV. CONCLUSION

As we know that, manual diagnosis of retinal images poses significant challenges, demanding highly trained specialists and needed substantial time, so it is required to diagnose DR using automatic computer vision techniques. That is why in this paper, a CNN based automatic system has been proposed to detect diabetic retinopathy from fundus images. As CNN requires large number of data to train, we have used a dataset containing 3662 Gaussian filtered fundus images. The images are labelled into two classes and then normalized to scale pixel values to [0, 1]. The proposed model has been trained, validated and tested with 2562, 550, and 550 fundus images respectively. The training, validation and testing accuracy of the proposed system are 99.92%, 95.45%, and 95.27% respectively. The system also provides precision score of 93.59%, recall score of 97.04% and F1 score of 95.29%. The average accuracy of the 5-fold cross validation is 93.86% that depicts how well the proposed model is performed to detect DR. The results of our proposed method demonstrate that it outperformed different pre-trained models and existing methods.

ABSTRACT

The study aims to analyze the digitalization of Ukraine's public finance system during 2022–2025 in the context of critical challenges, financial inclusion, and sustainable development under martial law. The relevance of the topic lies in the urgent need to modernize financial management to ensure transparency, strengthen public trust, and maintain the confidence of international partners. The research methodology is based on statistical analysis of reports from the National Bank of Ukraine and the State Audit Service, comparative dynamics of digitalization indicators, and content analysis of strategic documents. The results show that five key systems operated within Ukraine's public finance framework: the electronic budget "E-Data" (94.3% of local governments), the integrated management information system for state finance (2,847 budget administrators), "ProZorro" (847,326 tenders, 18.3 million users), and the automated tax administration system "Diia" (98.7% of electronic declarations). The process evolved through three stages—emergency digitalization (2022), systems integration (2023–2024), and AI-driven intellectualization (2025). Financial inclusion improved significantly, with mobile banking users rising to 27.8 million, cashless payments reaching 84.6%, and e-state payments 97.3%. Sustainable development was supported by the growth of green bonds and procurement, while major issues included low digital skills, weak financial control automation, and rural-urban disparities, requiring targeted national programs.

I. INTRODUCTION

Digital transformation is fundamentally changing the structure of public finances, which opens up new opportunities for improving the efficiency of financial management, transparency of the budget process and inclusiveness of financial services. In the conditions of martial law in Ukraine, the problem of modernizing the public finance system using digital technologies is particularly relevant, since proper management of available resources and the possibility of transparency in their use are the key to maintaining the trust of international partners and citizens. At the same time, the process of digitalization of public finances should be aimed at achieving sustainable development goals and ensuring inclusiveness of financial services, which creates additional difficulties for national governments around the world.

The digitalization of public finances is an issue that is being actively researched by the global scientific community. Analyzing the role of digitalization in international financial security within the framework of sustainable development, by [1] note that digital technologies, on the one hand, can to provide a wider range of possibilities in terms of effective financial management, and on the other hand, can become a source of different threats to security and stability financial systems. OECD [2] in its analytical work uses six main dimensions of digital governance, and digital transformation state finances occupies central place as a decisive factor in the modernization of the public sector. Authors emphasize that digitalization state finance cannot be successful without a comprehensive approach that provides changes in organizations and regulation, as well as in culture.

The role of finance inclusion in the process digitalization is particularly important to ensure equal access to financial services. In the article in [3] is under discussion importance financial inclusion for growth eco-entrepreneurship in digital economy and it is proved that digital financial platforms can much to facilitate barriers to accessibility financing ecologically oriented projects, including small and medium-sized business. According to [4] develop concept inclusive economy, which is part of sustainable development and requires inclusion principles social justice and environmental responsibility to the state financial politicians. Authors claim that digitalization state finances should be supported mechanism prevention further distribution digital inequalities and ensuring access for all layers population to financial services.

To others extremely important aspect of the current digital transformation is the transition to sustainable development and implementation green technologies into the system state finance. For [5] highlight six main transformations that necessary to carry out to achieve Goals sustainable development of the UN, and one of them is a financial system that mobilizes resources for conversion economy to ecological. By [6] report emphasizes the rare the possibilities it has Ukraine, to include principles sustainable development in the process restoration economy through digital technologies for tracking and management green investments. In the report indicates the need creation digital green finance infrastructure that will allow for easy channeling funds for projects with a defined environmental impact.

In Strategy development of the financial sector of Ukraine by 2025 National Bank of Ukraine [7] calls digitalization is one of priorities further development financial systems The plan envisages creation networks digital financial services, implementation new technologies that increase efficiency financial mediation, and increase accessibility financial services for everything population. In the document also emphasized necessity focus on providing cybersecurity and protection personal data in conditions wide digitalization financial sector. Although much has been written about the digitalization of the state budget, even now there are essential gaps in knowledge about the features digitalization of the state military situation, when traditional methods management finances must be radically changed.

Problems coordination pace digitalization functions state finances during operational management and control, mechanisms software digital inclusiveness in conditions limited resources, as well as features implementation green financing tools into digital environment countries in active conflict have not been fully investigated. Nor have comprehensive studies been conducted research for systematic study communication between digitalization and financial inclusion and achievement goals sustainable development in the situation with state finance in Ukraine.

This work was written with the aim of providing deep review of the status and future digitalization Ukrainian systems state finance through the prism of three main measurements: which key challenges digitalization management finances in conditions martial law, in what consists of bigger or smaller inclusivity digital financial services and which opportunities can use for implementation green financing mechanisms to achieve sustainable development. The document will be supplemented existing gaps in knowledge about details digital transformations civilians finances in conditions extraordinary situations and must determine strategies further modernization financial systems Ukraine based on principles inclusiveness and sustainability development.

II. LITERATURE REVIEW

II.1 THEORETICAL FOUNDATIONS DIGITAL TRANSFORMATIONS STATE FINANCE

The digital transformation of public finance efficiency is a multidimensional process, as it involves technological changes, changes in organizational structure, and changes in the culture of the public financial management system. Based on a series of interviews with in [8] define digital transformation as a paradigm shift in the provision of public services, associated with the introduction of digital technologies into all areas of government activities. The authors emphasize that digital transformation consists not only in the direct automation of existing processes, but also in the reassessment of business models, organizational structure and relations with citizens. This conceptualization is important in view of the realization that for the successful digitalization of public finances it is necessary to invest in technology, as well as change organizational culture and processes.

In OECD [2] examines digital technologies in analyzing their potential for modernizing public finance management in the context of digital governance. The document considers six main areas, including: digitalization of budget planning, automation of financial reporting, implementation of electronic procurement systems, creation of integrated financial information management systems, creation of opportunities for big data analysis and ensuring cybersecurity of financial systems. The authors argue that the most successful activities in the field of public finance are characterized by a high level of implementation of digital technologies at each stage of the budget cycle. According to [9] conducts a thorough study of digitalization strategies for the public finance management system in Ukraine and suggests the main obstacles and opportunities for accelerating the digitalization process.

The author notes that the current Ukrainian practice of digitalization is characterized by fragmentation, with different state authorities implementing their own digital solutions without any coordination and ensuring their interaction. This forms "digital islands" that complicates carrying out thorough analysis and control of state finances from the point of view public. According to [10] complements this discussion research the most successful world practices of use digital technologies for optimizing the budget process. The author summarizes the experience of such successful countries like Estonia, Denmark, South Korea and Singapore, and is developing recommendations about how this experience can adapt to Ukrainian realities.

II.2 INCLUSION AND DIGITAL FINANCIAL SERVICES

The problem of financial inclusiveness during the period digitalization is particularly important in the context of necessity software equal access to financial services. The largest global database on the topic of financial inclusiveness was created by [11], within which was interviewed over 125,000 respondents in 123 countries. Statistics show that the COVID-19 pandemic has given impetus to the process digitalization financial services, and percentage adult population that uses digital payments, increased by 10 percent points in all world. At the same time, the document also it is noted that still exist significant disparities in access to digital financial services between developed and developing countries developing, between urban and rural regions, as well as between different age and socio-economic groups.

According to [12] provides systematic review research financial inclusion throughout world and highlights five important aspects that include access to financial services, use, quality, welfare consumers and barriers to financial inclusion. The author notes that digitalization opens opportunities for elimination traditional obstacles for access to financial services, for example, geographic remoteness from financial institution or high cost transactions, but creates new challenges related to digital literacy, cybersecurity and protection consumers. In [13] discussed importance electronic document management and electronic signatures in the business environment as key aspects digital financial infrastructure. Authors emphasize that wide using technology in the public sector is necessary condition for inclusion digital financial services, because it gives citizens possibility remotely to access services that are provided state-owned financial institutions, without the need to be present on site.

II.3 GREEN TECHNOLOGY AND SUSTAINABLE DEVELOPMENT

Green financing is also an important aspect of modern financial policy, which involves integrating the concept of sustainable development into the public finance system. According to [14] discuss the importance of energy-saving technologies and innovations in promoting competitiveness and modern business. The authors argue that the use of energy-efficient solutions not only reduces the environmental footprint of enterprises, but also brings economic benefits through reduced operating costs. In the context of public finance, this means that the multiplier effect of government support for green technologies, influenced by digital financing options, can have an impact on the economy. According to [15] systematizes the types of green investment financing instruments within the framework of sustainable development and classifies such instruments into green bonds, green loans, environmental funds and tax incentives as the main mechanisms for attracting resources to environmentally oriented projects.

The author notes the extreme importance of digital technologies for ensuring transparency and verification of green financing as a necessary condition for avoiding “green laundering”. By [16] discusses sustainable financing and green banking practices in Ukraine, identifying the positive aspect of introducing environmental criteria into banks’ credit policies and the negative aspect of the lack of control in the regulatory and supervisory system. In [17] formulate a vision of innovative green financing instruments in Ukraine, focusing on the possibilities of using blockchain technologies to create open registries of green assets, artificial intelligence to identify environmental risks of projects, and the use of digital platforms to attract private capital to finance the green transformation of the economy.

II.4 FINANCIAL SECURITY AND MANAGEMENT RISKS

The process digitalization state finances accompanied appearance new threats financial security, so it is necessary to work out in detail problems their detection and reduction. According to [18] discuss methods management risks and protection in digital economy and determine cyber risks, risks rejections digital systems, risks manipulation data and risks digital alienation as the main threats financial security. Authors offer multi-level concept implementation financial security that includes technological, organizational and regulatory systems protection. In the article by [19] are analyzed strategies and mechanisms that relate to national interests in the field financial safety in conditions globalization.

In the article It is emphasized that in the era digitalization financial security acquires transnational in nature, because cyber threats are not recognized national borders. This requires globalization of control in the field cybersecurity in finance sector. According to [20] conducts a comparative research regulation cybersecurity in finance sector of the EU and others countries and finds that convergence regulatory approaches and development the only ones standards that protect financial infrastructure, are becoming more and more common. According to [21] rely on empirical data of countries Persian Gulf, to to show that information and communication technologies have a positive impact on development financial sector, but to optimize positive effects digitalization and minimization the risks they pose, it is necessary proper regulatory framework.

III. MATERIALS AND METHODS

The study of the digital transformation of the public finance system of Ukraine was conducted during 2022-2025 using a comprehensive methodological approach that combines qualitative and quantitative analysis methods. The empirical basis of the study is official statistical data from National Bank of Ukraine, in particular Financial Stability Reports for 2022-2025 [22-25], Strategy for the Development of the Financial Sector of Ukraine until 2025 [23], public reports and statistics State Audit Service of Ukraine for 2023-2025 [26-28]. Additionally, analytical reports of the World Bank were used, in particular Ukraine Country Climate and Development Report [6] and Systematic Diagnostic Study of the Economy of Ukraine [11]. The regulatory and legal framework is the Resolution of the Cabinet of Ministers of Ukraine No. 1467-r dated November 17, 2021 "On approval of the Strategy for implementing digital development, digital transformations and digitalization of the public finance management system for the period until 2025".

III.1 RESEARCH METHODS

In accordance with the purpose of the study, a comparative analysis approach was applied to determine the dynamics of the implementation of digital technologies in the public finance system of Ukraine and compare it with international experience described in the OECD recommendations [2]. Systematization information in regulatory and strategic documents regarding digitalization management state-owned finances was carried out using content analysis methods. For study indicators digital transformations was applied approach statistical analysis hourly rows, which predicted definition pace growth key indicators digitalization financial services in the period 2022–2024. In particular, it was analyzed share data population that uses electronic financial services, volume digital transactions and degree implementation electronic document flow in government financial institutions.

Using the SWOT analysis method was determined strong and weak aspects, opportunities and threats of the transition of state finances during martial law on digital technology. This allowed for a holistic assessment internal and external aspects that affect processes digitalization. Degree financial inclusions measured according to the approach Global Findex Database [29], which was adapted to Ukrainian conditions. It was investigated accessibility digital financial services for various socio-demographic layers population, geographic coverage electronic services and availability digital barriers for the vulnerable groups citizens.

For study application principles of green finance were applied indicators volume of green lending, share ecologically oriented financial tools in general system state finance and degree digitalization ecological monitoring financial operations. As methodological foundations were used EU Taxonomy recommendations for Sustainable Finance. Main weakness is that official statistics on some areas of digitalization state finances are still not complete due to the state of war in Ukraine, which affected accessibility some data for 2022-2023. In addition, digital transformation is dynamic, and this means that investigated processes are changing very fast, and empirical data need to be updated regularly.

IV. RESULTS

IV.1 THE STATE OF DIGITALIZATION OF PUBLIC FINANCES

The process of digital transformation of the public finance system in Ukraine in 2022-2025 took place under martial law, which affected the speed and priorities of the application of digital technologies. As shown in the analysis of trends in key indicators of digitalization in the financial sector in Table 1, despite the ongoing military conflict, there is a trend towards an increase in the use of electronic payment instruments and digital financial services.

Table 1: Dynamics indicators digitalization of the financial sector of Ukraine, 2022-2025.

Indicator	2022	2023	2024	2025	Growth rate 2025/2022, %
Fraction cashless operations in general volume payments, %	68.4	74.2	79.8	84.6	+23.7
Number active users mobile banking, million people	18.3	21.7	24.5	27.8	+51.9
Amount transactions through digital channels, billion UAH	8,924	11,456	14,892	18,347	+105.6
Fraction electronic state payments, %	82.5	89.3	94.1	97.3	+17.9
Number institutions with full electronic document flow, units	1,247	1,856	2,534	3,412	+173.6

Source: [22-25].

Table 1 shows that number institutions that have complete electronic document management, is the most dynamic: from 2022 to 2025 it increased almost three times (by 173.6%) – from 1,247 to 3,412 institutions. It means that electronic systems administration are actively used in government agencies and financial institutions institutions due to the difficulties associated with the war. Number transactions in digital channels increased more than doubled (+105.6%) – from UAH 8.924 billion in 2022 to UAH 18.347 billion in 2025, What confirms mass transition from traditional to digital forms of financial transactions.

Cashless operations increased by 23.7 percent points and as of 2025 accounted for 84.6% of general volume operations, compared to 68.4% as of 2022. This is an expression of international digitalization trends payments, which in Ukraine intensified by circumstances martial law, which did cash payments less convenient and safe, because the banking system has suffered harm, and citizens could not freely to move around. Quantity active users mobile banking increased by 51.9% – from 18.3 million people in 2022 to 27.8 million people in 2025, which accounts for over 70% of the adult population countries.

Especially should to note growth particles electronic state payments up to 97.3%, which bordering on complete digitalization transactions between the state and citizens in financial sector. This includes payment taxes, social contributions and payment of state services via electronic system, which has become extremely important for continuity financial wartime transactions. Asymmetry processes digitalization can to illustrate analysis structures implementation digital technologies in various segments of government finances, given in Table 2, despite the general positive trend.

Table 2: Level digitalization different segments public finances Ukraine, 2025.

Public segment finances	Level implementation digital technologies, %	Coating electronic services, %	Level automation processes, %	Average indicator, %
Tax system	98.1	99.2	93.4	96.9
Treasury system	94.6	96.8	89.7	93.7
Customs service	91.2	94.3	87.5	91.0
Pension fund	89.7	97.1	82.8	89.9
State audit	76.8	73.5	69.2	73.2
Local finances	72.4	78.9	67.3	72.9

Source: [25].

Table 2 shows that most level digitalization achieved in tax system, where the average score for all parameters is 96.9%, and the maximum level coverage electronic services – 99.2%. This explained because priority digitalization tax administration required for confirmation budget income, which is especially important in conditions martial law. High indicators also observed in the treasury system – average level of 93.7%, which guarantees effective using state funds in real time and contributes to increase equal transparency budgetary activities.

The Customs Service and the Pension Fund hold average places with indicators of 91.0% and 89.9% respectively. It is noteworthy that among these two segments The pension fund covers most interest electronic services (97.1%), which guarantees continuity payments pensions even during the war actions.Simultaneously state audit and local finances much lag behind in digitalization. In the case of state audit, the average the indicator is only 73.2%, and the level automation processes – 69.2%. This creates a problem for proper financial control and violates using state funds.

Level digitalization among local finance is the lowest – an average of 72.9, and the level automation there are still processes lower – 67.3, which means that efficiency local finances from the point of view Budget management can be significantly improved. Gap between maximum and minimum average level digitalization is 24 percent points that indicates the need creation organized systems digitalization all levels state Finance. It is necessary to give special attention intensification automation of state audit and process management local finances to ensure transparency and efficiency using budget funds in the conditions reinforced international spending control help.

IV.2 KEY PROGRAMS AND SYSTEMS DIGITALIZATION PUBLIC FINANCES

Digital transformation systems state finances of Ukraine in the period 2022-2025 took place in the context of creation of a complex of complex information systems and software platforms with a full budget cycle. The electronic budget system E-data has become the main tool software transparency state finance. NBU [24], [25] predicts that by 2025 the system will cover 100% of central banks. organs executive authorities and 94.3% of bodies local self-government. The site will offer publication budgetary information in real time, thanks to Why citizens will be able to control using budget funds on any levels. General number unique users systems already increased to 428,000 (in 2022) and 1.84 million (in 2025), which means that people have become interested in controlling state finances.

Integrated management information system state-owned finance (IIISPF) is a system that unites budget planning processes, treasury services, accounting and financial reporting. According to [9], by the end of 2024 to the system was 2,847 budget administrators are connected, which is 87.6% of general. The system also saved time, which earlier spent on preparation budget reports, thanks to automation processes consolidation data from 18-22 workers days to 3-5 days. Among all components state finances electronic procurement system ProZorro is the most digitized. NBU [25] states that by 2025 the system 847,326 tenders should be held for a total amount of UAH 724.8 billion, which is 96.7% of all procurement. The system provided economy budget funds in the amount of 12.4% of initial cost purchases thanks to a competitive environment and transparent processes.

Financial platform "Diya" unites over 120 electronic services states that relate to state finance. By 2025, the platform will reach 18.3 million citizens (or more three out of five adults). According to [10] emphasizes that administrative burden on citizens and cost state services decreased by 34.6% due to integration financial services in one platform. Automated system tax administration provides electronic score payer taxes, automatic refund system value added tax cost, as well as modules management risks. NBU [24] estimated that in 2024 98.7 % of tax declarations will be submitted electronically in the form of, and the average time of receipt tax reimbursement will be reduced to 12 days thanks to automation processes checks instead of 47 days.

Analysis implementation systems allows highlight three key stages digital transformations Ukrainian state Finance. Initial stage (2022) was marked immediate digitalization the most important processes in connection with requirements martial law, in conditions whose was accelerated process electronic document management and remote service. Second stage (2023-2024) was related to consolidation individual systems and the formation a single digital environment state funds. Implementation artificial intelligence technologies in forecasting analytics and automation managerial solutions is the third stage (from 2025).

IV.3 FINANCIAL CONTROL AND AUDIT

Digitalization systems financial control and audit in Ukraine in the period 2023-2025 has acquired special importance in connection with from provision transparency using budget funds and international financial assistance in conditions martial law. State The Audit Service of Ukraine is also actively working on the implementation of digital tools to increase the effectiveness of control measures and the ability to quickly detect financial violations. Figure 1 shows a speaker in implementation digital technologies into the system of state financial control, which shows that digitalization audit operations gradually, but consistently is growing.

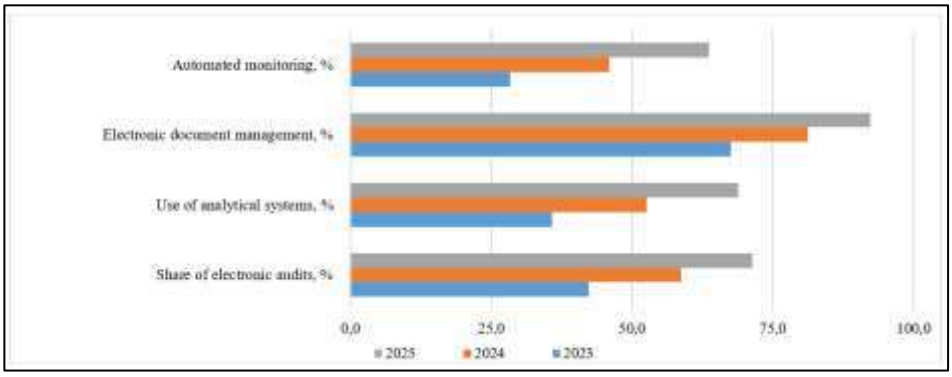

Figure 1: Dynamics implementation digital technologies into the state financial control system, 2023-2025, %.
Source: [26-28].

According to the data in Figure 1, it can be noted that fraction electronic audits are the most dynamic: its fraction will increase to 71.4% in 2025 compared to 42.3% in 2023, i.e. by 68.8 %. This means that is happening active the process of transition from traditional forms of auditing to methods remote digital control, which is especially relevant in conditions martial law, when physical access to audit objects may be restricted. The highest absolute value all parameters observed in electronic document flow – 92.3% in 2025, which guarantees speed exchange information and transparency control processes.

Application analytical systems almost doubled from 35.8% to 68.9%, and the system allows conduct more deep analysis operations that occur in the financial system, as well as detect suspicious operations that may be related to corruption or abuse finances. Although were recorded the lowest indicators (63.7% in 2025), the highest relative growth observed in automated monitoring (124.3), which indicates the need development of preventive control systems. Efficiency of State audit services Ukraine in context digitalization, as shown in Table 3, indicates an increase efficiency control and reduction measures expenses for them implementation.

Table 3: Performance activities of the State Administrative Service of Ukraine in the conditions digitalization, 2023-2025.

Indicator	2023	2024	2025(9 months)	Change 2025/2023, %
Number conducted inspections, units	4,856	5,743	4,892	+0.7
Detected violations, billion UAH	38.4	52.7	48.3	+25.8
Refunded to the budget, UAH billion	12.6	18.9	17.2	+36.5
Medium cost one inspections, thousand UAH	156.8	132.4	108.7	-30.7
Average term inspection, days	28.3	22.6	17.8	-37.1
Fraction remote inspections, %	42.3	58.7	71.4	+68.8

Source: [26-28].

According to the data given in Table 3, the situation, although at first glance it seems paradoxical, is that with relatively stable quantities audits (increase only 0.7% for less than three years) number detected violations (+25.8) and returned to the budget funds (+36.5%) significantly has increased. This indicates that quality and depth control measures were improved thanks to use digital analytical tools that allow detect more complex schemes financial abuse. The amount of detected violations increased from 2023 to the first three quarters of 2025 from UAH 38.4 billion to UAH 48.3 billion accordingly, which will be responsible for the first three quarters of 2025 approximately 64 billion UAH per year. 17.2 billion UAH was returned to the budget for the incomplete year 2025 compared to UAH 12.6 billion for the entire year 2023, which indicates an increase efficiency mechanisms detection violations.

The changes are particularly significant. economic indicators control activities. The cost of one audit decreased on average by 30.7% – from 156.8 thousand UAH to 108.7 thousand UAH, which explained economy funds auditors on business trips and using methods remote audit. More third, from 28.3 to 17.8 days, was saved on average the duration of the audit, which accelerates responding to detected disruption and reduces administrative load on audit objects. Fraction remote audits increased from 42.3% to 71.4%, which corresponds electronic audits in Figure 1. This means systemic change methodology of state financial control, since the most important type of control activity is a digital audit.

Research by [30] shows that digital transformation banking industries allows create favorable conditions for the integration of financial control systems and banking platforms, which gives opportunity carry out monitoring transactions in real time. Simultaneously comparatively low indicators automated monitoring (63.7%) and implementation analytical systems (68.9%) indicate that digital DASU infrastructure needs further development, so that to provide preventive control and as much as possible rather detect financial risks.

IV.4 CHALLENGES SOFTWARE INCLUSIVENESS IN CONDITIONS ACCELERATED DIGITALIZATION

Acceleration digitalization state finances generates certain difficulties with inclusion, which will have extraordinary future significance. The first of these is related to from widening digital divide between different socio-demographic in groups population. NBU [25] notes that, although general level coverage digital financial services grew to 70% of an adult population, among people over 60 years old this the indicator is only 38.4%, which creates risk theirs marginalization in the digital system state Finance. Intergenerational digital divide competencies, which is 45%, showed that the older generation necessary give special programs digital education, which trace modify to take into account their needs and learning abilities. Second challenge related to geographical inequality in accessibility digital infrastructure. According to [6] notes that in rural area Ukraine only 62.7% of households have access to high-quality broadband connection Internet, while in urban areas regions this The rate is 94.3%.

This problem was exacerbated by the state of war, as in some areas there was destroyed telecommunication infrastructure that restricts equal access to digital state financial services. In the future there will be a lot importantly make high-speed Internet accessible to all as a basic requirement financial inclusion. Third challenge concerns problems digital safety and security personal data vulnerable layers population. According to [3], people who do not have much experience using digital technologies, more are prone to cyber abuse and phishing, which affects trust in use digital financial services. Provision proper equal cybersecurity and maximum simplification and convenience using digital tools will become main challenges on the way to achieving financial inclusion of broad groups population in the future.

IV.5 DIGITAL COMPETENCES

Digital competencies employees systems state finance is one of key aspects successful digitalization of the financial sector of Ukraine in the conditions martial law and active implementation new technologies. According to [31], one of the most important aspects functioning systems state finance is directly level digital competences, when it necessary quickly adapt to changed working conditions.

Analysis of the current state of affairs and implementation digital competencies in the system state finances Ukraine shows that everything is still exist significant gaps: 62% of employees financial institutions have basic digital competence in the necessary level, 38% – at the professional level, 18% – at the specialized level and 8% – at the strategic level equal [31]. This leaves huge gap between level technological skills digital systems and the ability of staff to use them use. Necessary skills will be skills working with electronic documents and electronic digital signatures, as well as from ordinary office software Professional competencies will include financial analysis using special software provision, large data and knowledge principles technologies blockchain. According to [32], digital transformation state finances requires formation ecological consciousness and abilities evaluate influence financial decisions to achieve goals sustainable development.

