Keywords:
Industry 4.0, Artificial Intelligence (AI), Production Planning and Control, Electronic Meters, Operational Optimization, Automated System.

ABSTRACT

In the context of Industry 4.0, modern manufacturing environments increasingly rely on digital technologies to enhance efficiency and competitiveness. The production of electronic meters represents a complex industrial process that demands precise coordination of resources, materials, and scheduling. Traditional methods of production planning often face challenges such as bottlenecks, resource underutilization, and delayed delivery times. To address these issues, the integration of Artificial Intelligence (AI) into manufacturing processes has emerged as a promising solution. The main objective of this research is to develop an automated system for production planning of electronic meters that leverages AI techniques to optimize operational performance. The study proposes a model capable of analyzing historical production data, predicting demand fluctuations, and dynamically adjusting production schedules. The methodology involves the implementation of machine learning algorithms and optimization techniques within a simulated industrial environment. The system evaluates different production scenarios, prioritizes tasks, and allocates resources efficiently to meet production targets while minimizing delays. Results demonstrate that the proposed AI-based automated system significantly improves operational optimization. Key performance indicators, such as production throughput, resource utilization, and lead time, showed measurable enhancements compared to conventional planning methods. Moreover, the system enables real-time decision-making, which aligns with the principles of Industry 4.0 and supports adaptive, data-driven production strategies. In conclusion, the research highlights the potential of combining Artificial Intelligence and automated systems to advance production planning for electronic meters, contributing to more efficient, flexible, and responsive manufacturing processes in the Industry 4.0 era.

I. INTRODUCTION

The rapid technological evolution of the industrial sector has accelerated the transition toward Industry 4.0, a paradigm characterized by digital integration, cyber-physical systems, data analytics, and intelligent automation.

In this new industrial landscape, manufacturing processes increasingly depend on advanced computational tools capable of enhancing efficiency, adaptability, and connectivity. The production of electronic meters, in particular, has faced growing challenges due

to market expansion, demand variability, and the need for continuous improvement in quality and delivery performance. Traditional methods of Production Planning and Control often prove insufficient to handle the complexity of modern manufacturing environments, leading to inefficiencies such as delays, resource imbalances, and limited responsiveness to unforeseen changes [1-5]. To address these limitations, the introduction of Artificial Intelligence (AI) has emerged as one of the most transformative innovations in industrial operations. AI techniques—especially machine learning, optimization algorithms, and predictive analytics—offer the ability to process large volumes of data, identify patterns, and support decision-making with greater accuracy and speed. When applied to Production Planning and Control, AI enables systems to dynamically adjust schedules, predict bottlenecks, and optimize resource allocation in real time.

This creates a foundation for intelligent, flexible, and highly efficient manufacturing systems. In this context, the development of an automated system designed to enhance production strategies for electronic meters becomes essential. By integrating AI algorithms with industrial data streams, such a system can significantly contribute to operational optimization, reducing lead times, increasing production throughput, and minimizing waste. Furthermore, automation allows organizations to adapt more effectively to fluctuations in demand and operational disturbances, strengthening competitiveness in a globalized market [6-9]. Overall, the incorporation of Industry 4.0 concepts—combined with Artificial Intelligence and automated decision-making—marks a critical step toward transforming production environments. The application of these technologies to the manufacturing of electronic meters not only supports smarter Production Planning and Control but also aligns industrial processes with the current demands for agility, precision, and sustainability. This introduction lays the groundwork for exploring how intelligent systems can enhance industrial performance and redefine the future of automated production.

II. LITERATURE REVIEW

II.1 INDUSTRY 4.0

Industry 4.0 represents the fourth industrial revolution and is characterized by the deep integration of digital technologies, physical systems, and intelligent production processes. It emerged in response to the growing need for efficiency, customization, speed, and flexibility in modern manufacturing chains. Unlike previous revolutions, Industry 4.0 promotes the convergence of advanced automation, data analytics, interconnectivity, and computational intelligence, transforming traditional factories into fully connected and autonomous environments [10],[11]. Among its main characteristics is the adoption of cyber-physical systems capable of monitoring and controlling industrial processes in real time. These systems communicate with each other through the Internet of Things (IoT), allowing machines, sensors, and software to continuously exchange information. This connectivity creates a more transparent, efficient, and predictable production network. In addition, the use of Big Data and advanced analytics makes it possible to interpret large volumes of data generated during production, supporting strategic and operational decisions with greater accuracy. Within this ecosystem, Artificial Intelligence (AI) plays a central role. AI enables machines to learn patterns, predict failures, optimize routines, and make autonomous decisions. In industrial processes, machine learning algorithms assist in production planning, predictive maintenance, automated quality inspection, and performance analysis. AI also helps dynamically adjust production lines, reducing waste, increasing productivity, and ensuring greater reliability of results [12-15]. Another important characteristic of Industry 4.0 is horizontal and vertical integration. Horizontal integration connects different companies along the production chain, while vertical integration connects all levels of the organization—from the shop floor to corporate management. This integration ensures greater synchronization and efficiency. Thus, Industry 4.0 represents a transformative milestone, driving smart factories, data-driven decision-making, and a more flexible, sustainable, and competitive production model.

II.2 ARTIFICIAL INTELLIGENCE (AI)

Artificial Intelligence (AI) has established itself as a central element in modern technological advancement, especially when combined with other tools that make up the digital transformation ecosystem. Among these tools, the Internet of Things (IoT), Big Data, Machine Learning, and several techniques derived from advanced data analytics stand out. IoT enables continuous connectivity between machines, sensors, devices, and systems, allowing real-time data collection directly from the physical environment. This constant monitoring capability generates an enormous amount of information, which is subsequently stored and processed using Big Data technologies. Processing these large volumes of data is essential for AI to extract useful knowledge, identify patterns, and support faster and more accurate decision-making [16-18]. Within this context, Machine Learning—one of the main branches of Artificial Intelligence—plays a crucial role. Through learning algorithms, systems are able to analyze historical data, recognize trends, and continuously learn without direct human intervention. These techniques are widely used in industrial applications such as demand forecasting, predictive maintenance, fault detection, and process optimization. In addition, other complementary techniques, such as Deep Learning, Process Mining, Predictive Analytics, Expert Systems, and Cloud Computing, further expand the potential of AI applications. Deep Learning, for example, enables highly complex analyses and is used in computer vision and pattern recognition. Cloud computing ensures scalability, efficient storage, and processing for AI-based systems. The integration of all these technologies creates an intelligent and autonomous environment capable of improving operations, reducing costs, and increasing efficiency across various sectors, especially in modern industry. This synergy has driven the transition toward more connected, predictable, and data-driven production systems [19-21].

II.3 PRODUCTION PLANNING AND CONTROL

Production Planning and Control (PPC) is a set of essential practices to ensure that the production process takes place in an organized, efficient manner and is aligned with market needs. In industrial environments, PPC seeks to integrate resources, deadlines, productive capacities, and demand, ensuring that production occurs at the right time, in the desired quantity, and at the lowest possible cost. The first phase is planning, which involves demand forecasting, defining production targets, and estimating the required resources. At this stage, sales history, seasonality, inventory levels, and machine capacities are analyzed. Based on this information, the Master Production Schedule (MPS) is developed, a document that guides what to produce, when to produce it, and in what quantity.

The second phase is materials planning, also known as MRP (Material Requirements Planning). It determines which materials will be needed, in what quantities, and when they must be available. The objective is to avoid shortages that interrupt production and excess inventory that generates storage costs. Next comes capacity planning, which assesses whether productive resources—machines, teams, and available time—are sufficient to meet the plan. If constraints are identified, adjustments to the schedule or redistribution of the workload are made. The production scheduling phase defines the sequence of operations on the manufacturing line, optimizing machine usage and minimizing bottlenecks. This stage aims to establish clear and efficient production orders [22-25]. Finally, production control monitors execution in real time, comparing planned results with actual performance. Indicators such as productivity, efficiency, cycle times, and delays are analyzed to support quick decision-making. Thus, Production Planning and Control plays a fundamental role in industrial competitiveness, ensuring more stable, predictable, and economically efficient production processes.

II.4 ELECTRONIC METERS

Electronic Meters are essential devices used to measure, monitor, and record the consumption of electrical energy in residential, commercial, and industrial environments. Unlike traditional electromechanical meters, electronic meters operate using digital components and advanced sensing technologies capable of offering greater precision, real-time monitoring, and improved communication capabilities. Their evolution is strongly linked to the modernization of electrical grids and the global movement toward smarter, more automated energy management systems. One of the key characteristics of electronic meters is their ability to collect high-resolution data. Through embedded microprocessors and electronic sensors, these devices measure voltage, current, power factor, instantaneous consumption, and other electrical parameters with superior accuracy. This precise data collection supports utilities in analyzing consumption patterns, identifying losses, and improving demand forecasting. For consumers, it enables a clearer understanding of their energy usage, encouraging more conscious and efficient consumption habits [26-28]. Modern electronic meters also integrate communication technologies that allow remote data transmission. Through protocols such as RF mesh, PLC (Power Line Communication), or cellular networks, these meters can send consumption information directly to utility companies without the need for manual readings.

This feature forms the basis of Advanced Metering Infrastructure (AMI), which supports bidirectional communication and enables functionalities such as remote connection and disconnection, tariff updates, and automatic reporting of anomalies. In addition to basic measurement functions, electronic meters can include advanced features such as load profiling, event logging, tamper detection, and power quality monitoring. These capabilities increase the reliability of the electrical system by identifying irregularities like voltage dips, spikes, or unauthorized usage attempts. Electronic meters also play a fundamental role in the digital transformation of power distribution networks, often referred to as smart grids. Their integration with data analytics platforms and management systems enables utilities to optimize grid operations, reduce operational costs, and improve energy distribution efficiency [29-31]. Overall, electronic meters represent a significant advancement in metering technology, supporting intelligent energy management, strengthening grid stability, and contributing to the modernization of the electrical sector. As digital technologies continue to evolve, these devices are expected to become even more interconnected, accurate, and capable of supporting future smart energy solutions.

II.5 OPERATIONAL OPTIMIZATION

Operational Optimization is a central concept in modern management, focused on the continuous improvement of production processes, waste reduction, and increased efficiency in industrial and business environments. With the advance of digital transformation, intelligent systems have become indispensable tools for achieving higher levels of operational performance. These systems use Artificial Intelligence (AI), machine learning, real-time data processing, and automation to analyze operations, predict behaviors, and support strategic decision-making. One of the main differentiators of intelligent systems is their ability to collect and process large volumes of data from sensors, machines, corporate systems, and connected platforms. From this set of information, advanced algorithms can identify hidden patterns, diagnose problems, predict failures, and accurately suggest corrective actions. This allows companies to anticipate risks, reduce maintenance costs, and avoid unexpected downtime, directly contributing to increased productivity. In addition, intelligent systems are capable of dynamically optimizing processes. In production lines, for example, they can automatically adjust parameters such as operating speed, task sequencing, resource allocation, and energy consumption, promoting more efficient use of industrial infrastructure.

This real-time adaptability makes the process more agile, reliable, and aligned with current operating conditions [32-34]. Another fundamental aspect of operational optimization is data-driven decision-making. With analytical dashboards, automated reports, and AI-generated forecasts, managers can quickly evaluate operational performance, identify bottlenecks, and define strategic priorities in an informed manner. This reduces uncertainty and significantly improves the quality of decisions. Intelligent systems also contribute to integration between departments, enabling production, logistics, maintenance, and quality to operate in a synchronized way. Communication between machines and corporate systems enables more efficient workflows, full traceability, and greater control over results. In summary, operational optimization supported by intelligent systems transforms the way companies operate, making them more competitive, productive, and prepared for the challenges of the digital era. These systems not only automate tasks but also expand operational intelligence, fostering innovation and sustainability in industrial processes.

II.6 AUTOMATED SYSTEM

An Automated System plays a fundamental role in modern manufacturing environments, especially in the production of electronic devices, where precision, speed, and reliability are essential. As global demand for electronic products continues to rise, industries face the challenge of maintaining high productivity while ensuring strict quality standards. To meet these requirements, automated systems have been widely adopted, transforming traditional production lines into intelligent, efficient, and highly controlled environments. In the manufacturing processes of electronic products—such as circuit boards, sensors, smart modules, and electronic meters—automation enables repetitive activities to be performed with micrometric precision, reducing human error and ensuring consistency.

Stages such as machine soldering, automatic optical inspection (AOI), surface-mount technology (SMT) assembly, and functional testing are now largely carried out by automated systems capable of operating 24 hours a day. In addition to increasing productivity, Automated Systems contribute significantly to improved quality control. Embedded sensors, high-resolution cameras, and inspection algorithms detect defects in real time, allowing immediate corrections and reducing the number of rejected products. This continuous monitoring capability ensures that electronic components meet the safety and performance specifications required by the market. Another important benefit is the integration of these systems with digital platforms and corporate databases. This connection facilitates the collection and analysis of large volumes of operational data, which are used to optimize workflows, predict failures, and schedule preventive maintenance. Data-driven analysis also allows production parameters to be adjusted automatically, ensuring greater energy efficiency and cost reduction. Furthermore, automated systems promote greater flexibility in production lines. Instead of lengthy manual reconfigurations, robots and intelligent machines can be quickly reprogrammed to accommodate new product models or changes in demand, increasing the agility of the production process [35-38]. In summary, the implementation of an Automated System in electronic manufacturing environments represents a significant step toward intelligent production. These systems enhance operational efficiency, improve final product quality, and prepare industries to compete in an increasingly dynamic and technology-driven market.

III. MATERIALS AND METHODS

The proposed computational methodology is based on the principles of Industry 4.0, incorporating advanced digital technologies, real-time connectivity, and intelligent data analysis to enhance Production Planning and Control (PPC) in the manufacturing of Electronic Meters. The objective is to develop an Automated System capable of optimizing industrial operations through Artificial Intelligence (AI) techniques, ensuring greater efficiency, accuracy, and adaptability in production processes. The first stage of the methodology consists of data acquisition and integration, which is typical of Industry 4.0 environments. Sensors, programmable logic controllers (PLCs), Manufacturing Execution Systems (MES), and IoT platforms continuously collect information on machine performance, material consumption, cycle times, inventory, and production orders. These data are transmitted to a cloud infrastructure or an industrial server, where they are stored and organized. In the second stage, data processing is carried out using Big Data tools and preparation pipelines. Data cleaning, standardization, and transformation techniques are applied to ensure quality and consistency. Based on this, AI algorithms—especially Machine Learning—are trained to identify historical patterns, forecast demand for electronic meters, estimate manufacturing times, and detect potential operational bottlenecks. The third stage involves the development of an operational optimization module, responsible for applying mathematical optimization methods—such as Linear Programming, heuristics, and Genetic

Algorithms—to generate efficient production plans. The module considers multiple constraints, including line capacity, material availability, deadlines, scheduled maintenance, and specific requirements of Electronic Meters. The result is an optimized plan that sequences operations, balances workloads, and minimizes idle times. The fourth stage consists of implementing the Automated System, which integrates AI forecasts and optimized plans directly into the production line. This system sends automatic instructions to machines, monitors execution in real time, and continuously compares actual performance with planned targets. In the event of deviations—such as failures, delays, or material shortages—the system triggers a dynamic rescheduling mechanism [39-44]. Finally, the fifth stage involves the visualization and analysis of results, where intelligent dashboards present key performance indicators such as productivity, efficiency, lead time, and reliability. These insights enable continuous adjustments and foster a data-driven improvement culture. Thus, the computational methodology integrates AI, automation, and connectivity, enhancing the level of Operational Optimization in the production of Electronic Meters and aligning the process with Industry 4.0 principles.

III.1 INTENSITY OF THE TECHNOLOGICAL CHALLENGE

The research of this Development project involves uncertainties and challenges, which bring to light the original research premise with the objective of acquiring technical and scientific knowledge to implement tangible solutions. Due to these challenges, the project seeks to:

- Establish and manage the frequency and memory control of traceability devices and their processing capacity related to measurements, in order to maintain a stable state of data transmission and reception (Stages 1 and 2 of Ordinance 2,091);
- Identify patterns related to performance and quality indices to develop KPI control mechanisms and provide optimized decision-making recommendations (Stages 3 and 4 of Ordinance 2,091);
- Perform integrations with the hardware and software stack with minimal data loss and maximum quality in event synchronization to feed Business Intelligence systems (Stages 1 and 2 of Ordinance 2,091);
- Mitigate issues related to scrap, meter nonconformities, and dynamic changes in the production routing based on qualitative charts that generate insights for new solutions (Stages 3 and 4 of Ordinance 2,091).

The project proposes as a solution the development of an intelligent system capable of learning patterns based on events monitored and reported by testing devices, production routing and rescheduling mechanisms focused on electronic meters, and dashboards to support decision-making. The technical aspects of this project consolidate compliance with Ordinance No. 9,835/2022, Annex 1 (Intensity of the Technological Challenge):

I. **Level 4**: Conducting applied research — original research carried out with the objective of acquiring knowledge, primarily directed toward a specific practical objective or target;
II. **Level 3**: Conducting experimental development — systematic work based on pre-existing knowledge acquired through research or practical experience, aimed at producing new products and processes or improving existing ones.

III.2 SOLUTION STRUCTURING

The project includes technical constraints and limitations, making it essential to prioritize testing and validation in order to prove its effectiveness, in accordance with Ordinance No. 9,835/2022, Annex 1 (Solution Structuring).

I. **Solution structuring includes** identifying technical constraints or limitations for the solution and carrying out systematic development with validation tests. The limitations and restrictions are related to technical and security aspects that prevent certain processes, such as:

- **Monitoring area**: The project foresees the development of a traceability and data collection device with RS232 serial communication and via HTTP, TCP, and SSH. However, the monitoring area must be delimited according to the project scope;
- **Development sprints**: The project plans to adopt the technology in a localized space to control production-related events. However, due to time and cost constraints, development sprints were restricted to production control, traceability, quality, and monitoring;
- **Software and firmware upgrades**: The project includes materials and devices to meet its objectives; however, limitations regarding software and firmware upgrades were restricted to current data-processing technologies, which will be documented and delivered to the investing company.

To address these limitations, it is necessary to develop a system that monitors and generates indicators as a preventive premise against the project's technical limitations, highlighting innovation in the context of production rescheduling. For this purpose, several Industry 4.0 pillars will be implemented and incorporated, namely:

- **Data analytics**: To optimize decision-making processes and enable the system to inform and alert about possible harmful causes and effects of nonconforming process events, the project must implement data analysis measures using PyTorch and TensorFlow in Python, within a robust backend hosted on a server that provides adequate hardware for a well-defined Business Intelligence system. Simulation runs must be exhaustive in order to identify and define the best training architecture, thus delivering a viable computational model capable of supporting fluid and objective decision-making;
- **Systems integration**: Due to the business rules of each project module, it is necessary to separate responsibilities (Business Intelligence) through a microservices-based architectural model. For this purpose, stack definitions should focus on testing and simulating scenarios using Kubernetes, Docker, and/or other viable tools to minimize data-processing and systems-integration impacts, consolidating Stage 2 of Ordinance 2,091;
- **Artificial Intelligence**: AI will be used to perform production rescheduling with the premise of capturing causes and effects within the production system, enabling a proactive response to potential problems;
- **Internet of Things (IoT)**: IoT will be incorporated to collect real-time data from connected devices, providing a comprehensive view of the system and enabling dynamic adjustments as needed;
- **Digitalization**: Process digitalization will be a priority to ensure that all project stages are integrated and operate efficiently, enabling more effective management and a rapid response to any challenges that may arise.