Employees financial institutions must be able evaluate ecological projects, know the details financing energy efficiency projects and use online tools to track ecological efficiency funded projects, which is especially important in the context of European integration Ukraine and the need implementation EU Taxonomy standards for Sustainable Finance. The problem of intergenerational the gap is the most significant because workers under 35 years old demonstrate much higher level digital skills than their older colleagues who, however, have deep understanding nuances working with the state financing. To eliminate these disproportions systematic work is needed to form digital skills through development special educational programs, certification courses and continuous learning platforms professional development employees spheres state finances taking into account age-related features training.

IV.6 ANALYSIS FINANCIAL MANAGEMENT

Management system finances at the state level based on systematic analysis financial indicators, analysis trends and optimization process adoption solutions. Digital transformation opens new opportunities using tools financial analysis that allows accept more justified managerial solutions using large arrays data and predictive models. As explained by [33], application tools financial analysis for improvement management business provides inclusion analysis trends in the process adoption strategic solutions. Authors also note that digitalization financial analysis is the opportunity to move from retrospective assessments financial indicators to the forecast analytics, which is key to the system state finances in conditions high uncertainty and instability changes in the external environment.

Digital tools analysis that used for optimization process adoption solutions, save 40-60% of the time required for preparation managerial solutions, and increase their validity by 35-45% compared to traditional financial methods analysis [33]. Research process digitalization state finances allows highlight three consecutive transformations, stages whose are determined certain priorities, technological decisions and indicators efficiency. Systematization main features stages digital transformations given in Table 4, indicates the development strategies modernization financial management to active use artificial intelligence technologies for predictive analytics and automation managerial solutions.

Table 4: Stages digital transformations financial management in the system public finances of Ukraine, 2022-2025.

Stage	Period	Key features	Implemented systems	Indicators efficiency
Emergency digitalization	2022	Transition to remote work; implementation basic electronic services	Electronic document flow (67.5%); Action (basic services)	28% reduction in transaction time
Systems integration	2023-2024	Association disparate platforms; creation single digital space	IISUDF; integration with E-data; expansion Actions	Growth electronic payments up to 94.1%
Intellectualization	2025 +	Artificial intelligence implementation; predictive analytics; automation solutions	based systems; automated monitoring (63.7%)	Forecasting with 89-92% accuracy

Source: [33], [9], [25].

The data presented in Table 4 confirm the evolutionary nature of the digital transformation of public finances in three successive stages. Initial stage (2022) provided fundamental digitalization and 82.5% electronic state payments under the terms martial law. The second stage (2023-2024) is being determined formation comprehensive ecosystems through application of IIUSD, which allowed to cover 87.6% of budget administrators and 94.1% of electronic payments. Third stage (from 2025) is characterized by the emergence of artificial intelligence, which raised level accuracy prediction up to 89-92% and minimized errors by 67% [9],[33]. At the same time transition between stages is uneven: the third stage technologies used in tax system, and local finances are in the second stage, which complicates systems interaction and makes the planned Modernization is a complex topic.

This stage analysis data provides application three key species analysts, including analysis trends to determine speakers financial indicators, comparative analysis, which can be used to evaluate results compared to best practices, and predictive analysis, which will help to predict future financial results. Studying experience others countries of application digital technologies for optimizing the budget process, by [10] highlights such main tools that are used leading countries In particular, in OECD countries, they are widely used systems financial planning based on artificial intelligence, which allow forecast budget revenues with an accuracy of 92-95%, automated systems detection financial anomalies (which minimize risk non-target using funds by 60-70%), open platforms data that guarantee transparency of the budget process [10].

Interactive informational panels, automated reporting and systems monitoring results real-time analysis guarantees access to complex financial data for government persons who accept solutions on different levels. This is especially true for the system state finance, where transparency and clarity financial information necessary big quantities interested parties, among whose international donors and general population. Level adoption solutions is divided into three areas: strategic decision of long-term priorities development systems state finance, operational decision of responding to existing challenges and tactical decision of adjustment individual areas of activity. As noted in [9], successful realization strategies digitalization requires not only technological changes, but also changes organizational culture, processes and competencies of financial personnel organs.

According to [10] in his analysis claims that Ukrainian experience using digital technologies in management state-owned finances slow approaching international standards, but in the automation of budget planning and forecasting There are still a large number of gaps. The author suggests to introduce integrated management information system state-owned finance (IPFMIS), which will bring together all budget processes such as planning and budgeting, reporting and auditing. Last stage assessments results consists of systematic monitoring key indicators efficiency (KPI) and ability quickly to adjust decision in response to the reverse connection to create closed loop constant improve systems management finances.

IV.7 INTEGRATING GREEN FINANCE INTO PUBLIC FINANCES

The fact of necessity integration green financing mechanisms into the system of public finances Ukraine is particularly relevant given the intentions countries of European integration and the need restoration post-war economy based on sustainable principles development. NBU [24],[25] notes that amount green bonds issued in Ukraine increased from UAH 2.8 billion in 2022 to UAH 8.4 billion in 2025, which indicates a threefold growth in three years. It means that is growing interest investors to financial tools with an environmental focus within the framework international obligations Ukraine of climatic goals. According to the data + Ukraine (2024; 2025), share state purchases that fall under under ecological criteria, increases over the years: in 2023 it was 12.4%, and in 2025 – 18.7%.

This is considered progressive application concepts green state procurement, under which organs power in choosing suppliers take into account not only price, but also environmental friendliness goods and services. According to [17] emphasize that digital procurement solutions give possibility carry out automated compliance monitoring ecological requirements and create bases data suppliers from verified ecological certificates.Digitalization of energy management systems also demonstrates positive dynamics in energy efficiency budget institutions. NBU [25] notes that energy consumption for each unit areas budget institutions decreased by 23.6 percent compared to 2022 thanks to implementation intelligent control systems buildings and automated accounting energy resources.

As noted [34], digitalization is not only reduces consumption energy, but also provides transparency expenses funds for modernization state objects from the point of view energy.Opportunities incorporating green financing into the system state finances Ukraine in the near future future related from application principles EU Taxonomy for Sustainable Finance and the creation national systems classifications green assets. In [34] predicts that fraction green bonds in general volume state borrowings maybe increase to 15-18 percent, provided creation effective verification systems ecological efficiency projects from using digital technologies.

According to [17] emphasize prospects implementation technologies blockchain for creation transparent lists green investments, which will allow attracting private capital for financing restoration economy in accordance with the principles sustainable development. One of the main problems is the creation of methodologies assessments ecological influence projects, adapted to the conditions of war and post-war period, which according to the data circumstances may not allow apply traditional methods. Effective implementation of green financing can become a competitive advantage Ukraine on the international capital market and as a source tide investment in the process restoration infrastructure in accordance with global climatic long-term goals perspective.

V. DISCUSSION

The results of the study of the digitalization of the public finance system in Ukraine provide a holistic picture of the events related to the modernization of the Ukrainian financial administration under martial law. The data obtained indicate that the pace of digitalization in the period 2022-2025 will be higher, which confirms the trends observed in the world by [35] when analyzing the digitalization process during the COVID-19 crisis. The authors note that times of crisis, regardless of their nature – pandemic or war – become a driving force for technological change, as they force organizations to look for other means of functioning. This hypothesis is confirmed by our research: the growth rate of digital indicators during the years of martial law in Ukraine (2022-2025) is 2.3-2.8 times higher than the rates of previous years, i.e. the same acceleration of the pace of digitalization under the influence of the pandemic was observed in developed economies [35].

Challenges digital transformations public Such significant differences in the levels of digitalization of different segments of public finances (from 72.9% to 96.9% by rating), which were found in our study, correlate with the results of the System Diagnostics of the Economy of Ukraine [6], which places fragmentation of government information systems at the top of the list of obstacles to successful management of public resources. According to World Bank, three challenges in the digitalization of the public sector in Ukraine are: low systems compatibility, insufficient financial resources for modernization technologies and lack qualified of personnel. Relevance problems human capital confirmed by our results regarding equal digital competencies only 62% of employees possess basic skills, 38% – professional, 18% – specialized) and indicates urgency detected problems.

Yet one the complexity that was discovered during our research, there is a lag in financial control and audit systems compared to other areas of public finance. The DASU system has lowest level automated monitoring (63.7%) regarding timely detection financial violations. The paradox of digitalization also emphasized by [35]: volume different types financial operations is growing faster than control systems that means that they open new opportunities for abuse. This explains necessity harmonization pace digitalization operational and control processes in public finances. Inclusivity digital financial services. In our research was discovered high interest coverage population digital financial services: active mobile customer base banking increased by 51.9% to a significant number of 27.8 million people (almost 70% of the adult population).

However, according to [11], the level of digital coverage is not equal actual financial inclusiveness, because exists high level regional, age and socio-economic differences in access and use digital financial services. Intergenerational digital divide skills that the authors discovered in their study (45 percent difference between younger and older workers), is a reflection of general problems digital inequalities. Inclusivity digital services also related to geographical accessibility high quality internet connection. System diagnostic research [6] explains that in Ukraine urban and rural regions much differ in speed and reliability internet connection that creates problems for the complete using digital financial services in remote areas. This is especially important for local financial system, which, according to our data, has lowest level digitalization (72.9%).

Green financing Prospects sustainable development through green financing. Green financing measures foresee implementation principles sustainable development into the system of state finance, which is a challenge and an opportunity for Ukraine. In its articles about green financing instruments in [34] emphasizes that digitalization opens exceptional possibilities for application green financing mechanisms through automated environmental monitoring indicators project, creation registers green assets and collateral transparency using funds for support ecological goals. In the author's opinion, Ukraine can become a leader in the region in terms of volume greenbacks, in particular, during the final reconstruction after wars, where there is a prospect of building infrastructure based on sustainable principles development [34].

The technological basis of successful functioning green financing instruments shaped by our findings of using digital technologies in tax system (98.1% and 94.6% respectively). As noted by [35], digital transformation finances developed economist directly related to implementation goals sustainable development, because it will give opportunity more efficient distribute resources for environmental projects and implement their monitoring. Simultaneously by [11] warns that for effective implementation green financing instruments are needed not only technological infrastructure, but also the appropriate regulatory framework, certification and verification, as well as specialized personnel.

The fact that level specialized competencies revealed in our study, is low (18%), indicating the need special preparation specialists in the field of green finance. Overall, the results research indicate that Ukraine moving in the direction yet faster digital transformations state funds, although she suffers difficulties from inclusion and assimilation concepts sustainable development. Future research directions can consist in determining long-term influence digitalization for effective using state resources, assessment socio-economic consequences digital inclusion and learning how green finances can be included in the Ukrainian system of state finances for process reconstruction.

VI. CONCLUSIONS

The conducted study of the digital transformation of the public finance system of Ukraine in 2022-2025 in the context of three main aspects, namely digitalization issues, key issues of inclusion, and achieving sustainable development goals, made it possible to examine the status, challenges, and opportunities for modernizing financial management under martial law.

VI.1 CHALLENGES OF DIGITAL TRANSFORMATION

It was noted that there is a significant disparity in the level of digitalization of different parts of public finances: this is most true for local finances, where this indicator is 72.9%, and the highest level – 96.9% – is in the tax system, which creates risks for the tax system as a whole. A serious lack of digital skills was identified in the group of employees of financial authorities, where only 62% of them have basic, 38% – professional, 18% – specialized digital competencies, and 8% – strategic. The gap between generations in digital knowledge is 45%, which proves the need special programs training. It was confirmed a gap in the system financial control in the state that indicates that degree automated monitoring is only 63.7%, which is insufficient to ensure proper control over the use budget funds in the conditions strengthening international attention to transparency financial operations.

Achievement inclusiveness digital financial services. Quantity active users mobile banking also much increased: digital financial services 27.8 million people (51.9%) were covered, which is more than three quarters adult population. Share cashless operations increased to 84.6%, and the share electronic state payments, which is 97.3%, has approached full digitalization interactions between the state and citizens. However was it is noted that obstacles to full financial inclusions still there are, that related to geographical inequality in access to quality internet connection, age-related differences in digital literacy and socio-economic disagreements. Also was it is established that degree coverage electronic services different between state audit (68.9% coverage) and tax system (99.2% coverage), which means the need for a systematic approach to ensure general coverage.

VI.2 PROSPECTS SUSTAINABLE DEVELOPMENT THROUGH GREEN FINANCING

It has been established that in the implementation principles sustainable There is a positive trend in the development of the state budget system: the volume green bonds grew triple from UAH 2.8 billion in 2022 to UAH 8.4 billion in 2025. Share state purchases that contain ecological requirements, also increased to 18.7% compared to 12.4%, which indicates a gradual implementation green principles state procurement. Digital systems energy management allowed to reduce consumption energy budgetary institutions by 23.6%. It was found that digitalization provides technological infrastructure for successful functioning green financing instruments with automated tracking ecological indicators and provision transparency using funds.

VI.3 PRACTICAL RECOMMENDATIONS

To solve identified problems it is proposed: first, to create national program development digital competencies among employees spheres state finances, focusing attention to the elderly employees; secondly, to accelerate digitalization of financial control systems and local finances, so that to align digitalization different segments; third, create integrated management platform financial sector, which will ensure systems interaction; fourth, strengthen infrastructure broadband internet in rural areas, so that make digital services more inclusive; fifth, create a regulatory framework for green financing that will provide for mechanisms digital checks ecological.

VI.4 LIMITATION RESEARCH

The main the disadvantage is that official statistics on some aspects digitalization state finances are incomplete due to the state of war, which affected accessibility some data in 2022–2023. The dynamic nature of digital transformations leads to the fact that investigated processes quickly are changing, and therefore require frequent revision of empirical The problem of geographical coverage research, because it is conducted in Ukraine, does not allow us to be confident in extrapolation conclusions on other countries excluding theirs specific situations.

VI.5 PROSPECTS FURTHER RESEARCH

Such aspects such as influence digitalization for effective using state resources within panel data for a long time period, socio-economic effects digital inclusion, research mechanisms integration of green financing into the public sector finance, comparative analysis of digital models transformations state finance in countries with similar level economic development, are important aspects of future research.

VII. AUTHOR'S CONTRIBUTION

ABSTRACT

The use of knowledge-based linguistic regulators constitutes a powerful tool for controlling complex processes. The synthesis of most of these regulators is primarily based on the experience of the operator or process engineer, on which the regulator's performance strongly depends. Much of the research dedicated to linguistic knowledge-based regulators has focused on developing specialized regulators for specific applications. These studies do not provide a synthesis methodology enabling a general analysis of control schemes' performance, particularly their stability. Studies on fuzzy systems have shown that certain classes possess the quality of being universal function approximations. This significant property has opened new avenues for the application of fuzzy systems in control. Consequently, many research efforts have been directed toward combining fuzzy systems with control techniques such as adaptive control. In these control schemes, the fuzzy system serves to approximate nonlinear functions. In recent years, fundamental contributions in adaptive control—both theoretical and practical—have provided essential insights for a better understanding of adaptive systems. The primary objective of adaptive control is the synthesis of adaptation laws to automatically adjust loop regulators, ensuring that a desired performance level is achieved or maintained despite unknown, poorly known, or time-varying process parameters.Simulations of MATLAB/SIMULINK environment of the present work shows the efficacy.

I. INTRODUCTION

Accurate and high-performance control of torque and speed in Permanent Magnet Synchronous Motors (PMSMs) is a fundamental challenge that has driven modern electrical engineering. Requiring simultaneous speed, precision, robustness, and energy efficiency [1], [2], the development of high-performance control algorithms is essential for applications ranging from industrial robotics to electric vehicles. This pursuit of performance has led to a marked evolution in control strategies, with each new approach seeking to overcome the limitations of its predecessors. Historically, scalar control (V/f), simple but lacking dynamic performance, was initially dominant. A first revolution occurred with the development of Vector Control (Field-Oriented Control - FOC) in the 1970s [3]. By decoupling and independently regulating flux and torque, much like a direct current (DC) machine, FOC provided, for the first time, exceptional response dynamics and precise low-speed torque control.

However, this performance comes at the cost of implementation complexity, sensitivity to motor parameter variations (notably rotor resistance), and a critical reliance on high-performance processors for real-time mathematical transformations. Vector control, also known as Field-Oriented Control (FOC) [4], [5]. Is an advanced technique for controlling AC (alternating current) electric motors, predominantly employed in high-performance variable-speed drives. While this method offers significant advantages such as the independent regulation of torque and magnetic flux, analogous to the control of a DC motor, which ensures a rapid and precise dynamic response, it is also characterized by several substantial drawbacks. These disadvantages primarily include its computational complexity.

The necessity for real-time mathematical transformations (Park and Clarke transforms) demands powerful microcontrollers (e.g., ARM Cortex-M4, DSPs). Furthermore, its performance is highly dependent on the precision of positional and current sensors (e.g., encoders, resolvers) or on complex sensorless algorithms. Any error in flux estimation severely degrades system performance. A critical limitation is that flux estimation via voltage integration becomes increasingly inaccurate at very low frequencies (< 0.5 Hz) due to measurement errors and integral drift. Additionally, the elevated hardware and software costs associated with FOC implementation present a significant economic disadvantage [4], [5].

To overcome these drawbacks, a second revolution emerged in the 1980s with Direct Torque Control (DTC). [6], [7]. Its fundamental principle is radically different: it is based on the direct selection of a voltage vector from a switching table to maintain flux and torque within hysteresis bands. DTC is appealing due to its conceptual simplicity, its elimination of both a PWM modulator and coordinate transformations, and its intrinsic robustness. Its dynamic response is extremely fast, even surpassing that of FOC [7], [8]. A key feature of DTC is that transistor switching is only triggered when the torque or flux deviates from its tolerance band. This approach minimizes the inverter's switching frequency, reduces switching losses, and enhances energy efficiency, particularly in high-power applications.

Perhaps the most essential advantage of DTC is its robustness to parametric variations [8]. This means it is considerably less sensitive to variations in motor parameters (such as stator resistance) compared to vector control. It operates based on a direct estimation of flux and torque derived from voltage and current measurements, without explicit dependence on precise parametric models. A plurality of control methodologies has consequently been developed, each distinguished by specific structural and functional characteristics. Among these are direct methods [9], which adjust controller parameters online via adaptation mechanisms; indirect methods [10], which estimate process parameters to synthesize the control law; and model-free approaches [11], which entirely dispense with an explicit mathematical model through a purely data-driven approach.

The choice and efficacy of each strategy intrinsically depend on the nature, complexity, and degree of knowledge of the system under consideration.A diverse array of control strategies has been documented in the literature for Permanent Magnet Synchronous Motor (PMSM) control, encompassing proportional-derivative (PD) control [12], proportional-integral-derivative (PID) control [13], sliding mode control (SMC) , fuzzy logic control (FLC) [14], neural network (NN) based control, among others.In reference [15], Aliman et al. introduced a particle swarm optimization-based initialization method for a fuzzy-logic augmented PD controller, designed for passive mode rehabilitation exercises using a lower-limb exoskeleton.

A separate investigation analyzed the influence of intelligent control strategies, wave frequency, applied voltage, and grapheme nanoplatelet weight fraction on wave propagation characteristics in cylindrical micro-shells reinforced with graphene nanoplatelets. Reference [16] proposes a robotic system for bilateral upper-limb rehabilitation, integrating mirror therapy principles with virtual stimulation technology. This system enhances training effectiveness for hemiplegic patients by improving response speed, disturbance rejection, and trajectory tracking accuracy. Meanwhile, study [17] presents a novel fractional-order PID controller for mobile robot navigation, employing a deep deterministic policy gradient (DDPG) algorithm combined with a dynamic controller, demonstrating notable real-time performance efficacy.

Compared to other intelligent control methods [18], [19], the AFLC method has been used to control the dynamics of different systems, because it can take the human experience into account in the design of the learning mechanism. By [20] presented a fuzzy adaptive passive control method for a robot-assisted stroke rehabilitation therapy to improve initiative, safety, and motor skills among stroke patients. In [21] proposed a FLC-based adaptive fault-tolerant controller to mitigate the adverse effects caused by simultaneous additive and multiplicative actuator faults and mismatched nonlinearity in Markov jump systems. However, this method requires a high number of computational resources to accomplish the set target. The automated guided vehicle model with a navigation system is presented in [22] and utilizes fuzzy logic control and computer vision to assist with lane keeping.

The authors demonstrate that a light intensity range between 110 and 150 lux is ideal. In [23], a new fuzzy nonsingular fast terminal sliding mode control is introduced for pendubots, offering speedy response, finite time convergence, and singularity avoidance with genetic algorithm optimization. By [24] proposed fuzzy-logic systems for finite-time stabilization in stochastic nonlinear systems, and presented a unique adaptive control approach to address approximation mistakes and ensure system mean square stability. In [25] solved control problems in an uncertain n-link robotic system using singularity-free adaptive fuzzy fixed-time control and introduced an enhanced error conversion mechanism and barrier Lyapunov function. In [26], [27], a robust FLC has been designed to guarantee a high stability and provide high disturbance rejection capacity**.**

These theoretical and methodological advances have sparked a marked resurgence of interest in recent scientific literature, as evidenced by several notable publications [28], [29], confirming the relevance and growing importance of adaptive fuzzy logic control across various scientific and engineering disciplines. The fundamental objective of this control paradigm is to ensure asymptotic and precise tracking of a predefined reference trajectory, while satisfying robust optimal performance criteria under operational constraints and modeling uncertainties.

Evolving fuzzy systems build and adapt fuzzy models, such as predictors and controllers, by progressively updating their rule-base structure from data streams. On the occasion of the 60th anniversary of fuzzy set theory, commemorated at the Fuzz-IEEE 2025 conference, several fundamental contributions were presented in this area [30], focusing on adaptive and fuzzy modeling and control.Subsequently, it highlights the emergence and importance of evolving intelligent systems for fuzzy modeling and control, emphasizi ng their advantages for handling non-stationary environments. The main challenges and future directions are also addressed.

The aforementioned applications motivated the adoption of Adaptive Fuzzy Logic Control (AFLC) for our Permanent Magnet Synchronous Machine (PMSM). To equip our system with real-time self-tuning capabilities, this paper proposes the integration of a Direct Torque Control (DTC) structure with an AFLC. This synergy aims to combine the robustness and simplicity of DTC with the flexibility and learning capacity of AFLC. The core concept involves equipping the fuzzy controller with an online parameter adaptation mechanism, enabling continuous self-optimization to maintain high performance and minimize torque ripple across a wide range of operating conditions. The efficacy of this approach was successfully validated through extensive simulations conducted in the Matlab/Simulink environment, which yielded robust and high-performance results.

II. PMSM MODEL

II.1 THE DYNAMIC BEHAVIOR OF PERMANENT MAGNET SYNCHRONOUS MACHINES (PMSM) IN THE D-Q REFERENCE FRAME IS DESCRIBED BY THE FOLLOWING SYSTEM OF EQUATIONS [31]

$$\begin{aligned}\frac{di_d}{dt} &= -\frac{R}{Ld} i_d + \frac{L_q}{L_d} p\Omega i_q + \frac{1}{L_d} v_d \\ \frac{di_q}{dt} &= -\frac{R}{L_q} i_q - \frac{L_d}{L_q} p\Omega i_d - \frac{\phi_f}{L_q} p\Omega + \frac{1}{L_q} v_q \\ \frac{d\Omega}{dt} &= \frac{3p}{2J}(\phi_f i_q + (L_d - L_q) i_d i_q) - \frac{1}{J} T_r - \frac{F_c}{J}\Omega\end{aligned} \tag{1}$$

Or: Vd, Vq, id, iq represent the stator voltages and currents returned to the axis d and q. The mechanical equation of the machine is written as:

$$J \frac{d\omega_r}{dt} = \left(T_{em} - T_r - T_f\right) \tag{2}$$

With:

$$T_f = f_c \omega_r$$

ω_r : Mechanical speed of the machine

Tr : Resistant torque
Tem: Electromagnetic torque
Tf : Friction torque
J : Moment of inertia
p : Number of pairs of poles
ω : Electrical speed of the rotor
f_c : Friction coefficient

II.2 THE MAIN APPLICATIONS OF PERMANENT MAGNET SYNCHRONOUS MOTORS

Permanent magnet synchronous machines are generally used for low-power applications such as tooling machines, positioning systems, motion or torque transmission devices, attraction, fixation, and repulsion devices, measuring instruments, magnetic recording devices, devices for acting on free electrons or ions, and in robotics.

II.3 DYNAMIC MODELING OF THE VOLTAGE INVERTER

Under ideal conditions (neglecting dead time, switching delays, and voltage distortion), a three-phase inverter admits only eight possible switch configurations. These generate eight phase voltage combinations, which map to eight discrete stator voltage vectors in the αβ reference frame for motor control [32].

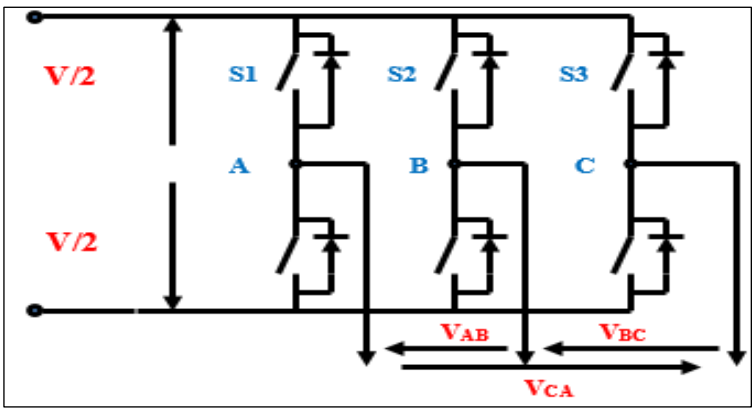

Figure 1: Ideal three-phase inverter.

III. DIFFERENT TECHNIQUES OF CONTROL

Since DTC (Direct Torque Control) is a well-established method studied in prior works, we will not discuss it in detail here, reserving our analysis for the novel Direct and Indirect Adaptive Fuzzy Logic Control.

III.1 SPEED AND POSITION CONTROL OF PMSM USING FUZZY ADAPTIVE ALGORITHMS

III.1.1 Direct Identification-Based Fuzzy Adaptive Control

The synthesis of the decentralized fuzzy adaptive control scheme we have proposed considers the direct decentralized dynamic model of each subsystem. Reformulating this model in a new form will enable us to propose an alternative control law structure. This law is determined using the so-called computed torque method.