III.3 SOLUTION STRUCTURING

The project includes technical constraints and limitations, and therefore testing and validation must be prioritized in order to demonstrate its effectiveness, in accordance with Ordinance No. 9,835/2022, Annex 1 (Solution Structuring).

I. **Solution structuring includes** identifying technical constraints or limitations for the solution and carrying out systematic development with validation testing. The limitations and restrictions are related to technical and security aspects that prevent certain processes, such as:

- **Monitoring area**: The project foresees the development of a traceability and data collection device with RS232 serial communication and via HTTP, TCP, and SSH. However, the monitoring area must be delimited according to the scope of the project;
- **Development sprints**: The project plans to adopt the technology in a localized space to control production-related events. However, due to time and cost limitations, development sprints were restricted to production control, traceability, quality, and monitoring;
- **Software and firmware upgrades**: The project includes materials and devices to meet its objectives; however, limitations regarding software and firmware upgrades were restricted to current data-processing technologies, which will be documented and delivered to the investing company.

To address these limitations, it is necessary to develop a system that monitors and generates indicators as a preventive premise against the technical limitations of the project, highlighting innovation in the context of production rescheduling. For this purpose, several Industry 4.0 pillars will be implemented and incorporated, namely:

- **Data analytics**: To optimize decision-making processes and enable the system to inform and alert about possible harmful causes and effects of nonconforming process events, the project must implement data analysis measures using PyTorch and TensorFlow in Python, within a robust backend hosted on a server that provides adequate hardware for a well-defined Business Intelligence system. Simulation runs must be exhaustive in order to identify and define the best training architecture, thus delivering a viable computational model capable of supporting fluid and objective decision-making;
- **Systems integration**: Due to the business rules of each project module, it is necessary to separate responsibilities (Business Intelligence) through a microservices-based architectural model. For this purpose, stack definitions should focus on testing and simulating scenarios using Kubernetes, Docker, and/or other viable tools to minimize data-processing and systems-integration impacts, consolidating Stage 2 of Ordinance 2,091;

- **Artificial Intelligence**: AI will be used to perform production rescheduling with the premise of capturing causes and effects within the production system, enabling a proactive response to potential problems;
- **Internet of Things (IoT)**: IoT will be incorporated to collect real-time data from connected devices, providing a comprehensive view of the system and enabling dynamic adjustments as needed;
- **Digitalization**: Process digitalization will be a priority to ensure that all project stages are integrated and operate efficiently, enabling more effective management and a rapid response to any challenges that may arise.

III.4 CURRENT STATUS OF THE SYSTEM

Considering the company's current scenario, there is a Lean Intelligent Manufacturing System (SIME) in place, in which a system foundation has already been developed through a data persistence layer (DBMS) using a MySQL database hosted on a central server. There is also a business layer that uses a set of tools to optimize request processing, such as FastAPI, Celery, WebSockets, among others, all of which use Python as the main programming language, creating a DevOps environment and architecture for communication with the system. Finally, there is a presentation layer that visually displays some production-related raw data, such as the number of meters produced, production targets, and overall line production rates. However, this information is not individualized by each piece of equipment, as it is accounted for through the meter sealing control module.

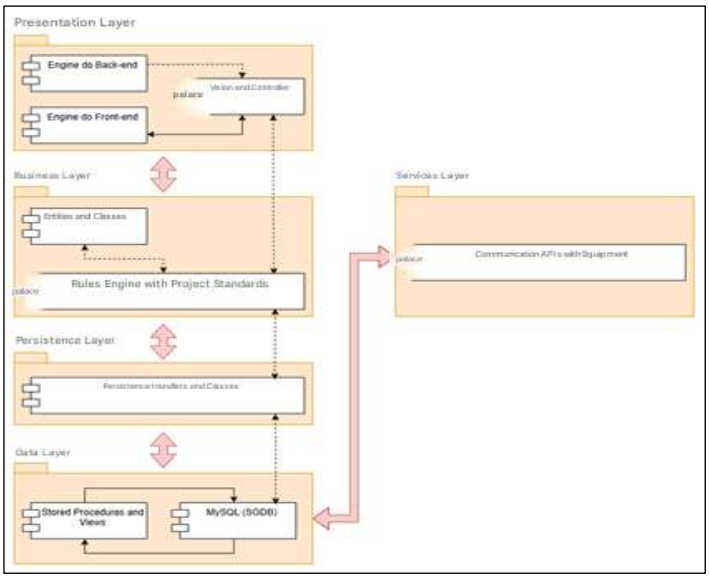

Figure 1: Current Status of the System.
Source: Authors, (2026).

Figure 1 presents a representation of these layers of the existing system, providing a visualization of what they represent and how they are interconnected. This is known as the Model-View-Controller (MVC) model, which revolves around the definition of design patterns that manage stored data, either for display in the presentation layer or for direct data editing through communication with the persistence layer. In summary, this structure was developed within the SIME software and encompasses user and permission management, as well as Business Intelligence through the HORUS API, which organizes data from two main modules: Meter Sealing Control and Inventory Control. These two modules allow monitoring of resource relationships and data on the number of meters produced, with a dedicated dashboard for this purpose. The current project aims to improve the SIME system to encompass the development of an intelligent system for production planning. This system is based on monitoring production events, which indicate actions to be taken to follow the planned schedule, integrating resource management and the Bill of Materials (B.O.M.), currently managed by the JUNDSOFT software, while optimizing business rules with new design patterns.

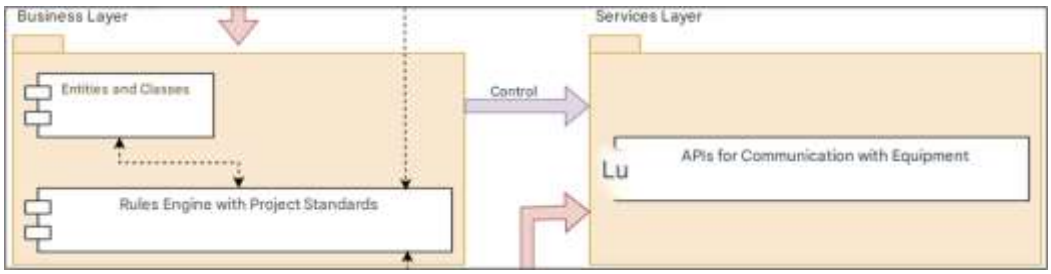

Figure 2: Business and Services Layers.
Source: Authors, (2026).

The current research aims to improve the SIME system to encompass the development of an intelligent system for production planning. This system is based on monitoring production events, which indicate actions to be taken to follow the planned schedule, integrating resource management and the Bill of Materials (B.O.M.), currently handled by the JUNDSOFT software, while optimizing

business rules with new design patterns. As can be seen in Figure 2, the services layer contains the APIs developed for communication with the equipment and, therefore, continuously collects data from these devices directly into the database.

III.5 TRACEABILITY DEVICE

In this project, the objective is to integrate the software stacks (services layer API) with the hardware stacks (Traceability Device), which in turn are connected to equipment that generally use RS232 serial communication. The device will serve as the interface to communicate with the equipment and connect them to the internal network, advancing the equipment from a Stage 1 maturity level to Stage 2, where connectivity exists for data collection from each piece of equipment in a pilot line, which will be used to validate the data collection. Some devices in this pilot production line do not have connectivity and will receive a traceability device for data collection, as outlined below:

- **Parameterization Device**: This prototype device will be responsible for configuring the product's memory, recording the serial number, and allowing verification of other quality parameters to ensure that the product meets the customer's purchase order requirements (Verification according to the production order). This system must operate automatically, without operator intervention. Based on the production order number, the system will query via API which configurations and checks need to be performed on the product. Since these configurations are based on customer parameters, the device is called Parameterization.
- **PIMA Asynchronous Serial Output Device**: This device will be a functional test prototype for the product's communication protocol. It will ensure that the product functions and communicates correctly and that the serial code recorded in memory (done by the Parameterization Device) is correct. This stage occurs after the product is permanently closed, ensuring that there is no error in lid exchange or that the mechanical closing process did not damage the product. To determine what should be tested, the system will query via API, based on the production order number, the correct serial number in the production sequence, the communication protocol, and other optional items to be verified.

III.6 SYSTEM MODULES

With the collection of these data, which will be presented in detail in the project scope, it is possible to create new business rules in a new module called the **Production Control Module**, which is responsible for receiving data from each piece of equipment in real time and associating it with production events. These events represent higher-level information that allows for more assertive decision-making. Through this module, the project aims to develop intelligent system software for production planning. The **Traceability Module** is designed to organize data regarding product batches and their journey through the production line. This makes it possible to identify potential batch failures because, in the case of a defect in a meter during the final testing stage, it is possible to track the exact moment the product passed through each piece of equipment. This increases reliability in quality control processes, among other benefits of product traceability. These data allow the creation of business rules for updating the production planning based on traceability information. Meanwhile, the **Quality Control Module** collects, organizes, and makes visible the data related to product quality, allowing for a more comprehensive analysis of detected defects to define standards that will be used to adjust production planning and optimize the company's quality processes. Finally, the **Equipment Module** is not related to the products themselves but to the machines that produce them. Data from this module will be collected to observe patterns in equipment operation, enabling the scheduling of preventive maintenance and providing a basis for predictive maintenance. Additionally, with business rules associated with machine productivity, it is possible to reorganize production planning concerning machine health, operating hours, and reduce failure cycles. Each of these modules is a fundamental component for improving visibility and gathering information to determine production events, which contributed to the creation of an intelligent production planning system. For this, the data to be digitized from each module were defined, and from this data, relevant indicators will be constructed. These are high-level information derived from real-time data and are used to determine production events and shape production planning. The modules and their data and indicators are organized as follows:

- **Production Control:**

  - *Digitized Data:* Equipment utilization rate; production cycle time; number of products manufactured; machine downtime and corrective/preventive maintenance data; raw material consumption.
  - *Relevant Indicators:* Productivity rate; unplanned downtime index; raw material optimization index; reduction rate of losses and rework.

- **Traceability:**

  - *Digitized Data:* Complete batch history (dates, locations, and responsible personnel); detailed production step records; event logs and movements of each product/batch; return and defective product data.
  - *Relevant Indicators:* Real-time visibility index; tracking error reduction rate; response time for fault and return identification; efficiency in locating problematic or defective batches.

- **Quality Control:**

  - *Digitized Data:* Rejection rate per batch; nonconformities identified in inspections; test and quality assessment results; history of rework and repairs performed.
  - *Relevant Indicators:* Defect rate per batch; product compliance with quality standards; number of customer complaints; inspection and quality control time.

- **Equipment:**

  - *Digitized Data:* Equipment operating and downtime; frequency and type of maintenance performed (preventive/corrective); component and part lifespan; energy efficiency and resource consumption data.
  - *Relevant Indicators:* Mean time between failures (MTBF); mean time between corrective maintenance; operational efficiency of equipment; maintenance costs.

IV. RESULTADOS

Equipment, Quality Control, and Production

Initially, a review of the PUR was conducted, along with a study on non-connected devices to define the traceability system. The possibilities for integration with the SIME and JUNDSOFT software were evaluated to obtain metadata from the B.O.M. During this process, the operation of the **Parameterization Device** and the **Asynchronous Serial Output Device (PIMA)** was analyzed. The use of a **Raspberry Pi 5** for data collection and processing was considered, given its memory capacity and compatibility with multiple programming languages, which facilitate real-time solution implementation.

IV.1 PARAMETERIZATION DEVICE

The Parameterization Device was identified as a critical system for the automatic configuration of product memory. Its function is to ensure that each manufactured unit complies with the company's customer specifications, recording the serial number and verifying essential quality parameters. The operation of this device will be fully automated, eliminating the need for manual intervention. Integration via API will allow querying configurations and checks for each produced item, providing more precise and efficient quality control. This approach aims to eliminate human errors and ensure standardization in production, improving product safety and reliability.

IV.2 ASYNCHRONOUS SERIAL OUTPUT DEVICE (PIMA)

The PIMA device is responsible for performing functional tests on the product's communication protocol. This equipment ensures that the serial number recorded in memory is correct and that the product operates as expected. Verification occurs after the product is permanently sealed, preventing issues such as incorrect lid exchanges or mechanical damage during the closing process. The PIMA operation will also be automated, allowing it to automatically query production order information via API. This process ensures the accuracy of the production sequence, validates the communication protocol, and performs additional tests according to customer specifications. Implementing this device aims to increase production reliability and reduce operational failures.

IV.3 INTEGRATION AND DEVELOPMENT OF THE PRODUCTION CONTROL MODULE

From the data collected by these devices, the **Production Control Module** will be developed to consolidate real-time information and transform it into production events. These events enable a deeper analysis of production line performance, facilitating strategic decision-making and optimizing manufacturing management.The integration of these devices with the Production Control Module will enable:

- Real-time monitoring of parameterization and verification processes;
- Automatic alerts for deviations from quality standards;
- Equipment performance analysis and identification of potential production bottlenecks;
- Creation of a traceability history for each manufactured unit.

Integrating the Parameterization and PIMA devices into the new Production Control Module will provide significant benefits for production management, increasing efficiency and reducing operational failures. The use of automated technologies and API integration allows for a more robust approach to quality control and process standardization. During the analyses, it was identified that if mechanical adjustments are needed for device integration into the production environment, **CAD (Computer-Aided Design)** modeling will be used. CAD allows the creation, modification, analysis, and optimization of 3D digital projects, providing precision and efficiency in developing mechanical components.

For this purpose, **SolidWorks** software will be used, one of the most advanced tools for parametric modeling and mechanical simulation. SolidWorks enables detailed part and assembly design, structural analysis, and fit testing before manufacturing. Using this technology will facilitate the creation of supports, enclosures, and other adaptations required to install the devices in the industrial environment, ensuring better performance and integration with the systems.

IV.4 CONNECTIVITY AND NETWORK

A microcomputer kit was considered to process data directly on the devices and communicate with the systems being developed. The **Raspberry Pi 5** is a compact and versatile microcomputer with 8GB of RAM. As shown in the following figure, it is suitable for projects requiring real-time data processing and storage. This model is particularly appropriate to support the development of the Parameterization and PIMA prototypes, as it allows local data processing and the execution of parameterization and production analysis software.

Figure 3: Raspberry Pi 5 8GB.
Source: Authors, (2026).

It has high memory capacity, and its compatibility with multiple programming languages will allow the creation of a robust and agile testing environment, in addition to facilitating integration with sensors and devices. In this context, the **Raspberry Pi 5** will play a highly relevant role in the communication between devices and the software developed for the project. The research conducted during this period highlighted the main contributions, including:

- **Communication Interface:** Can act as a communication gateway, connecting the Parameterization and PIMA devices to the Production Control Module;
- **Data Collection and Processing:** Allows real-time acquisition of data generated by the devices, ensuring integrity and efficient transmission to the analysis systems;
- **Integration via Industrial Protocols:** Supports protocols such as MQTT, Modbus, and OPC UA, enabling interoperability between different equipment and the system;
- **Automation and Control:** Can be used to automate commands, ensuring devices operate according to the guidelines established by the control software;
- **API Connectivity:** Facilitates integration of devices with system APIs, allowing dynamic queries and real-time adjustments to production settings.

The implementation of the Raspberry Pi 5 will enhance system efficiency and reliability, reducing response times and optimizing device management on the production line. This period of activities also included a review of the **Connectivity and Network** point, as described in the PUR assumptions, due to the following condition:

- **Connectivity and Network:** Assumes that the SIME system execution environment, as well as the monitored machines, have the capacity to be connected to SIME through a local network (LAN), either directly or via an intermediate IoT prototype (microcomputers, e.g., Raspberry Pi) and sensors for data collection.

Analyzing this assumption was important to assess the feasibility of communication between the SIPE system and the monitored machines. This initial study helped identify potential technical limitations, such as network infrastructure constraints, and define strategies to ensure effective device connection. Additionally, it enabled the selection of the best approach for data transmission through intermediate devices like the Raspberry Pi, which assist in collecting and sending real-time information. With efficient connectivity, **SIPE** will be able to consolidate operational data reliably, enabling precise analyses to optimize decision-making. Implementing sensors and intermediate devices like the Raspberry Pi will allow the integration of devices connected to the system, ensuring that all equipment can communicate with the production management platform. Furthermore, compatibility with industrial protocols such as MQTT, Modbus, and OPC UA will allow standardized and secure communication between the system's different components. During this project period, research also focused on analyzing frameworks, libraries, and technological protocols essential for system development. Solutions for Front-End and UI/UX development, inter-system communication, database management, and real-time data processing were evaluated. This study identified the most efficient tools to meet project requirements, ensuring technical and operational feasibility, as summarized below.

a) **Front End and UI/UX:**

- **Vue.js:** JavaScript framework for creating dynamic and modular user interfaces;
- **Vue Router:** Library for managing routes in Vue.js applications;
- **Vue I18n:** Plugin for internationalization and localization of applications;
- **VueUse:** Collection of utilities for interacting with APIs and sensors;
- **Quasar/Naive UI:** Component frameworks for developing web, mobile, and desktop applications.

b) **Data Visualization:**

- **ECharts:** Library for creating interactive and dynamic charts;
- **Moment.js:** Library for date manipulation and formatting.

c) **Front End and Back End Communication:**

- **Axios:** HTTP client for asynchronous communication with RESTful APIs.

d) **Back End and Database:**

- **FastAPI:** Framework for building fast and secure APIs, with support for static typing;
- **SQLAlchemy:** ORM library for efficient interaction with SQL databases;
- **Redis:** In-memory database for caching and processing large volumes of data;
- **Celery:** Library for executing asynchronous tasks and distributed processing.

e) **Communication Protocols:**

- **WebSockets:** Protocol for real-time bidirectional communication.

f) **Validation and Testing:**

- **Pydantic:** Library for data validation based on Python typing;
- **Pytest:** Framework for unit, integration, and end-to-end testing.

g) **Internet of Things (IoT):**

- **IoT:** Technology for interconnecting physical devices, enabling real-time data collection and analysis, applied in parameterization and PIMA.

A careful analysis of technologies, tools, and frameworks enabled the selection of solutions suitable for an efficient and structured implementation. The combined use of these technologies will ensure a modular, secure, and high-performance system aligned with the project's objectives. Subsequently, the integrated systems development team focused on researching traceability devices—particularly the Parameterization and Asynchronous Serial Output (PIMA) devices—and structuring the embedded architecture with the Raspberry Pi 5 as the central processing and communication hub. The IoT Developer, Cássia Gabrielly de Souza Lopes, actively participated in the technical review of the PUR, contributing to the validation of hardware components, with emphasis on the Raspberry Pi 5, considered a key element in the collection, processing, and transmission of data from the devices. The researcher conducted detailed analyses of the embedded board's technical specifications, such as its ARM Cortex-A76 processor, 8GB RAM, GPIO interfaces, and support for industrial protocols (MQTT, OPC UA, Modbus), highlighting its potential for integration with the management system and connected devices. She also assessed the feasibility of using serial and USB interfaces for direct communication with production and testing devices. The Raspberry Pi 5 was identified as an essential component for the system architecture, playing a central role in communication between devices and the developed software. The research highlighted its main contributions, including its ability to act as a communication gateway connecting the devices to the Production Control Module, enable real-time data acquisition and processing, integrate via industrial protocols such as MQTT and HTTP, automate operational commands, and provide connectivity with system APIs for dynamic queries and real-time adjustments. Implementing this device will significantly enhance system efficiency and reliability, optimizing device management on the production line. Research was also conducted on the embedded board's electrical diagram, as shown in Figure 4.

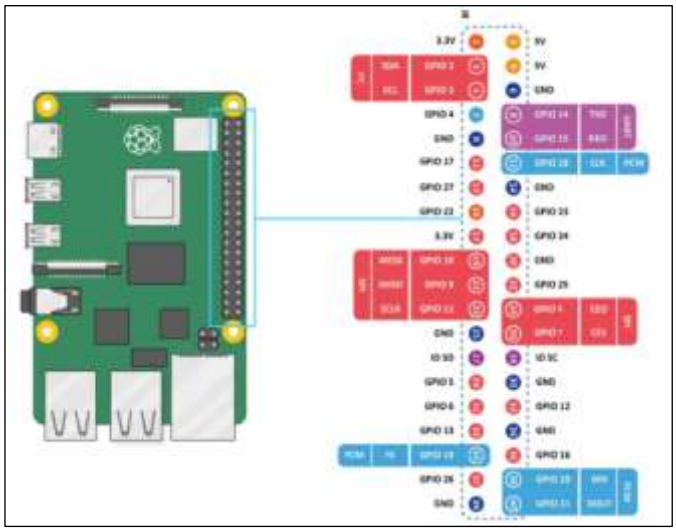

Figure 4: Raspberry Pi5.
Source: Authors, (2026).

This embedded model is the most advanced version of the popular single-board computer line developed by the Raspberry Pi Foundation. With significant improvements in performance and connectivity, the device provides a robust solution for industrial applications, automation, and IoT. Its main technical specifications are as follows:

- **Processor:** Quad-core ARM Cortex-A76, with a frequency of up to 2.4 GHz, delivering performance approximately three times higher than its predecessor, the Raspberry Pi 4.
- **RAM:** Available in 4 GB and 8 GB LPDDR4X-4267 versions, allowing greater energy efficiency and improved performance for multitasking applications.
- **Storage:** MicroSD UHS-I slot, with additional support for storage via PCIe 2.0 (through a dedicated connector), enabling the use of NVMe SSDs for higher read and write speeds.
- **Connectivity:** Includes two USB 3.0 ports and two USB 2.0 ports, plus a Gigabit Ethernet port that supports Power over Ethernet (PoE) when used with an additional module.
- **Graphic Interfaces:** Equipped with two micro-HDMI 2.0 outputs, supporting 4K resolution at 60 Hz and HDR compatibility, ideal for applications requiring high-quality graphics.
- **Graphics Processing:** VideoCore VII GPU with support for OpenGL ES 3.1, Vulkan 1.2, and hardware-accelerated video decoding for H.265 (4Kp60) and H.264 (1080p60).
- **Wireless Connectivity:** Supports Wi-Fi 5 (802.11ac) and Bluetooth 5.0, ensuring stable connections for wireless networks and Bluetooth devices.
- **PCIe Bus:** Integrates a PCIe 2.0 connector, allowing the addition of high-performance peripherals, such as storage controllers or expansion modules.
- **GPIO Pins:** Features 40 GPIO pins compatible with previous Raspberry Pi versions, enabling connections to sensors, actuators, and other devices.
- **Power Supply:** Uses a USB-C connector for power input, supporting 5V/5A, providing sufficient power to operate additional peripherals.

To ensure efficient communication of the traceability and functional testing devices, the Raspberry Pi 5 will be used as an intermediary between the devices and the management system. The Parametrization Device will be connected to the Raspberry Pi via USB or GPIO, allowing automated configuration of the product memory and recording of the serial number. Through API queries, the Raspberry Pi will receive the appropriate configurations and transmit them to the Parametrization Device. The PIMA Asynchronous Serial Output Device will also be integrated with the Raspberry Pi 5, which will serve as a validator of the product's functionality. The Raspberry Pi will communicate with the PIMA via serial protocol, verifying the correct recording of the serial number and checking the device's functional communication. In case of inconsistencies, it will be able to log faults and alert the production system in real time. The study identified technical limitations related to network infrastructure and defined strategies to ensure efficient device connectivity.

Compatibility with industrial protocols such as MQTT, Modbus, and OPC UA will ensure standardized and secure communication between system components. During the analyses conducted, no mechanical adjustments were identified as necessary for integrating the devices into the production environment. Therefore, CAD modeling—which allows for the creation and optimization of three-dimensional projects—was not required at this stage. To Marcelo Maia do Nascimento, a senior embedded hardware and software developer, collaborated with the IoT Developer in developing the functional prototype for reading data from electronic meters via the national PIMA protocol. He conducted a comprehensive technical study of PIMA, covering its packet structure (preamble, identifier, size, scope + index, data, and CRC) as well as ANEEL regulatory requirements for interoperability across PLC, RF, and RS-485 networks. He developed the communication logic between the meter and the microcontroller through serial terminals (MTx and MC), with subsequent data transmission to a WebServer embedded in the Raspberry Pi 5, accessible remotely via web browsers.

IV.5 STUDY OF THE PIMA PROTOCOL AND APPLICATION

The Developer conducted an in-depth study of the PIMA protocol, created in Brazil to ensure interoperability among meters from different manufacturers and management systems. The protocol was analyzed in its entirety, from operation over media such as PLC, RF, and RS-485 to its data packet structure, including preamble, identifier, size, scope + index, data, and CRC fields. This deep understanding allowed technical implementations to comply with the 2400 bps speed parameter and the unidirectional asynchronous transmission structure of electronic meters, according to ANEEL specifications.

IV.5.1 Development of the Serial Communication Prototype with WebServer

It will be necessary to adapt the PIMA device, based on the Raspberry Pi 5 microcontroller, to read data sent via the unidirectional serial output of the meters (MTx and MC terminals). Communication between the meter and the microcontroller will be established using physical jumpers, enabling the capture of transmitted packets. The Raspberry Pi 5, with native Wi-Fi connectivity, can be programmed to communicate with a local WebServer, which will display the measurement information in an interface accessible remotely via a browser. The workflow is illustrated in Figure 5.

Figure 5: Serial Communication Prototype with WebServer.
Source: Authors, (2026).

IV.5.2 Data Conversion and Visualization

During the research, it was observed that the structure of the PIMA packet is decoded to extract the data of interest, such as the meter serial number, voltage, current, and power parameters, among others. After reading and decoding, the data will be organized and sent to the WebServer, which will display the values in real time for the operator. This functionality will enable continuous monitoring of energy consumption, promoting greater awareness and control by the consumer. Figure 6 shows the simplified electrical diagram of unidirectional asynchronous serial communication between the meter and the remote device (PIMA Device). On the left side, the serial outputs of the meter are represented, while on the right side, the serial input of the receiving device can be observed. Although the components may vary according to the manufacturer, the basic connection configuration was maintained in this project: the MRx pin of the PIMA device is connected to the MTx pin of the meter, while the MC is grounded. When the meter transmits data through the MTx pin, the device receives the information packets, processes the data, and makes them available on a WebServer developed for visualization. This implementation ensures compatibility with the PIMA standard, allowing proper reading and display of the measurement information.

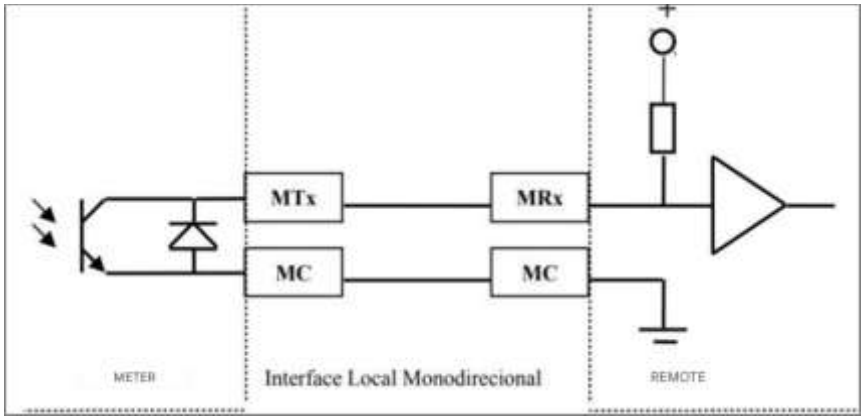

Figure 6: PIMA Electrical Diagram.
Source: Authors, (2026).

The formation of the data packets sent through the asynchronous serial output must follow the specific formatting described below:

- **Preamble:** Initial signaling of a packet. It consists of 2 bytes with the hexadecimal characters AA and 55;
- **Identifier – Meter serial number:** Composed of 5 bytes in BCD format, allowing a 10-digit numbering;
- **Length:** Count of the number of bytes related to the SCOPE + INDEX characters and DATA. Composed of 1 byte;
- **Scope + Index:** Identifier of the type of information to be sent, according to the standard defined in Table 1;
- **Data:** Corresponds to the actual measurement values, presented in BCD format. These data must comply with the definitions of the Application Protocol established by the Brazilian Association of Technical Standards (ABNT);
- **CRC:** Refers to the cyclic redundancy check character of the CRC16 message ($X^{16} + X^{15} + X^2 + 1$), applied over all bytes of the packet, except for the PREAMBLE and the CRC itself.

Automated communication with the meters will enable detailed traceability of the produced units and real-time validation of readings, ensuring greater safety and efficiency on the production line. The development enabled the creation of a continuous flow for reading, decoding, and visualizing meter data, validating the serial number, electrical parameters, and the overall operation of the product. The embedded architecture ensures real-time communication, with the possibility of integration with the SIPE system through APIs, promoting full traceability of the produced units. During the period under analysis, significant hours were dedicated to conducting in-depth technical studies aimed at directly assisting the technical coordinator and the hardware and IoT developers in refining the functional and operational requirements of the system under development.

The author's contribution was essential in consolidating the understanding of demands related to parameterization and communication with electronic energy meters, ensuring that the proposed solutions were aligned with the technical standards of the Brazilian electrical sector, especially with regard to the implementation of connectivity in the PARAMETERIZATION device. In addition, the researcher contributed to defining strategies for integration between physical devices and the embedded and web software architecture, providing a solid foundation for the development and validation of the prototype. The Parameterization Device is an industrial piece of equipment used in the process of configuring and writing parameters to electronic energy meters during the manufacturing phase or final calibration. It plays a fundamental role in customizing meters according to customer technical specifications or current regulatory requirements (e.g., ANEEL, INMETRO, ABNT).

IV.5.3 Objectives and Main Functions

The main objective of the device is to automate the writing and verification of the meter's internal parameters, ensuring its identity, functionality, and compliance with technical standards. Among the functions adopted at Wasion are:

- Writing the serial number to the meter (unique identifier).
- Configuration of tariff tables and calendars.
- Parameterization of demand limits, load profiles, and events.
- Enabling communication modes (e.g., PIMA, DLMS/COSEM).
- Writing technical data such as nominal voltages, base currents, and frequencies.
- Validation and verification of embedded firmware.
- Updating cryptographic keys in meters with advanced security functions.
- Integration with traceability systems and production order databases.

a) Architecture of the PARAMETERIZATION Device

The architecture of the parameterization device includes:

- Central Controller (Arduino Mega microcontroller) with dedicated software.
- Programmable power supply to energize the meter according to its nominal parameters.
- Read and Write Module (via serial port).
- Cryptographic Security Module (in meters with authentication).
- Computer application for configuration and visualization.
- Local database to store parameters and operation logs.

b) Communication Technologies

In discussions with the Technical Team, a study was conducted to identify potential connectivity applications for the device:

- IEC 62056-21 standard optical port: very common in meter parameterization.
- RS-232 or RS-485 serial interface: mainly used for bench parameterization.
- USB port with optical converters: allows connection with parameterization software.
- Wi-Fi / Ethernet interface: in more modern devices with remote control.
- Protocol standards: the most common are PIMA (in Brazil) and DLMS/COSEM (international).

c) Application of the PARAMETERIZATION Device at Wasion

It was identified that Wasion has flexibility in its production lines, which are fully customizable to adapt manufacturing processes as needed. Regardless of the production line, the parameterization device is used at specific stages:

Post-assembly / Pre-closing

- Writing production and identification data.
- Verification of basic operation.

Post-calibration

- Parameterization based on the results of metrological adjustment.

d) Integration with Production Systems

e) Currently, the parameterization device does not have integration with:

- MES (Manufacturing Execution System): enables traceability of the produced unit.
- ERP: for consultation of production orders and customer requirements.
- SQL / NoSQL databases: where parameters are stored and versioned.

Automation/connectivity of the device will minimize human errors, increase productivity, and ensure technical compliance, being a mandatory step in the metrological certification of meters by INMETRO.

a) Standards and Regulations

b) The operation and parameterization of meters follow standards and regulations, among which the following stand out:

- INMETRO Ordinance No. 457/2021: regarding legal metrology of meters.
- ANEEL Resolution No. 844/2019: establishes guidelines for metering and quality.
- ABNT NBR 14522 Standard: specific characteristics of electronic meters.
- IEC 62052 and IEC 62056 Standards: address communication protocols and general requirements.

In the context of the research, the Parameterization Device will be used to:

- Automate the writing of serial numbers and technical parameters of meters.
- Integrate with the traceability module, sending data to an internal WebServer.
- Automatically verify whether the meter complies with the production order specification.
- Record data in an internal database for quality control and statistical analysis.

During this period, the team also assessed the need for mechanical adjustments to the devices, with planned use of SolidWorks software for modeling supports and enclosures. Integration with the SIME and JUNDSOFT systems was considered in defining database structures and communication protocols, establishing a foundation for the development of traceability, production control, and quality control modules. The result of this activity was the consolidation of a robust technical infrastructure for the development of embedded devices, establishing the foundations for functional testing, real-time data collection, and integration with the production management systems of the investing company. During the current month, activities related to the Integrated Systems Development stage advanced significantly, with the direct involvement of the IoT Developer, the Technical Technology Specialist, and the Senior Embedded Hardware and Software Developer. The main focus was on the technical enhancement of the Parameterization Device for electronic meters, a strategic element of the SIPE system to ensure traceability, quality control, and customization of devices according to Wasion's requirements.

The IoT Developer focused efforts on creating two fundamental diagrams for updating the parameterization device, based on the technical and structural studies carried out in the previous month. From a detailed analysis of the functions, communication ports, and capabilities of the Raspberry Pi 5 microcontroller, the electronic components required to ensure proper communication between physical devices and the production management system were defined. The diagrams were developed prioritizing functional logic compatible with the existing structure of the equipment, respecting component datasheets and carefully distinguishing electrical circuits from electronic circuits. This distinction was essential to ensure that interconnections between signal and power elements were designed safely and accurately. The first diagram, an electrical circuit modeled using Proteus software, focused on integrating the Raspberry Pi 5 into the parameterization device circuit. This simulation was essential to validate interactions among components before physical construction.

In the designed circuit, the Raspberry acts as the main interface, receiving configuration parameters via API and transmitting this information to the meter. Communication between the embedded system and the meter was enabled through a USB-to-TTL adapter, which connects the Raspberry's serial ports to the pins responsible for reading and writing data on the meter. The device interface was also designed to display the parameterization status to the operator, providing real-time visibility and greater control over the process. Before practical assembly, all connections were meticulously simulated in Proteus, allowing the anticipation of failures such as short circuits, voltage incompatibilities, and risks of damage to sensitive components. This virtual validation ensured the integrity and safety of the circuit. After this phase, physical assembly began in a segmented manner, enabling modular testing at each stage, which increased efficiency in fault identification and contributed to a more stable and secure final integration.

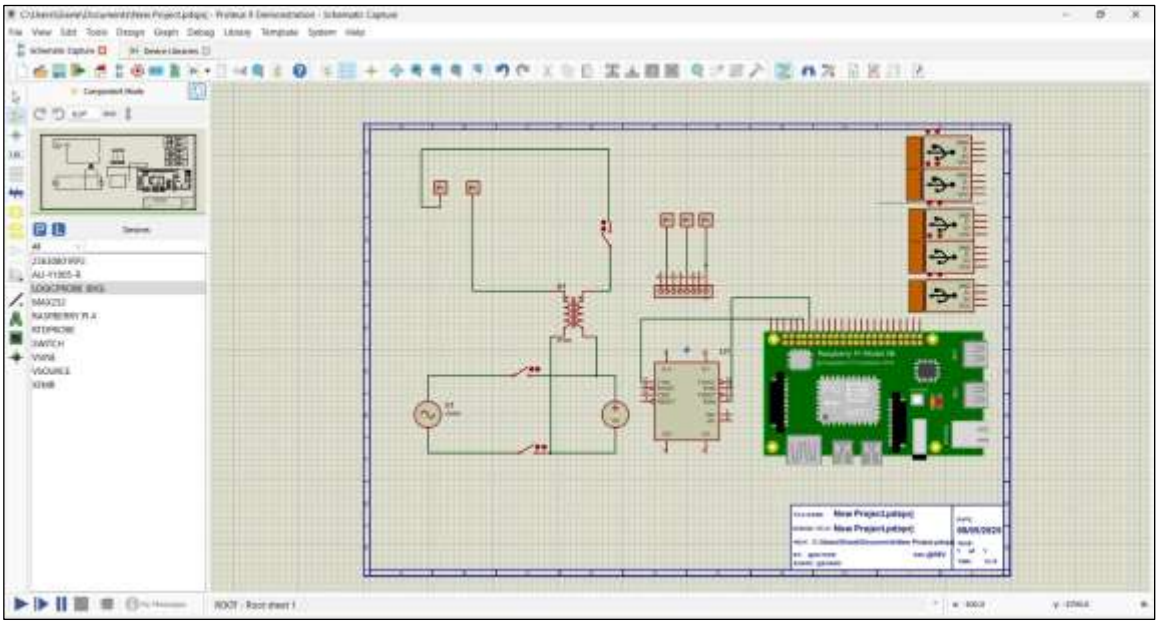

Figure 7: Electrical diagram of the parameterization device.
Source: Authors, (2026).

In parallel, the research deepened its investigation into the company's production structure, mapping with greater precision the stages of the assembly line in which the parameterization device is inserted. This analysis was formalized through technical flowcharts, as presented in the figure below, and enabled a more detailed understanding of the critical integration points between the equipment and production flows, especially at the pre-closing stage of the meters, known as the Ultrasonic Station. As a result of this mapping, meetings were held with the company's team to discuss the compatibility of communication protocols with the manufactured meters. In these meetings, emphasis was placed on the technical and regulatory feasibility of implementing the PIMA protocol, considering the requirements of ANEEL, INMETRO, ABNT, and IEC.