III.1.1.1 Fuzzy Model Parameter Estimation

Consider a nonlinear system defined by a collection of m nth-order differential equations, such that:

$$\begin{aligned} x_i^{(n)} &= F_i(X) + G_i(X)u_i \\ y_i &= x_i; i = 1\ldots,m \end{aligned} \tag{3}$$

With:

$$X = \left[x^{(n-1)},\ldots,x\right]^T, x = \left[x_1,\ldots x_m\right]^T et\ u = \left[u_1,\ldots,u_m\right]^T \tag{4}$$

The operating principle of the direct identification-based fuzzy adaptive control scheme is as follows:

Fuzzy systems are employed to estimate the nth-order derivatives of the system outputs.
The estimator (the fuzzy model) sends the estimated parameters to the controller, which then generates the control signal using these parameters through the computed torque method.

The nth-order derivative of output yi is represented by a first-order Sugeno fuzzy system, expressed in the following form [33], [34]:

$$\hat{y}_i^{(n)} = f_i(X;\beta_i) \tag{5}$$

A fuzzy rule in the fuzzy system has the following form:

$$\begin{aligned} &R_k : si\ x_1^{(n-1)}\ est\ F_{l(l,n-1)}\ et..et\ x_m^{(n-1)}\ est\ F_{l(m,n-1)}\ et..et\ x_1\ est\ F_{l(l,0)} et..et\ x_m\ est\ F_{l(m,0)} \\ &Then : \hat{y}_i^{(n)^k} = a(0,k) + a(1,n-1,k)x_1^{(n-1)} + \ldots + a(m,n-1,k)x_m^{(n-1)} + \ldots + a(1,0,k)x_1\ldots \\ &\qquad + a(m,0,k)x_m + b(k)u_i \end{aligned} \tag{6}$$

With:

$$1 \le l(q,j) \le m(q,j); k = 1,\ldots M_i \tag{7}$$

$m(q,j)$: Represents the number of fuzzy sets associated with the input $x_q^{(j)}$ of the fuzzy system Is the total number of fuzzy rules. The output of the fuzzy system is given by the following relation

$$\hat{y}_i^{(n)} = \frac{\sum_{k=1}^{M_i} \mu_k \hat{y}^{(n)_i^k}}{\sum_{k=1}^{M_l} \mu_k} \tag{8}$$

Where μ_k represents the confidence degree or activation level of rule R_k , given by:

$$\mu_k = \mu_{F_{l(1,n-1)}} \times \mu_{F_{l(2,n-1)}} \times \ldots \times \mu_{F_{l(m-1,0)}} \times \mu_{F_{l(m,0)}} \tag{9}$$

The estimation of the fuzzy system parameters - including both premise and consequence parameters - is performed using a modified gradient-based learning algorithm. This algorithm adaptively adjusts the fuzzy system parameters $f_i(.)$ to minimize the instantaneous error between the actual value and the fuzzy system output $\hat{y}_i^{(n)}$. The error function is defined as:

$$e_i(t) = y_i^{(n)} - \hat{y}_i^{(n)} \tag{10}$$

The adaptation law is expressed by the following equation:

$$\hat{\beta}_i(t) = \hat{\beta}_i(t-1) + p(t)\psi(t)e_i(t) \tag{11}$$

$$\psi(t) = \frac{\partial f_i(X.\beta_i)}{\partial \beta_i} / _{\hat{\beta}(t-1)}$$

Where represents the estimation algorithm gain, determined by the following relation:

$$p(t) = \frac{\alpha_1 I}{\alpha_2 + \psi^T(t)\psi(t)}; \alpha_1 \rangle 0, \alpha_2 \rangle 0 \tag{12}$$

III.1.1.2 Control Law Computation

Once the estimation step is completed, the estimator (the fuzzy model) sends the estimated parameters to the fuzzy controller. These parameters are used to construct the controller's rule base. Consequently, a rule of the proposed controller takes the following form:

$$R_k : si\ x_1^{(n-1)}\ est\ F_{l(l,n-1)}\ et..et\ x_m^{(n-1)}\ est\ F_{l(m,n-1)}\ et..et\ x_1\ est\ F_{l(1,0)}\ et..et\ x_m\ est\ F_{l(m,0)}$$
$$Then\ \ num(u_i) = v_i - y'(k)\ et\ \ den(u_i) = b(k)$$

With:

$$v_i = y_{di}^{(n)} + k_n\left(y_{di}^{(n-1)} - y_i^{(n-1)}\right) + ... + k_1(y_{di} - y_i)$$
$$y'(k) = a(0,k) + a(1,n-1,k)x_1^{(n-1)} + ... + a(m,n-1,k)x_m^{(n-1)} + ... + a(1,0,k)x_1 + ... + a(m,0,k)x_m$$

Where:

The coefficients k_i are chosen such that the polynomial $s^n + k_n s^{n-1} ... + k_1$ is a Hurwitz polynomial (i.e., its roots have negative real parts). [12]. The control input applied to subsystem i is given by the following relation:

$$u_i = \frac{num(u_i)}{den(u_i)} \tag{13}$$

Where:

$$num(u_i) = \frac{\sum_{k=1}^{M_i} \mu_k (v_i - y'(k))}{\sum_{k=1}^{M_i} \mu_k} \tag{14}$$

And:

$$den(u_i) = \frac{\sum_{k=1}^{M_i} \mu_k b(k)}{\sum_{k=1}^{M_i} \mu_k} \tag{15}$$

From this, it follows that:

$$u_i = \frac{\sum_{k=1}^{M_i} \mu_k (v_i - y'(k))}{\sum_{k=1}^{M_i} \mu_k (b(k))} \tag{16}$$

Figure 2 presents a schematic overview of the direct-identification-based adaptive fuzzy control principle.

✓ Application to Permanent Magnet Synchronous Motor

a) Speed Regulation

The control structure can be represented by the schematic diagram in Figure 3. The adaptive fuzzy controller generates the current i_{qref} , which is multiplied by a coefficient $\left(\frac{3p\emptyset_f}{2}\right)$to produce the electromagnetic torque T_{emref} . This torque, along with the reference flux Φ_{ref} , is then utilized in the Direct Torque Control (DTC) scheme to generate the inverter control signals.

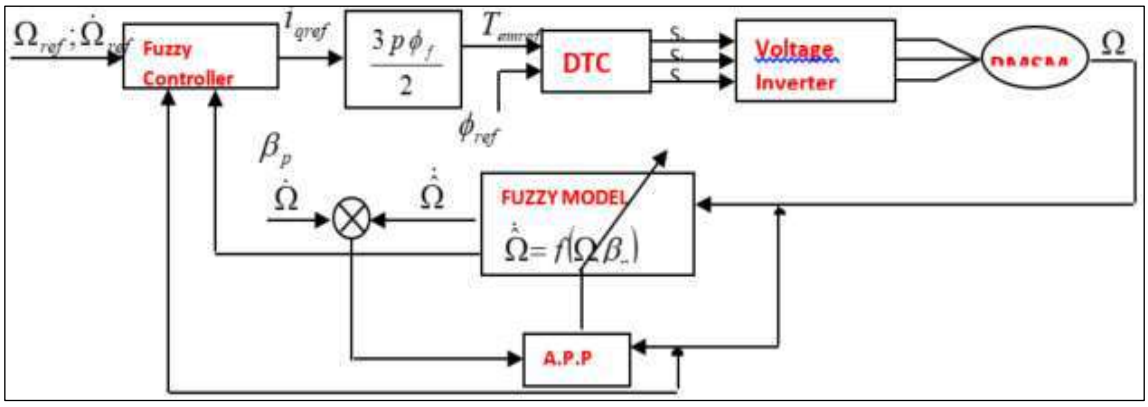

Figure 3: Speed control structure using the adaptive fuzzy control method based on direct identification.
Source: Authors, (2026).

We have:

$$J\frac{d\Omega}{dt}+f\Omega=\frac{3p\phi_f}{2}i_q-T_r \tag{17}$$

Hence:

$$\frac{d\Omega}{dt}=\frac{3p\phi_f}{2J}i_q-\frac{T_r}{J}-\frac{f}{J}\Omega \tag{18}$$

This equation can be described by the following equation:

$$\frac{d\Omega}{dt}=F(X)+G(X)i_q \tag{19}$$

With:

$$F(X)=-\left(\frac{T_r}{J}+\frac{f\Omega}{J}\right);G(X)=\frac{3p\phi_f}{2J};X=[\Omega] \tag{20}$$

In adaptive fuzzy control based on direct identification, the speed derivative is approximated by a fuzzy system, such that:

$$\hat{\dot{\Omega}}=\frac{\sum_{k=1}^{3}\mu_k\,\hat{\dot{\Omega}}_k}{\sum_{k=1}^{3}\mu_k} \tag{21}$$

Where: μ_k represents the confidence degree of rule R_k, and $\hat{\dot{\Omega}}$ is its consequent. This consequent is defined

By:

$$\dot{\hat{\Omega}}_k = a(0,k) + a(1,k)\Omega + b(k)i_{qref}$$

The adaptive fuzzy controller provides the desired current i_{qref}, which is expressed as:

$$i_{qref} = \frac{\sum_{k=1}^{3} \mu_k (v - y'_k)}{\sum_{k=1}^{3} \mu_k b(k)} \tag{22}$$

Where: $v - y'_k$ and $b(k)$ are, respectively, the numerator and denominator of rule R_k of the fuzzy controller. Their expressions are given by:

$$v = \dot{\Omega}_{ref} + k_\Omega(\Omega_{ref} - \Omega)$$
$$y_k = a(0,k) + a(1,k)\Omega$$

From which, the reference electromagnetic torque is obtained by the equation: [3]

$$T_{emref} = \frac{\sum_{k=1}^{3} \mu_k (v - y'_k)}{\sum_{k=1}^{3} \mu_k b(k)} \times \frac{3p\phi_f}{2} \tag{23}$$

b) Position Control

The control adjustment structure of this system is illustrated in Figure 4.

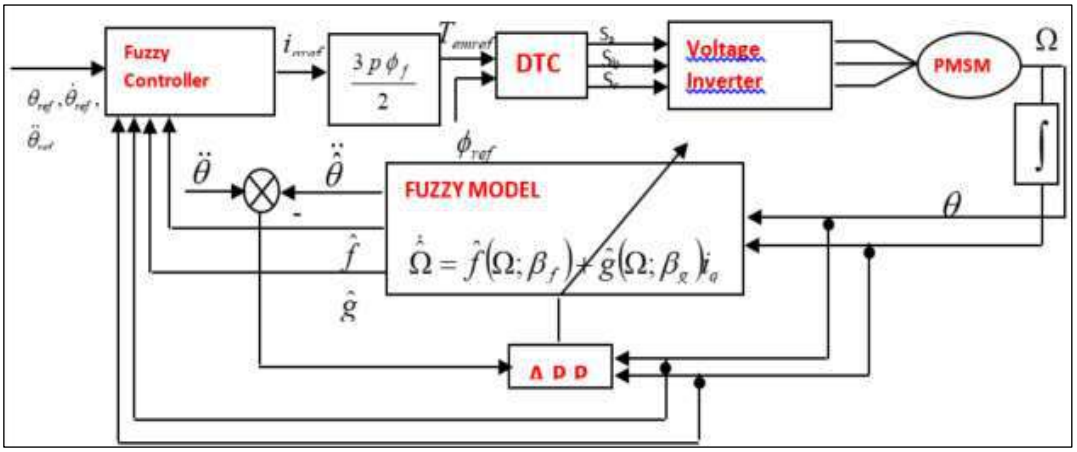

Figure 4: Position control structure using indirect adaptive fuzzy linearizing control method.
Source: Authors, (2026).

From Equation (19), we obtain:

$$i_{qref} = \frac{2J}{3p\phi_f}\frac{d\Omega}{dt} + (f\Omega + T_r)\frac{2}{3p\phi_f} \tag{24}$$

Given that $\dot{\theta} = \Omega$, it follows:

$$i_{qref} = \frac{2J}{3p\phi_f}\ddot{\theta} + (f\dot{\theta} + C_r)\frac{2}{3p\phi_f} \tag{25}$$

Equation (24) allows us to write:

$$i_q = F(X)\ddot{\theta} + G(X) \tag{26}$$

Where:

$$F(X) = \frac{2J}{3p\phi_f}; G(X) = (f\dot{\theta} + C_r)\frac{2}{3p\phi_f}; X = [\theta, \dot{\theta}] \tag{27}$$

From Equation (25), we have:

$$\ddot{\theta} = F(X) + G(X)i_q \tag{28}$$

Where:

$$F(X) = -\left(\frac{C_r}{J} + \frac{f\Omega}{J}\right); G(X) = \frac{3p\phi_f}{2J}; X = [\dot{\theta}] \tag{29}$$

To implement the proposed method, we replace $\dot{\theta}$ with a first-order Sugeno fuzzy system:

$$\ddot{\theta} = f(\dot{\theta}, \beta) \tag{30}$$

This system has a single input $\dot{\theta}$. In our application, three membership functions are assigned to this input. The fuzzy system output is expressed as:

$$\ddot{\theta} = \frac{\sum_{k=1}^{3} \mu_k \ddot{\theta}_k}{\sum_{k=1}^{3} \mu_k} \tag{31}$$

Where μ_k is the firing strength of rule R_K and $\ddot{\theta}_k$ is its consequent, defined by:

$$\ddot{\theta}_k = a(0,k) + a(1,k)\dot{\theta} + b(k) i_{qref} \tag{32}$$

The adaptive fuzzy controller output is given by:

$$i_{qref} = \frac{\sum_{k=1}^{3} \mu_k (v - y'_k)}{\sum_{k=1}^{3} \mu_k b(k)} \tag{33}$$

Where:

$$\begin{aligned} v &= \ddot{\theta}_{ref} + k_{1\theta}(\dot{\theta}_{ref} - \dot{\theta}) + k_{2\theta}(\theta_{ref} - \theta) \\ y'_k &= a(0,k) + a(1,k)\dot{\theta} \end{aligned} \tag{34}$$

With $v - y'_k$ and $b(k)$ being respectively the numerator and denominator of the fuzzy controller's rule R_K
Thus, we obtain the reference electromagnetic torque through:

$$C_{emref} = \frac{\sum_{k=1}^{3} \mu_k (v - y'_k)}{\sum_{k=1}^{3} \mu_k b(k)} \times \frac{3p\phi_f}{2} \tag{35}$$

We observe that the adaptation algorithm requires speed derivative measurement, which is computed through numerical differentiation - an approach that may prove problematic with noisy measurements.

- Numerical Simulation

To demonstrate the proposed control method's effectiveness, we conducted numerical simulations. The coefficients governing the PMSM's desired response were set to 220.852, 45, and 708.75 respectively. Figures (5, a-c) respectively illustrate the PMSM's dynamic and static performance during , a speed regulation at 157 rad/s (no-load) , Load conditions and Rotation reversal. Results analysis reveals:

Excellent reference tracking and disturbance rejection, mere 0.39% speed deviation during disturbances, Rapid 0.018s disturbance recovery, Robust flux-torque decoupling maintained under severe operating conditions

Figures (6, a-c) demonstrate position regulation performance for, 5 rad reference (no-load) and load conditions as well as Position reversal. We also note Precise position reference tracking, fast disturbance rejection (0.2s recovery), minimal 0.086% position deviation during disturbances. The stator flux magnitude successfully reaches its reference value while maintaining an essentially circular trajectory. The flux-torque decoupling remains unaffected even under severe operating conditions.

III.1.2 Indirect Identification-Based Fuzzy Adaptive Control

In this section, we propose a novel approach to indirect adaptive fuzzy control, combining fuzzy systems with the so-called computed torque method. Fuzzy systems are employed to provide a representative model of the direct dynamics of the system to be controlled. The control law is then derived from this model using the computed torque method. [13]

III.1.2.1 System Identification Using Fuzzy Systems

Consider again the system described by equation (3).

$$\begin{aligned} x_i^{(n)} &= F_i(X) + G_i(X)u_i \\ y_i &= x_i; \quad i = 1,\ldots,m \end{aligned} \tag{36}$$

The objective of the proposed control strategy is to generate a local control law based on (36) (a decentralized control structure), using estimates of the functions. F_i and $G_i$the control synthesis is performed in two steps:

- System identification: The model of the system to be controlled is identified using fuzzy systems.
- Control computation: The control law is derived via the computed torque method using the identified fuzzy model.

From Equation (40), we can write:

$$\hat{x}_i^{(n)} = f_i(X;\beta_{fi}) + g_i(X;\beta_{gi})u_i \tag{37}$$

The functions $f(.)_i \; and \; g_i(.)$ are first-order Sugeno fuzzy systems with linguistic descriptions of the following form: [24]

- For fuzzy system $f_i(\cdot)$:

$$\begin{aligned} &R_K^f : si\ x_l^{(n-1)}\ est\ F_{l(l,n-1)}^{\mathbf{f}}\ et..et\ x_m^{(n-1)}\ est\ F_{l(m,n-1)}^{f}\ et..et\ x_i\ est\ F_{l(1,0)}^{\mathbf{f}}\ et\ x_m\ est\ F_{l(m,0)}^{f} \\ &Alors\ \ s_f(k) = a_f(o,k) + a_f(1,n-1,k)x_1^{(n-1)} + \ldots + a_f(m,n-1,k)x^{n-1}{}_m + \ldots + a_f(1,0,k)x_1 \ldots \\ &\qquad + a_f(m,0,k)x_m \end{aligned} \tag{38}$$

- For fuzzy system : $g(\cdot)$:

$$\begin{aligned} &R_K^g : si\ x_l^{(n-1)}\ est\ F_{l(l,n-1)}^{\mathbf{g}}\ et..et\ x_m^{(n-1)}\ est\ F_{l(m,n-1)}^{g}\ et..et\ x_i\ est\ F_{l(1,0)}^{\mathbf{g}}\ et\ x_m\ est\ F_{l(m,0)}^{g} \\ &Alors\ \ s_g(k) = a_g(o,k) + a_g(1,n-1,k)x_1^{(n-1)} + \ldots + a_g(m,n-1,k)x^{n-1}{}_m + \ldots + a_g(1,0,k)x_1 \ldots \\ &\qquad + a_g(m,0,k)x_m \end{aligned} \tag{39}$$

The final outputs of the fuzzy systems $f_i(.) \; and \; g_i(.)$ are respectively given by:

$$f_i(X;\beta_{fi}) = \frac{\sum_{k=1}^{M_{fi}} \mu_{fk} s_f(K)}{\sum_{k=1}^{M_{fi}} \mu_{fk}} \tag{40}$$

$$g_i(X;\beta_{gi}) = \frac{\sum_{k=1}^{M_{gi}} \mu_{gk} s_g(k)}{\sum_{k=1}^{M_{gi}} \mu_{gk}} \tag{41}$$

Where:

$$\mu_{fK} = \mu_{l(1,n-1)}^{f} \times \mu_{Fl(2,n-1)}^{f} \times \ldots \times \mu_{Fl(m-1,0)}^{f} \times \mu_{Fl(m,0)}^{f} \tag{42}$$

$$\mu_{gK} = \mu_{l(1,n-1)}^{g} \times \mu_{Fl(2,n-1)}^{g} \times \ldots \times \mu_{Fl(m-1,0)}^{g} \times \mu_{Fl(m,0)}^{g} \tag{43}$$

The unknown parameters $\beta_i = \lfloor \beta_{fi}, \beta_{gi} \rfloor$ are estimated recursively using a modified gradient learning algorithm. In this algorithm, the parameters β_i are adjusted to minimize the instantaneous error between. $y_i^{(n)} et \; \hat{y}_i^{(n)}$ This error is given by: [35]

$$e_i(t) = y_i^{(n)} - \hat{y}_i^{(n)} \tag{44}$$

The proposed adaptation law takes the form [22]:

$$\hat{\beta}_i(t) = \hat{\beta}_i(t-1) + p(t)\psi(t)e_i(t)$$
$$\psi(t) = \frac{\partial y_i^{(n)}}{\partial \beta_i} = \left[\frac{\partial f_i(\cdot)}{\partial \beta_{fi}}; \frac{\partial g(\cdot)}{\partial \beta_{gi}}\right] \quad (45)$$

Where:

$$p(t) = \frac{\alpha_1 I}{\alpha_2 + \psi^T(t)\psi(t)}; \alpha_1 > 0, \alpha_2 > 0$$

III.1.2.2 Control Law Computation

Our objective is to design a control law such that each subsystem tracks its reference y_{id}. For this purpose, the control law, computed via the computed torque method, is given by:

$$u_i = \frac{v_i - f_i(X;\beta_{fi})}{g_i(X;\beta_{gi})} \quad (46)$$

Where:

$$v_i = y_{di}^{(n)} + k_n\left(y_{di}^{(n-1)} - y_i^{(n-1)}\right) + \ldots + k_1(y_{di} - y_i)$$

The coefficients k_i are selected such that the polynomial $s^n + k_n s^{n-1} \ldots + k_1$ is a Hurwitz polynomial (roots with negative real parts). This control law ensures critical damping for the error dynamics. Figure (7) schematically illustrates the principle of the proposed control strategy. [35].

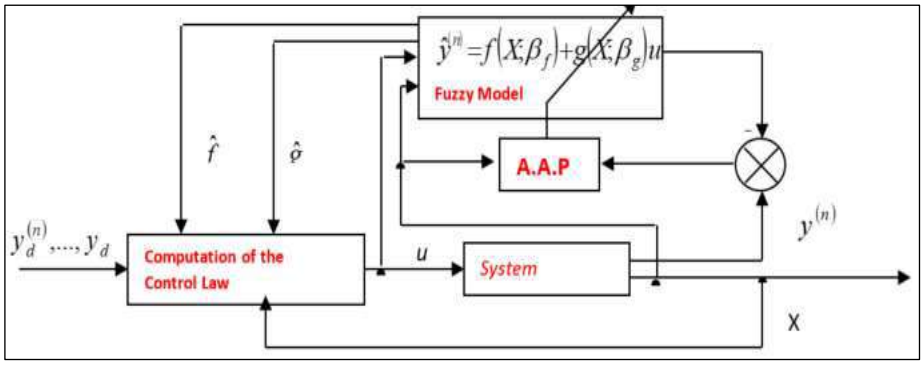

Figure 7: Principle of indirect adaptive fuzzy linearizing control.

✓ **Application to PMSM (Permanent Magnet Synchronous Motor)**

a) Speed Regulation

The structure of the indirect adaptive fuzzy linearizing control is illustrated in Figure (8). The adaptive fuzzy controller generates the current i_{qref}, which is multiplied by a coefficient $\left(\frac{3p\emptyset_f}{2}\right)$ to produce the electromagnetic torque T_{emref}. This torque, along with the reference flux Φ_{ref}, are then utilized in the Direct Torque Control (DTC) scheme to generate the inverter switching commands.

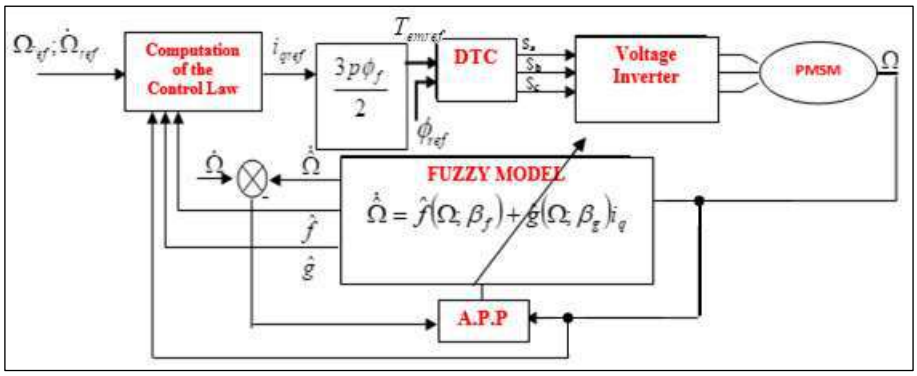

Figure 8: Speed control structure using the indirect adaptive fuzzy linearizing control method.
Source: Authors, (2026).

Considering equation (36), the selected model for identifying the speed derivative has the following form:

$$\dot{\Omega} = f(\Omega;\theta_f) + g(\Omega;\theta_g) i_q \tag{47}$$

With: $f(.) and\ g(.)$ are fuzzy systems with unknown parameters. These systems are characterized by a single input, with three membership functions assigned to this input. [35]. The final outputs of the fuzzy systems $f(.) et\ g(.)$ are respectively given by:

$$f(\Omega;\beta_f) = \frac{\sum_{k=1}^{3} \mu_{fk} s_f(k)}{\sum_{k=1}^{3} \mu_{fk}}$$
$$g(\Omega;\beta_g) = \frac{\sum_{k=1}^{3} \mu_{gk} s_g(k)}{\sum_{k=1}^{3} \mu_{gk}} \tag{48}$$

Where: $\mu_{fk} and\ \mu_{gk}$ represent the confidence degrees of rules $R_{fk} and\ R_{gk}$ for the fuzzy systems $f(.) and\ g(.)$. While $s_f(k) and\ s_g(k)$ are the consequences of these rules, defined as:

$$s_f(k) = a_f(0,k) + a_f(1,k)\Omega$$
$$s_g(k) = a_g(0,k) + a_g(1,k)\Omega \tag{49}$$

The output provided by the adaptive fuzzy controller is expressed as:

$$i_{qref} = \frac{v - f(\Omega;\beta_f)}{g(\Omega;\beta_g)} \tag{50}$$

With:

$$v = \dot{\Omega}_{ref} + k\Omega(\Omega_{ref} - \Omega)$$

From this, we obtain the reference electromagnetic torque through the equation:

$$T_{emref} = \frac{3p\phi_f}{2} \frac{v - f(\Omega;\beta_f)}{g(\Omega;\beta_g)} \tag{51}$$

b) Position Control

The control structure for position regulation is illustrated in Figure (9).

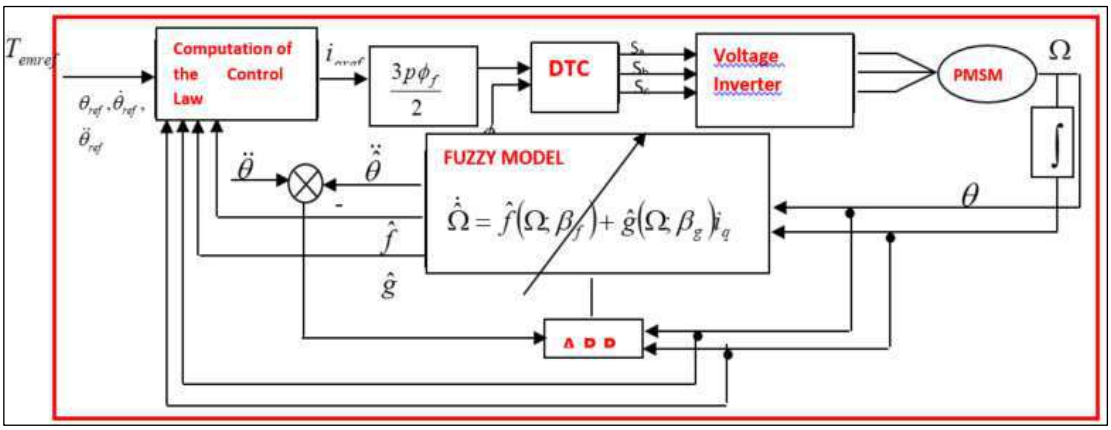

Figure 9: Position control architecture using indirect adaptive fuzzy linearization control methodology.
Source: Authors, (2026).