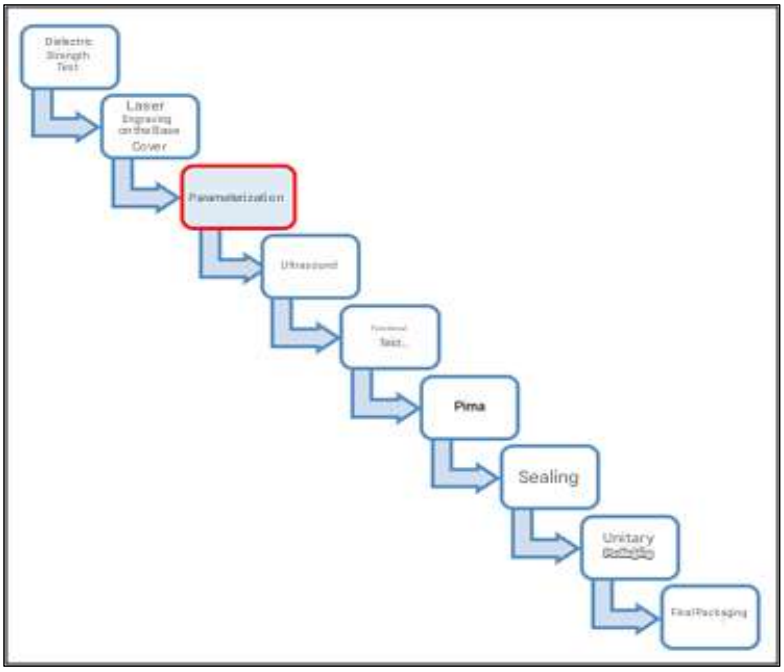

Figure 1 Process Flowchart for Single-Phase Meters.
Source: Authors, (2026).

Simultaneously, the Senior Embedded Hardware and Software Developer directed efforts toward advancing the technical solution of the parameterization device. Initially, the technical and functional requirements of the prototype were defined, with a focus on compatibility with the communication standards adopted by Wasion. Acting as an operational interface, the device was designed to allow operators to configure meters in an automated, secure, and traceable manner. Parameters such as serial number, calibration, firmware version, and operational data were defined as essential to the process. The Raspberry Pi 5 was retained as the core of the system, and logical level converters, USB-to-Serial adapters, and EEPROM modules were incorporated into the project, which are necessary for simulations of writing, reading, and integrity verification. The test circuit was initially modeled using Draw.io. The device firmware was structured using Python, with libraries such as *pyserial* for serial communication and *smbus2* for I²C integration. The initial routines focused on reading unique identifiers, secure write commands, and subsequent validation through reading, ensuring robustness even under conditions of noise or protocol variations, as shown in Figure 9.

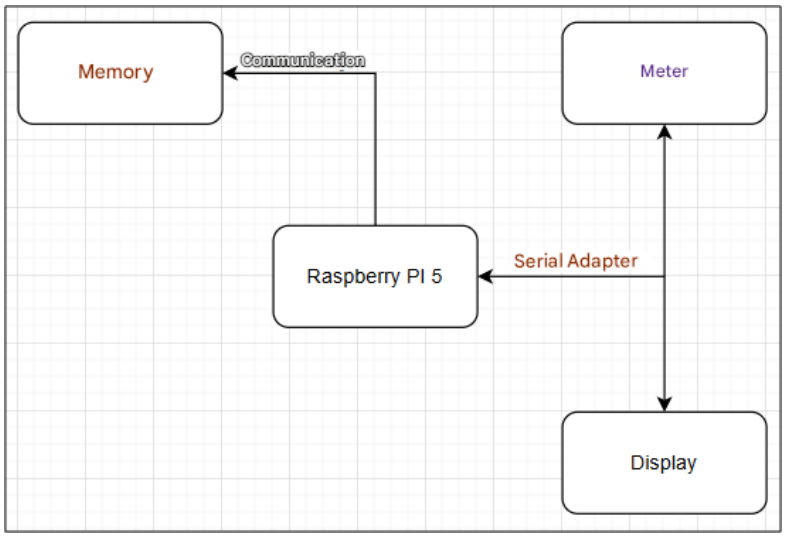

Figure 9: Diagrama para o circuito de teste.
Source: Authors, (2026).

Additionally, an in-depth analysis of the electrical and logical interconnection points was carried out, considering critical aspects such as:

- Power supply compatible with the factory infrastructure (12 V, 24 V, or 220 V AC/DC).
- Shielding against electromagnetic interference, which is common in industrial machine environments.
- Robust and reliable communication interfaces, using standards such as RS-485, Ethernet, MQTT, Modbus, and communication via REST APIs.

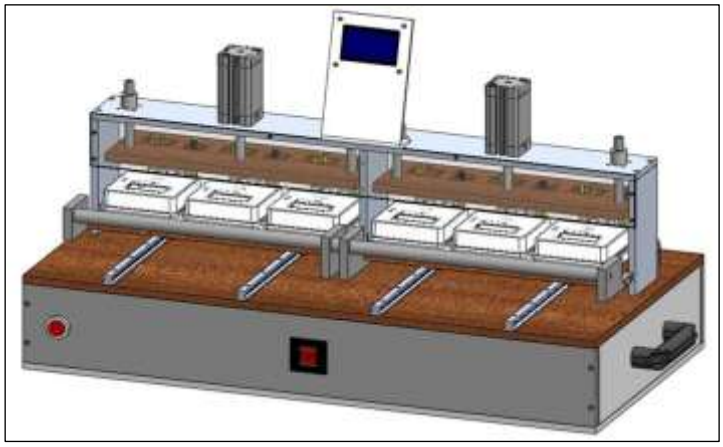

Figure 10: 3D Model of the PIMA Verification Device.
Source: Authors, (2026).

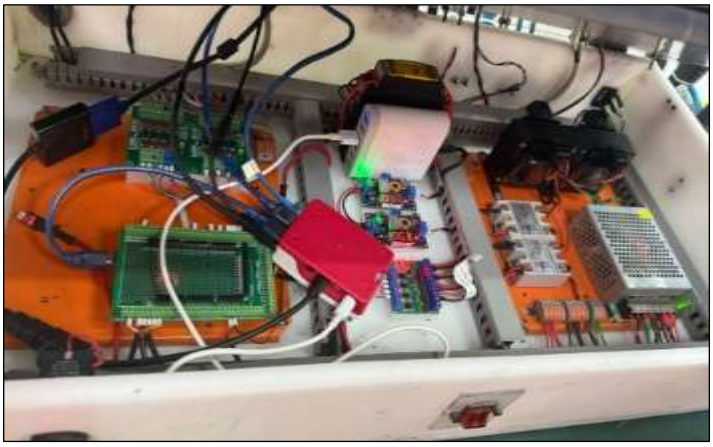

Figure 11: Hardware of the PIMA Verification Device.
Source: Authors, (2026).

Complementing this architecture, the use of Apache Kafka was defined as a distributed messaging platform, serving as the core of data communication between the physical devices (Parameterization and PIMA Device) and the backend systems. Kafka enables real-time event processing, offering (Figure 12):

- High fault tolerance.
- Unlimited horizontal scalability, with the possibility of expanding brokers as data volume grows.
- Long-term data persistence, ensuring reliability in the transport of critical production messages and events.

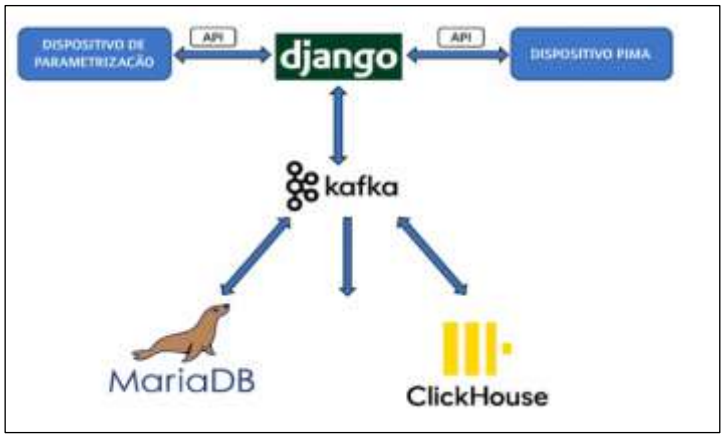

Figure 12: Backend and Communication Architecture Diagram.
Source: Authors, (2026).

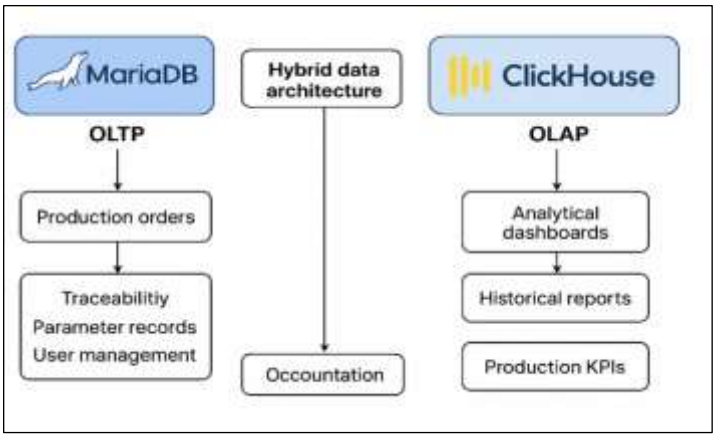

Figure 13: Hybrid architecture for data storage.
Source: Authors, (2026).

Regarding data storage, a hybrid architecture was consolidated, combining two databases with distinct purposes:

- **MariaDB**, adopted for OLTP (Online Transaction Processing), is responsible for managing operational data such as production orders, traceability, parameterization records, and user control. Its selection was based on robustness, relational integrity, scalability, and wide adoption in industrial environments.
- **ClickHouse**, adopted for OLAP (Online Analytical Processing), is intended for managing analytical data, allowing the processing of billions of rows with extremely high-speed queries. Its columnar architecture is ideal for generating analytical dashboards, historical reports, production performance monitoring, and KPIs such as OEE (Overall Equipment Effectiveness) and FPY (First Pass Yield).

MongoDB was also considered during the evaluation process, mainly for storing semi-structured data. However, given the specific project requirements—which demand high transactional consistency and large-scale analytical performance—the technical decision prioritized the combination of MariaDB and ClickHouse, providing robustness and superior performance. Figure 13 clearly and objectively illustrates the hybrid data storage architecture adopted in the project, combining MariaDB (OLTP) and ClickHouse (OLAP), each performing specific and complementary roles within the ecosystem of the developed solution.

IV.5.4 Frontend Development and Operational Interface

The frontend team, composed of Leonardo and Matheus, made significant progress in defining the visual architecture and prototyping system screens, highlighting:

- **Adopted Framework:**

  - Vue.js, combined with Tailwind CSS for styling and Vite for build optimization and agile development.

During subsequent technical meetings (Figures 14, 15, and 16), the use of the Vue.js framework was defined as the basis for system interface development. The choice considered its lightweight nature, ease of integration with WebSocket, modularity, and accessible learning curve, facilitating collaboration among team members. Vue.js will enable the creation of reactive components for real-time data visualization, with reduced complexity in maintenance and scalability of the application.

Figure 14: Vue.js.

A Simplified Architecture Diagram was created to clearly, objectively, and visually represent the structure of the system for parameterization and segregation of electronic energy meters. The main goal of this representation was to provide a high-level view of the system's key components, their functional responsibilities, and the communication flows between software modules, embedded hardware, and external backend systems, as shown in Figure 17.

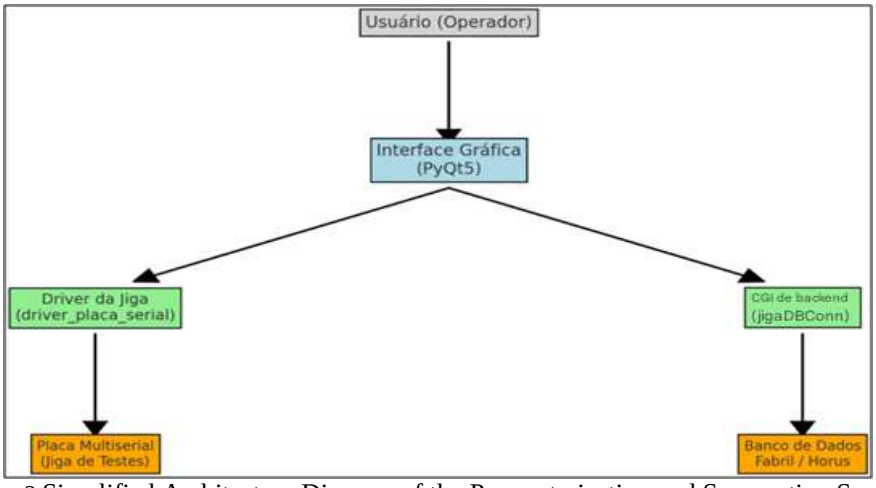

Figure 2 Simplified Architecture Diagram of the Parameterization and Segregation System.
Source: Authors, (2026).

IV.5.5 Main Application – Main

The test results are returned through the carregaMeterStatus slot, which dynamically updates the table with the obtained results, using colors to indicate the success or failure of each meter. At the end of the test batch, if all fields are filled, the interface displays the message "Serial Test Completed!" In the event of critical failures during driver execution, the system calls the erroNoEngine function, which displays an error message to the operator and logs the issue as a critical error. This control reinforces the reliability of the system even under adverse conditions. Another notable feature is the segregar function, which allows the operator to manually record a failed meter outside the automatic flow. When activated, this function opens a segregation window where the operator enters the defective meter's data, and the system records this event in the backend, ensuring full traceability. Additionally, the resetarWidgets function is used at the start of each new work order or in case of a connection error, ensuring the interface is cleared, fields are disabled, and styles are reset for a new work cycle. This structure allows the system to operate in a modular, asynchronous, and visually clear manner. The architecture of paramFechDialog follows industrial software engineering principles, ensuring data consistency, an intuitive operator experience, and seamless integration with other system components. Within this framework, the loginDialog class plays a fundamental role in controlling application access. Its integration with the backend, visual window management, and user feedback mechanisms provide a secure, clear, and efficient interface, aligned with the requirements of industrial environments that handle sensitive data and real-time equipment, as shown in Figures 18 and 19.

Figure 18: Main.
Source: Authors, (2026).

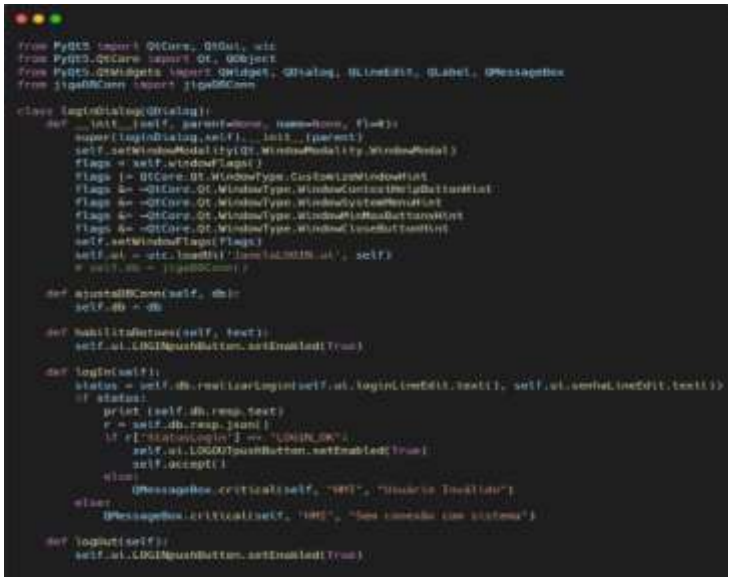

Figure 19: Login.
Source: Authors, (2026).

Therefore, the DialogoSegregarMedidor class represents an important layer of the developed solution. It not only allows operational exceptions to be handled in a user-friendly manner but also reinforces the principles of traceability, data integrity, and compliance with industrial quality and safety best practices. Integrated with the rest of the application through dependency injection and signaling flow, this window helps maintain smooth and secure factory operations even in the face of unexpected events (Figure 20). To ensure consistency and reliability in handling this data, foreign keys (FKs) were applied, and optimized indexes were created based on status, version, and dates, providing better performance for complex queries and greater transactional integrity. Additionally, standardization of possible record states—draft, published, and archived—was established from the beginning, reinforcing the principle of immutability for published versions. This approach, while allowing flexibility during the draft phase, ensured that published versions remained unalterable, guaranteeing the traceability required in a regulated manufacturing environment. To accelerate development and approval cycles, minimal seeds were inserted into the migrations, allowing environments to be initialized with representative data for testing. This strategy reduced the time spent setting up validation scenarios and facilitated the development team's work, enabling them to quickly test functionalities without compromising data integrity. By the end of the first week, the system's relational core was already consolidated, providing a reliable foundation on which subsequent development stages would be built (Figure 21).

IV.6 QUANTITATIVE PERFORMANCE EVALUATION OF THE SYSTEM

Following the gradual implementation of the SIPE modules on the pilot production line for electronic meters, quantitative analyses were conducted to evaluate the system's impact on operational performance. Key performance indicators (KPIs) were monitored before and after the adoption of traceability devices, the Production Control module, and integration with the existing system (SIME). Among the analyzed indicators, the most notable were: productivity rate (meters/hour), average production lead time, rework and rejection rates, average time to identify defective batches, and the unplanned equipment downtime index.

The results indicated a significant reduction in the average lead time of the pilot line, with a decrease in the total time between the start of production and the completion of final testing. An increase in productivity rate was also observed, mainly due to the reduction of unplanned stops and greater predictability in the sequence of operations. In terms of quality, the integration of traceability data and functional testing devices enabled a decrease in rework and rejection rates, as recurring failures were identified more quickly, allowing targeted corrective interventions. Additionally, the time required to locate and isolate problematic batches was significantly reduced, positively impacting the non-conformance analysis process and customer support. Overall, the quantitative results demonstrated that SIPE contributed to increasing the overall efficiency of the pilot line, reducing waste, and enhancing the reliability of production processes, confirming the potential of the proposed approach for industrial environments seeking to adopt Industry 4.0 principles.

IV.7 IMPLEMENTATION AND EVALUATION OF ARTIFICIAL INTELLIGENCE MODULES

The Artificial Intelligence modules developed within the SIPE framework focused primarily on supporting production planning and replanning, as well as forecasting critical operational variables. Supervised machine learning approaches were used for demand forecasting, cycle time estimation, and identification of production bottleneck patterns. The dataset used to train the models consisted of production order histories, records of meters passing through workstations, machine downtime information, quality test results, and device configuration parameters. These data were extracted from SIME, the new traceability modules, and the Production Control Module, covering a representative period of the pilot line's operation. After data cleaning, normalization, and feature selection, different algorithms were evaluated, including regression, decision trees, and neural network-based models. Model evaluation was performed using metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE), considering cross-validation scenarios. The results indicated error levels compatible with practical use in decision-support scenarios, allowing cycle times and workload predictions in advance to support production schedule adjustments. In parallel, classification models were investigated to indicate, based on historical patterns, the likelihood of bottlenecks occurring at specific workstations or an increase in the rejection rate. The integration of the AI modules with the Production Control Module allowed forecasts to be consumed in near real-time by the system, generating automatic replanning suggestions in cases of significant deviations. Although the final decision remained the responsibility of the Production Planning and Control (PPC) team, the use of AI-generated recommendations helped reduce response time to unexpected events and made the planning process more proactive and data-driven.

IV.8 CASE STUDY ON THE PILOT PRODUCTION LINE OF METERS

To validate the practical applicability of SIPE in a real production environment, a case study was conducted on a pilot production line for electronic meters. The study focused on the integration between the different system modules, demonstrating how the microservices architecture and asynchronous communication between components contribute to operational efficiency and process traceability. The selected pilot line includes workstations with varying levels of automation, from fully connected equipment to devices without native connectivity, which were integrated through the traceability devices developed. SIPE was implemented gradually, starting with the integration of the traceability and production control modules, followed by the implementation of the technical sheet system, and finally the activation of analysis modules and dashboards. One of the most relevant aspects of the case study was the validation of the layered architecture implemented in the system. The presentation layer, developed with Vue and TypeScript, allows operators and managers to view production data in real time through interactive dashboards. The business logic layer, implemented with custom hooks and stores (Zustand), processes and transforms raw data collected from the equipment into actionable information. The communication layer, based on TanStack Query and Axios, manages asynchronous requests to backend services, implementing intelligent caching and automatic retry in case of network failures.

Finally, the backend services layer, composed of the microservices service-auth, service-datasheet, and service-tests, processes business rules and persists data in a distributed manner. The integration between microservices was tested in a real production scenario. When an electronic meter passes through the parametrization device, the system records the event in the traceability module. This event is then processed by the production control module, which updates the production order status and calculates performance indicators. Simultaneously, the technical sheet system is consulted to verify whether the meter specifications comply with the approved template. If any non-conformance is detected, the system generates an alert and records the event in the quality control module, which can trigger automatic production replanning. Service communication was implemented using asynchronous standards with distributed caching (Redis) and exponential backoff retry. For example, when the technical sheet service needs to validate a user profile for approval, it queries the authentication service through the ProfileValidationService. This service implements a cache mechanism with a TTL (Time To Live) of 15 minutes, significantly reducing the number of calls to the external service and improving operation latency. In case of communication failure, the system performs up to 3 attempts with increasing intervals (exponential backoff), ensuring resilience even under unstable network conditions.

During the validation period, a practical scenario demonstrated the effectiveness of the proposed architecture. When a sudden increase in the rejection rate was detected at a functional testing station, SIPE automatically identified the issue through pattern analysis in the traceability data. The production control module correlated the failure events with production batches, identifying that the problem was associated with an improper adjustment on a specific device. The system then issued automatic alerts to the responsible team and suggested partial replanning of production orders, temporarily redirecting the workflow to another set of equipment. This action was executed in less than 15 minutes, from detection to solution implementation, significantly mitigating the impact on daily production targets. The microservices architecture also demonstrated its scalability during the case study. The web service was configured to operate with 4 replicas in the production environment, using Docker Swarm for orchestration and Traefik as a load balancer. This setup allowed the system to maintain high availability even during demand peaks, automatically distributing the load among instances. The technical sheet service, in turn, was dimensioned to process up to 50 signing operations per second, as validated by performance tests, ensuring that the system would not become a bottleneck during critical approval operations. Beyond quantitative benefits, the case study highlighted qualitative gains related to process visibility, standardization of records, and support for decision-making.

Operators and engineers gained an integrated view of the production line, with real-time access to each equipment's data, test results, and production order status. This visibility facilitated root cause identification of recurring problems and allowed prioritization of continuous improvement actions based on objective data. The case study also validated the effectiveness of the electronic signature system integrated with SIPE. During the validation period, over 500 template and technical sheet approvals were processed, all with full traceability through audit logs. The SHA-256 hash system ensured document integrity, and automatic invalidation of signatures when templates were modified ensured that only approved versions were used on the production line. This functionality was particularly relevant to ensure compliance with regulatory requirements and industry quality standards. In summary, the case study on the pilot line demonstrated that the microservices architecture, combined with asynchronous communication, distributed caching, and real-time processing, provides a robust, scalable system capable of supporting the demands of an industrial production environment. The integration of SIPE's different modules enabled more efficient production management, with increased visibility, traceability, and responsiveness to unexpected events, confirming the potential of the proposed approach for digital transformation in manufacturing environments.

V. CONCLUSÕES

It is concluded that the development of an Automated System for Control and Production Planning of Electronic Meters with Artificial Intelligence represents a significant advancement in the modernization of industrial processes, aligning technology, efficiency, and reliability. The adoption of the Internet of Things (IoT) enabled the interconnection of production equipment, allowing real-time monitoring, continuous information exchange, and decision-making based on accurate and up-to-date data. The use of traceability and parametrization devices, combined with the asynchronous PIMA serial output, contributed to rigorous control of the production flow, ensuring the individual identification of each electronic meter throughout all stages of the process. This was essential for strengthening traceability, providing a complete history of production, configuration, and testing, as well as supporting quality control through early fault detection and reduced rework.

The integration of electronic meters with the Raspberry Pi 5 (8GB) proved to be an efficient and low-cost solution, offering high performance for data collection, processing, and analysis. The communication interface, together with integration via industrial protocols, ensured interoperability between heterogeneous systems, facilitating automation and control of the production process. Through data collection and processing, combined with artificial intelligence techniques, it was possible to enhance production planning, optimize resources, and increase the reliability of management information. Connectivity with APIs, networks, and digital services expanded system scalability, allowing integration with corporate platforms and cloud environments. Thus, the proposed system proves to be robust, flexible, and aligned with Industry 4.0 concepts, promoting greater operational efficiency, final product quality, and competitiveness in the electronic meter sector.

ABSTRACT

Trust has become crucial in a digitized world for the sustainability of online platforms. As the web interfaces have been playing a vital role in day-to-day activities, ethical design has become essential to protect user autonomy and promote informed decision-making by them. Dark patterns are deceptive design strategies that can harm users' trust and are dangerous, especially in the e-learning environment. This paper presents a refined Bidirectional Encoder Representations of Transformers (BERT) classifier to automatically detect dark patterns on educational online systems. The framework starts with web scraping of the digital interface followed by organized preprocessing, such as content extraction, text cleansing, normalization, and tokenization. An algorithm to calculate a Credibility Index (CI) of e-learning systems is proposed based on the frequency and the severity of perceived dark patterns. The online systems are categorized into one of the three threat levels—*Safe*, *Moderate*, or C*ritical*, which gives clear indication to users regarding the trustworthiness of the site. Using the proposed framework, a customized educational website called SkillNest was developed to predict user trust. It was classified as *Moderate* due to its CI value of 0.64. This work may help developers in enhancing transparency and trust in educational technology by reducing the manipulative practices for developing e-learning systems.

I. INTRODUCTION

Dark patterns are untrustworthy and manipulative user interface (UI) design methods that are used by digital platforms to control user behavior in a way that can harm their choices, threaten trust, and break down faith [1-3]. The term dark pattern was given by Brignull [4] to describe ways of using mind tricks and psychological rules to make the platform earn the most money, usually at the cost of what's best for the users [2]. They include biases caused by social pressure, as well as the way choices are presented to push users toward performing things they wouldn't normally do [5], [6]. Also, such manipulative actions increase digital inequality, affecting digitally illiterate groups, and increasing the need for stricter rules on how platforms need to be designed [7]. Dark patterns restrict the users' rights to make a fair decision. Difficult procedures make it difficult for users to leave online services and thus limit their control over their personal data and online activities [6], [8].

These malpractices raise serious concerns about designing guidelines for developing online systems [2], [7]. Even the Department of Consumer Affairs has banned 13 different types of dark patterns. Since many people are not aware of these malpractices, there is a strong demand for authentic websites. Though various studies in literature report the types and effects of dark patterns [9], their automated identification in real time and measuring their impact has remained a challenge [3]. Manual detection of dark patterns requires a lot of time and effort and may be error-prone for complicated digital interfaces [10]. To address these issues, designers and customers need automated tools to detect and fix the causes of dark patterns [1]. Without these tools, people may find it challenging to follow the law and make informed decisions due to the increasing complexity of these dishonest strategies [11].

Finding the UI design malpractices on a huge scale is now feasible due to improvements in tools that understand natural language and learn from data, known as machine learning (ML). Large Language Models (LLMs), such as BERT [12], are capable of interpreting

the meaning and context of language [13]. This feature may be utilised in discovering elusive context-based dark patterns, which are otherwise difficult to catch by simple rule-based systems [14]. Also, these language models may offer deeper insights into these patterns of user behavior. These transformer models have also been utilised in other applications. For example, the BERT model has been used to extract and categorize large amounts of critical information from social media platforms [15]. Research by Kaur et al. [16] has showcased the application of the BERT model for quantifying the quality of online learning systems.

The proposed study presents an automated system to detect dark patterns and measure their impact to classify the educational platforms. It involves gathering of data, followed by preprocessing, including cleaning up the text and standardizing it using normal methods to make sure the data used is of high quality [17]. The refined BERT model calculates the chance that the user interface text is manipulative [18]. In addition, the proposed system also calculates the value of CI for digital platforms. The CI is a trust score that indicates the trustworthiness of a website by looking at the frequency and seriousness of the dark patterns. The digital platforms are assigned a threat level—*Safe*, *Moderate*, or *Critical*, based on the value of CI. It facilitates users' understanding of whether they can safely access the site or need to be careful or avoid the site altogether.

This work focuses on building credibility and trust by bringing it to the education world, where manipulative design practices can harm a student's confidence and engagement in e-learning platforms. Introducing the CI may help the students in using the trustworthy websites only. Though there are numerous ways of building trust. Sharma et al. [19] proposed that faith and trust in e-commerce can be developed by fixing problems like missing information and addressing bad reputations on business websites. Though this study has focused on educational websites, the framework is flexible and can be used for any digital platform. The main aim of the study is to develop an automatic system for predicting the credibility of educational websites. This research mainly addresses the problems caused by poor design on the educational platforms by focusing on the following objectives:

1. To build a system that automatically detects the dark patterns on learning websites using smart language models (like BERT).
2. To compute the CI of the online system based on the frequency and severity of the dark patterns identified.
3. To classify the online e-learning systems into three levels—*Safe*, *Moderate*, or *Critical* based on the value of CI.
4. To support fairness and transparency in digital educational environments.

The paper is divided into several parts: Section 2 provides a literature review of past research work on dark patterns and methods for finding them automatically. Section 3 presents the methodology for predicting the credibility of the educational online systems, while Section 4 discusses the test results. Finally, Section 5 concludes the paper with a summary of its main contributions.

II. LITERATURE REVIEW

Dark patterns are malign strategies that affect user trust. A lot of research is being done to identify and categorize the dark patterns. However, there are still gaps in terms of applying effective technology to identify these patterns in particular contexts. Luguri and Strahilevitz [2] were the first to recognize and categorize dishonest website layouts, such as the "sneak into basket," which produced the fundamental concepts for future studies. This classification was later expanded by Narayanan et al. [1] through interviews with experts, revealing 12 ethical issues, among which were “compulsory continuity” and “interface interference.” Mathur et al. [20] provided comprehensive evidence for this by analysing 11,000 shopping websites and arriving at 15 categories of dark patterns. Their results showed the effect of manipulative user interfaces on cognitive biases, thus emphasizing the immediate need for fast, scalable, and automated detection systems.

Gunawan et al. [21] presented that the dark patterns are significantly different between conventional sites and mobile applications, which means that lying tactics differ based on the platform. These studies provided valuable background knowledge towards the definition and description of dark patterns but failed to present an implementable, machine learning-powered, quantifiable assessment system in real time. It is in this regard that the necessity to have an automated system that constantly identifies and analyses dark patterns on digital platforms arises. Research in the field of behavioural economics has deeply searched for the psychological reasons of why dark patterns are used. A. Golandaz and U. Sharma [9] showed the way the dark patterns capitalize on cognitive biases such as loss aversion and default effects, and Greenberg et al. [8] have pointed to their usage in spatial interfaces in terms of close interactions. Mobile app analysis by Brignull [4] discovered that 95% of apps are designed in a manipulative fashion.

The work by Nouwens et al. [22] focused on the study of GDPR consent pop-ups using web scraping to reveal huge fraudulent cases. All these studies demonstrate how dark patterns restrict user autonomy, but studies continue to be limited by the differences in susceptibility by demographic, especially in educational contexts. Current methods of detection have numerous issues related to scalability and are not effective in terms of extensive tracking. Newer machine learning concepts have prospects and need to be explored fully as suggested by Mathur et al. [20], but have limitations due to the existing data sets. The proposed work bridges this gap by using the language model, which is sophisticated. Additional related literature in misinformation detection by Soni et al. [23] depicted that BERT based models and sentiment characterization can achieve good performance in identifying and interpreting manipulative information on social media using natural language processing (NLP) based approaches in detecting trust-violating patterns.

Ready-to-train transformer architectures, such as BERT [13] and RoBERTa presented by Liu et al. [14], have greatly contributed to the understanding of language formations, especially where manipulative design hints are hidden in minor textual details. These models generate deep contextual settings and support specific classification adaptation, as given by Sun et al. [24]. The introduction of the ELECTRA model by Clark et al. [25] enhances training effectiveness using substituted token detection. Though generally used for NLP, such models have not been well studied in identifying dark patterns. In this paper, these architectures are being used for autonomous identification of fraudulent user interface designs. Trust and credibility are important to the online platform, particularly in the face of fake features of designs, such as dark patterns, which possess more power to impact user behavior.

Little and Green [26] presented a framework for trust that is based on concepts like faith and leadership that doesn't depend on formal titles, reliability, and being seen as an expert. This framework shows that the developers have an opportunity to promote informed decision-making via reliable design. P. Paithane [27] stressed the importance of a structure-based framework that relies on both interaction

and behavioural data to measure faith in the online setting. Most critically, Corritore et al. [28] came up with a scale that can be used to measure customer trust on websites in accordance with the fact that a reliable tool is lacking in gauging online trust. Bedi and Gaur [18] extended the knowledge of trust among agent systems by including dimensions such as usability, performance, integrity, and security. It is on these grounds that the need to incorporate trust modelling into the process of identifying manipulative interfaces is amplified.

Lanier [29] suggested user-focused platforms that give importance to transparency and independence, while T. Nyström and A. Stibe [7] highlighted the wider risks of surveillance-based design with their ethical assessment. The Department of Consumer Affairs of the Government of India has also provided official guidelines in 2023 prohibiting certain dark patterns. As noted by S. Han and C. Anderson [30] regarding methodological biases in digital research, technical challenges with data collection persist. Scalable and integrated automated measurement tools and trust appraisal are still minimal, especially in education, where fairness is of great importance. Building upon these insights, this study examines an integrated approach, which is a combination of transformer-based classification and a CI intended to detect, measure, and report manipulative design practices, which is crucial for strong assessment of trust in e-spaces.

III. MATERIALS AND METHODS

Detection of dark patterns is crucial for the sustainability of the digital platforms. As the manual methods for identification of dark patterns are neither effective nor scalable. This research proposes an automated framework for dark pattern detection using the BERT model. The first step of the proposed work involves the extraction of the relevant e-content followed by preprocessing to clean and standardize the text. An optimally adjusted BERT-based model is utilised to identify instances of dark patterns with accuracy. To assess the general reliability of the online platforms, the Credibility Index algorithm is presented that considers the frequency and the severity of the discovered patterns. Figure 1 demonstrates the suggested framework to predict the credibility of online platforms. The framework comprises of the following steps: Data Extraction, Preprocessing of data, Pre-Trained BERT Model, Fine-Tuning of Model, Segregation of Dark Patterns, and Computation of CI, which are explained below.

III.1 DATA EXTRACTION

Data extraction involves downloading the raw HTML content of the URL on the online platform with the help of web scraping software like BeautifulSoup and Scrapy. This may consist of descriptive information, user reviews and policy documents. The raw HTML content is then changed to structured form.

III.2 PREPROCESSING OF DATA

The extracted data is processed using preprocessing operations to make it suitable for machine learning tasks. The raw content is first cleaned, i.e. HTML tags, special characters and other irrelevant content such as advertisements or navigation menus are removed. Linguistic noise is eliminated by normalizing the text, turning all letters to lowercase, and eliminating stop words. Lastly, the text is divided into a set of separate words or phrases called tokens, which can be interpreted by the language model.

III.3 PRE-TRAINED BERT MODEL

BERT is a language model that provides the semantic meaning of text by looking at the preceding and succeeding words simultaneously. It is a two-way text-processing model that processes the text in both directions at once and enables to see the whole picture of each token. It has been trained on large-scale corpora, such as BookCorpus and English Wikipedia, to predict and identify relationships between sentences. In this paper, the BERT-base-uncased model is used because of its good performance in natural language understa nding and high transfer learning, making it appropriate for detection of the dark patterns. The extracted data is initially processed with cleaning and tokenizing operations and then sorted into a prediction set for fine-tuning the model.

III.4 FINE-TUNING BERT MODEL

Even though the pre-trained BERT model provides an outstanding initial point for understanding language in general, it needs to be fine-tuned for detecting and classifying dark patterns. Fine-tuning involves adjusting the learning parameters of a model based on domain-specific knowledge so that it can learn to pick up the finer linguistic details and contextual differences that may signal deceptive interface designs.

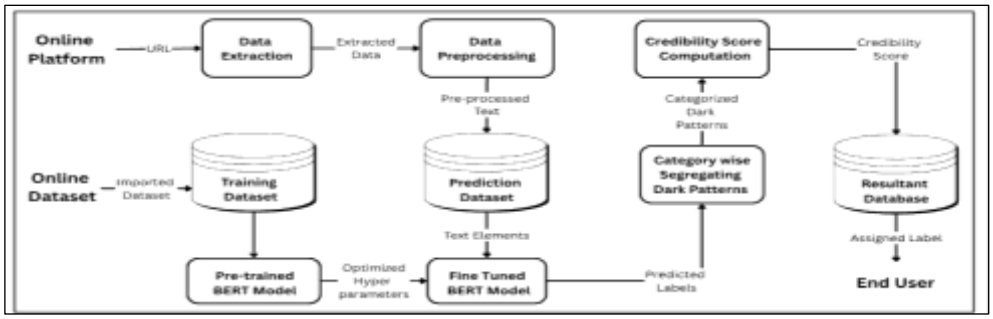

Figure 1: Proposed framework for determining the credibility of an online system.
Source: Authors, (2026).

At this step, the model does not change the transformer encoder architecture but instead changes the output layer by a task-specific classification head that is adapted to binary classification. The annotated dataset is trained with the optimal set of hyperparameters

so that the model can change the representations it learns based on the language and contextual clues that are commonly used in deceptive design.

III.5 SEGREGATION OF DARK PATTERNS

After identifying dark patterns with the help of the fine-tuned BERT model, these are classified according to the predefined taxonomies. This step is important in going beyond identification to find out the cause of the manipulative design. A labelled classification schema is used to map each instance to one of a set of predefined categories that enables the analysis without sacrificing the context of each manipulation strategy. This taxonomy helps to evaluate the behavioural capabilities of the interface of websites not only by their occurrence but specifically by the types of dark patterns used.