Based on equation (28), the selected identification model for $\ddot{\theta}$ is formulated as:

$$\ddot{\theta} = f(\ddot{\theta};\beta_f) + g(\ddot{\theta};\beta_g) i_q \tag{52}$$

Where $f(\ddot{\theta};\beta_f)\ and\ g(\ddot{\theta};\beta_g)$ represent fuzzy inference systems characterized by a single input variable. In the present study, we implement three Gaussian membership functions for this input. The aggregated outputs of these fuzzy systems are mathematically expressed as: [36]

$$f(\dot{\theta},\beta_f)=\frac{\sum_{k=1}^{3}\mu_{fk}s_f(k)}{\sum_{k=1}^{3}\mu_{fk}}$$
$$g(\dot{\theta},\beta_g)=\frac{\sum_{k=1}^{3}\mu_{gk}s_g(k)}{\sum_{k=1}^{3}\mu_{gk}} \quad (53)$$

The control signal generated by the adaptive fuzzy controller is given by:

$$i_{qref}=\frac{v-f(\dot{\theta},\beta_f)}{g(\dot{\theta},\beta_g)} \quad (54)$$

With:

$$v=\ddot{\theta}_{ref}+k_{1\theta}(\dot{\theta}_{ref}-\dot{\theta})+k_{2\theta}(\theta_{ref}-\theta)$$

The reference electromagnetic torque is consequently derived from:

$$T_{emref}=\frac{3p\phi_f}{2}\frac{v-f(\dot{\theta},\beta_f)}{g(\dot{\theta},\beta_g)} \quad (55)$$

Remark 1: The adaptation algorithm necessitates real-time measurement of the angular velocity derivative. While numerically estimated in this implementation, we note that such approximation may introduce significant errors under noisy measurement conditions, potentially c]ompromising control performance.

- Numerical Simulation and Performance Analysis

The closed-loop system dynamics were rigorously evaluated through numerical simulations investigating both speed and position regulation using the proposed indirect adaptive fuzzy linearization approach. The critical control parameters, determining the PMSM's dynamic response characteristics, were optimally tuned to 620.54, 61.5704, and 473.86 respectively. The transient and steady state performance metrics, illustrated in Figures (10, a-c) and (11, a-c) demonstrate:

- Exceptional disturbance rejection capability:
- Maximum speed deviation: 0.55% of nominal value
- Maximum position error: 0.46% of reference
- Perturbation recovery time constants: 5ms (speed) and 290ms (position)
- Robust flux-torque decoupling
- Complete independence maintained even under severe operational regimes
- No observable coupling effects during rapid torque transients

IV. CONCLUSIONS

This research has systematically investigated two adaptive fuzzy control approaches for permanent magnet synchronous motors (PMSMs): direct and indirect adaptive fuzzy control methodologies. The study demonstrates how fuzzy systems can effectively approximate unknown continuous nonlinear functions in both control paradigms, while maintaining complete independence from prior knowledge of the PMSM's dynamic model structure or parameters. Our contributions include:

Direct Adaptive Fuzzy Control: A novel control architecture where fuzzy logic systems directly generate control signals through online adaptation.
Indirect Adaptive Fuzzy Linearization Control: An identification-based approach employing fuzzy systems for model approximation and linearization
Both decentralized control strategies exhibit:
Robust position and speed regulation capabilities
Model-free operation without requiring parametric knowledge
Fuzzy rule bases derived directly from the corresponding fuzzy models
Consistent operation across various dynamic regimes

However, these techniques require the measurement of the machine's speed derivative, which is calculated numerically, which can be detrimental in the case of noisy measurements. The study establishes a theoretical framework for advanced fuzzy control applications in PMSM drives, particularly suitable for industrial applications requiring both precision and robustness under uncertain operating conditions. Future work should focus on experimental validation and computational optimization for real-time implementation.

ABSTRACT

As it might lead to the loss of productivity and an economy, high absenteeism of employees badly affects organizations. With regard to courier companies, the methods of machine learning (ML) are utilized for the absenteeism of employees. The research uses inductive learning method, using conventional methods of data mining (DM), like data preprocessing, feature selection (FS) by Particle Swarm Optimization (PSO), and data classification by using such ensemble techniques, like Boosting, Voting, Bagging, and Stacking. The dataset with 21 attributes were 740 instances and this was processed to eliminate irrelevant features and transformed for effective analysis. The proposed model was very accurate with Boosting being the most successful ranking at 99.8 accuracy. The research indicates that FS is significant in enhancing accuracy of predictions and it is a useful instrument that managers can use to reduce the effects of absenteeism in organizational performance. In future, it will be possible to incorporate additional datasets, investigate more advanced methods of FS and to incorporate external variables to improve prediction.

I. INTRODUCTION

ML is regarded as a pivotal domain in research, aimed in uncovering or forecasting subjects [1]. Artificial intelligence enables machines to exhibit cognitive functions. Furthermore, artificial intelligence enhances the cognitive capabilities of machines. ML constitutes a domain within the field of artificial intelligence study.[2] Certain researchers assert that intelligence cannot be cultivated without education. [3] All of these methods have been used for categorizing the subjects of dataset. In supervised learning, a training set of examples with corresponding targets is supplied, and algorithms responding properly to all the potential inputs depending on this training set. Supervised learning encompasses classification and regression. [4] The semi-supervised learning methodology can be defined as a variant of supervised learning. In addition, unlabeled data was used for the training task in this approach. [5] Furthermore, DL is a part of ML built on a set of algorithms. [6] There is an urgent need for ML approaches in today's environment in order to reduce human effort while reducing errors and achieving the greatest degree of automation.[7] Absenteeism is widely seen as a significant signal of inadequate performance inside a business.[8] Absenteeism from work has negative impact on the country's gross domestic product.

Furthermore, the annual expense of absenteeism in nations is approximated to be between 1.2 and 2% of GDP.[9] Absenteeism among blue-collar workers may stem from several factors, including religious and social commitments, inadequate housing, also subpar working circumstances. Organizations employ several strategies to mitigate absenteeism, such as adopting work rotation and enrichment, providing financial incentives and bonuses, and enforcing punctuality regulations. [10] Absenteeism is a pertinent issue in human resource management across many industries and organizations [11], [12] in the context of international human resource management (IHRM). The Micro-HR management can be defined as the sub-functions regarding HR policy and it has two main categories: the first one is related to the management of people and small groups, which involve the selection and recruitment, orientation and training, performance management, in addition to rewards. The other is work organization management and employee voice systems [13], [14]. The issue of absenteeism is a major obstacle which must be tackled by any company and employee.

The employees should have a sense of fulfillment in their employment and the employers should help them have this good experience in every possible way. Absenteeism is a common pattern of non-attendance of some responsibility or duty. The issue of absenteeism in employees is not purely a financial issue; it has a great effect on employee morale as well. Absenteeism in the workplace can be a pointer to low morale among the employees and management [15]. Therefore, one of the important issues to consider when making predictions of human behavior, especially absenteeism, is the means in which large datasets can be shifted or refined. The FS is an initial step in the process of DM. It aims at removing the extraneous and redundant features of the original data [16], [17]. In most cases, companies strive to increase their profits.

On-demand, casual, and temporary employment (which is common in the gig economy) can be used in organizations where employees are involved in simple tasks because of a lesser number of contractual obligations. The importance of employee specialization and job permanence are increased in companies where employees are doing specialized tasks. The importance of skills and knowledge has been defined and the ability to engage in learning continuously has been an urgent need to firms. The paper will be structured as mentioned: the second part clarifies a number of approaches and evaluates the relevant literature, whereas the third part outlines the data analysis, feature extraction, and CV classification techniques, and describes the proposed ML system. Part IV outlines the experimental results as well as the analysis of results. The fifth part compares the proposed model with the existing studies. The conclusion is marked in the end by Section VI.

II. THEORETICAL REFERENCE

Prior study endeavored to employ various data mining techniques or integrate distinct models to address the issue of absence prediction. Martiniano and colleagues. A neuro-fuzzy network was created using a multilayer perceptron design in an artificial neural network, implementing the error backpropagation method. This report offers initial findings from the utilization of the neuro-fuzzy network in forecasting workplace absence [18], [19]. A fuzzy neural network was constructed using error backpropagation algorithm with a multilayer perceptron to forecast absenteeism. Nonong and colleagues A study was undertaken to develop decision tree designed for detecting prevalent traits regarding employees who often exhibit absenteeism from work [20]. In a recent research, Gayathri employed naive Bayesian classifiers, multiclass perceptron, also J48 classifiers for developing classification model for predicting the employee absenteeism over extended or short durations [21].By [22] They employed artificial neural networks in their study.

Furthermore, in a pertinent study [23], researchers advocated for using neural networks (NNs) as well as DL algorithms for predicting employee commitment behaviors within the workplace. Conducting comprehensive research on large amount of data that is collected via businesses is a laborious and resource intensive task. Too much irrelevant information makes it hard to understand and comprehend [24]. As a result, effective filtering and narrowing down of large volumes of data is one of the focal points of human behavior prediction, especially when it comes to absenteeism. One of the most important preprocessing stages in DM is FS, which tries to remove irrelevant and redundant features of the original dataset [25], [26]. Addition of extraneous and redundant data into the model can lead to high expenditures, long time wastage, and reduction in the accuracy [27], [28]. The existing literature focuses on the lack of studies that use DM-based research to predict absenteeism and the lack of emphasis on the crucial aspect of FS.

By [29] noted that no studies aimed at the development of appropriate methods to compare and evaluate the effectiveness of different DM classification methods and the current literature also content highlight the lack of research using DM methods to predict absenteeism, which has led to the description of the absence of emphasis on the critical aspect of FS. Noted that there is no research aimed at developing adequate approaches to compare and evaluate the effectiveness regarding various DM classification methods and specific sets of features [29]. An alternative ML algorithm is applied in [30]. The study uses the linear regression and support vector regression (SVR) for the purpose of coming up with prediction model of absenteeism. Linear regression is performed with the use of all characteristics, and SVR is performed with consideration of two variables, namely, age and season. The results of the two algorithms are used to show that they are effective in predicting occupational absenteeism with high accuracy [31].

The proposed research will search and evaluate suitable ML tools to predict and evaluate workplace absenteeism. Parameters in the information being reviewed are age, education, employment category, day, month and term of service consisting of 125,000 records in total. The Weka tool is used to compare and contrast different algorithms in terms of accuracy, precision, and sensitivity [32]. This paper is an analysis of the absenteeism within courier company located in Brazil. Methods of ML were applied for understanding and prediction. It has already passed through preprocessing and different ML classification methods have been applied and these include ZeroR, J48 tree-based, k-NN, and NB classification methods. The study introduces the algorithms which could predict the absenteeism to accuracy of 92%. In addition, disciplinary failure has come out as one of the most predictive of absenteeism among the first 20 qualities [33].

The purpose of the presented work was discovering significant aspects as well as the best classification algorithms enhancing predicting absenteeism accuracy. We utilized FS methods for improving the efficiency regarding absenteeism prediction. The results of the experiment proved the importance of the selected features. Moreover, bagging has the best performance with accuracy of 92% in the seven prominent methods that apply CFS in FS [34]. Absenteeism is a major threat to businesses in the world. Our experimental group used logistic regression (LR), random forest (RF), XGBoost, and SVM for analyzing the data of 32 blue-collar employees within fast-moving consumer goods organization between 2017 and 2019. XGBoost and RF possessed F1 of 0.6399 and 0.6461, respectively, indicating fair predictive accuracy of absence. However, there are major growth prospects [35].

III. ADOPTED METHODOLOGY

III.1 PROPOSED METHOD

The research will attempt to formulate a predictive model of employee absenteeism in a courier company through inductive learning model. The model employs the conventional DM, which involves the application of Scikit-learn in Python. The model follows 3 stages including data preparation, FS with the help of PSO, and classification using ensemble methods.

It is aimed at precisely predicting absenteeism to help managers make decisions. This model applies preprocessing, PSO, bagging, boosting, voting, and stacking techniques in order to boost the predictivity. The performance related to integrated classification model is evaluated in terms of statistical metrics.

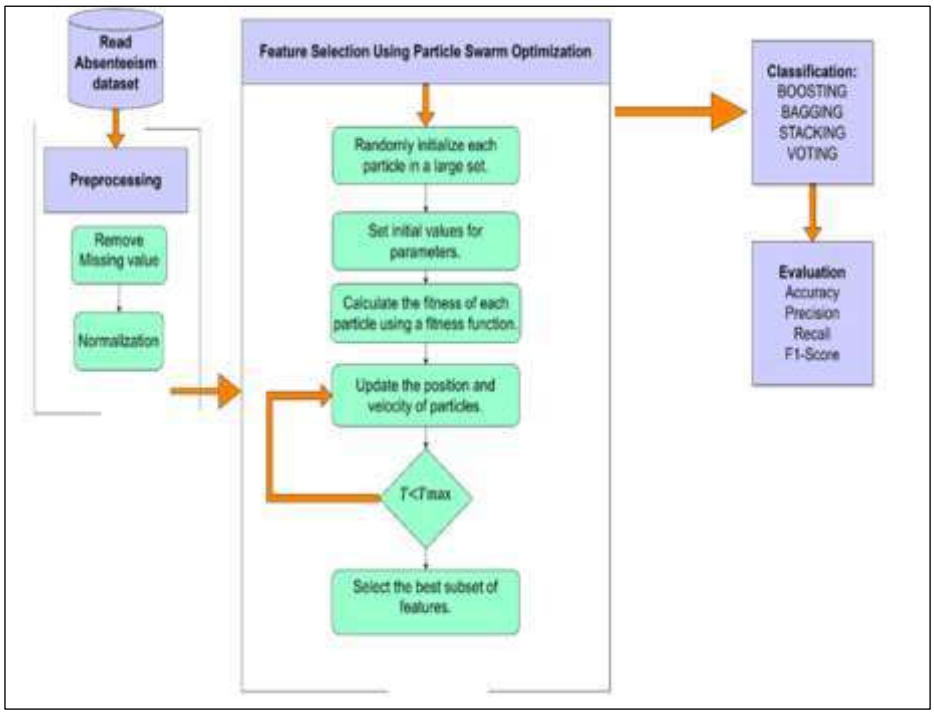

Figure 1: The proposed methodology for resume classification.
Source: Authors, (2026).

III.2 DATA SET

In this paper, we will examine absenteeism in courier company in Brazil using a dataset. The dataset is on Kaggle and records employees' attendance and cause of absenteeism among the employees, and other factors. It assists in determining trends and offers information on factors that have an impact on absenteeism. There are also work-related parameters such as work load and achievement targets. This dataset consists of 740 incidences of more than 21 attributes in three years. The paper proposes ML solutions to successful human resource strategies and employee interaction. The DL techniques, however, are not used because of its small size. Data is broken into training and test data.

III.3 FEATURE SELECTION USING PARTICLE SWARM OPTIMIZATION

III.3.1 Particle Swarm Optimization

In the PSO algorithm, each one of the particles is represented as a vector containing continuous values between 0 and 1. Each element in this vector represents a particular feature in the dataset. These continuous values are converted to binary values (0 or 1) using a binary conversion function. In the case when the value is greater than a specified threshold (0.5), it is assigned to 1 (feature is selected), and if it is less than the threshold, it is assigned to 0 (the feature is not selected).

III.3.2 Fitness Function

The objective function is the criterion by which the quality of each particle (solution) is evaluated. In this code, objective function is designed to evaluate the performance regarding a selected set of features based on two main criteria:

III.3.2.1 Error Rate

A classification model (such as Bagging, Boosting, Stacking and voting) is trained using the selected features from the particle. The error rate is then calculated depending on the model's performance on validation data. The goal is to minimize the error rate as much as possible.

III.3.2.2 Feature Size

The number of selected features is minimized to avoid overfitting and improve model efficiency. The goal is to select the fewest possible features while maintaining classification accuracy

$$\text{fitness} = \text{ErrorRate} * \alpha + \beta * \frac{\text{Number of Selected Features}}{\text{Total Features}} \quad (1)$$

The importance of each criterion is controlled using the parameters α and β, where α represents the weight of the error rate (0.99), prioritizing classification accuracy, while β = 1 - α represents the weight of the number of features (0.01), reducing the impact of the number of features compared to the error rate. The error rate is calculated based on the performance of the classifier, and the number of selected features is the number of features selected from the total number of features

III.4 ENSEMBLE CLASSIFICATION

III.4.1 Bagging

Bagging is implemented with the use of RF algorithm, where random samples are taken with the return from the training data. Multiple independent decision trees are trained on these samples, and their results are then combined utilizing majority voting in classification. The figure 2 illustrates how Bagging works, where random samples of data are taken, sub-models (RF) are trained in parallel on these samples, and then their results are combined to obtain the final prediction

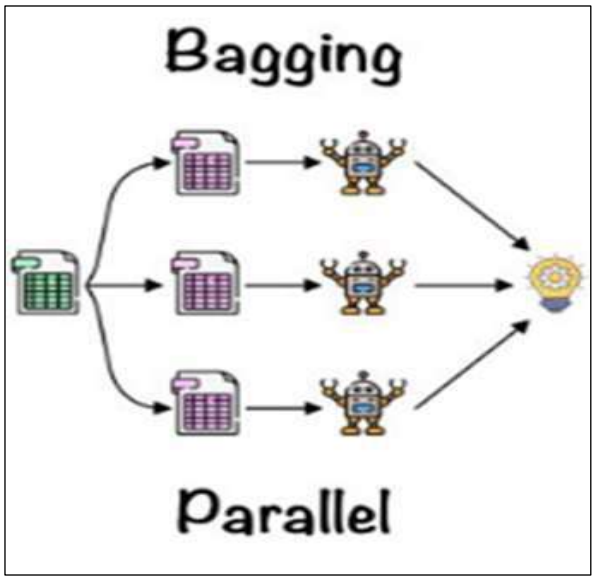

Figure 2: Bagging process.
Source: Authors, (2026).

III.4.2 Boosting

Boosting is based on the RF, and weak models are trained in sequence. The weight assigned to the samples that were misclassified at every step to enhance their performance in the successive models is higher. The outcome of the models is progressively increased in a way that enhances a stronger and more accurate classifier. The figure 3 depicts the Boosting process in the project whereby the models (RF) are trained in series, and all the models enhance the performance regarding other models upon the errors of preceding model and finally, the results are combined to acquire a strong classifier.

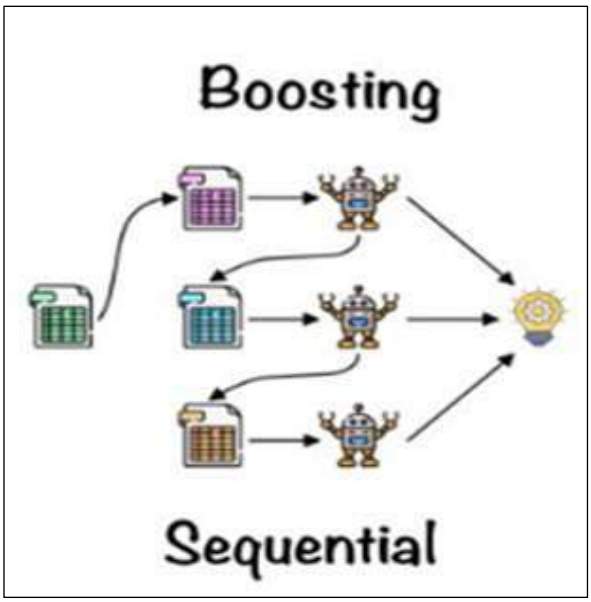

Figure 3: Boosting process.
Source: Authors, (2026).

III.4.3 Voting

The results of three basic models (LR, NB and SVM) were combined by voting in order to enhance the classification accuracy. This is the method by which hard voting is applied to the final decision which is made based on the principle of voting. Both models are applied to the same dataset and the final choice in the models is made based on the majority of the predictions of the models. The figure 4 presents the performance of three simple classifiers (LR, NB, and SVM) on the same dataset. The voting component is used to combine the results of these classifiers and make the final decision based on the majority.

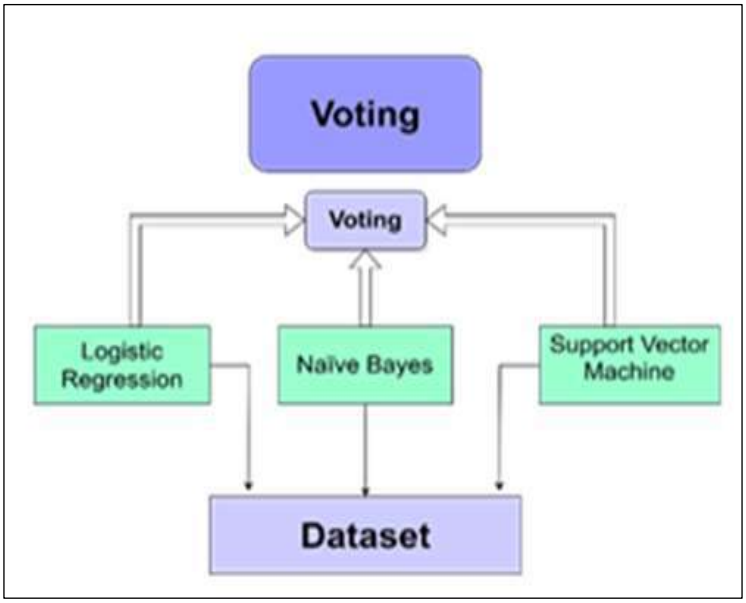

Figure 4: Voting process.
Source: Authors, (2026).

III.4.4 Stacking

The method is dependent on the training of a number of weak base models, including LR, k-NN, and SVM, on training data. The predictions of these models are used as features to train a stronger meta-model, which in this research is Gaussian Naïve Bayes. The aim of this process is combining the strengths related to weak models to obtain a more accurate and stable model. The figure 5 illustrates the two-level stacking process:

Level 0: Weak models (LR, KNN, and SVM) are trained on the training data and generate predictions.
Level 1: The predictions of the weak models are utilized as input to train a stronger model (Gaussian Naïve Bayes), which makes the final prediction.

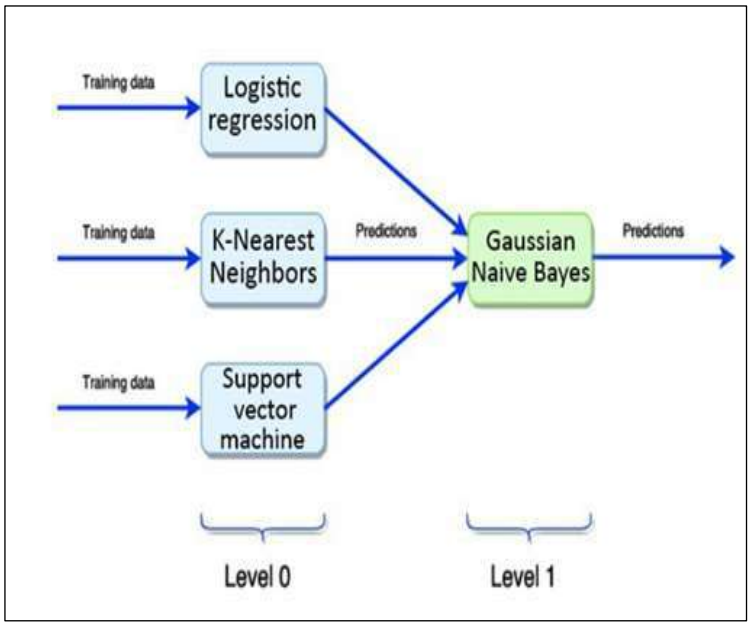

Figure 5: Stacking process.
Source: Authors, (2026).

III.5 ALGORITHM: PSO WITH MODEL (BAGGIN, BOOSTING, STACKING AND VOTING)

Input: Dataset (X, Y), Number of particles (N), Maximum iterations (T), Evaluation criterion (Fitness)

Output: Best feature set, Final model

Step 1. Initialize particles:

- For each particle, randomly initialize a position (feature set) and velocity.

Step 2. Evaluate fitness:

- For each particle, calculate the fitness of the feature set using the evaluation criterion.

Step 3. Update best positions:

- Update the personal best (Pbest) for each particle based on its fitness.

- Update the global best (Gbest) based on the best fitness among all particles.

Step 4. Update velocity and position:

- For each particle, update its velocity using the formula:

Velocity = w * Velocity + c1 * r1 * (Pbest - Position) + c2 * r2 * (Gbest - Position)

- Update the position of the particle based on its new velocity.

Step 5. Repeat steps 2-4:

- Continue for a specified number of iterations (T) or until the stopping criterion is met.

Step 6. Select the best feature set:

- The feature set represented by the global best particle (Gbest) is selected.

Step7. Train Bagging model:

- Use the selected features to train a model on the dataset.

Step 8. Output:

- Return the best feature set and the trained model.

IV. EVALUATION METRICS

In analyzing the results of the proposed models, the use of standard classification metrics was used, like Precision, Accuracy, F1-Score, and Recall. The measures give a detailed insight on the effectiveness of the classifier.

- Accuracy is a general correctness of the model that is specified as the percentage of the correct classification of instances (negative and positive):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{2}$$

- Precision is the fraction of times positive predictions are made correctly among the instances that are being predicted as positive:

$$precision = \frac{TP}{TP+FP} \tag{3}$$

- Recall (Sensitivity) determines the percentage of correctly recognized positive results relative to the number of all the actual positive cases

$$Recall = \frac{TP}{TP+FN} \tag{4}$$

- F1-Score is the arithmetic mean of Recall and Precision, which provides a balance in the measurement of the two

$$F1 - score = 2 \times \frac{Recall \times precision}{Recall + precision} \tag{5}$$

These measures provide a reasonable comparison between classifiers, particularly when there is imbalance between classes, since they are not only concerned with the overall accuracy but also with the capability of the model to recognize minor classes correctly.

V. RESULTS AND DISCUSSIONS

In the presented section, the experimental results are given as well as analyzed on the basis of the proposed methodology. The data were split into testing and training sets with training set utilized for developing the models and the testing set being used to test the models. The major aim of the evaluation was to look into the efficiency of PSO in the FS alongside ensemble classification methods Table 1 contains the parameters used to evaluate the effectiveness of various optimization techniques in the field of FS through particle fusion, i.e., Bagging, Boosting, Stacking, and Voting. The widely accepted metrics that were used to determine the model performance included Precision, Accuracy, F1-Score, Recall, and the Area Under the Curve (AUC). Furthermore, the results indicate that PSO dramatically enhanced the models through the removal of redundant and irrelevant features hence improving accuracy and inter-computation efficiency.