III.6 COMPUTATION OF CREDIBILITY INDEX (CI)

CI is a composite measure that shows the overall interface credibility of a platform based on the occurrence, frequency, and nature of dark patterns. It is calculated through the aggregation of weighted scores of identified dark patterns. Each dark pattern has been assigned a weight, which is based on empirical analysis and corresponds to the extent of loss the given dark pattern can bring. Weights may be procured from the domain experts. The proposed method uses the frequency (F) of each dark pattern and the weight of the dark pattern to derive a Severity Score. The values of the severity score and CI are computed using Eq. (1) and (2), respectively.

$$\text{Severity } Score = \left\{ \sum_{i=1}^{\lambda} (F_i \times W_i) \right\} \tag{1}$$

$$Credibility\ Index = 1 - Severity\ Score \tag{2}$$

Where:

- F_i – Frequency of the i^{th} dark pattern
- W_i – Weight of the i^{th} dark pattern
- λ – Type of unique dark patterns

Algorithm 1: Computation of credibility index.

Let Fi be the frequency of the i^{th} dark pattern, λ represent the maximum possible number of dark pattern types detectable by the system, and let W_i be the weight of the i^{th} dark pattern on the webpage.

for i = 1 to λ do

*SeverityScore ← SeverityScore + (Fi * W_i)*

end

CredibilityIndex ← 1 – SeverityScore

Return CredibilityIndex ∈ [0, 1]

Source: Authors, (2026).

Essentially, the Severity Score measures the disbelief on a digital platform in terms of the footprint of dark patterns, while CI is the extent to which the interface of a platform is trustworthy. The pseudocode of appraising the CI on the basis of the occurrence and severity of the dark patterns identified is given in Algorithm 1. The final value of CI lies between 0 and 1, which indicates the credibility of an online platform. More value of CI indicates a highly trustworthy site and vice-versa. It helps users to make wise choices and promotes the establishment of more equitable and transparent digital landscapes. A threat level is assigned to each website using CI to support the interpretation. CI is computed for each of the webpages of the site, and an average is taken to assign an overall threat level to the platform. Three levels of threat—*Safe*, *Moderate* and *Critical* are assigned, with *Critical* being the most manipulative design. The classification enables users to be aware of potential risks associated with the online systems.

IV. IMPLEMENTATION AND RESULTS

To see the application of the proposed framework, the bespoke website *SkillNest*, consisting of three webpages with a variety of dark patterns to allow more comprehensive and realistic evaluation, was created using Python at the backend for extracting and processing data and running algorithms. The user interface was designed using JavaScript, HTML, and Flask. And MySQL was used as the structured data storage, which guarantees the efficiency and scalability. The proposed framework aimed at categorizing seven classes of dark patterns, which are chosen due to their significance and frequency in digital user interfaces [20]. These are discussed in brief.

1. *Sneaking*: The deliberate concealment or omission of critical information to mislead users, such as hiding additional charges until the final checkout stage.
2. *Urgency*: It induces fake time constraints and forces them to take impulsive decisions.
3. *Misdirection*: Visual or textual indicators are provided to distract their attention away from relevant content, often leading them to take inadvertent actions.

4. *Social Proof*: It exploits users' psychological nature to follow others in unseen or unknown situations by showing fake or exaggerated data influencing the users' decisions.
5. *Scarcity*: It persuades the users by displaying limited stock available regardless of the actual availability.
6. *Obstruction*: It creates impediments to user workflows, thus intentionally obscuring crucial actions like subscription cancellations or privacy setting modifications.
7. *Forced Action*: It compels users to perform tasks such as mandatory account creation before accessing content or services. that are not directly relevant for accessing the primary intent,

These design patterns are often used to influence the user choices in a subtle or coercive manner. Each category of dark pattern targets a particular form of deception and could be beneficial for interface-based manipulation. Such a categorization schema is essential for model training, as well as credibility computation. The framework allows analysing manipulative design strategies in a granular and consistent manner by mapping identified patterns to particular behavioural strategies and improving the intelligibility and the responsibility of the detection system. The next step after the classification is the technical implementation of the framework with a strong system architecture. The proposed system used the following architecture:

1. *Content Extraction & Preprocessing*: Raw HTML content of the website SkillNest is scraped, parsed, and cleaned to retain relevant text and semantic elements.
2. *Model Integration*: A fine-tuned BERT model identifies and classifies textual elements indicative of dark patterns.
3. *Database Storage*: Model predictions, metadata, and user feedback are stored in a MySQL database.
4. *Interface Layer*: The front end is a Flask-based application that links the users to the backend services through the use of the HTTP paths so that users interact seamlessly with the real-time outcomes.

An uncased BERT model was fine-tuned utilising TensorFlow 2.0 plus the Transformers library in a Python environment and was used for the classification process. A snapshot of the implementation is presented in Figure 2.

```
train_InputExamples, validation_InputExamples = convert_data_to_examples(
    train, test, DATA_COLUMN, LABEL_COLUMN
)

train_data = convert_examples_to_tf_dataset(list(train_InputExamples), tokenizer, max_len=128)
train_data = train_data.shuffle(100).batch(16)

validation_data = convert_examples_to_tf_dataset(list(validation_InputExamples), tokenizer, max_len=128)
validation_data = validation_data.batch(16)

model.compile(optimizer=tf.keras.optimizers.experimental.AdamW(learning_rate=3e-5, weight_decay=0.01),
              loss=tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True),
              metrics=['accuracy'])

model.fit(train_data, epochs=3, validation_data=validation_data)
```

Figure 2: The BERT classifier configuration parameters.
Source: Authors, (2026).

A labelled dataset [20] was utilised from the publicly available Yamana Lab repository [31] to fine-tune the BERT model. The resulting data set consisted of a combination of manipulative and non-manipulative elements of UI text, each of which was labelled as either dark (1) or not dark (0) by domain experts having knowledge of interface design and regulatory standards. Some of the examples of dark patterns found in the dataset were sneaking, urgency messages, social proof, forced action, and obstruction, and the non-dark patterns included transparent consent prompts and user-respecting design choices. To confirm the practical relevance of the trained model, an operating assessment pipeline was created in Python. This included the process of loading the fine-tuned classifier, preprocessing text found within HTML, and outputting predictions to find out the dark patterns. The 5-fold cross-validation was used to train the classifier so that it can generalize and minimize overfitting.

Every fold was trained on part of the data, and the remaining data was used for validation. This trial process was used to achieve the stable performance and emphasized the capabilities of the model to recognize obscure manipulative signals and context-sensitive wording that are employed in dark patterns. Table 1 provides the optimal hyper-parameter configuration that was used to fine-tune the BERT classifier, with the decisions being made based on performance and efficiency. The length of the maximum sequence was fixed to 128, which is the highest number of tokens that were handled each time a single input is given. *AdamW* optimizer is a weight decay adaptive optimization algorithm that was used in updating parameters. The classification objective function—*Cross-Entropy Loss* was used. The training was done in three epochs, and the architecture consisted of twelve transformer encoder layers. The number of samples processed by an update was set to 16.

Training was done with a fixed learning rate of 3×10^{-5}. An activation function—*GELU* was applied to allow nonlinear transformations. The model was evaluated using a five-fold stratified cross-validation method to maintain the balance in classes across folds. The regularization was carried out using a dropout rate of 0.1 in order to minimize overfitting. The system was combined into a lightweight Flask web server to facilitate real-time interaction. The requests were received by POST, processed by the backend (BERT predictions), and re-emitted back to the frontend to be displayed. This arrangement enabled the user to study webpages as they loaded with the feedback on deceptive patterns on the page. The core of the prediction process is the specialized BERT model, which outputs whether a phrase has a dark pattern or not. In case a pattern is identified, the model also categorizes it with the use of multi-label classification. This last step bridges the gap between detection and interpretability because users and researchers can interpret not only the existence of manipulation but also the nature of the applied deceptive strategy.

A CI was calculated on a one-on-one basis for each of the webpages of the *SkillNest* website. The index was computed using Algorithm 1, and values were stored in a MySQL database, which has scaled values across websites and user sessions and allows efficient access and retrieval of values that may be analysed further. To supplement the classification process, the framework was tested with the help of 5-fold cross-validation of the fine-tuned BERT classifier. The standard measures of classifier effectiveness—Accuracy, Recall, Precision, and F1-score were utilised. Accuracy is a measure of the correct predictions, and it gives a rough measure of the effectiveness of the model. Recall, or sensitivity, is the ability of the model to identify all true instances of dark patterns, which reduces false negatives. Precision is the frequency of the patterns that are actually represented by the model and minimize false alarms.

The F1-score represents the harmonic mean of the Precision and Recall in a single value, trading off one of the types of errors. Collectively, these measures provide a balanced evaluation of the capacity of the classifier in identifying manipulative patterns of the content presented in the websites. Table 2 summarises the results. To maximize the interpretability of the CI, the framework uses the notion of normalized Severity Scores, which measure the extent of damage each type of dark pattern causes. A survey was conducted with ten participants, comprising seven academicians with expertise in e-learning systems and three domain experts in digital ethics and online consumer protection, to derive the severity scores for the educational website *SkillNest* on a scale of 0—1. The participants evaluated significant dark patterns identified by Mathur et al. [20] for their applicability to educational platforms. These patterns were assigned weights based on cost, time, and effort required to evaluate the dark pattern, where cost refers to the potential financial loss imposed on users if a dark pattern successfully misleads them. Effort and time denote the additional effort and duration users spend to identify, understand, and evade the dark pattern. The final weight values for each dark pattern are presented in Table 3.

Table 1: Hyper-parameter settings of the BERT classifier.

Hyper-Parameters	Optimal Value
Max. Sequence Length	128
Optimizer	AdamW
Loss Function	Cross Entropy Loss
No. of Epochs	3
No. of Layers	12
Batch Size	16
Learning Rate	3e-5
Activation Function	GELU
Training Strategy	5-Fold Stratified Cross Validation
Dropout	0.1

Further, the proposed framework was used for finding and analysing dark patterns in a realistic but controlled setting. The content of the websites was pre-processed in a methodical manner removing HTML tags, scripts, repeated lines, and other invalid bits in order to make clean and pertinent input in the analysis. Figure 3 shows the interface of the educational website that was developed and demonstrates the way the embedded dark patterns can be incorporated into the familiar layouts. The snapshot is a representation of design norms that can be observed in a very large variety of educational platforms. This real-world background enhances the validity of findings by showing how the manipulative design may work well in a real-world environment. The observed dark patterns were subsequently employed to calculate a CI, which indicates the fairness and reliability of the overall structure of the platform.

(a) Webpage 1. (b) Webpage 2. (c) Webpage 3.
Source: Authors, (2026).

To give some context to the calculated credibility indices on the analysed cases, a system was prepared that categorized the websites into specific levels of threats in consultation with academicians and domain experts. This system relies on the average value of CI, which is the summation of the index values of all the webpages on the website. Based on this, every website can be rated as one of three levels— *Safe*, *Moderate*, and *Critical*, considering its general credibility and how deceptive features of design can affect the trust of the users and jeopardize online security. As shown in Table 4, a CI value between 0.86 and 1.00 is regarded as *Safe*, meaning that there is slight use of dark patterns of low severity and frequency. The interfaces in this range are usually transparent, just, and harmless for users to interact with. A CI value between 0.61 and 0.85 is classified as *Moderate* indicating the existence of moderately severe dark patterns or a comparatively concentrated mass of manipulation tactics that might quietly undermine user trust. Lastly, the score that falls below or at 0.60 is considered *Critical*, meaning that there is high usage of severe dark patterns with a high density. Potentially harmful possible interfaces in this range raise serious issues of ethical design and user control.

Table 4: Credibility Index Thresholds and Associated Threat Levels.

.No.	Mean Index Range	Threat Level	Implication
1	0.85 <	Safe	Minimal dark patterns, negligible threat.
2	0.60 < Credibility Index ≤ 0.85	Moderate	Be wary and take decisions carefully.
3	≤ 0.60	Critical	Highly manipulative and can't be trusted.

Source: Authors, (2026).

Webpage 1 shown in Figure 3(a) showed the least amount of deception, with 4 instances of the *Sneaking* dark pattern detected in 30 phrases of the content. This trend is not pronounced and is rare, but it gives a high CI value of 0.94. The content on the webpage seems open and trustworthy, which is not very threatening to users and has a high credibility with a minimum number of low-severity dark patterns. The webpage is designated as *Safe*. -Webpage 2 shown in Figure 3(b) contains a lot of deceit, with 3 instances of dark patterns *Obstruction* and 1 instance of *Social Proof*. The severity and intensity of these patterns were too high, resulting in a significant low value of CI as 0.777 and was classified as *Moderate*. The level of deception in webpage 3 shown in Figure 3(c) was observed as *Critical*, with 8 cases of dark patterns, including 5 instances of *Misdirection* and 3 instances of *Forced Action*. This is evident by the value of CI as 0.213, which shows a severely deceitful webpage, and should be avoided. The frequency and diversity of patterns are very misleading that decrease the levels of user trust. The evaluation of the website SkillNest is summarized in Table 5.

Table 5: Summary of evaluated webpages.

Webpage	**Dark Pattern Types Identified**	**Severity Score= (Frequency * Weight)**	**CI = 1-Severity Score**	**Interpretation**
Webpage 1	Sneaking-4	4*0.015=0.06	0.94	Less severe dark patterns; credibility is very high, and the web page seems to be trustworthy.
Webpage 2	Obstruction-3, Social Proof-1	3*0.019 + 1*0.166 = 0.223	0.777	Same number of patterns as in page1 but more severe; moderately deceitful.
Webpage 3	Misdirection-5, Forced Action-3	5*0.155 + 3*0.004 = 0.787	0.213	A high amount of deception and lack of credibility may be destructive.

Source: Authors, (2026).

The website SkillNest is considered to be a *Moderate* site, according to the average value of the CI as 0.643. It is prone to many threats and is less difficult to navigate without facing dark patterns. The proposed framework is able to identify and measure the impacts of dark patterns on educational sites. It offers easy-to-interpret credibility indexes by using a fine-tuned BERT model and severity-based score to enable users to make informed decisions.

V. CONCLUSIONS

This work introduced an automatic, online system for finding and analysing dark patterns that are present on online educational systems. The majority of research on manipulative interface design has focused in the fields of social media, and e-commerce, leaving their existence and impact in academic contexts largely unexplored. Since education is very dependent on trust and transparency, interpretation and preventing manipulation on educational sites is very essential. A novel framework is designed to identify dark patterns on educational systems, estimate their potential damage, and quantify trust in a definite and explicable way. The proposed system incorporated automated web scraping, high-level text processing, NLP, and a fine-tuned BERT model. This is done to identify manipulative designs that are included within education web interfaces. Besides identification of the dark pattern, the system divides these patterns into various categories to obtain a better view of the specific misleading patterns used. Additionally, a CI was introduced as a quantifiable measure that reflects the frequency and the severity of observed patterns on the websites. Weights were assigned to the dark patterns according to their potential to cause harm to user trust. Based on the value of CI, the educational systems were assigned the threat levels such as *Safe*, *Moderate* or *Critical*. These labels may help the users to make an informed decision about visiting or preventing the site.

ABSTRACT

The performance of PVD coated carbide inserts for various machinability aspects during machining of hardened alloy steel AISI 43100, under a dry cutting environment. Spindle speed, feed, and depth of cut were considered as major governing parameters. Workpiece surface roughness, machining forces (Fx, Fy, Fz) were taken as measures of the performance estimation of PVD coated (Ti16Zr)cutting inserts in this work. All the input variables were observed to have influence over workpiece surface roughness and cutting forces in the case of coated carbide inserts. In the current research, the effects of machining parameters on the dry turning rotation of the SS43100 with uncoated and Ti16Zr coated tool inserts have been investigated and the optimal machining specifications are computed using the Taguchi L27 experimental design. The Regression analysis with regression equations is mentioned and inspected the significance of individual factors for responses. The machining operations can be performed at a higher spindle speed(250r.p.m.,450 r.p.m.,650 r.p.m.),feed (0.085mm/rev,0.2 mm/rev, 0.45 mm/rev), depth of cut(0.2mm,0.3mm,0.4mm) without compromising results when cermets inserts are used. Carbide exceeded the performance on cutting force and workpiece surface roughness, though carbides outperformed regarding feed and cutting force(FY). The depth of cut was found to be the most significant when feed and cutting forces were concerned, while it was true for radial force using carbides. Speed affected workpiece surface roughness the most. Feed was the most important parameter while the surface roughness of the workpiece was taken into account.

I. INTRODUCTION

According to Pal et al. [1] machining of work piece material having hardness up-to 45 HRC is treated as soft machining. On the other hand, machining of work piece having hardness in the range of 45-70 HRC is considered under hard machining . They have done turning operations on AISI 4340 steels of hardness values 35, 45, 55 HRC with the help of mixed alumina ceramic tools. Harder work piece resulted in higher cutting forces, higher tool-chip interface temperature but lower surface roughness. Surface roughness was more prominently affected by feed rates whereas radial forces by the depth of cut. Cutting speed and depth of cut were more significant when it came to average chip-tool interface temperature. This finding is in line as per the experiments done by Chinchanikar and Choudhury [2] on AISI 4340 steel with single-layer TiAlN coated (PVD) and multi-layer TiCN/ Al2O3/ TiN coated (CVD) carbide tools [3]. They have seen the chip-tool interface temperature to increase rapidly with cutting speed, slightly with feed but to remain almost same with the depth of cut. Moreover, the temperature was found to be greater in case of CVD coated tools than PVD coated ones.

They have also developed a mathematical model to predict chip-tool interface temperature which was valid over a wide range of cutting conditions[4]. D'Errico et al. [5] used uncoated and TiN, Ti(C,N) coated cermet inserts with and without chamfered edge in

continuous and interrupted turning operation of SAE 1045 steel. From the experimental results they concluded that PVD coated inserts without chamfered edge performed well only in continuous turning rather than interrupted turning [6]. Furthermore, they stated that tools with chamfered edge are better for interrupted turning where the high depth of cut is involved. There was no significant effect of coating on tool life irrespective of their cutting edges in interrupted turning. Suresh R [7] worked on the capabilities of TiN coated cermet tools on high speed machining of austenitic stainless steel. SEM images discovered that the failure of cutting edges of cermet tools started with micro-cracks which grew gradually to cause the tool failure due to low fracture toughness.

It gave satisfactory results to use cermet tools while machining at low speed, feed and depth of cut because of good surface finish and long tool life. Selvaraj D. Philip [8] the authors recommended to keep the cutting speed under 300 m/min, feed rate under 0.2 mm/rev and depth of cut under 0.3 mm to have a satisfactory tool life. The similar point of view was shared by Noordin et al. [9] who found the tool life of TiCN based cermet inserts to be highest at low cutting speed and feed rate. [10] However, the performance of coated carbides was superior at medium and high cutting speed and feed. Also, from the experimental results, they observed that with an increase in negative side cutting edge angle, tool life increased. But, Sahoo A. et al. [11] showed there is a decrease in tool life and surface finish with increasing negative rake angle. This was due to increase in cutting force and excessive heat generation.

[12]Tool life was also dependent on the speed of cutting. At high speed, tool life was shorter but at the same time, the surface finish was found out to be finer. H. Hong et al. [13] investigated on the wear mechanisms in the end milling with wet machining operation of steel and titanium alloys steel using TiN coated carbide and uncoated cermet inserts. Håkan Tahoor's, H [14] They assessed that the flank wear at the flank face predominantly controlled the tool wear phenomenon. Besides, they observed that the time taken by coated carbides to initiate cracking and fracturing is more than that of uncoated cermet. [15] They also concluded with low cutting parameters, uncoated cermet's experience more uniform and gradual wear compared to coated carbides. Autor performed various experiments by using Taguchi method on material SS431and optimize surface roughness by PVD coated TiZr tool [16].

II. MATERIALS AND METHODS

Selection of optimal parameters was carried out by performed number of pilots experiments, discussion with manufacturing industry experts. Range finalized for final experiments shown in table 1 . Input parameters are cutting speed, feed and depth of cut. Output parameter is surface roughness (Ra) . These experiments were performed on HMC Lathe machine MONO 200XL . Std. CNC machine capacity has turning Dia. Mm 200, Swing Over Bed Mm 500 , Max. Turning Length Mm 700, Dist. Between Center Mm 750.

Figure 1: ITI surf test RS 232" (make: ITI, India) surface roughness tester.
Source: Authors (2026).

Coated carbides are Tungsten, Cobalt based, designated by CNMG120408EN The shape of the inserts was rhombic (80º point angle) specific chip breaker geometry which was mounted on tool holder of ISO designation PSBNR 2525M12 as shown in Fig. The tool holder has the following cutting geometries i.e. clearance angle = 0º, back and side rake angle = -6º, entering angle = 75º, point angle = 90º and nose radius = 0.8 mm.Roughness Ra value of machined sample is measured using "ITI surf test RS 232" (make: ITI, India) surface roughness tester. Cutting inserts were Tungsten carbide. PVD coating method was used for coating inserts by Calo technique. Researchers were selected different combination of material, here Ti16Zr used for coating. Hardness of this material and anti corrosion properties are more affected for surface finish for parent material.

III. RESULTS AND DISCUSSIONS

Parameters. Developed models are used for prediction and validation (confirmation) experiments. In confirmation experiments predicted results are compared with experimental results. With the help of regression equation obtain best optimum value for surface roughness from output response . From the conformation experiments for the surface roughness, we select the set of parameters for first experiment are cutting speed 650r.p.m. feed .45mm/rev and depth of cut .3mm. The experimental value obtain are 1.412µ and 2.321µ while predicted surface roughness value is 1.039µ. Error identified for this first set of experiment is 0.8275%. We have repeated this procedure for remaining three sets of experiments and identified error -0.0345%, 0.543% and 1.079%. At the end of experiments for surface roughness we conclude that the errors are less than 10% which shows that the confirmation tests results are adequate with cutting speed 650 r.p.m , feed 0.45mm/rev and depth of cut 0.3 mm.for optimum value of surface roughness.

Source: Authors (2026).

Table no 2 shown Regression analysis of RA done with the help of MINITAB software. Total no of degree of freedom were 26. Maximum significant factor was cutting speed. Secondary factor is feed which have p-value less than 0.005.

Table 4: Model Summary.

S	R-sq	R-sq(adj)	PRESS	R-sq(pred)
0.215099	94.38%	92.35%	1.44360	98.81%

Source: Authors (2026).

Regression R-sq(adj) and R-sq (pred) values are displayed in the model summary. Greater than 90% for the coefficient of determination R-sq value unambiguously shows that the models are suitable for use in the future.

Very little variation exists between R-sq(pred) and R-sq(adj). Table 3 represents a safe number for the coefficient of determination indicates that the model created for surface roughness using the combinations of the input parameter sets is sufficient

RA=3.285 - 0.002697 Cutting Speed - 0.888 Feed - 0.311 Depth of cut

Regarding PVD coated (Ti16Zr) carbide tool inserts, regression equation models are created independently for each of the output responses. obtained the optimal values for additional input parameter combinations. Experiments involving prediction and validation (confirmation) employ developed models. Predicted and experimental findings are contrasted in confirmation experiments. Obtain the greatest possible value for surface roughness from the output response with the aid of the regression equation.

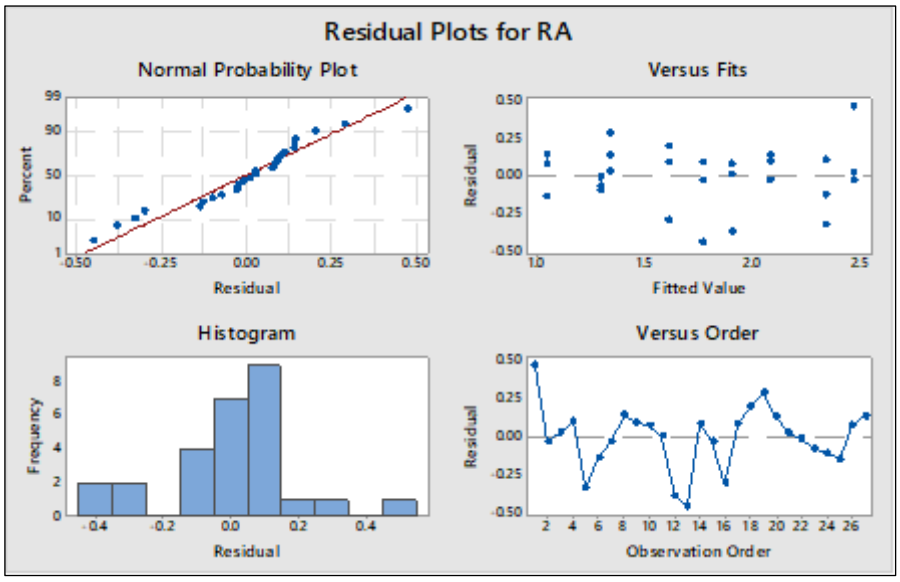

Figure 2: Residual plots for Ra.
Source: Authors (2026).

In above residual shows number of combinations which have interaction plots in between various input responses. Total combination of interactions are shown in graphically in above figure 2.

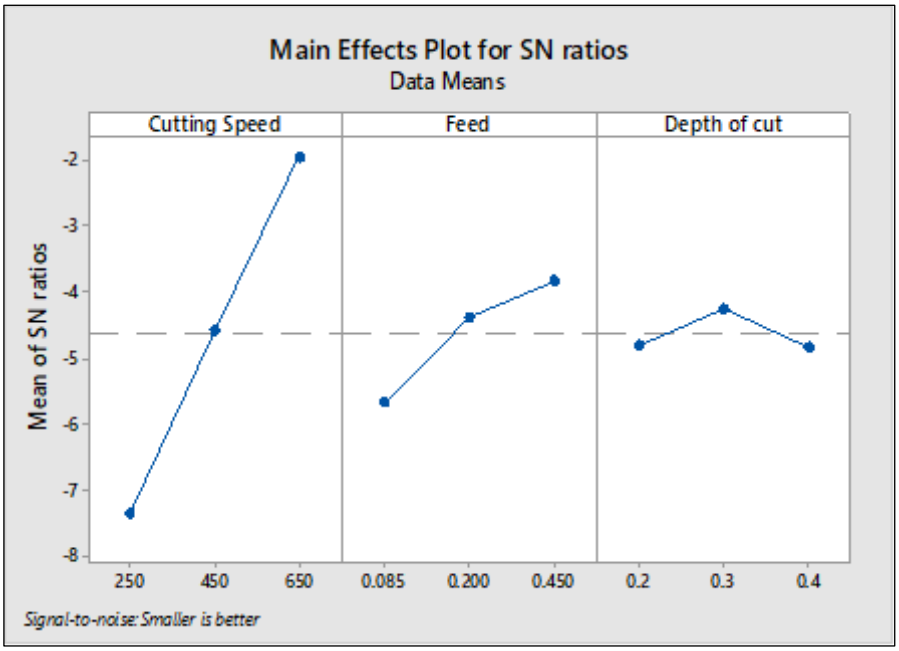

Figure 3: Main effects plot for signal to noise ratio for RA.
Source: Authors (2026).

From figure 3 shows that best value for surface roughness RA is obtained at 250 r. p.m. cutting speed , feed is 0.085 mm/rev, depth of cut is 0.3 mm experiments cutting speed is most dominant parameter which affects the value of surface roughness. Martensitic AISI SS43100 is hard to cut material if we increase cutting speed then the friction increased in between tool and work piece material. With this temperature increase at zone of machining also so it is directly affect the value of surface roughness. In pilot experiments the

effects of feed is very important it was main factor for machining, now cutting speed is most dominant factor for machining. These graphical analysis of different parameters were shown in above fig.3. Table no 4 shows confirmation experiments for roughness.

Table 5: Confirmation experiments for RA.

Sr. No.	Cutting speed	Feed	Depth of cut	Exp.RA	Pred RA	Mean RA	ERROR (mean-pred)

IV. CONCLUSIONS

From above fig. 5 shows comparison between Predicated value of RA and Mean value of RA the result table of ANOVA demonstrates that the most important surface roughness factors (RA) Models of correlation for surface roughness are developed by Ti16Zr-coated carbide inserts. Final experiments have been carried out L27 for the individual parameters, the determination of coefficient value has been found for surface roughness is 92.35%.

ABSTRACT

Named Data Networking (NDN) revolutionizes content-centric communication through intrinsic in-network caching, yet optimal cache management remains challenging under dynamic content popularity and resource constraints. This paper introduces GT-DRLCache, a novel framework that synergistically integrates non-cooperative game theory with multi-agent deep reinforcement learning (MADRL) for intelligent caching decisions. We formulate the distributed caching problem as a stochastic congestion game with provable Nash equilibrium existence. Each router employs a hybrid Double-DQN/Proximal Policy Optimization (PPO) agent that learns equilibrium-aware caching strategies while adapting to temporal traffic patterns. Extensive simulations using ndnSIM 2.8 on GEANT, Abilene, and synthetic Barabási-Albert topologies demonstrate consistent performance improvements: 32–56% higher hit ratios, 28–44% latency reduction, and up to 50% upstream traffic savings compared to LRU, LFU, MPC, ProbCache, and DRL-only baselines. This work provides comprehensive theoretical foundations, complete algorithmic implementation, and thorough experimental validation of the proposed unified caching framework.

I. INTRODUCTION

The exponential growth of content-centric applications—streaming video, Internet of Things (IoT) data dissemination, and immersive metaverse experiences—has exposed fundamental limitations of traditional host-centric Internet architecture. Named Data Networking (NDN) emerges as a promising information-centric networking paradigm that shifts the architectural focus from where (host location) to what (content itself) by naming data directly rather than their physical locations [1]. This fundamental architectural transformation enables intrinsic in-network caching at every router, potentially revolutionizing content distribution efficiency and network resource utilization. Despite this compelling theoretical advantage, practical NDN deployment faces significant caching optimization challenges that have attracted considerable research attention. First, volatile and non-stationary content demand patterns make static caching policies ineffective [2].

Second, stringent storage capacity constraints at intermediate routers necessitate intelligent cache replacement decisions. Third, strategic competition among selfish routers maximizing individual utility creates coordination problems in distributed environments. Fourth, complex temporal dependencies in content popularity require adaptive learning mechanisms [3]. Finally, the lack of effective coordination mechanisms in distributed caching environments leads to content redundancy and suboptimal global performance. Classical caching policies like Least Recently Used (LRU) and Least Frequently Used (LFU) offer implementation simplicity but demonstrate suboptimal performance under dynamic network conditions [4]. Probabilistic approaches such as ProbCache [5] and predictive methods like Most Popular Content (MPC) [6] incorporate sophisticated heuristics but fundamentally lack real-time adaptability to changing traffic patterns.

Recent deep reinforcement learning (DRL) solutions [7], [8] enable learning from environmental feedback but often exhibit slow convergence and lack stability guarantees in multi-agent settings where multiple routers learn simultaneously. Game theory provides powerful analytical tools for modeling strategic interactions and characterizing equilibrium behavior in distributed systems [9]. However, traditional game-theoretic caching models typically assume static environments and complete information availability, significantly limiting their practical applicability in dynamic NDN scenarios. This paper bridges this critical gap by proposing GT-DRLCache, a novel hybrid framework that synergistically combines DRL's adaptive learning capability with game theory's equilibrium stability guarantees. The central research question addressed in this work is: How can we design an intelligent distributed caching system that simultaneously achieves adaptive learning from dynamic environments and strategic equilibrium in multi-router NDN networks?

To answer this question, we establish three primary research objectives. First, formulate distributed NDN caching as a finite stochastic potential game with provable pure Nash equilibrium existence. Second, develop a hybrid Double-DQN/PPO multi-agent architecture that enforces equilibrium-aware caching decisions through potential-based reward shaping. Third, validate the proposed framework through comprehensive simulations on realistic network topologies with detailed comparative analysis against state-of-the-art baseline methods. The research hypothesis posits that integrating game-theoretic equilibrium constraints with deep reinforcement learning will yield superior caching performance compared to either approach in isolation. The importance of this study lies in providing both theoretical foundations and practical solutions for intelligent content distribution in future information-centric networks. The primary limitation is the computational overhead during the training phase, though inference remains efficient for real-time deployment.

II. THEORETICAL REFERENCE

II.1 NAMED DATA NETWORKING FUNDAMENTALS

NDN's data-centric model relies on two packet types: Interest and Data. When a Data packet returns, routers can cache it based on their caching policy [1]. The core optimization problem is deciding what to cache and when to evict content to maximize metrics like cache hit ratio and minimize latency under storage constraints.

II.1.1 Traditional NDN Caching Strategies

II.1.1.1 NDN Architecture and Caching Mechanisms

Named Data Networking represents a paradigm shift in Internet architecture design, focusing on named content rather than host addresses. In NDN, communication is receiver-driven through Interest packets that request content by name, and Data packets that carry the requested content back to requesters [1]. Every NDN router maintains three key data structures: the Content Store (CS) for caching retrieved content, the Pending Interest Table (PIT) for tracking forwarded Interest packets, and the Forwarding Information Base (FIB) for routing decisions based on name prefixes. The intrinsic caching capability of NDN enables any router along the delivery path to cache and serve content, fundamentally different from traditional content delivery networks where caching occurs only at designated edge servers [2]. This ubiquitous caching architecture creates both opportunities and challenges. The opportunity lies in dramatically reducing content retrieval latency and network traffic through strategic content placement. The challenge emerges from the need to coordinate caching decisions across distributed routers with limited storage capacity and incomplete information about global network state [10].

II.1.2 Traditional NDN Caching Strategies

Early NDN caching research focused on adapting classical replacement policies developed for CPU caches and web proxies. LRU maintains a temporal ordering of cached content and evicts the least recently accessed item when cache capacity is reached [11]. LFU tracks access frequency and removes the least frequently accessed content during replacement [11]. First In First Out (FIFO) simply evicts the oldest cached item regardless of access patterns. While these policies offer implementation simplicity and low computational overhead, they perform suboptimally under variable demand patterns characteristic of real-world content distribution [4].Recognizing these limitations, researchers proposed NDN-specific caching strategies.

ProbCache introduces probabilistic caching where the probability of caching content decreases with distance from the content source, aiming to reduce redundant caching along delivery paths [5]. The Betweenness Centrality (Btwn) strategy leverages network topology information to cache popular content at strategically important routers with high centrality [12]. MPC employs Markov chain prediction to forecast future content popularity based on historical access patterns, proactively caching content expected to be requested [6]. Despite these improvements, heuristic approaches fundamentally lack the adaptability required to handle non-stationary traffic conditions and dynamic popularity shifts that characterize modern content distribution workloads [13].

II.2 REINFORCEMENT LEARNING FOR CACHING

II.2.1 Fundamentals of Deep Reinforcement Learning

Reinforcement Learning (RL) provides a mathematical framework for sequential decision-making under uncertainty, where an agent learns optimal behavior through trial-and-error interaction with an environment [14]. The agent observes environmental states, selects actions according to a policy, receives rewards indicating action quality, and transitions to new states. The learning objective is to discover a policy maximizing expected cumulative discounted reward over time. Deep Reinforcement Learning extends classical RL by employing deep neural networks as function approximators, enabling learning in high-dimensional state and action spaces infeasible for tabular methods [15]. Q-learning represents a fundamental value-based RL algorithm that learns an action-value function Q(s,a) estimating expected cumulative reward for taking action a in state s and following the optimal policy thereafter [16]. Deep Q-Networks (DQN) approximate Q-functions using deep neural networks, introducing experience replay and target networks to stabilize training [17]. Double DQN addresses Q-value overestimation bias by decoupling action selection and evaluation [18].

Policy gradient methods directly optimize parameterized policies, with Proximal Policy Optimization (PPO) providing stable updates through clipped surrogate objectives [19].

II.2.2 RL Applications in Network Caching

The application of reinforcement learning to network caching problems has gained significant research attention. Early Q-learning approaches demonstrated promising results in single-agent caching scenarios but suffered from poor scalability to large state spaces encountered in realistic networks [20]. Deep reinforcement learning solutions leverage neural network function approximation to handle high-dimensional state representations encompassing content popularity, cache occupancy, and network conditions [7]. Multi-agent reinforcement learning (MARL) extends RL to scenarios with multiple simultaneously learning agents, naturally matching distributed caching architectures where each router independently makes caching decisions [8]. However, MARL introduces additional challenges including non-stationarity, where each agent's learning affects the environment dynamics observed by other agents, and coordination difficulties in achieving globally optimal outcomes without explicit communication [21]. Independent Q-learning, where agents learn independently treating others as environment components, often leads to suboptimal solutions and training instability [22].

II.3 GAME THEORY FOR DISTRIBUTED CACHING

II.3.1 Game-Theoretic Modeling Fundamentals

Game theory provides mathematical models for analyzing strategic interactions among rational decision-makers, offering tools to characterize equilibrium behaviors and predict system outcomes [9]. A strategic game consists of players (decision-makers), strategies (available actions), and utility functions (payoffs) mapping strategy profiles to real-valued outcomes. Nash equilibrium represents a central solution concept where no player can improve their utility through unilateral deviation, capturing strategically stable outcomes [23]. Potential games constitute an important game class exhibiting strong equilibrium properties. An exact potential game admits a potential function where the change in any player's utility from unilateral deviation equals the change in the potential function [24]. The existence of a potential function guarantees pure strategy Nash equilibrium existence and enables convergence analysis for learning dynamics. Congestion games, where player utilities depend on resource congestion levels, form a natural potential game subclass relevant to caching scenarios [25].

II.3.2 Game-Theoretic Caching Models

Game theory has been extensively applied to distributed caching problems. Pricing games model cache resource allocation through pricing mechanisms that incentivize efficient content placement [26]. Coalition formation games address cooperative caching where routers form coalitions to collectively store and share content [27]. Redundancy control games explicitly model content duplication costs and design utility functions penalizing excessive replication [28]. Mean-field game approximations handle large-scale caching systems by modeling individual routers' interactions with aggregate population statistics rather than explicit consideration of all players [29]. Stackelberg games capture hierarchical caching architectures with leader-follower structures common in content delivery networks [30]. Despite these theoretical advances, existing game-theoretic caching models typically assume static environments with fixed content popularity and complete information availability, limiting practical applicability to dynamic NDN scenarios [13].