Boosting outperformed the other ensemble methods by a significant margin, and the generalization was almost perfect with near-perfect results. Bagging and Stacking also demonstrated high results, which testifies to them being reliable ensemble methods. Although the Voting classifier had slightly lower performance compared to the rest, it still had strong and competitive performance. In general, the findings demonstrate the significance of FS in the process of optimization of models. The proposed framework based on the combination of PSO and ensemble techniques proved to be effective and stable in predicting absenteeism. These performances imply the practical situational applicability of the framework in the management of human resources, and organizations can predict the negative effect of employee absenteeism in their productivity as well as operation proactively.

Table 1: PSO Parameters.

Parameter	Description	Value/Default
N	Number of particles	15
T	Maximum number of iterations	20
w	Inertia weight	0.9
c1	Cognitive acceleration factor	2
c2	Social acceleration factor	2
k	Number of neighbors in KNN	7
thres	Threshold for binary conversion	0.5
alpha	Weight for error rate in objective function	0.99
beta	Weight for feature size in objective function	0.01

Source: Authors, (2026).

IV.1 BOOSTING

The Boosting-based model recorded the best performance with an AUC of 1.0 which is a perfect value in terms of classification in figure 6. The convergence of the PSO fitness values over iterations was found to be very rapid, which proves the efficiency of the algorithm in finding the optimal feature subsets. The performance measures were very high with recall (0.987), precision (0.999), accuracy (0.998), and F1-score (0.993) and Boosting was the highest-performing ensemble method used in this study.

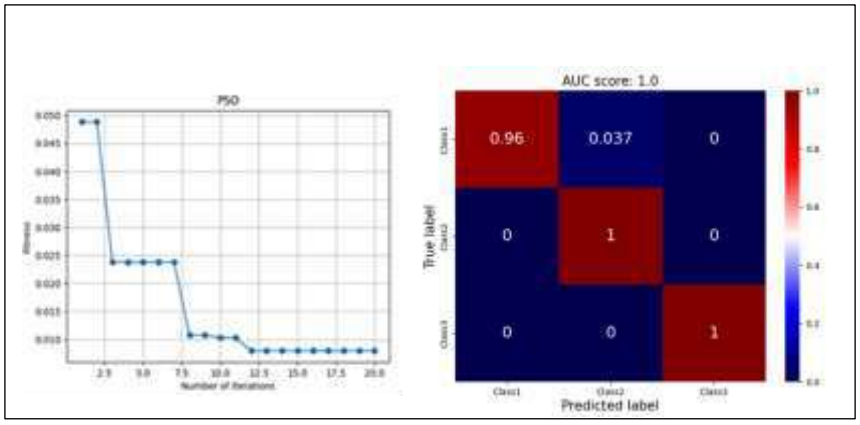

Figure 6: Performance Evaluation of PSO-Based FS and Boosting Classification.
Source: Authors, (2026).

IV.2 BAGGING

The Bagging classifier had an AUC of 0.97 which indicates high classification performance in figure 7. Class 1 had a low level of misclassification (13% to Class 2), whereas Class 2 and Class 3 were classified correctly and 100 per cent. The PSO optimization curve was also characterized by a steady decrease in the values of fitness as the iterations increased maintaining a minimum value, which is indicative of a high degree of convergence. Altogether, Bagging has obtained 0.956 recall, 0.997 precision, 0.993 accuracy, and 0.975 F1-score, which is strong evidence of its strength.

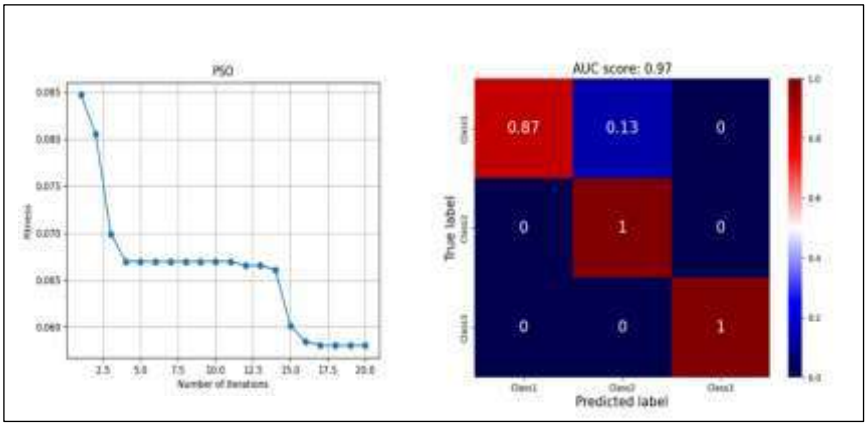

Figure 7: Performance Evaluation of PSO-Based FS and Bagging Classification.
SOURCE: AUTHORS, (2026).

IV.3 STACKING

The Stacking method used weak base models (LR, K-Nearest Neighbors, and SVM), which were in turn followed by a Gaussian Naive Bayes meta-model to fuse their results. The results obtained in this two-level architecture were very reliable with an AUC score of 0.98 in figuer 8 . The technique was able to detect the correct classification of 96 percent of the total data cases which validates that the combination of the multiple learners is effective. The precision, recall, and F1-score of 0.967 as well as the accuracy of 0.990 were the performance metrics used to demonstrate the stability and strength of the stacked model.

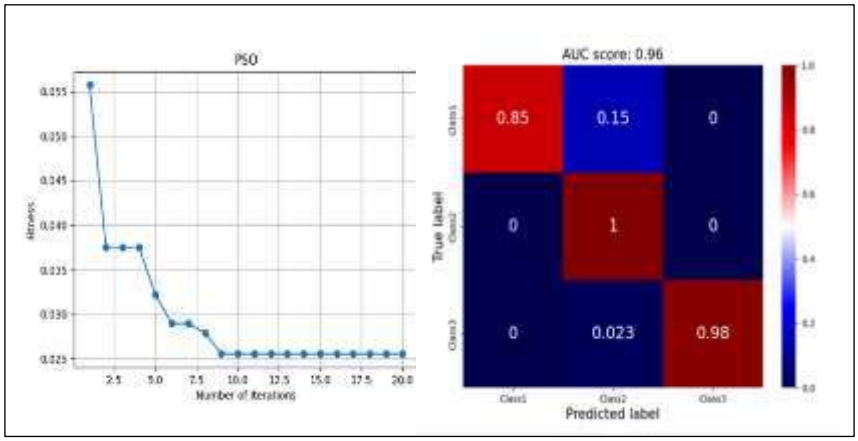

Figure 8: Performance Evaluation of PSO-Based FS and Stacking Classification.
Source: Authors, (2026).

IV.4 VOTING

The Voting classifier used hard voting to combine LR, SVM and NB to come up with the final decision. The approach had an AUC value of 0.981 and was able to classify 98% of the data in figuer 9. Although Voting was less successful in performance than Boosting, it gave precise results with a high recall (0.916), F1-score (0.951), and accuracy (0.982). These findings affirm Voting is a competitive ensemble method as it is used in predicting absenteeism.

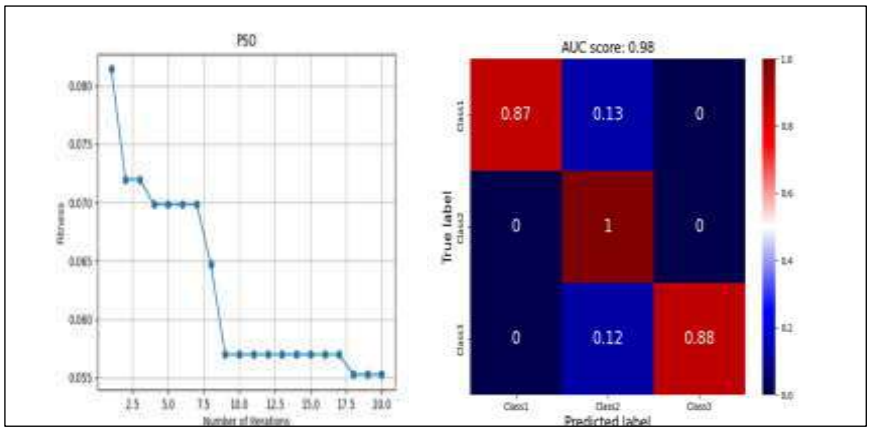

Figure 9: Performance Evaluation of PSO-Based FS and voting.
Source: Authors, (2026).

IV.5 COMPARISON OF MODEL PERFORMANCE METRICS

The performance of the four ensemble techniques Boosting and Bagging Stacking and Voting compares remarkably in table 2. Boosting was the most effective of them with the highest scores in all metrics with recall of 0.987, precision of 0.999, AUC score of 1.0, F1-score of 0.993, and an accuracy of 0.998. Close behind is bagging, which has good results with 0.997 precision, 0.956 recall, 0.975 F1-score, 0.970 AUC score and 0.993 accuracy. Stacking approach was also found to be reliable where the precision is 0.996, recall 0.943, F1-score 0.967, AUC score 0.956 and accuracy is 0.990. Lastly, Voting classifier although slightly lower than the rest, also had competitive scores, showing recall of 0.916, precision of 0.993, AUC score of 0.981, F1-score of 0.951, and its accuracy was 0.982.

These findings affirm that Boosting is the best ensemble technique of predicting absenteeism and Bagging and Stacking have almost similar performance with slight sacrifices in recall. Voting, even though it is slightly lower in performance than the rest, nevertheless, provides good and consistent classification performance.

Table 2: result of evaluation criteria for classification methods.

Method	Precision	recall	f1-score	AUC Score	accuracy
Boosting	0.999	0.987	0.993	1	0.998
Bagging	0.997	0.956	0.975	0.970	0.993
Stacking	0.996	0.943	0.967	0.956	0.990
Voting	0.993	0.916	0.951	0.981	0.982

VI. CONCLUSIONS AND FUTURE WORK

This study proposes a predictive model for employee absenteeism in a courier organization, utilizing PSO for FS combined with ensemble techniques such as bagging, boosting, Stacking, and Voting classification. The methodology involves a three-step workflow: data preprocessing, FS, and ensemble classification using Scikit-learn in Python. Results indicate that PSO effectively removes redundant features and boosts classifier performance, with Boosting achieving the highest accuracy. The model can be used as a decision-support tool by managers and HR specialists in order to control the impacts of absenteeism on productivity through the better management of the workforce. Future studies may include different datasets of various industries, improved FS, incorporation of external variables such as employee satisfaction surveys and use in the real-time decision support systems to improve dynamism in monitoring and predicting absenteeism.

ABSTRACT

Accurate identification of crop leaf diseases is essential for sustainable agriculture, yet variations in leaf morphology and disease symptoms across species remain challenging for traditional machine learning approaches. This study proposes a meta-learning–based stacking ensemble that integrates Convolutional Neural Networks (CNN), Support Vector Machines (SVM), and Random Forest Classifiers (RFC) for multi-species leaf pathology recognition, evaluated on apple and tomato datasets. Each base model independently learns discriminative visual features, and their class-probability outputs are fused through an RBF-SVM meta-learner. Experimental results show that individual models achieve accuracies of 89% (CNN), 88% (SVM), and 85% (RFC), while the proposed stacking ensemble significantly outperforms them with an accuracy of 98% and macro and weighted F1-scores of 0.975. These results demonstrate the effectiveness of heterogeneous meta-learning ensembles in enhancing robustness and generalization for multi-species crop disease classification.

I. INTRODUCTION

Crop leaf diseases pose a significant threat to crop yield and quality, making early and accurate detection critical for sustainable agriculture [1], [2]. Traditional diagnosis methods rely on visual inspection by experts, which is time-consuming, labor-intensive, and prone to human error. Automated image-based detection techniques have therefore emerged as promising alternatives, enabling rapid and objective disease monitoring [3]. Over the past decade, deep learning (DL), particularly CNNs, has demonstrated remarkable performance in plant disease recognition. CNNs automatically extract hierarchical visual features such as texture, color variations, and lesion patterns from leaf images, often surpassing traditional handcrafted feature methods [4], [5]. However, purely CNN-based approaches can face challenges, including sensitivity to lighting conditions, background noise, inter-class similarity, and the need for large annotated datasets to avoid overfitting [6]. On the other hand, classical machine learning (ML) models, such as SVMs and RFCs, are known for their robustness on limited datasets and ability to handle high-dimensional feature spaces [7], [8].

Yet, these models typically require handcrafted features or pre-extracted embeddings, limiting their ability to capture complex visual patterns inherent in leaf diseases. To overcome these limitations, hybrid ensemble approaches have gained attention in recent studies. Combining CNN feature extraction with classical classifiers can leverage the strengths of both paradigms: the representational power of deep learning and the robustness and interpretability of classical ML [9], [10]. Moreover, stacking ensembles—where predictions from multiple base learners are fused via a meta-learner—enable capturing complementary information from heterogeneous models, often leading to improved generalization compared to individual models or simple averaging strategies [11]. The primary motivation behind this work is to address the limitations of using a single CNN or classical machine learning model by combining their complementary strengths. The proposed heterogeneous stacking ensemble leverages the hierarchical feature extraction capability of the CNN, the margin-based discriminative power of the SVM, and the robustness of Random Forests.

The outputs of these base models are then fused using an RBF-SVM meta-learner, which captures non-linear relationships among the predicted probabilities and ensures an optimized integration of the individual classifiers' predictions. The approach offers several key

advantages: (i) intelligent weighting of base models per class, allowing the system to exploit the strengths of specific classifiers for different disease categories; (ii) enhanced classification performance, improving accuracy and F1-scores compared to individual models or naive ensembles; and (iii) robustness with limited or imbalanced datasets, ensuring reliable multi-class leaf disease recognition across different species. The remainder of this paper is organized as follows: Section II reviews related work in plant disease detection and ensemble methods. Section III presents the contributions and details of the proposed architectures. Section IV describes the dataset and performance metrics used. Section V presents the experimental results, and Section VI concludes the paper.

II. RELATED WORK

Automated detection of plant leaf diseases has been an active research area due to its potential to reduce manual labor and improve agricultural productivity. Early approaches relied on handcrafted feature extraction methods such as color histograms, shape descriptors, and texture features (GLCM, LBP) combined with classical classifiers like SVM or Random Forest [12], [13]. While these methods are relatively simple and robust on small datasets, they often fail to capture complex patterns of disease lesions, especially under variable environmental conditions.

II.1 DEEP LEARNING FOR PLANT DISEASE RECOGNITION

The emergence of deep learning, particularly Convolutional Neural Networks (CNNs), has significantly advanced plant disease recognition [14]. CNNs automatically learn hierarchical visual features, including texture, color variations, and lesion morphology from leaf images, often outperforming traditional handcrafted feature methods [14], [15]. For instance, the EnConv framework (2024) employs depthwise separable convolutions and inverted residual blocks to achieve 99.87 % accuracy on a dataset of 39 plant disease classes, including apple leaves [16].

Similarly, multi-head CNN architectures (2023) have been developed to enhance robustness and generalization across large and diverse datasets [17]. Despite their success, CNN-based methods still face challenges, such as sensitivity to lighting variations, background noise, inter-class similarity, and the need for large annotated datasets to avoid overfitting [18]. Moreover, most existing deep learning studies focus on single-species datasets, limiting their ability to generalize across multiple crops and disease types.

II.2 HYBRID APPROACHES: CNN + CLASSICAL ML

To address these limitations, recent studies have combined CNN feature extraction with classical machine learning classifiers. For example, an ensemble model integrating CNN feature extractors with Random Forest classifiers (2024) demonstrated improved performance and robustness on heterogeneous or limited datasets [19]. Similarly, a 2025 study proposed a robust ensemble combining multiple deep learning architectures (InceptionResNetV2, MobileNetV2, EfficientNetB3) to exploit their complementary strengths and improve generalization across different datasets [20]. Moreover, hybrid CNN-Vision Transformer frameworks (2025) have been explored to capture both global and local features, reflecting the current trend towards multi-modal and heterogeneous architectures for plant disease detection [21]. Nevertheless, these works typically still focus on a single species, such as apple or tomato, highlighting a need for models capable of handling multiple crop species simultaneously.

II.3 RECENT REVIEWS AND SURVEYS

Recent reviews provide comprehensive summaries of progress and remaining challenges in plant disease detection. A systematic review of deep learning techniques for plant diseases (2024) highlighted both the achievements and challenges, including model generalization to field data and the need for diverse datasets [22]. Another comparative study (2024) evaluated CNN, classical ML, and hybrid methods, showing that ensemble approaches often outperform individual models, particularly under varying environmental conditions [23]. The reviews summarize key studies in plant leaf disease detection, highlighting their methods, targeted crop species, dataset characteristics, and limitations.

Most existing works focus on single-species datasets, which limits their generalizability across multiple crops. While CNN-based approaches achieve high accuracy, they often require large annotated datasets and are sensitive to environmental variations. Hybrid and ensemble methods, such as CNN combined with SVM or Random Forest, improve robustness, but few studies integrate multiple paradigms into a heterogeneous stacking framework capable of handling multi-species disease recognition. This emphasizes the need for our proposed meta-learning based stacking approach.

II.4 RESEARCH GAP

Despite these advances, few studies have simultaneously integrated three paradigms—CNN (as feature extractor and base classifier), classical ML classifiers (SVM and Random Forest on CNN embeddings), and a meta-level fusion via stacking—for crop leaf disease recognition across multiple species. Most existing works focus either on deep architectures (CNN or CNN + ViT) or on homogeneous ensembles for a single crop species, leaving a gap for heterogeneous stacking ensembles that exploit complementary strengths of deep learning and classical machine learning in a multi-species context**.**

III. CONTRIBUTIONS AND DETAILED ARCHITECTURES

Motivated by the critical need for robust and accurate diagnostic tools in precision agriculture, this study introduces a novel heterogeneous stacking ensemble framework for image-based plant disease classification across multiple crop species, utilizing more challenging and diverse datasets to demonstrate the model's robustness and generalizability.The core contribution of this work is the integration of three powerful, yet distinct, learners—CNN, SVM, and RFC—into a cohesive stacking architecture. This integration is strategically designed to capitalize on their complementary advantages:

- CNNs provide superior hierarchical feature extraction from raw image data.
- SVMs offer strong generalization and margin maximization in high-dimensional feature spaces.
- RFCs contribute robust ensemble decision-making and resistance to overfitting.

A meta-learner then synthesizes the predictions from these base models to produce a final, refined classification. Beyond achieving state-of-the-art performance on plant disease datasets, this framework demonstrates applicability across multiple crop species, offering a robust tool for deploying hybrid and ensemble strategies in agricultural image analysis. The following sections describe the architectural components and their interactions, designed for optimal performance in plant disease classification across heterogeneous, multi-species datasets.

III.1 PROPOSED CNN ARCHITECTURE

The custom CNN developed for this study consists of a sequential architecture designed to extract hierarchical visual features and perform robust image classification. The model is divided into two main stages: a feature extraction phase and a classification phase. Figure 1 illustrates the proposed CNN architecture. In the feature extraction stage, the network applies three consecutive convolutional blocks, each using 3×3 kernels and ReLU activation. The first block contains a single Conv2D layer with 32 filters, followed by a 2×2 MaxPooling layer and a Dropout rate of 0.2. The second block increases the representational capacity by stacking two Conv2D layers (with 32 and 64 filters, respectively), followed by a 2×2 MaxPooling layer and 0.25 Dropout. The third block further deepens the architecture with Conv2D layers using 64 and 128 filters, again followed by 2×2 MaxPooling and 0.3 Dropout.

These blocks progressively reduce spatial dimensions while capturing increasingly complex patterns, transitioning from low-level edges and textures to high-level semantic structures. A Flatten layer then transforms the final feature maps into a one-dimensional vector for classification. The classification stage consists of a fully connected Dense layer with ReLU activation, used to learn non-linear combinations of extracted features, followed by a Dropout layer with a higher rate of 0.5 to prevent overfitting at the decision level. The final output layer is a Dense layer with Softmax activation, producing a normalized probability distribution over the target classes. The training settings were configured as follows:

- Optimizer (Adam): chosen for its adaptive learning rate, balancing convergence speed and stability.
- Loss Function (Categorical Cross-Entropy): suitable for multi-class classification.
- Learning Rate: 0.001 the default value used by the Adam optimizer, providing a stable and efficient convergence for most training scenarios.
- Batch Size (32): balances training efficiency and stability.

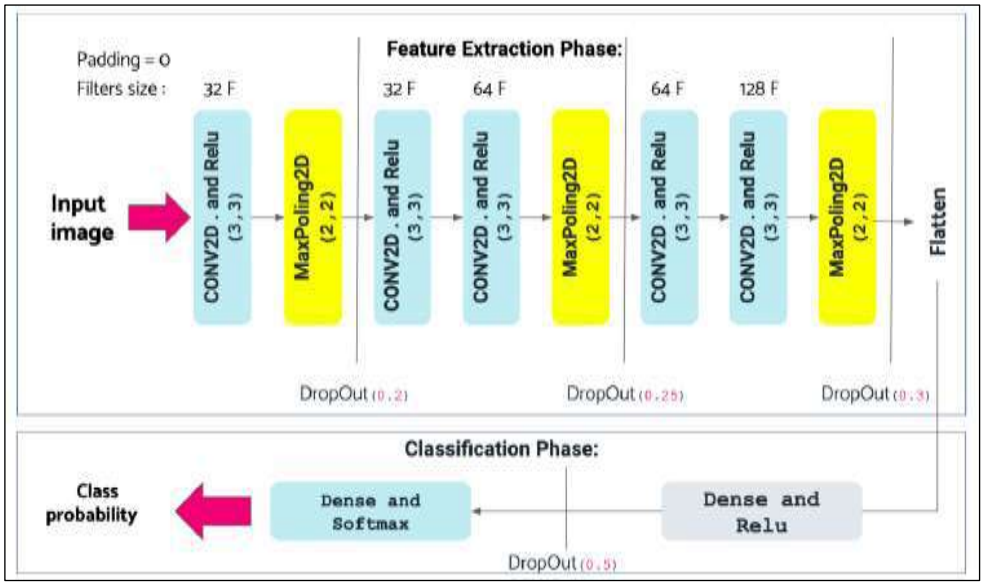

Figure 1: Proposed CNN architecture for crop leaf disease classification.
Source: Authors, (2026).

III.2 SVM MODEL

The SVM model for dataset image classification was developed following a standard preprocessing pipeline. Images were first resized to a uniform dimension and converted to a suitable format for model input. To ensure unbiased evaluation, the dataset was split into training and testing sets. The training set was used to train the SVM model, while the testing set provided an independent basis for performance assessment. Various SVM configurations were explored. Initially, a linear kernel was tested, but it produced suboptimal results. Consequently, alternative kernels were considered, and the Radial Basis Function (RBF) kernel was ultimately adopted, resulting in improved classification accuracy. Further optimization was performed by fine-tuning the regularization parameter, C, to balance model complexity and prevent overfitting. After comprehensive experimentation and evaluation, the SVM configuration yielding the best performance was selected. Figure 2 illustrates the structure and workflow of the finalized SVM model.

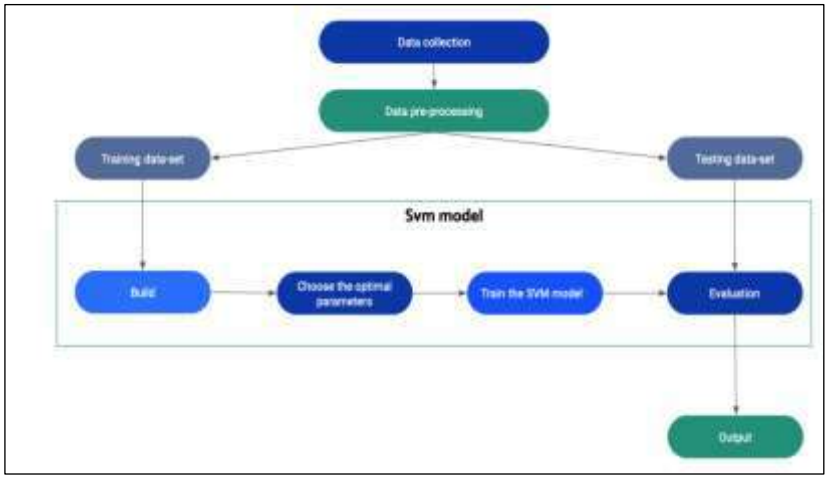

Figure 2: Workflow and structure of the SVM classification model.
Source: Authors, (2026).

III.3 RFC MODEL

The development of the Random Forest Classifier (RFC) model for disease classification began with a standard preprocessing pipeline. All images were resized to a uniform dimension and converted into an appropriate format for model input. Each image was then flattened into a one-dimensional raw pixel vector, which served as the input feature for the RFC. To ensure unbiased evaluation, the dataset was divided into separate training and testing subsets. The training set was used to train the RFC with standard parameters, while the testing set served as an independent dataset for objective performance assessment. This methodology ensured fairness and minimized potential evaluation bias. Figure 3 illustrates the structure of the RFC model.

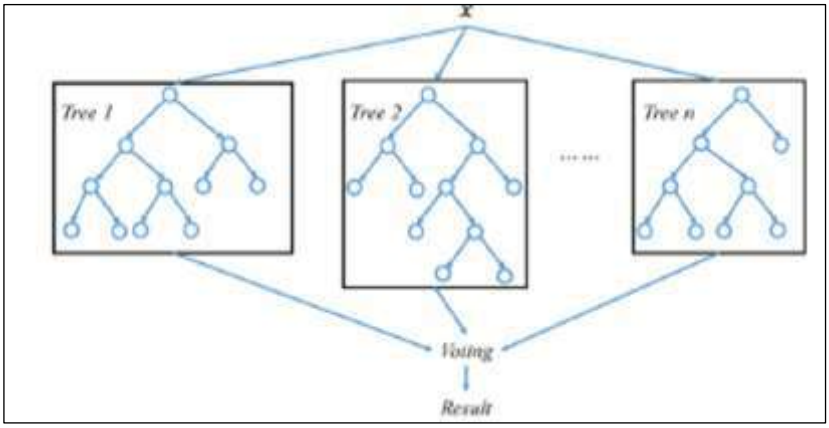

Figure 3: Random Forest classifier architecture.
Source: Authors, (2026).

III.4 ENSEMBLE LEARNING MODEL

The proposed stacking approach introduces an RBF-SVM meta-model which is trained on the outputs of the base classifiers rather than the raw input images. Specifically, for each training sample, the class probability predictions from CNN, SVM, and RFC are concatenated to form a meta-feature vector. The SVM with a RBF kernel is then fitted on these meta-features and the corresponding true class labels. The RBF kernel enables the SVM to capture non-linear relationships among the base classifier outputs. To achieve optimal performance, the hyperparameters C (regularization parameter) and γ (RBF kernel coefficient) are tuned using cross-validation. This procedure ensures that the meta-model generalizes well, effectively integrating the complementary strengths of the base classifiers to improve the overall prediction accuracy.Figure 4 illustrates the proposed meta-learning based architecture and Algorithm 1 details different steps of the proposed.

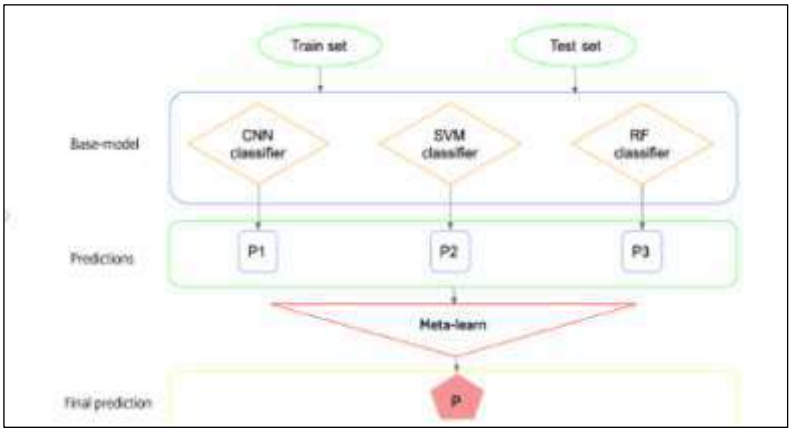

Figure 4: RBF-SVM Meta-learning architecture.

Algorithm 1: Stacking Ensemble with RBF-SVM Meta-Model.

Input: Training dataset $D = \{(x_i, y_i)\}_{i=1}^{N}$
Base classifiers: CNN, SVM, RFC
Meta-model: SVM with RBF kernel

Output: Trained stacking ensemble model

Steps:

1. Train Base Classifiers:
   - Train CNN, SVM, and RFC on D.
2. Generate Base Predictions:
   - For each $x_i \in$ D, compute probabilities: $P_i^{CNN}, P_i^{SVM}, P_i^{RFC}$
3. Prepare Meta-Model Input:
   - Concatenate probabilities: $P_i = [P_i^{CNN}, P_i^{SVM}, P_i^{RFC}]$
4. Train Meta-Model:
   - Fit RBF-SVM on $\{(x_i, y_i)\}$
   - Optimize C and γ via cross-validation
5. Prediction:
   - For new sample x_{new}, compute base probabilities
   - From $P_{new} = [P_{new}^{CNN}, P_{new}^{SVM}, P_{new}^{RFC}]$, predict final class: $\widehat{Y_{new}}) = SVM_{RBF}(P_{new})$
   - End

IV. DATASET AND METRIC PERFORMANCE

IV.1 DATA COLLECTION

The dataset used in this study comprises images of apple and tomato leaves sourced from the publicly available PlantVillage repository [24]. All images are fully anonymized, and their collection complies with open-access ethical guidelines.
The dataset is structured as follows:

- Apple Dataset: Comprising 9,714 images of apple leaf disease .
- Tomato Dataset: Containing 20,661 images across ten tomato leaf disease classes.

Figure 5 shows the sample images representing ten classes of tomato leaf disease, and Figure 6 shows the four cases of apple disease. Tables 1 and 2 summarize the image distributions for the tomato and apple datasets, respectively.

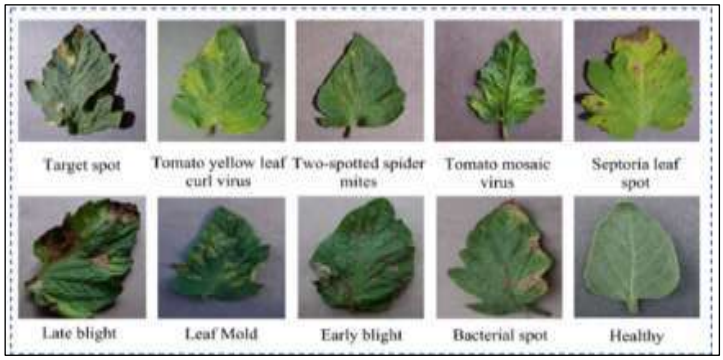

Figure 5: Tomato leaf disease classes used in the dataset.
Source: Authors, (2026).

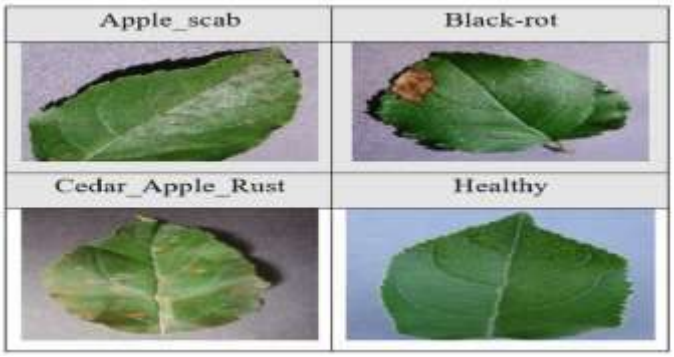

Figure 6: Apple leaf disease classes used in the dataset.
Source: Authors, (2026).

Table 1: Distribution of Images across the Disease Categories.

Disease Category	Number of Images
Early Blight	1136
Late Blight	2168
Septoria Leaf Spot	2013
Bacterial Spot	2431
Leaf Mold	1071
Yellow Leaf Curl Virus	6137
Mosaic Virus	405
Target Spot	1591
Two-spotted-spider mite	1904
Healthy	1805

Table 2: Distribution of apple images across the disease categories.

Diseases	Number of images
Apple Scab	2520
Black Rot	2484
Cedar Apple Rust	2200
Healthy	2510

Source: Authors, (2026).

IV.2 DATA SPLITTING AND DATA PREPROCESSING

Each dataset was split into three subsets: 70 % for training, 15 % for validation, and 15 % for testing. All images were resized to 64 × 64 pixels and normalized to the [0, 1] range by scaling pixel intensities by 1/255. To improve model generalization and mitigate overfitting, on-the-fly data augmentation was applied to the training subset. The augmentation parameters were carefully defined for reproducibility and included: rotation (±20°), zoom scaling (0.8–1.2), shear deformation (0.1), horizontal flipping, and brightness adjustments (±15%). The validation and test sets were only normalized, without any augmentation, to ensure unbiased evaluation. No external images were added to these subsets, preserving the integrity of the experimental setup. Additionally, to address class imbalance, particularly within the tomato dataset, a class-weighted loss function was employed during training. This ensures that both minority and majority classes contribute proportionally to the optimization process, enhancing overall classification robustness.

IV.3 PERFORMANCE METRICS

To evaluate our models, we used the well-known metrics derived from the confusion matrix, based on true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). The following standard performance metrics were computed:

$$Precision = \frac{TP}{TP+FP} \tag{1}$$

$$Recall = \frac{TP}{TP+FN} \tag{2}$$

$$Accuracy = \frac{TP+TN}{Total} \tag{3}$$

$$F1-score = 2 * \frac{Precision*Recall}{Precision+Recall} \tag{4}$$

V. RESULTS AND DISCUSSIONS

V.1 EXPERIMENT RESULTS

In this section of our thesis, our primary objective is to substantiate the effectiveness of our multi-species disease classification system, which leverages ensemble learning techniques. We aim to present empirical evidence supporting the validity and performance of our proposed approach. Additionally, we provide a comprehensive overview of the development tools and techniques employed during the implementation of our solution. Table 3 summarizes the hardware specifications of the personal computer (PC) used to conduct all experiments.

Table 3: PC's characteristics.

Processor	AMD Ryzen 9 7940HS
RAM	16 GB
Graphics Card	NVIDIA GeForce RTX 2070
Storage	15 GB

Source: Authors, (2026).

- CNN model

The CNN model demonstrated the strongest performance among the three base models, achieving an overall accuracy of 89%. Both the macro and weighted averages for precision, recall, and F1-score consistently fall within the 0.887–0.889 range (Table 5). This indicates robust and balanced performance across all classes. The marginally higher weighted averages suggest the model is particularly effective at classifying the more populous classes, such as Yellow Leaf Curl Virus and Tomato-Healthy (Table 4). These results underscore the CNN's superior capability in extracting complex hierarchical features from image data.

Table 4: Classification Performance per Class for CNN model.

	Class	**Precision**	**Recall**	**F1-score**
Apple Classes	Apple-Scab	0.86	0.82	0.84
	Black-Rot	0.86	0.89	0.88
	Cedar-Apple-Rust	0.94	0.94	0.94
	Apple-Healthy	0.89	0.90	0.89
Tomato Classes	Early Blight	0.88	0.86	0.87
	Late Blight	0.89	0.88	0.88
	Septoria Leaf Spot	0.90	0.88	0.89

- SVM model

The SVM model achieved solid performance, with an overall accuracy of **88%** (Table 7)**.** Its macro and weighted averages for all metrics are closely aligned near 0.867–0.869, indicating consistent performance without significant bias towards any particular class (Table 6). While its metrics are consistently approximately 0.02 lower than the CNN's across the board, it remains a strong and reliable model for this classification task.

Table 6: Classification Performance per Class for SVM model.

	Class	**Precision**	**Recall**	**F1-score**
Apple Classes	Apple-Scab	0.84	0.80	0.82
	Black-Rot	0.85	0.87	0.86

- RFC model

The RFC model achieved a baseline accuracy of **85%**. Its performance metrics macro and weighted averages ~0.83 (Table 9) are the lowest among the three individual models. The per-class F1-scores show a more pronounced drop, particularly for classes like Apple-Scab (0.78) and Target Spot (0.79) (Table 8), indicating areas where the model struggles compared to the CNN and SVM.

Table 8: Classification Performance per Class for RFC model.

	Class	Precision	Recall	F1-score

- RBF-SVM meta-learning model

As showing in Tables 10 and 11, the proposed ensemble learning achieved remarkably high performance, with macro and weighted averages above 0.975 across all metrics, indicating both high precision and strong generalization.

Table 10: Classification Performance per Class for RBF-SVM meta-learning.

Class Type	Class	Precision	Recall	F1-score
Apple Classes	Apple-Scab	0.97	0.95	0.96

The ensemble model significantly outperforms all individual models. By leveraging complementary strengths—CNN's feature extraction, SVM's margin-based generalization, and RFC's ensemble diversity—the stacking approach improves both minority and majority class predictions, achieving near-perfect performance. This demonstrates the effectiveness of ensemble learning in multi-class leaf disease classification. As illustrated in Figure 7, the accuracy curves show a consistent upward trend for both the training and validation sets across the epochs.

The validation curve closely follows the training curve, suggesting that the model learns meaningful representations without exhibiting overfitting. After a rapid improvement during the initial epochs, both curves stabilize and converge toward values exceeding 98%. Similarly, the loss curves display a steady decrease for both training and validation data. Throughout most epochs, the validation loss curve remains slightly below the training loss curve, indicating stable learning dynamics and good generalization capability. The parallel behavior of the two curves and the absence of divergence further confirm that the model maintains reliable performance without signs of overfitting.

V.2 DISCUSSION AND COMPARISON

In this study, an RBF-SVM was employed as the meta-learner to integrate predictions from three independently trained base models—CNN, SVM, and RF—across multi-crop leaf disease datasets. Individually, the CNN, SVM, and RF achieved accuracies of 89%, 88%, and 85%, respectively. Each base model contributed complementary information: the CNN extracted hierarchical visual features, while the SVM and RF leveraged raw pixel vectors for independent predictions. By synthesizing the predictions from the individual base models, the RBF-SVM meta-learner achieved a significantly higher overall accuracy of 98%, as illustrated in Figure 8, effectively handling more challenging and diverse datasets, including multiple crop species with varying leaf shapes, disease patterns, and imaging conditions. This stacking ensemble strategy demonstrates both robustness and generalizability, highlighting the effectiveness of meta-learning for complex, multi-species disease recognition tasks.

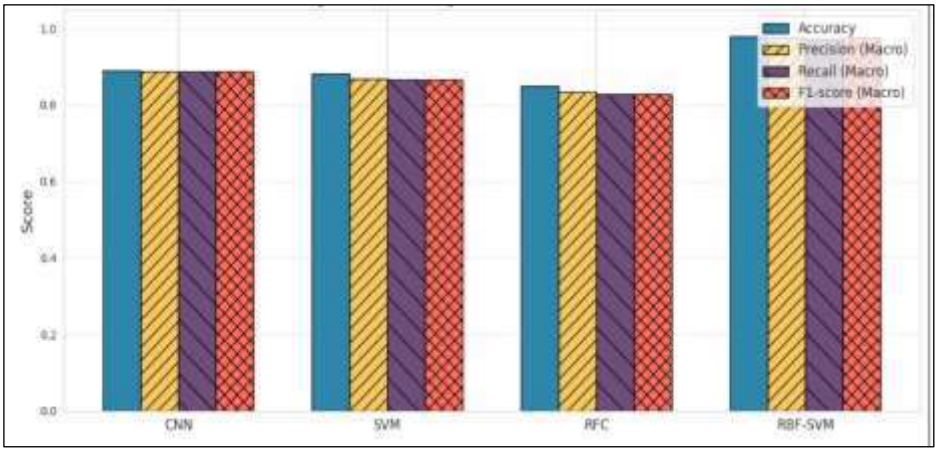

Figure 8: Performance comparison between the base models and RBF-SVM meta-learner model.
Source: Authors, (2026).

Table 12 compares our results with state-of-the-art approaches evaluated on the same dataset (PlantVillage). The table demonstrates that our proposed heterogeneous stacking ensemble outperforms or matches the performance of recent state-of-the-art methods while addressing key limitations. Previous studies [20–23] primarily focus on CNN-based architectures, hybrid CNN-classical ML models, or CNN + Vision Transformer approaches. These methods achieve high reported accuracies, typically in the 95–99% range, with Liang et al. [21] reporting 99.24% on apple leaves and ~98% on corn. However, these studies are largely restricted to single-species or controlled datasets, limiting their generalization to diverse, real-world conditions.

In contrast, our approach combines CNN, SVM, and Random Forest classifiers through an RBF-SVM meta-learner, achieving 98% overall accuracy across multiple crop species, including apple and tomato. By leveraging the complementary strengths of deep learning and classical ML models, the ensemble is able to maintain high accuracy on more challenging, multi-species datasets, demonstrating robustness and generalization beyond conventional single-model approaches. This comparison highlights that, while previous methods perform well on controlled datasets, our stacking ensemble provides a versatile and reliable framework for multi-species plant disease classification, making it well-suited for practical applications in precision agriculture.

Table 12: Comparing our ensemble with related works.

Ref	Year	Approche / Models	Dataset / Species	Reported Accuracy

VI. CONCLUSIONS

This study proposes a meta-learning–based stacking ensemble for multi-species crop leaf pathology recognition, integrating Convolutional Neural Networks (CNN), Support Vector Machines (SVM), and Random Forest Classifiers (RFC) as heterogeneous base learners. Each model was trained independently using its own feature representation: the CNN learned hierarchical visual features directly from images, while the SVM and RFC were trained on raw pixel vectors obtained from resized and flattened images. Their individual predictions were then combined by a meta-level SVM, which learned to exploit complementary strengths across the three models. This stacking strategy resulted in a significant improvement in overall classification performance compared to any single model alone.

Experimental results demonstrated that while individual models achieved accuracies between 85 % and 89 %, the stacking ensemble reached near-perfect performance with macro and weighted F1-scores of 0.975, highlighting its ability to generalize across multiple crop species, including apple and tomato. These results confirm that combining diverse learning paradigms via meta-learning effectively addresses the limitations of single-model approaches, particularly in multi-class and multi-species scenarios. The proposed framework provides a robust, accurate, and generalizable tool for automated crop disease detection, which can support precision agriculture and early disease management. Future work will focus on extending this approach to additional crop species, incorporating field-acquired images under variable conditions, and exploring lightweight architectures to enable real-time deployment on mobile or edge devices.

ABSTRACT

Throughout the first decade of this century, the forging industry has experienced rapid expansion, with an increased demand for high-quality forged products requiring zero defects. This article lays the groundwork for limiting forging defects in the crankshaft forging industry sector. Success in this field demands a small rejection or scrap percentage, shortened lead times, and minimal waste in part production. Using a defect tracking matrix, this study identifies common defects such as underfills, laps, and cracks, which are primarily caused by improper material handling, inadequate die design, and insufficient process control. This defect tracking matrix, or cause effect matrix, has the ability to serve as a profound aid for both the design engineer and the producer for any and all aspects of forging and work piece topography that are destined for use in industry sectors that deal with crankshaft production. Key strategies to address these issues include optimizing die design, enhancing process monitoring, and improving operator training. The implementation of corrective measures led to a significant reduction in defects, with the final rejection rate decreasing from 4.57% to 1.93%. The most notable reductions were in defects like underfills, laps, and cracks. This approach not only improves product quality but also enhances overall efficiency in crankshaft manufacturing. The methodologies and strategies outlined can be broadly applied across the forging industry to achieve similar improvements in defect reduction and process performance.

I. INTRODUCTION

The forging industry has expanded considerably during the course of this century. Most of the credit for this growth goes to the rapid emergence of more specialized technology, better materials, and heftier presses. Because of this, conflict among forging enterprises has heated up, and 'precise 1st time' products have become a top priority. Using forging systems quickly to make more assemblies has increased the demand for forgings that are free of flaws [1]. The method of metal forging is an effective one for the production of by facilitating a robust structural parameter that meets compliance with the channel flow. Mass manufacturing of accurate components, including crankshafts and connecting rods, may be accomplished at a reduced cost. Forging deforms metals plastically using regionalized compressive forces. Manual or power hammers, presses, or other forging-specific machines apply these forces. Forging transforms a billet or ingot into the desired product [2]. When defects show up during the forging process, they need to be fixed quickly in order to meet both industry standards and the needs of local customers. To satisfy the requirements of the industrial evaluation criteria and the service standard, forging shortcomings are required to be resolved quickly.

During all stages of the forging process, this sector has a lot of problems, such as mis-location, laps, mismatch, un-filling, and seam cracks [3]. Getting closer to this goal could be helped by having a reliable model aid system that helps people avoid the most common kinds of mistakes. Because it's hard for a designer to find the best way to shape a product in as few steps as possible [4], this technology needs to be made. The metal handbook [5] specifies the following steps for forging procedures to be performed: trimming forging parts to remove flashes from the final forged part; hammering or pressing the hot billet in various imprint dies. The quality of a forged product depends on the billet's metal and configuration, die and material temperature, and the quantity and structure of intermediary dies.

Forged crankshafts are employed when load stress is applied, and mitigating measures are vital [6]. Within an internal combustion engine, there is a significant part called the crankshaft that rotates at a rapid speed [7]. The crankshaft is a crucial component of diesel engines and cars, and its complicated design includes cylinders that serve as bearings and arms that serve as crank webs, and it has a direct role in determining the engine's overall performance in terms of both power and efficiency [8]. It turns the reciprocating motion of the piston into rotary motion and then back into reciprocating motion with a simple mechanism. [9] The primary processes involved in producing the crankshaft in the forging industry are shown in (Figure 1). In this process, after heating, the billets are placed beneath the upper and lowest dies and pressed through into the desired form.

This happens in three steps: first, in the roller section, where the part is pre-shaped; second, in the blocker, where the part is rough-forged; and third, in the finisher die, where the finished shape is done. Based on analytical and practical designs as well as real experience, this article discusses the basic necessity of a defect tracking system. While defects may be found using simulations, their origin is still mostly unknown. Because of this, it would be helpful to have a system that lists problems, what makes them happen, and how to fix them. Forging defects and their likely sources are catalogued and organised into categories with accompanying guidance in the cause-effect matrix or by using a defect tracking system. This Defect-Tracking (Cause Effect) Matrix might be implemented into an intelligent system that directs the factory towards achieving "valid 1st time" output.

II. MATERIALS AND METHODS

II.1 MATERIALS FOR THE FORGED STEEL CRANKSHAFT

Materials for the crankshaft should be readily formed and produced, in addition to having sufficient strength, durability, and rigidity, as well as fatigue resistance power. Ingots of metal(steel) are formed into predetermined forms using specialized presses and other forging equipment to produce crank shafts. Because of advances in the technology used to make steel, it is now feasible to eliminate contaminants in the materials used to create crankshafts [10], [11-12]. Crankshafts are often produced from AISI 1040, AISI 1045, or a comparable kind of steel that is forged [13-14]. Medium-carbon steel alloys contain iron and 0.25-0.45 percent carbon, as well as chromium, nickel, manganese, silicon, cobalt, molybdenum, vanadium, and other elements. Manganese-molybdenum steel is an inexpensive forging steel used for petrol engine crankshafts; chromium-molybdenum steel for light commercial diesel engines; and nickel-chromium-molybdenum steel for heavy-duty diesel engines. Nickel-chrome-moly alloy AISI 4340 is a popular choice for high-performance crankshafts owing to its high strength, fatigue resistance, and ductility [15-17].

Crankshafts are typically made from various types of forged steel grades. Figure 2 illustrates a comparison of mechanical properties among different crankshaft materials. The development of new materials aims to reduce costs by utilizing enhanced micro-alloyed steels. These steels eliminate the need for heat treatment and offer improved material qualities, providing more options for product design. The assessed micro-alloy grades show potential cost savings compared to conventional materials such as tempered and quenched alloy steel (AISI 4140) or carbon steel (AISI 1050), with a reduction of 11% to 19%.In terms of performance, the fatigue strength of micro-alloy grades is generally equal to or higher than that of existing materials, while maintaining superior machinability. This makes micro-alloyed steel a common substitute for forged steel. By using 38MnVS6 or VANARD 925 air-cooled micro-alloyed steel instead of the typical AISI 4142 steel, the cost of the finished crankshaft can be reduced by 13% [18].

II.2 PRODUCTION METHOD OF THE FORGED STEEL CRANKSHAFT

One of the most important steps in the production process is forging. It results in a product with higher mechanical qualities and less waste. In comparison to other methods of production, such as casting, this is a significant advantage [19]. Forging is a traditional method of producing high-performance or elevated crankshafts; it involves heating a billet to the proper forge temperature, and afterwards repeatedly hammering or pressing it between pairs of dies at quite high pressure. The dynamic qualities of a crankshaft, such as its resistance to impact, as well as cyclic loads, are improved during the forging process. The methodical procedure for producing a crankshaft [20] is shown in (Figure 3). Crankshafts that are forged are typically made by primarily using the processes of hot forging in combination with machining in order to put together the final product. [18-20] Monitoring the geometric diversity that results from shifts in temperature may be done in a number of different ways [21]. As the billet moves through the top and lower die configurations, it is purposefully distorted so that the ultimate product will be as good as it can possibly be [5], [22].

II.3 DEFECTS IN THE PRODUCTION OF CRANKSHAFTS DURING THE FORGING PROCESS

Operators and engineers may discover defects at any point after or during an activity or process and must speculate as to when, how, and why the defect emerges. At some point, researchers might require certain sources of evidence in order to predict the cause of the problem, the kind of part, the position of the defect on the component or part, the severity of the defect, etc. [23-24]. A framework of the defect diagnosis process is shown in (Figure 4) [25-26]. Forging defects are often the result of defective ingots, inaccurate heating, bad forging circumstances, inappropriate forging procedures, and unequal chilling of the stock upon forging [27]. In every forging operation, the manufacturer may run across a wide range of defects throughout the production process.

The product is often pulled off the market as a consequence of these problems. The defects in forged metallic components may be discovered with the use of image recognition, and the authors speculate that this method might be used to reduce stresses and fatigue throughout a physical assessment [28]. A cost-effective forged product free of forging defects is ensured by a well-designed shape and respect to the normal flow. Also among these factors are full cavity filling, good material properties, little die wear, longer die life, and good material properties [29]. To achieve an ideal design with a focus on stress distribution [1], forging defects must be eliminated, and metallic grain flow must be improved throughout the forging process.

When it comes to forged components, the most typical cause of rejection or failure is the appearance of cracks on the inside [30]. The best strategy for decreasing forging defects was determined using the AHP-TOPSIS Method. The under-fill error is a significant issue in the field of investigation since it happens at such a high incidence in this sector [31]. Using the defect matrix, the first step entails the categorization of possible offenders into the following six groups: cracks, surface inadequacies, owing to shear flaws, folds, overlap defects, and form and structural defects. The second step classifies potential causes into different categories by using a tool called the defect matrix. This tool illustrates how different defects interact with each other as well as the factors that contribute to them [32]. The Deform-3d software application [33] can reliably forecast defects like underfill, residual stresses, and folds during fast heating. Defects are common in the crankshaft forging sector (Figures 5), with reflecting practices of recurrence [19].

II.4 METHODS AND STRATEGIES USED TO REDUCE REJECTION RATE IN CRANKSHAFT FORGING

This research article centers on crankshafts manufactured through hot forging, tailored for use in single-cylinder engines produced by Forge and Forge Pvt. Ltd. Rajkot. Industry faces an Approx. 5% rejection rate. Table 1 highlights production metrics over two consecutive 12-month periods: before corrective measures (2019-2020) and after (2020-2021) for the forging of single-cylinder crankshafts. Table 2 details defect types before and after implementing corrective measures. Table 3 outlines specific measures for preventing and addressing catastrophic major forging defects encountered in crankshaft production.

Table 1: Monthly Production Data and Defect Analysis Before and After Corrective Measures.

Metrics	Before Corrective Measures (12 Months)	After Corrective Measures (12 Months)
Total Production	120,284	113,112
Parts Accepted	114,783	110,927
Ultimate Rejection	5501	2185
Percentage of Final Rejection	4.57%	1.93%

Source: Authors, (2026).

Table 2: Defect Analysis and Contribution of each defect.

Defect Type	Counts, Before Corrective Measures (12 Months)	Counts, After Corrective Measures (12 Months)
Unfilling	3594	1565
Lap	716	188
Mislocation	521	229
Mismatch	355	122
Crack	73	44
Burnt	47	7
Scale Pit	177	30
Dent	11	0
Oversize	7	0
Total	5501	2185

Table 3: Preventing and correcting catastrophic forging defects in crankshafts.

Defect grading	Main forging defects	Protective and restorative measures
UF	Unfilling	Embed the blocker mode of operation of the dies by highlighting the areas that are not filled with the appropriate material.
		It is possible that the counterbalance masses for forged crankshaft may be revised or omitted altogether.
		Ensure that the employee receives the time and care they need in order to reduce the likelihood of mistakes occurring.
		Choose the kind of lubricant that is most suited for the specific die you are using and the corresponding raw material benchmark really has to be implemented as soon as possible.
		The integrity of the billet for the length of time provided may be easily confirmed by doing a physical check at many places more than thrice.
		Check the design of the roller and raise the depth by two to three millimetres in o rder to combat the underfilling effect.
		Set the burner towards the ideal temperature in order to heat it up enough.
LA	Overlap	To reduce the likelihood of incidents, provide a thorough training programme.
		In order to ensure consistency in quality, the right raw - materials norm must be implemented.
		Using a rubbing motion to grind the die's chamfered edges is advised.
		In order to fulfil the specifications of the design, the deformity of the blocker dies had to be eliminated.
		Before the user starts, the user should first preform the shape at the exact angle.

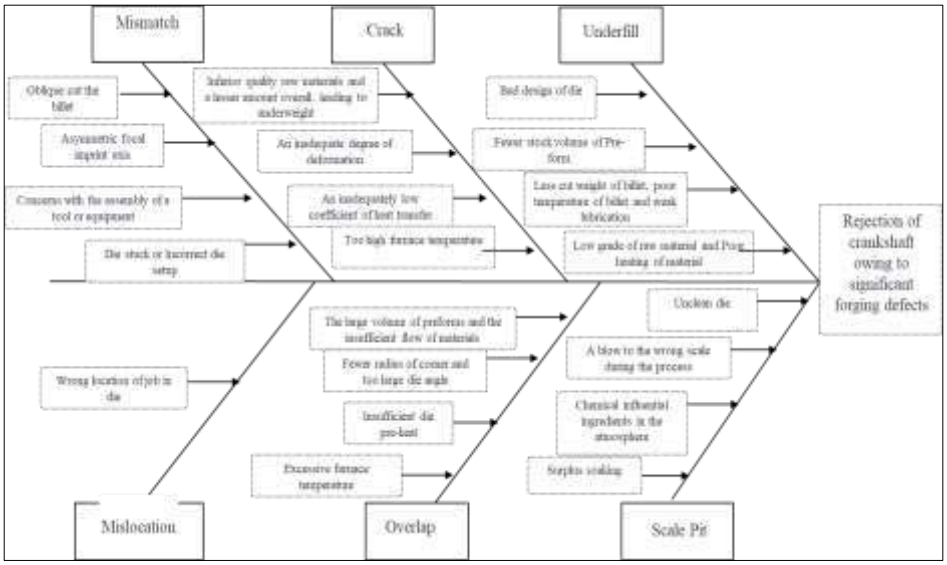

Figure 6: Cause effect of crankshaft rejection diagram for major defects of forging industry.
Source: Authors, (2026).

The cause-effect diagram (Figure 6) for significant defects in the forging sector, particularly with crankshaft rejections, depicts the main causes that contribute to incidences of rejection. The image above classifies significant defects and links their origins to certain root causes. By categorizing these components into distinct groups such as materials, processes, equipment, and human factors, it aids in the identification of possible causes of defects and provides direction for improvement initiatives. This tool is very beneficial for systematically assessing and correcting quality concerns in the forging process, with the goal of reducing rejection rates and improving overall product quality. Pareto analysis is a method used to discover and rank the most important factors that contribute to a challenge. Figure 7 illustrates the distribution of forging defects and percentages of rejection for single cylinder forged crankshafts in their original state, prior to the implementation of any remedial actions.

The defects are often classified according to their frequency or the extent to which may affect rejection rates. The highest bars in the Pareto chart represent the problems that occur most often or have the greatest severity. These bars suggest the areas where efforts should be concentrated in order to minimize rejection rates and enhance overall quality, prior to implementing remedial measures. The investigation reveals that over 80% of rejection difficulties stem from 20% of the detected faults. The Pareto principle implies that a vast majority of the rejections may be ascribed to a limited number of distinct fault categories. According to this research, the main reasons for rejecting single cylinder crankshafts forging are under-fills and overlaps, which account for over 75% of the rejections. This information is shown in Figure 7.

Figure 8 illustrates the outcomes of Pareto analysis after the implementation of remedial actions to resolve the highlighted defects from Figure 7. The image displays a revised proportion of defects and rates of rejection, demonstrating the influence of the implemented remedial measures. Optimally, after the implementation of measures such as process optimizations, quality control advancements, training initiatives, or equipment enhancements, the tallest bars in Figure 8 ought to indicate decreased frequencies or severities of faults. This indicates a positive advancement in reducing the number of rejected products and attaining superior product quality in the forging operation. According to the investigation, the main reasons for rejecting single cylinder crankshafts forging are under-fills and overlaps, which account for over 80% of the rejections. This information is shown in Figure 8.

III. RESULT AND DISCUSSIONS

III.1 DEFECT – TRACKING MATRIX FOR CRANKSHAFT FORGING INDUSTRY

An author [32] came up with the idea of a defect matrix, which is a tool that can be used to tie a forging defect first to factors that have the potential to cause it. A cause-effect diagram is a visualization tool that may be used to logically arrange the potential causes of a certain issue or repercussion by visually portraying those potential causes in greater detail. It can also reveal causal links between different hypotheses. A fishbone diagram, or an Ishikawa diagram, is one of the most common names for this form. [34-36] Figure 11 is a cause-and-effect diagram that illustrates the massive defects that led to the crankshaft rejection during the manufacturing process. The design and arrangement of a defect-tracking matrix is shown in (Figure 9-11), which is relevant to the crankshaft forging industrial sector.

The Defect-Tracking Matrix has twenty-two flaws arranged vertically and upwards of five groups (Table 4) of probable causes for the defects arranged horizontally. The major groups are presented just to make the matrix simple to read; nevertheless, in (Figure 9-11), a portion of the whole Defect-Tracking Matrix or Cause Effect Matrix is shown; this section contains the characterization of the self-styled foundation as like specialist assistance for forging. In (Figure 9-11) the symbol "*" shows that there is a link between both the main causes or possible factors contributing to rejections and forging defects. (Figure 9-11) depicts the second defect tracking matrix for the crankshaft forging sector in accordance with the operator and materials factors. (Figure 9-11) depicts the first defect tracking matrix, or cause and effect matrix, for the crankshaft forging enterprise in terms of tool and machine factors.

(Figure 9-11) depicts the second defect tracking matrix for the crankshaft forging sector in accordance with the methods and environmental factors. The marks in the defect-tracking-matrix are dependent on the process that is currently being used, which is the reason why a cause-effect matrix is required to be developed for each and every type of forging process. A task of this kind will need much too much time and will be very challenging to summarise. Because of this, the processes need to be separated into their respective primary groups according to criteria such as the geometry of the tool and workpiece or the operation that is more frequent. For each Defect-Tracking-Matrix, the marks that indicate the link between the defect and what might cause it will produce an agenda that is unique to the process that is now being carried out.

Table 4: Five groups' Parameters for possible causes laid out horizontally.

Vertically Forging Defects	**Horizontally Probable causes**				
	Main Group 1 Process	**Main Group 2 Environmental**	**Main Group 3 Tools**	**Main Group 4 Materials**	**Main Group 5 Operators**
Example Laps	Sub group 1 Sub group 2	Sub group 1 Sub group 2	Sub group 1 Sub group 2	Sub group 1 Sub group 2	Sub group 1 Sub group 2

III.2 EFFECTIVENESS OF CORRECTIVE MEASURES IN REDUCING DEFECTS AND IMPROVING QUALITY

Based on the data analysis presented in Tables 1, 2, and insights from Table 3 regarding corrective measures, significant improvements in production quality and defect reduction are evident following the implementation of strategies at Forge and Forge Pvt. Ltd. Rajkot. Over a 12-month period, total production slightly decreased from 120,284 to 113,112 parts and the acceptance rate improved from 114,783 to 110,927 parts. Notably, ultimate rejections dropped from 5,501 to 2,185 parts, with final rejection rates decreasing from 4.57% to 1.93%. Specific defect reductions include unfills (3,594 to 1,565 occurrences) and lap defects (716 to 188 instances). These improvements reflect effective strategies like die design optimization, process controls, and operator training, enhancing quality, customer satisfaction, and operational efficiency in the competitive forging industry.

IV. CONCLUSIONS

1. The Defect-Tracking-Matrix or Cause-Effect Matrix may provide guidance to the manufacturing and design specialists, allowing them to resolve a problem with the product and create a robust component. The foundation of a Defect-Tracking-Matrix was created for the economic advantage of the crankshaft forging industrial sectors to correct forging defects. The developer may get direction from the cause- effect matrix using any of two approaches. The first approach is referred to as the "detection mode," and it's used when the developer wants to figure out why a certain defect is present in the product and exactly how to get rid of it. Because the Defect-Tacking Matrix is being used horizontally throughout this context, it is feasible, for a given defect, to acquire data on which variables might produce the defect as well as a potential strategy to avoid it. This is because the defect-tracking-matrix is used in this context.

The 'advising solutions mode' of the Cause Effect Matrix is another use of its capabilities. With the 'advising solutions mode' method, the Defect-Tracking-Matrix is used in a vertical orientation, providing information on the defect possibility associated with each operating factor. It presents the theoretical foundation for a method to reduce the overall quantity of defects in a forged product. The Defect-Tracking - Matrix is a database or catalogue of defects that may be generated for a wide range of forging methods and workpiece shapes to serve as a helpful tool for the design process. It is possible for a design engineer to employ a Defect-Tracking-Matrix in practice, although the factors of that procedure may not match those given here. Because of this, more tests using numerical or parametric methods may be needed to back up the Defect-Tracking-Matrix results.

2. The implementation of targeted corrective measures at Forge and Forge Pvt. Ltd. Rajkot effectively reduced total rejection rates and specific major forging defects, significantly enhancing production quality and operational efficiency.

ABSTRACT

Accurate assessment of photovoltaic (PV) power output under varying environmental conditions is essential for evaluating solar energy performance and optimizing its application. This study employs a Feedforward back propagation neural network (FFBPNN) approach to predict the output power of a solar panel using a combination of electrical and weather-related parameters. The input variables include short-circuit current (I_{sc}), open-circuit voltage (V_{oc}), maximum voltage (V_{max}), maximum current (I_{max}), efficiency (EFF) - represents how effectively it converts incident solar energy into electrical energy., fill factor (FF) - the ratio of the maximum obtainable power to the product of the open-circuit voltage and short-circuit current, solar radiation (G), wind speed (v), ambient temperature (T_{am}), and panel temperature (T_{panel}) under solar radiation intensity in the ranges of 200–400, 400–600, 600–800, and 800–1000 W/m². Three artificial neural network (ANN) models, ANN-10 (10 inputs), ANN-8 (8 inputs, except I_{sc} and V_{oc}), and ANN-6 (6 inputs, except I_{sc}, V_{oc}, V_{max} and I_{max}), are developed for 496 dataset and compared based on their prediction accuracy using the coefficient of correlation (R) by varying a number of neurons in the hidden layer from 1 to 15. Among them, the ANN-8 model (8-10-1) demonstrates the highest prediction accuracy (R value of training, testing, validation and overall model exceeding 0.999) particularly at high solar radiation levels (800–1000 W/m²). The results confirm that FFBPNN-based modelling is a reliable and effective tool for forecasting PV output power under diverse operating conditions. This approach supports solar energy potential assessment and performance optimization across various geographical and climatic contexts.

I. INTRODUCTION

In response to growing global energy demand, environmental degradation, and the urgent need to reduce reliance on fossil fuels, solar energy has become a cornerstone of sustainable development. Among renewable energy sources, solar power is particularly attractive due to its abundance, scalability, and minimal environmental impact [1]. Photovoltaic (PV) technology, which converts sunlight directly into electricity, plays a central role in harnessing this resource [2]. The increasing integration of PV systems across residential, commercial, and utility-scale applications reflects a global shift toward clean energy. However, the intermittent and variable nature of solar irradiance, shaped by geographic, meteorological, and temporal factors, poses significant challenges to the consistent and efficient operation of PV systems [3]. Accurate forecasting and modelling of PV output are thus critical for grid stability, energy planning, and operational efficiency [4].

PV system performance is governed by complex, nonlinear relationships between environmental parameters (e.g., solar irradiance, temperature, wind speed, humidity) and electrical outputs (e.g., voltage, current, power) [5]. Predicting output under varying conditions is vital not only for system monitoring and control but also for optimizing energy storage, demand response, and economic dispatch, especially in smart grids and hybrid energy systems. Despite its importance, accurately modelling PV behaviour remains difficult due to the stochastic and nonlinear nature of these influencing factors [6]. Traditional modelling approaches, empirical, analytical, and physics-based, have laid the foundation for PV system analysis. These methods often rely on simplified assumptions and require parameter calibration, which may not generalize well under dynamic real-world conditions [7]. For instance, the widely used single-diode model requires parameters that could be hard to measure or that vary over time. Similarly, regression-based methods assume fixed functional relationships, limiting their ability to capture the nonlinear dynamics of PV performance. These limitations highlight the need for more adaptable, data-driven approaches [8].

In this context, machine learning (ML) has emerged as a promising alternative for modelling complex systems, including PV output prediction. Among ML techniques, Artificial Neural Networks (ANNs) are particularly well-suited for this task due to their ability to model nonlinear relationships, manage noisy data, and generalize from historical patterns [9]. Modelled after the human brain, ANNs comprise layers of interconnected neurons that transform input features through weighted connections and activation functions to generate outputs. This structure allows ANNs to approximate complex functions without requiring predefined mathematical models [10]. The application of ANNs to PV modelling represents a shift from equation-driven to data-driven methodologies [11]. Leveraging large volumes of operational and meteorological data, often collected by sensors and monitoring systems, ANNs adapt to different PV technologies, configurations, and climate conditions. They could also be integrated with other intelligent systems such as fuzzy logic, genetic algorithms, or hybrid ML frameworks to further improve prediction accuracy and robustness [12]. Numerous studies have validated the effectiveness of ANNs in predicting PV performance [13- 15].

For instance, a Levenberg-Marquardt back-propagation ANN model with six input parameters and a hidden layer of up to 35 neurons achieved high accuracy in output prediction [16]. Other studies compared radial basis and feed-forward topologies using different training algorithms, finding mean bias errors below 1% and prediction errors between 0.05% and 1% [17-20]. In another case, an MLP model with seven inputs predicted maximum voltage (V_m) and current (I_m) with high precision using a single hidden layer of up to ten neurons [21]. A feed-forward ANN with two hidden layers, trained on six meteorological variables, achieved R^2 values as high as 99.9% when predicting mono-crystalline PV output [22]. Mellit et al. (2013) demonstrated that even simple ANN structures could effectively predict PV output. Using one year's worth of data for a 50 W_p module, their model, with just a single hidden neuron, achieved determination coefficients of 96–97% on sunny days and 93–97% on cloudy days [23]. Compared to traditional techniques, ANN-based models consistently offer superior accuracy in capturing the effects of environmental variability, shading, and system degradation.

They also provide practical benefits in terms of implementation speed and computational efficiency, especially with modern hardware and software capabilities [24]. Nevertheless, the effectiveness of ANN models depends on factors such as network architecture, input feature selection, training algorithms, and data quality [25]. Despite their promise, ANN-based models in PV energy forecasting often face challenges such as overfitting, convergence instability, and limited interpretability. Recent advances, however, are steadily overcoming these limitations. Regularization strategies, ensemble learning, and data augmentation enhance generalization, while adaptive optimizers, metaheuristic-assisted training, and advanced initialization improve convergence speed and stability. Furthermore, explainable AI tools, attention mechanisms, and hybrid physics-informed networks enhance transparency and trust in predictions. Together, these developments expand the reliability and applicability of ANN models, enabling more accurate forecasting, fault detection, and system optimization, thereby strengthening their role in modern PV energy research and grid integration [26]. Despite the demonstrated success of ANN-based models in PV output prediction, several research gaps remain.

Many existing studies focus on limited datasets, specific PV technologies, or narrow environmental conditions, which restrict the generalizability and robustness of the models [24], [26]. Furthermore, there is a lack of systematic comparison between different ANN architectures in terms of prediction accuracy, training efficiency, and sensitivity to input features. Additionally, few studies explore the integration of real-time meteorological data or assess model performance across diverse climatic zones [25]. These limitations highlight the need for more comprehensive, adaptable, and scalable ANN frameworks tailored to dynamic, real-world conditions. The present study aims to address these gaps by developing a data-driven ANN model that leverages diverse environmental inputs and evaluates multiple neural network configurations to optimize PV power output prediction. The novelty of this work lies in its systematic exploration of ANN architectures under varying climatic conditions, the inclusion of a broader set of input features, and the evaluation of model performance across different PV technologies. This approach not only enhances prediction accuracy but also contributes to the development of more reliable and transferable forecasting tools for modern energy systems.

Hence, this study aims to develop and evaluate an ANN model for accurately predicting the output power of photovoltaic (PV) systems under varying environmental conditions. The primary objective is to investigate the impact of different electrical and meteorological input parameters on the accuracy of PV power prediction. Specifically, the study seeks to: (i) assess the predictive performance of ANN models using a combination of electrical parameters (short-circuit current (I_{sc}), open-circuit voltage (V_{oc}), maximum voltage (V_{max}), maximum current (I_{max}), efficiency (EFF), fill factor (FF)) and environmental factors (solar radiation, wind speed, ambient temperature, and panel temperature); (ii) analyse the effect of different solar radiation intensity ranges on model accuracy; (iii) optimize ANN architecture by varying the number of input features and hidden layer neurons; and (iv) compare the prediction accuracy of three ANN models (ANN-10, ANN-8, and ANN-6) using the coefficient of correlation (R). The findings aim to support the application of ANN-based modelling for PV performance evaluation and solar energy forecasting across diverse climatic conditions.

II. METHODOLOGY

This study develops an ANN model to predict the output power of a photovoltaic (PV) module under varying environmental conditions. The model is trained and evaluated using field experimental data collected over a one-month period at UCSI University Field Campus, Kuala Lumpur, Malaysia (Latitude: 3.079548° N, Longitude: 101.733216° E, Elevation: 70 m). The site experiences a tropical climate, making it suitable for solar energy potential assessment and performance prediction.

II.1 PV MODULE SPECIFICATIONS AND MEASUREMENT INSTRUMENTS

The solar panel model ZDNY-250C60 is made of Monocrystal (a-Si) material. The panel size is 1650×992×40 mm, and it consists of 60 cells. Its maximum power output is 250 W. The open-circuit voltage (V_{oc}) is 37.85 V, the short-circuit current (I_{sc}) is 8.40 A, the voltage at maximum power (V_{max}) is 31.17 V, and the current at maximum power (I_{max}) is 8.03 A. The maximum system voltage is 1000 V, and the maximum fuse current is 15 A. The output tolerance is 0/+3%, and the measurements were taken at a temperature of 25°C. Each cell has a dimension of 125×125 mm Figure (1).

II.2 DATA COLLECTION AND INPUT FEATURES

Data were collected using the experimental setup shown in Fig.(1), over a month period from 25 June to 26 July 2025, with measurements taken daily between 9:00 a.m. and 5:00 p.m. A PROVA 200A I-V Tracer Solar Module Analyzer was used to measure Open circuit voltage (V_{oc}), Short-Circuit current (I_{sc}), Voltage at max power (V_{mp}), and Current at max power (I_{mp}) capture the electrical characteristics of the PV module. The surface temperature of the panel was measured using a FLUKE 59 Mini IR Thermometer, while ambient temperature was recorded via a wired Mercury thermometer. Wind speed was monitored using a handheld anemometer. The following parameters were recorded at regular intervals: (i) Electrical parameters: I_{sc}, V_{oc}, V_{max}, I_{max}, Efficiency (EFF), Fill Factor (FF), (ii) Environmental parameters: Solar Radiation (G), Wind Speed (v), Ambient Temperature (T_{am}), Panel Temperature (T_{panel}), and (iii) The PV output power served as the target (output) variable for the ANN model. To evaluate model performance under different irradiance conditions, solar radiation data were grouped into four categories: 200–400, 400–600, 600–800, and 800–1000 W/m².

II.3 ANN MODELLING

Artificial Neural Network (ANN) is a computational modelling framework inspired by the structure of the human brain, consisting of interconnected processing units (neurons) arranged in three layers: input, hidden, and output [27]. In this study, a feed-forward Multilayer Perceptron (MLP) architecture was employed Figure (2), implemented in MATLAB 2024. Each input parameter is supplied to a neuron in the input layer, processed through synaptic weights and activation functions within the hidden layer, and finally transformed into the predicted output in the output layer [28].

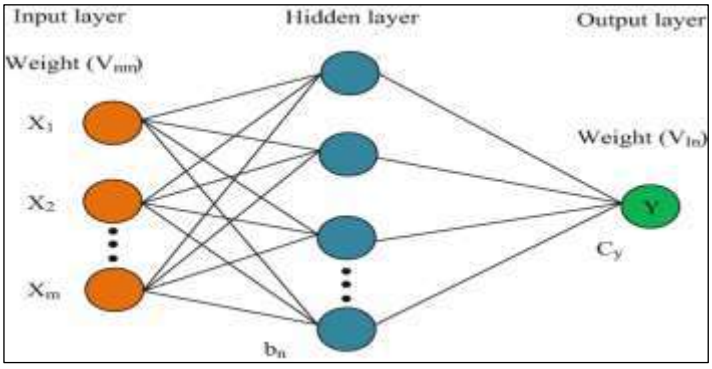

Figure 2: General architecture of ANN.
Source: Authors, (2026).

The dataset containing 40 entries was divided into 70% training, 15% testing, and 15% validation. Before training, all input parameters were normalized to a [0, 1] range using the Eq. (1):

$$X_i = \frac{0.8}{d_{max} - d_{min}} \left(d_j - d_{min}\right) + 0.1 \quad (1)$$

Where d_{max}, d_{min}, and d_i are the maximum, minimum, and current values of the dataset, respectively. The ANN model was trained using the Levenberg–Marquardt algorithm, known for its fast convergence. The common activation functions used in ANN are provided in Eq. (2). The sigmoid activation function was used in the hidden layer to introduce nonlinearity and enable the ANN to learn the complex nonlinear relationships inherent in solar radiation and PV electrical behaviour. The output layer used a linear activation function because the target variable (PV output power) is continuous and unbounded, requiring an unrestricted output range. This sigmoid–linear combination is the standard architecture for regression tasks and ensures both stable training and accurate numerical prediction.

$$f(s) = \begin{cases} S\ linear\ function \\ \frac{1}{1+e^{-s}}\ \ sigmoid\ function \\ \frac{e^{-s}}{e^{+s}+e^{-s}}\ \ hyerbolic\ tangent\ function \end{cases} \quad (2)$$

The error function, as given in Eq. (3), to be minimized during training is given in by:

$$E = \frac{1}{2}\sum_{k=1}^{l}(\overline{y_k} - y_k)^2 \quad (3)$$

The ANN models were evaluated using Coefficient of Correlation (R), which measures the strength of the linear relationship between predicted and actual output. To analyse the influence of different input combinations(in shown Table 1), three ANN models were developed:

Table 1: Different input combinations used in the ANN models.

	Model	Input parameters
1	ANN-10	I_{sc}, V_{oc}, V_{max}, I_{max}, EFF, FF, G, v, T_{am}, T_{panel}
2	ANN-8	V_{max}, I_{max}, EFF, FF, G, v, T_{am}, T_{panel}
3	ANN-6	EFF, FF, G, v, T_{am}, T_{panel}

Source: Authors, (2026).

For each model, the number of neurons in the hidden layer was varied between 1 and 15, and the architecture was trained multiple times to identify the configuration that yielded the best pre curacy. The methodology of the ANN model is illustrated in Figure 3.

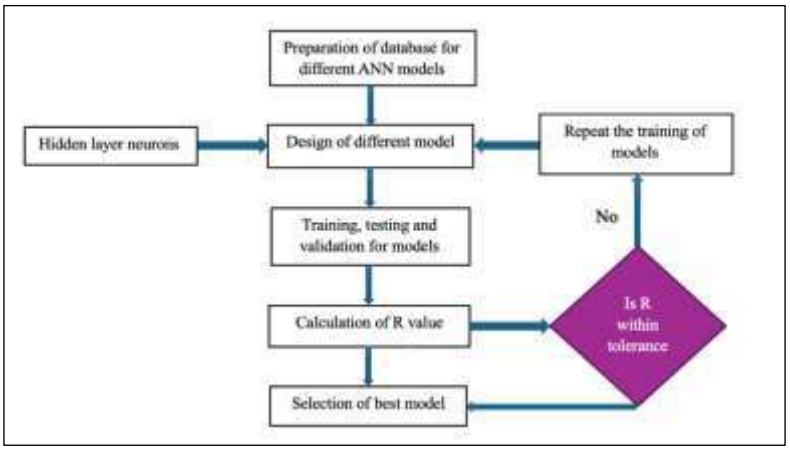

Figure 3: Implementation of methodology for ANN in the present study.

III. RESULTS

This manuscript investigates the effect of different multilayer perceptron (MLP) architectures on the performance of three artificial neural network (ANN) models for predicting solar radiation across various intensity ranges (200-1000 W/m²). The study evaluates the influence of the number of neurons in the hidden layer on the correlation coefficient (R), which measures the accuracy of model predictions. The analysis reveals that ANN-10 demonstrates consistent and high predictive performance across multiple neuron configurations, particularly excelling in the 800-1000 W/m² range Fig(4). It maintains high R-values (mostly above 0.95), reflecting stability, robustness, and optimal model complexity. ANN-8, consistently achieves high and stable R-values, indicating superior generalization and minimal oscillations across neuron configurations. In contrast, ANN-6 exhibits significant fluctuations and instability across all ranges, suggesting higher sensitivity to network structure and potential overfitting or underfitting issues. These irregular trends highlight the challenges of model complexity in this configuration.

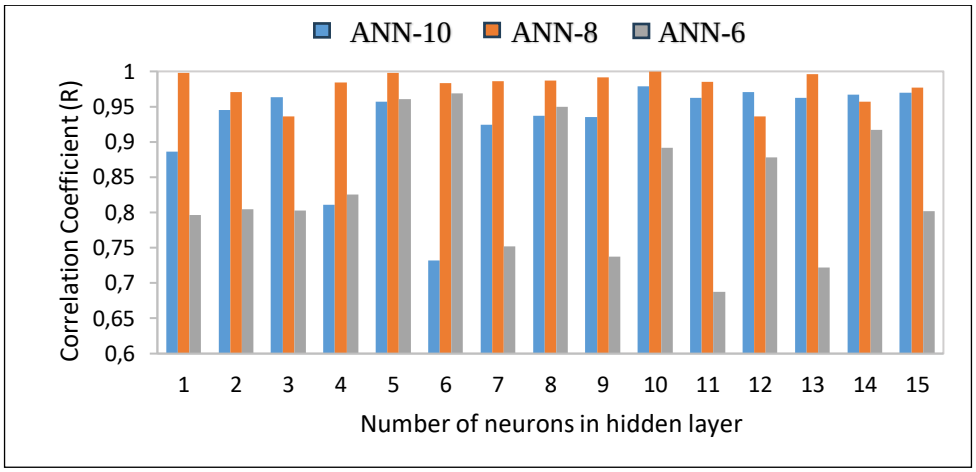

Figure 4: Effect of MLP architecture on ANN fitting performance for three models of solar radiation range (800-1000 W/m^2).
Source: Authors, (2026).

Overall, the findings suggest that while ANN-10 and ANN-8 perform well across specific ranges, ANN-10 stands out for its consistent high performance in the 800-1000 W/m² range, making it a strong candidate for solar radiation modelling in these higher intensity ranges. Figure (5) presents the effect of multilayer perceptron (MLP) architecture, specifically the number of neurons in the hidden layer, on the correlation coefficient (R) for three artificial neural network (ANN) models: ANN-10, ANN-8, and ANN-6, developed for predicting solar radiation within the range of 600-800 W/m². The correlation coefficient (R) quantifies the agreement between predicted and measured solar radiation, with values approaching unity indicating higher model accuracy and generalization capability.

As shown in the Fig (5), all three ANN configurations exhibit variations in correlation coefficient values with changes in the number of neurons in the hidden layer, reflecting the sensitivity of model performance to network complexity. The ANN-10 model (blue line) displays relatively stable and high R-values across most configurations, predominantly ranging between 0.90 and 1.00, with minor fluctuations at specific neuron counts. The ANN-8 model (orange line) also achieves strong predictive performance but exhibits more pronounced oscillations, with R-values varying between 0.80 and 1.00 depending on the number of neurons. In contrast, the ANN-6 model (green line) shows significant instability and broader fluctuations in R, ranging between 0.70 and 0.98, suggesting higher sensitivity to the chosen network structure and potential overfitting or underfitting at certain configurations.

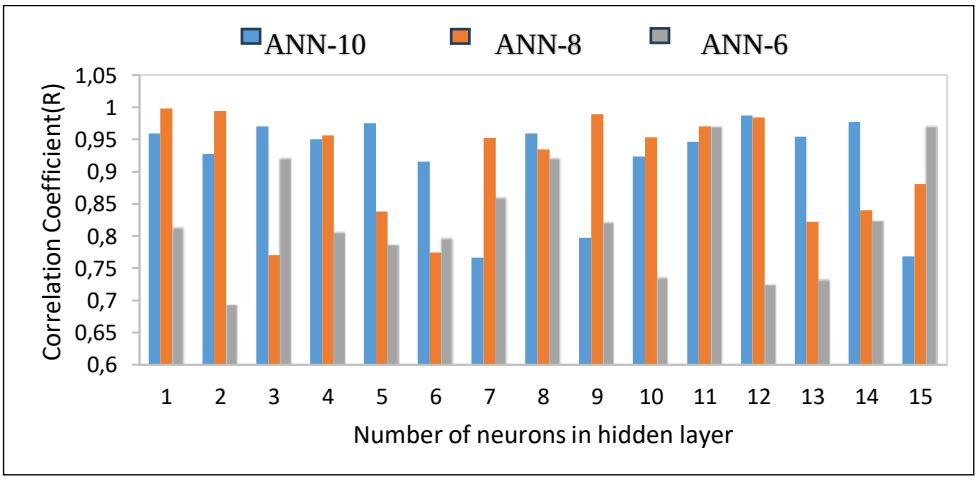

Figure 5: Effect of MLP architecture on ANN fitting for three models of solar radiation range (600-800 W/m^2).
Source: Authors, (2026).

Based on the observed R-values, the ANN-6 model demonstrates the best overall performance, maintaining high correlation coefficients (mostly above 0.95) across a wide range of hidden-layer neuron counts. This indicates superior stability, robustness, and generalization in fitting the nonlinear relationships governing solar radiation within the specified range. The consistently high R-values imply that ANN-6 achieved an optimal balance between model complexity and learning efficiency, resulting in minimized prediction errors and better adaptability to unseen data. Conversely, the irregular trends observed in ANN-8 and ANN-6 suggest less consistent learning behaviour and potential over-dependence on the number of hidden neurons.

Figure (6) presents the effect of multilayer perceptron (MLP) architecture specifically the number of neurons in the hidden layer on the correlation coefficient (R) for three artificial neural network (ANN) models: ANN-10, ANN-8, and ANN-6, developed for predicting solar radiation within the range of 400-600 W/m². The correlation coefficient (R) quantifies the agreement between predicted and measured solar radiation, with values approaching unity indicating higher model accuracy and generalization capability. As shown in the figure, all three ANN configurations exhibit variations in correlation coefficient values with changes in hidden-layer neuron numbers, reflecting the sensitivity of model performance to network complexity.

The ANN-10 model (blue line) displays relatively stable and high R-values across most configurations, predominantly ranging between 0.90 and 1.00, with minor fluctuations at specific neuron counts. The ANN-8 model (orange line) also achieves strong predictive performance but exhibits more pronounced oscillations, with R-values varying between 0.80 and 1.00 depending on the number of neurons. In contrast, the ANN-6 model (green line) shows significant instability and broader fluctuations in R, ranging between 0.70 and 0.98, suggesting higher sensitivity to the chosen network structure and potential overfitting or underfitting at certain configurations.

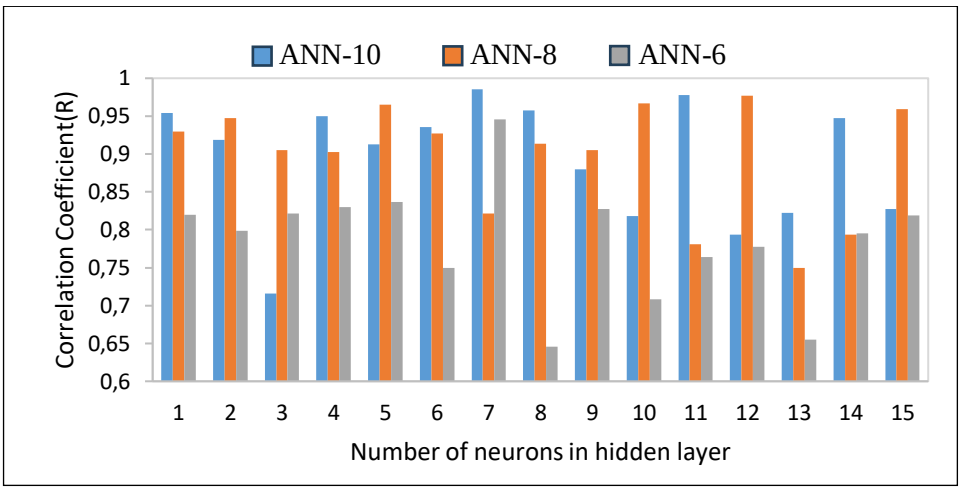

Figure 6: Effect of MLP architecture on ANN fitting for three models of solar radiation range (400-600 W/m^2).

Based on the observed R-values, the ANN-10 model demonstrates the best overall performance, maintaining high correlation coefficients (mostly above 0.95) across a wide range of hidden-layer neuron counts. This indicates superior stability, robustness, and generalization in fitting the nonlinear relationships governing solar radiation within the specified range. The consistently high R-values imply that ANN-10 achieved an optimal balance between model complexity and learning efficiency, resulting in minimized prediction errors and better adaptability to unseen data. Conversely, the irregular trends observed in ANN-8 and ANN-6 suggest less consistent learning behaviour and potential over-dependence on the number of hidden neurons.

Figure (7) presents the effect of multilayer perceptron (MLP) architecture specifically, the number of neurons in the hidden layer on the correlation coefficient (R) for three artificial neural network (ANN) models: ANN-10, ANN-8, and ANN-6, developed for predicting solar radiation within the range of 200-400 W/m². The correlation coefficient (R) represents the strength of the relationship between predicted and measured solar radiation values, where values closer to 1 indicate superior prediction accuracy and stronger model generalization. As shown in the figure, all three ANN models exhibit noticeable variations in R-values as the number of hidden-layer neurons increases, reflecting the sensitivity of model performance to architectural complexity.

The ANN-8 model (orange line) consistently demonstrates the highest and most stable R-values across nearly all configurations, maintaining correlations predominantly above 0.95, with minimal fluctuations. This trend indicates that ANN-8 effectively captures the nonlinear patterns in the solar radiation data while avoiding overfitting or underfitting. The ANN-R10 model (blue line) shows moderate performance, with R-values generally ranging between 0.80 and 0.95. Although it achieves strong correlations at certain neuron counts (e.g., around 5–6 and 10–11 neurons), the performance exhibits greater oscillations, suggesting sensitivity to the network structure and possible inconsistencies in generalization when the architecture changes. The ANN-6 model (green line), by contrast, demonstrates the lowest and most unstable R-values, fluctuating between 0.55 and 0.95, which implies weaker learning stability and a higher likelihood of overfitting or underfitting across different hidden-layer configurations.

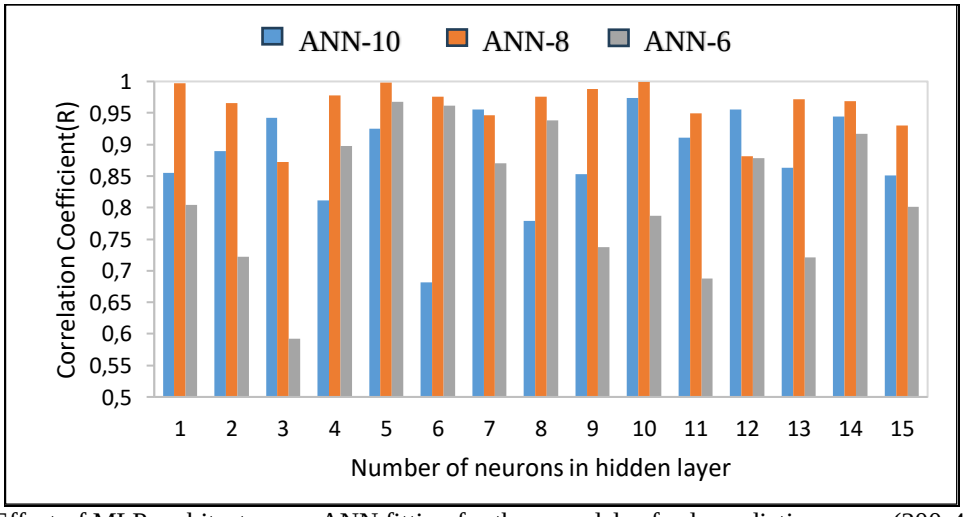

Figure 7: Effect of MLP architecture on ANN fitting for three models of solar radiation range (200-400 W/m^2).
Source: Authors, (2026).

Based on the observed results, the ANN-8 model is identified as the best-performing MLP architecture for this solar radiation range. Its consistently high R-values and minimal oscillations indicate superior predictive robustness, stability, and adaptability across varying hidden-layer neuron counts. This suggests that ANN-8 achieved an optimal balance between model complexity and learning efficiency, leading to more reliable and accurate solar radiation predictions.

VI. DISCUSSION

For manuscript discussion, these findings highlight that while all models are influenced by hidden-layer neuron variations, ANN-8's architecture demonstrates the most reliable and generalizable learning behaviour. The stability of its correlation coefficients indicates that it effectively captures the underlying physical and nonlinear dependencies of solar radiation within the 200-400 W/m² range, making it the most suitable architecture for practical modelling and forecasting applications.

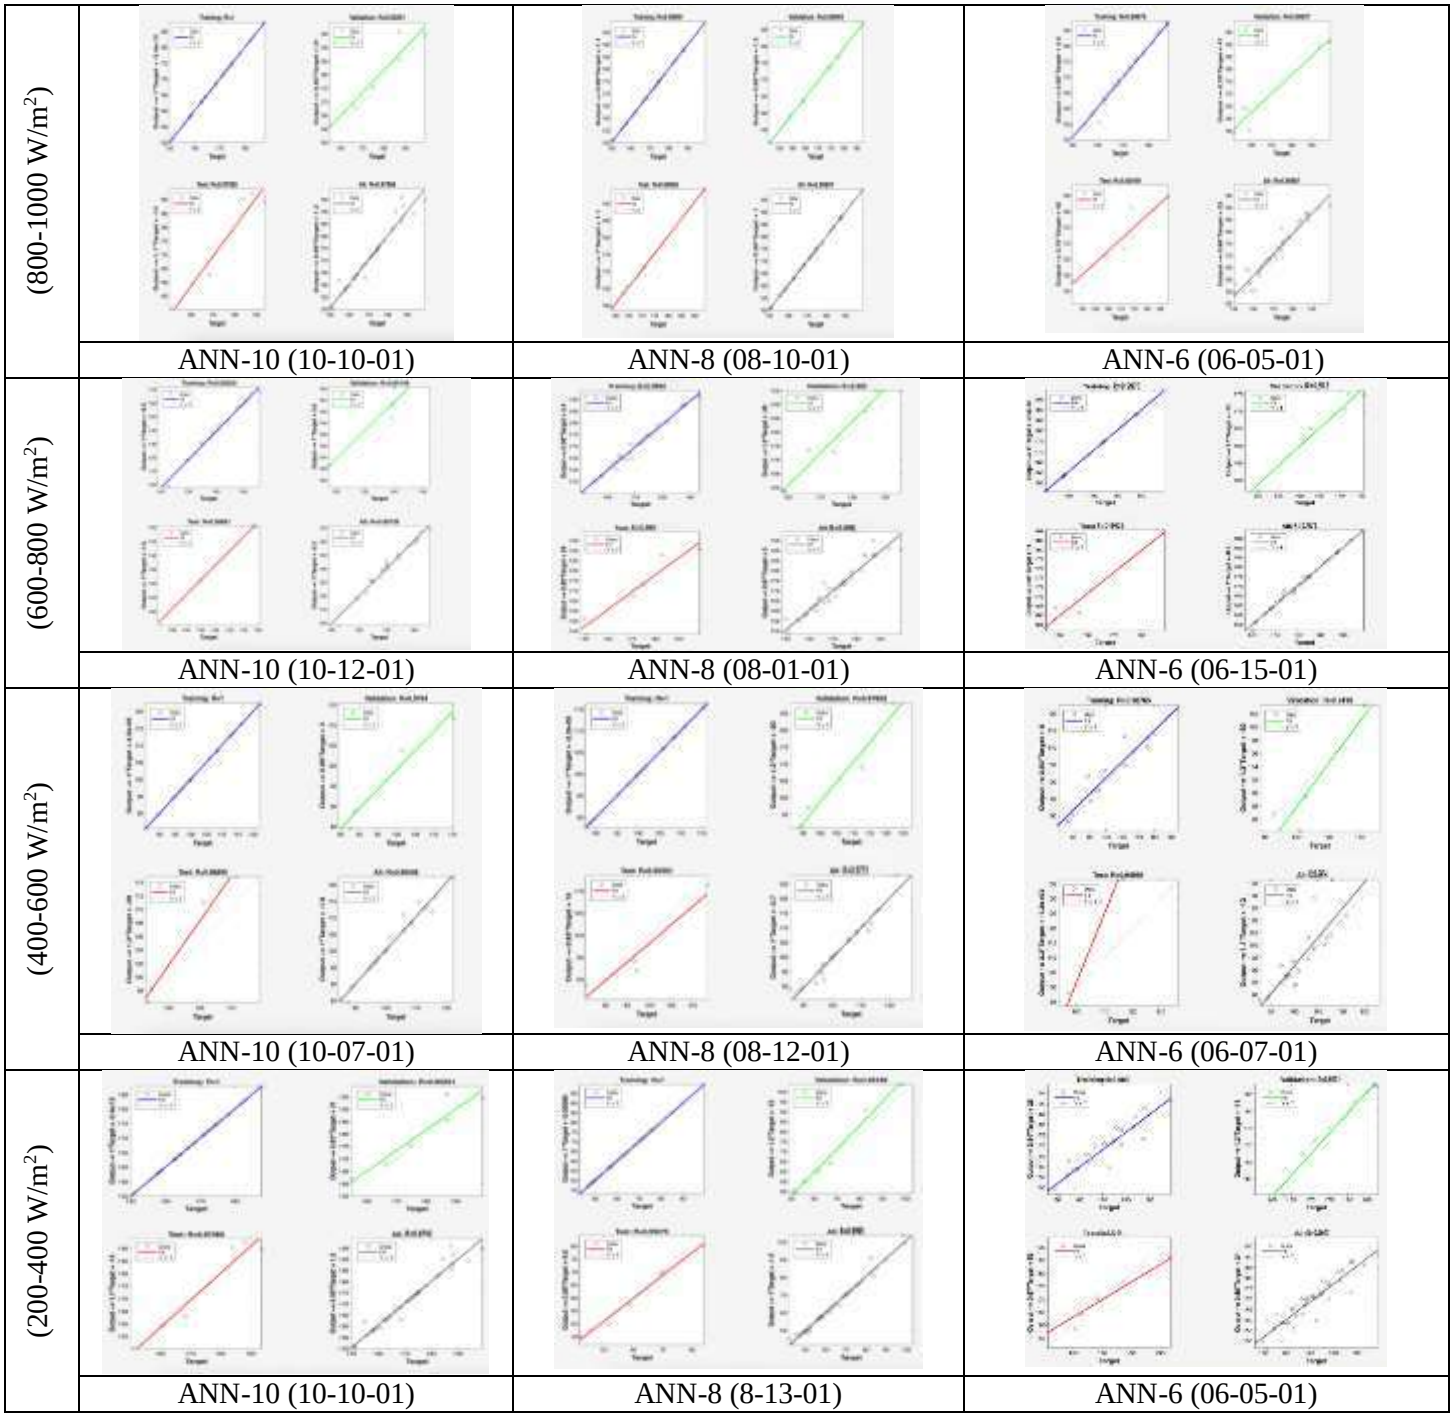

Figure 8: Regression performance of ANN-10, ANN-8, and ANN-6 models at different solar radiation ranges (200–1000 W/m²) showing correlation coefficients (R) for training, validation, testing, and overall datasets.
Source: Authors, (2026).

The regression plots for all models (ANN-10, ANN-8, and ANN-6) under different solar radiation ranges (200–1000 W/m²) are presented in Fig (8). The correlation coefficient (R) was used to evaluate the prediction accuracy of each model.

Among the tested configurations, the ANN-8 model consistently achieved the highest R-values across training, validation, and testing datasets, indicating strong predictive reliability and superior generalization capability. At higher radiation levels (800–1000 W/m²), ANN-8 achieved an almost perfect fit (R ≈ 0.9999), while ANN-10 and ANN-8 recorded slightly lower but still high correlations. Similarly, for mid-range radiation (600–800 W/m²), ANN-10 exhibited an R ≈ 0.985, demonstrating robust prediction with minimal deviation. At lower radiation levels (200–400 W/m² and 400–600 W/m²), all models maintained good predictive capability, though minor reductions in R were observed, possibly due to increased variability in measured data. Overall, ANN-8 outperformed ANN-10 and ANN-6 across all radiation categories, suggesting that its architecture and parameter tuning were most effective in capturing the nonlinear behaviour of solar radiation. The comparative evaluation of ANN architectures across different solar radiation ranges demonstrates the strong influence of input size and hidden layer configuration on model performance. The results consistently reveal that the number of input features plays a decisive role in predictive accuracy, while the hidden layer size contributes to fine-tuning the learning and generalization capability of the models [29].

For the highest radiation range (800–1000 W/m²), ANN-R8 with eight inputs emerged as the most effective configuration. The MLP (8-10-1) architecture achieved nearly perfect regression values across training, testing, and validation, highlighting its ability to capture the nonlinear relationships in this intensity band. In contrast, models with six inputs (ANN-6) showed weaker performance, with the best architecture (6-5-1) still underperforming relative to the 8- and 10-input models [30]. This suggests that reducing the dimensionality of the input space limits the ability of network to learn the complex patterns inherent in high-intensity solar radiation data. In the 600–800 W/m² range, the superiority of ANN-8 (8 inputs) was reinforced. The MLP (8-1-1) model provided the highest consistency, achieving regression values close to unity across all phases. Interestingly, in this radiation band, some 6-input models also delivered competitive performance, particularly MLP (6-15-1), which maintained strong validation accuracy. This indicates that for mid-range radiation intensities, the complexity of input features can be somewhat reduced without severely compromising prediction accuracy, provided that the hidden layer is configured effectively [31].

At the 400–600 W/m² range, the results once again emphasized the strength of the 8-input models. ANN-8 with MLP (8-15-1) delivered outstanding regression values, demonstrating robustness and generalization ability across datasets. The 10-input model (ANN-10) with MLP (10-11-1) also showed high reliability, but its performance fluctuated more across different subsets, suggesting occasional overfitting. The 6-input models in this range displayed greater variability, with certain configurations performing well (e.g., MLP 6-7-1) while others struggled, indicating that fewer input features reduce stability and predictive robustness [32]. For the lowest radiation range (200–400 W/m²), the pattern remained consistent: 8-input models were the most effective, particularly ANN-8 with MLP (8-13-1), which achieved near-perfect regression values across training, testing, and validation. The 10-input models performed well in certain configurations, such as MLP (10-7-1), which balanced accuracy and generalization effectively. However, the 6-input models again showed inconsistent performance, with only a few architectures like MLP (6-7-1) delivering reliable outcomes [33]. This reinforces the observation that reducing input dimensionality to six features constrains the capacity of model to capture variability in the lower radiation bands.

A critical aspect revealed by the results is the balance between overfitting and underfitting. Some 10-input networks, particularly those with larger hidden layers, demonstrated very high training accuracy but weaker performance on validation data. This suggests a tendency toward overfitting, where the model memorizes training patterns without effectively generalizing to unseen data [34]. On the other hand, some 6-input models, especially with fewer hidden neurons, showed underfitting, as they were unable to capture sufficient complexity to accurately represent solar radiation variability. The 8-input networks consistently avoided both extremes by maintaining strong generalization, indicating an optimal balance between model complexity and predictive stability. The findings across all radiation ranges demonstrate that ANN-8 models with eight input features consistently outperformed both the 10-input and 6-input networks. The 8-input configurations not only provided superior predictive accuracy but also ensured stability and generalization across different solar radiation ranges. The results further highlight the importance of optimizing hidden layer size, as models with too few or too many neurons occasionally exhibited reduced generalization despite high training accuracy [35].

Thus, selecting the appropriate number of inputs alongside a balanced hidden layer configuration is critical for achieving robust solar radiation prediction. Among all tested architectures, ANN-8 with MLP (8-10-1) stands out as the most effective, offering both computational efficiency and high predictive reliability across radiation ranges. From a practical perspective, these findings have direct implications for solar energy applications. Reliable solar radiation prediction is essential for photovoltaic (PV) system design, energy storage planning, and grid integration. Accurate forecasts help optimize the sizing of PV modules and batteries, improve energy dispatch strategies, and reduce reliance on fossil-fuel backup systems. The demonstrated stability of the 8-input models indicates that such configurations can provide dependable forecasts under varying radiation conditions, thereby supporting more efficient energy management. Furthermore, the insights on overfitting and underfitting emphasize the need for careful architecture selection to avoid unreliable predictions that could compromise planning and operational decisions in solar energy systems [36]. The superior performance of ANN-8 across all radiation ranges demonstrates its robustness and adaptability in modelling nonlinear solar radiation behaviour.

The near-unity correlation coefficients (R > 0.99) in both training and testing phases indicate excellent learning and generalization capability. The slightly reduced performance of ANN-10 and ANN-6 in certain ranges may be attributed to overfitting or inadequate neuron configuration, which limits the model's ability to adapt to complex variations in input–output relationships. The stability of ANN-8 across both high and low radiation levels confirms its optimized network architecture and well-balanced hidden layer design. These results affirm that ANN-based models, particularly ANN-8, are highly reliable for solar radiation estimation and serve as an efficient computational alternative to traditional empirical or statistical methods. The performance of three artificial neural network (ANN) models (ANN-10, ANN-8, and ANN-6) was evaluated across different solar radiation ranges (200–1000 W/m²) to understand the effect of multilayer perceptron (MLP) architecture, specifically the number of neurons in the hidden layer, on the correlation coefficient (R). The results revealed that ANN-10 demonstrated the most consistent and robust performance, particularly in the 800–1000 W/m² range, maintaining high R-values (between 0.90 and 1.00) across various neuron configurations, suggesting optimal stability and generalization capability.

In contrast, ANN-8 achieved the highest and most stable R-values, particularly in the 200-400 W/m² range, consistently exceeding 0.95. This indicates its superior ability to generalize and effectively capture the nonlinear relationships in the data, with minimal fluctuations in performance across hidden-layer neuron changes. However, ANN-6 exhibited significant instability across all radiation ranges, with fluctuating R-values ranging from 0.55 to 0.98, pointing to overfitting and underfitting challenges due to its sensitivity to network complexity. Overall, the findings suggest that the choice of ANN architecture plays a crucial role in predicting solar radiation, with ANN-10 being most suitable for higher radiation ranges and ANN-8 offering superior reliability in lower ranges, while ANN-6 showed less consistent results, making it less ideal for accurate predictions [37].

This section presents a comparison of current state-of-the-art regression models for photovoltaic power forecasting, evaluated using the R^2 regression metric in Table 2.

Compared to the research articles referenced in Table 1, the proposed model presented improved results in photovoltaic power prediction as measured by the R^2 regression metric. However, the novel aspect of the model is located in the portability of the most effective regression technique. The proposed model has achieved a R^2 value of 0.999 in 800–1000 W/m² range and utilises a novel preprocessing approach and method. The feature engineering process in the proposed model employed correlation coefficients to extract significant features from the dataset.

V. CONCLUSION

This study developed and evaluated ANN models for predicting the output power of photovoltaic (PV) systems under varying environmental conditions. Three ANN configurations with different input combinations (10, 8, and 6 parameters) were evaluated across four solar radiation ranges (200–400, 400–600, 600–800, and 800–1000 W/m²). The results demonstrate that model performance strongly depends on both the number of input features and the hidden layer architecture. Among the tested models, ANN-8 (8 inputs) consistently outperformed ANN-10 (10 inputs) and ANN-6 (6 inputs), achieving near-perfect regression values ($R \approx 0.999$) across most radiation ranges. This indicates that selecting an optimal subset of input variables, rather than using all available parameters, enhances predictive accuracy and reduces computational complexity. The findings also confirm that ANN models are highly effective in capturing the nonlinear relationships between electrical and environmental parameters influencing PV performance. Overall, the study highlights the robustness of ANN-based modelling for solar energy forecasting and system performance evaluation. By systematically comparing different ANN architectures, this work provides practical insights into input feature selection and network design, supporting the deployment of reliable and efficient prediction tools for PV applications across diverse climatic conditions.