II.4 HYBRID LEARNING-GAME APPROACHES

Recent research explores synergistic combinations of reinforcement learning and game theory. In wireless edge caching, multi-agent reinforcement learning combined with game-theoretic equilibrium concepts demonstrated improved convergence speed and solution quality compared to pure learning or game-theoretic approaches [31]. Federated learning frameworks enable distributed caching optimization while preserving data privacy through local model training and aggregated updates [32]. Mean-field MARL approximates large-scale multi-agent systems by modeling individual agent interactions with mean-field population statistics, significantly reducing computational complexity while maintaining performance [33]. However, these hybrid methods have not been comprehensively adapted to NDN's unique characteristics including name-based routing, universal caching capabilities, and specific forwarding mechanisms [34].

This paper addresses this gap by developing GT-DRLCache specifically designed for NDN distributed caching with rigorous game-theoretic foundations and practical DRL implementation. While [31] combines MARL with game theory for wireless caching, it assumes centralized coordination unavailable in NDN. Reference [33] uses mean-field approximations unsuitable for NDN's moderate-scale networks where individual router interactions matter. Our work uniquely addresses NDN's specific constraints through: (1) potential game formulation capturing NDN's content-centric forwarding, (2) hybrid DDQN/PPO architecture stable under NDN's dynamic popularity patterns, and (3) practical coordination protocol operating with local information Exchange.

III. MATERIALS AND METHODS

III.1 SYSTEM MODEL

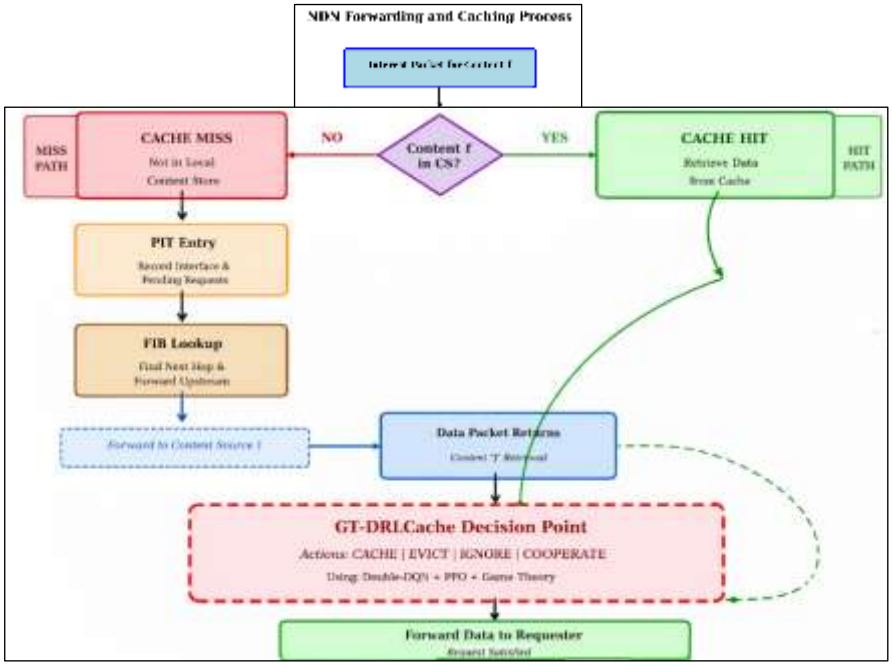

Figure 1: NDN Forwarding and Caching Process.
Source: Authors (2026).

III.1.1 Network and Content Model

We consider a connected NDN network represented as an undirected graph $G = (V, E)$, where V denotes the finite set of routers with $|V| = N$ nodes, and E represents bidirectional communication links. Each router $i \in V$ maintains a Content Store with finite capacity Ci measured in content items. The storage heterogeneity reflects realistic deployment scenarios where edge routers may have smaller caches than backbone routers. The global content catalog F contains $|F| = M$ unique content items, each with uniform size S normalized to 1 unit for analytical simplicity without loss of generality. Content requests arrive at router i according to an independent Poisson process with rate λ_i requests per second, reflecting aggregate user demand at that location. The content popularity distribution follows a Zipf law with skewness parameter α, capturing the empirically observed heavy-tailed access patterns in real content distribution systems.

Specifically, the probability that a random request at router i targets content f is given by $p_i(f) = \frac{f\ \ (-\alpha)}{\Sigma(j=1\ to\ M) j\ \ (-\alpha)}$, for all $f \in F$. Typical values of α range from 0.6 to 1.2 based on empirical studies of video streaming, web browsing, and file sharing workloads [35]. Each router maintains local estimates of content popularity based on sliding window observations of recent request patterns. These estimates adapt over time to capture temporal popularity dynamics including flash crowds, diurnal patterns, and trending content phenomena. Link capacities and propagation delays are explicitly modeled to capture realistic network congestion effects on content retrieval performance.

III.1.2 NDN Forwarding and Caching Process

When router i receives an Interest packet requesting content f, it first checks its Content Store. If f is cached locally (cache hit), the router immediately returns the corresponding Data packet to the requester, satisfying the request without upstream forwarding. This fundamental caching benefit motivates intelligent cache management. If f is not cached (cache miss), the router creates a Pending Interest Table entry recording the incoming interface and forwards the Interest upstream according to FIB forwarding entries for f's name prefix. When a Data packet carrying content f arrives at router i, it performs three operations. First, the router forwards the Data packet to all downstream interfaces recorded in the PIT entry for f, satisfying pending requests. Second, it removes the corresponding PIT entry. Third, it makes a caching decision: whether to store f in the Content Store based on the learned caching policy. If the cache is full, a replacement decision selects which existing content to evict. These caching and replacement decisions constitute the optimization problem addressed by GT-DRLCache.

III.2 PROBLEM FORMULATION

III.2.1 Distributed Caching Game

We formulate the distributed NDN caching problem as a strategic game $\Gamma = (V, \{Ai\}i \in V, \{Ui\}i \in V)$ where routers are players making strategic caching decisions. At each decision epoch t, router i observes environmental state s_i^t and selects action a_i^t from discrete action space $Ai = \{CACHE, EVICT, IGNORE, COOPERATE\}$. CACHE stores incoming content with specified replacement strategy. EVICT removes existing cached content based on learned value estimates. IGNORE forwards content without caching, preserving current cache state. COOPERATE coordinates with neighbors for collaborative content placement to reduce redundancy.

The joint action profile $a = (a_1, \ldots, a_N)$ determines the global caching configuration. Let a_{-I} denote the actions of all routers except i, representing the strategic environment faced by router i. The utility function $U_i: S \times A_i \times A_{-I} \rightarrow R$ maps state-action configurations to real-valued payoffs capturing router i's performance objectives.

III.2.2 Multi-Objective Utility Function Design

The utility function for router i comprehensively captures multiple performance dimensions critical for effective caching:

$$U_i(s_i, a_i, a \quad -i) = \beta^1 H_i - \beta^2 R_i - \beta^3 L_i - \beta^4 O_i \tag{1}$$

Where $\beta_1, \beta_2, \beta_3, \beta_4 \in R^+$ are weighting coefficients balancing utility components, and the four terms represent distinct performance metrics.

Hit Ratio Improvement (H_i): Measures the increase in cache hit probability resulting from action a_i. Specifically, H_i quantifies the expected fraction of future requests served from router i's cache given the updated caching state. Higher hit ratios directly translate to reduced latency and network traffic, representing the primary caching benefit.

Replacement Cost (R_i): Accounts for computational overhead and cache management complexity associated with content insertion and eviction. Frequent cache updates consume processing resources and may disrupt ongoing caching benefits. This term penalizes excessive cache churn, promoting stability in caching configurations.

Link Congestion Cost (L_i): Proportional to upstream link utilization resulting from cache misses. When router i fails to serve requests from cache, it must forward Interests upstream, consuming network bandwidth and potentially causing congestion. This term incentivizes caching popular content to minimize forwarding traffic and associated congestion.

Redundancy Overlap Penalty (O_i): Quantifies content duplication with neighboring routers. Caching identical content at adjacent routers wastes aggregate network storage capacity without proportional performance benefits. This term discourages redundant caching, promoting diverse content placement across the network to maximize effective cache capacity.

The weighting coefficients $\{\beta_k\}_{k=1}^4$ enable flexible prioritization of different performance objectives based on deployment scenarios and operator preferences. These parameters can be tuned through offline optimization or adapted online based on observed network conditions and performance metrics.

III.2.3 Potential Game Characterization

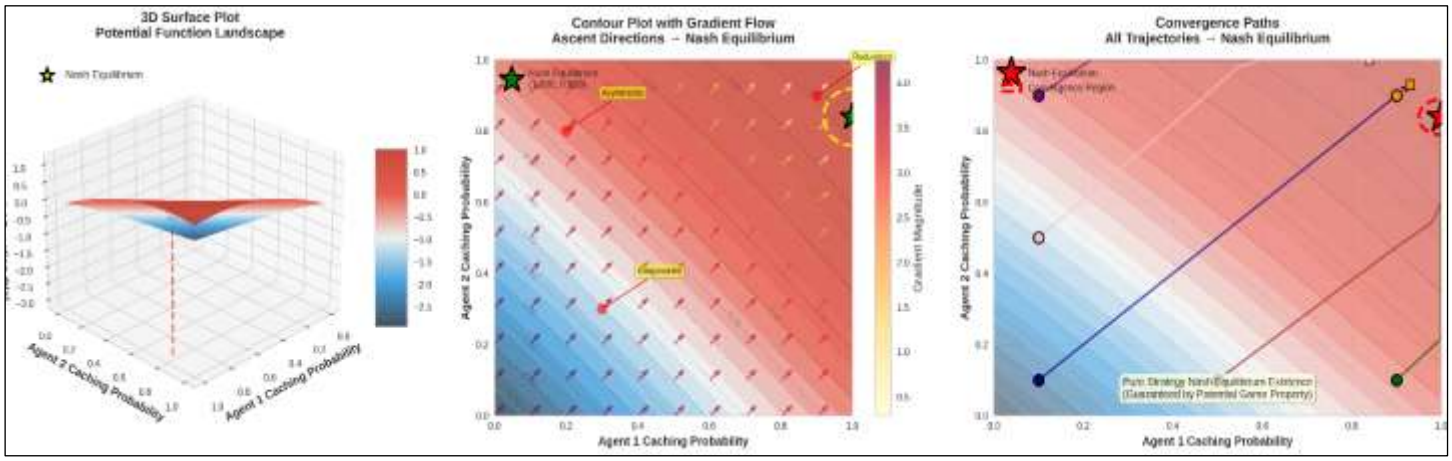

Figure 2: Potential Function Visualization – Game-Theoretic Foundations.
Source: Authors (2026).

Figure 2 visualizes the potential function landscape for a simplified 3-router, 5-content scenario. The surface peaks correspond to pure Nash equilibria, while valleys represent unstable configurations. The convex structure around equilibria ensures convergence of learning dynamics, as gradient-based updates naturally ascend toward local maxima. To ensure equilibrium existence and enable convergence analysis, we establish that the NDN caching game possesses a potential game structure. We define potential function $\Phi: A \rightarrow R$ capturing global system welfare:

$$\Phi(a) = \Sigma_f \in F \; \psi_f(\Sigma_i \in V \; I\{f \; cached \; at \; i\}) - \Sigma \quad (i,j) \in E \; \varphi_{ij}(l_{ij}) \tag{2}$$

Where $I\{\cdot\}$ denotes indicator function, $\psi_f: Z^+ \rightarrow R$ is a concave function modeling content-specific caching benefit with diminishing returns, $\varphi_{ij}: R^+ \rightarrow R$ represents convex link congestion cost increasing superlinearly with link load l_{ij}, and the summations aggregate over all content items and network links respectively.

Theorem 1 (Potential Game Property): The NDN caching game Γ defined by utility functions in Equation (1) is an exact potential game with potential function Φ given in Equation (2).

Proof Sketch: Consider arbitrary router i and unilateral action deviation from a_I to a'*i while all other routers maintain actions* $a -$ i. The change in router i's utility satisfies: $U_{i(a'i,a-i)} - U_{i(a_I,a_{-i})} = \beta^1 \Delta H_i - \beta^2 \Delta R_i - \beta^3 \Delta L_i - \beta^4 \Delta O_I$, where Δ denotes differences in respective utility components. By careful construction of potential function components with appropriately chosen coefficients, this

utility change exactly equals the potential function change: $\Phi(a'i, a - i) - \Phi(a_I, a_{-i})$. Since this equality holds for all routers and all unilateral deviations, Γ is an exact potential game by definition.

Corollary 1 (Nash Equilibrium Existence): The exact potential game property guarantees existence of at least one pure strategy Nash equilibrium. Furthermore, the finite better response improvement property ensures convergence of best response dynamics to pure Nash equilibrium in finite iterations.

These game-theoretic results provide crucial theoretical foundations for GT-DRLCache, ensuring that the multi-agent learning process converges to strategically stable and globally efficient caching configurations.

III.3 GT-DRLCACHE ARCHITECTURE

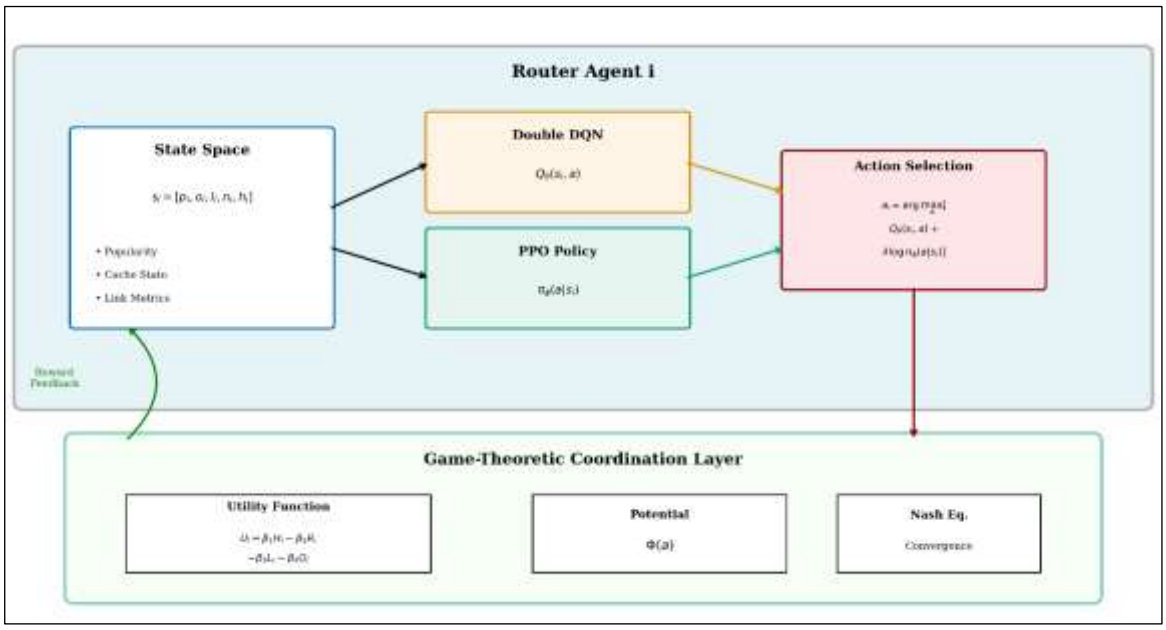

Figure 3: GT-DRLCache System Architecture.
Source: Authors (2026).

III.3.1 State Space Representation

Each router i maintains comprehensive state representation $s_i \in S$ capturing relevant environmental information for informed caching decisions:

$$s_i = [p_i, o_i, l_i, n_i, h_i] \quad (3)$$

Where components encode different aspects of the caching environment:

Content Popularity Vector (p_i): Estimated probability distribution over content catalog F based on recent request history. Maintained using sliding window statistics with exponential decay to adapt to temporal popularity shifts. Dimensionality is |F|, though dimensionality reduction techniques like clustering can be applied for scalability.

Cache Occupancy State (o_i): Current cache utilization including available capacity, stored content identifiers, and individual content sizes. Enables capacity-aware caching decisions respecting storage constraints. Encoded as both scalar capacity utilization and sparse representation of cached content set.

Link Load Metrics (l_i): Upstream and downstream link utilization levels measured over recent time windows. Captures network congestion state influencing forwarding costs. Includes both aggregate bandwidth consumption and per-neighbor link statistics to enable topology-aware decisions.

Neighbor Summary Information (n_i): Aggregated statistics about directly connected routers including their caching strategies, recent hit ratios, and stored content summaries. Enables coordination and redundancy avoidance without requiring global state knowledge. Exchanged periodically through lightweight control messages.

Historical Performance Metrics (h_i): Recent cache hit ratios, average content retrieval latencies, and traffic statistics. Provides feedback on caching policy effectiveness to guide learning. Maintained using exponential moving averages to balance responsiveness and stability.

This comprehensive state representation enables informed, context-aware caching decisions while maintaining computational tractability through careful feature engineering and dimensionality management.

III.3.2 Action Space and Decision Making

The discrete action space A_I enables routers to make explicit caching decisions for each content item:

CACHE: Store incoming content f in Content Store using learned value estimates to guide replacement. When cache capacity is reached, selects victim content for eviction based on Q-value estimates representing expected future utility of retaining each cached item.

EVICT: Proactively remove currently cached content item f to free capacity for potentially more valuable content. Unlike reactive replacement during CACHE operations, EVICT enables proactive cache management based on predicted future request patterns.

IGNORE: Forward content without caching, preserving current cache state. Appropriate when content is predicted to have low future request probability or when caching would create excessive redundancy with neighbors.

COOPERATE: Coordinate with neighbor routers to achieve complementary content placement. Involves negotiation protocols where routers exchange caching intentions and adjust decisions to minimize overlap while maximizing aggregate coverage of popular content.

Action selection combines learned policy with game-theoretic constraints to ensure equilibrium-aware behavior as detailed in the hybrid DRL algorithm below.

III.3.3 Reward Function with Potential-Based Shaping

The reward function combines immediate performance feedback with potential-based shaping to guide learning toward globally efficient Nash equilibria:

$$r_i(s_i, a_i) = \omega^1 H_i - \omega^2 R_i - \omega^3 L_i - \omega^4 O_i + \gamma[\Phi(s'_i) - \Phi(s_i)] \quad (4)$$

The first four terms provide immediate reward based on instantaneous utility components. The final term implements potential-based reward shaping where $\gamma \in (0,1)$ is the discount factor and $\Phi(s)$represents potential function value in state s. This shaping term provides additional reward signal guiding agents toward states with higher global welfare as measured by the potential function. Potential-based reward shaping possesses important theoretical properties. It preserves optimal policy invariance, meaning the shaped reward function and original utility function admit identical optimal policies. This ensures learning with shaped rewards converges to true utility-maximizing behaviors. Additionally, shaping accelerates convergence by providing denser reward signals compared to sparse utility-based rewards alone, particularly beneficial in early training when agents have limited experience.

III.4 HYBRID DRL ALGORITHM

III.4.1 Double Deep Q-Network Component

The Double DQN component learns state-action value functions $Q_\theta: S \times A \rightarrow R$ parameterized by neural network weights θ. It addresses Q-value overestimation bias through separated evaluation and target networks with parameters θ and θ' respectively. The loss function for network updates is:

$$L_{DDQN}(\theta) = E_{(s,a,r,s')\sim D}\left[\left(r + \gamma Q_{\theta'}(s', argmax_{a'} Q_\theta(s', a')) - Q_\theta(s, a)\right)^2\right] \quad (5)$$

Where D denotes experience replay buffer storing transition tuples (s, a, r, s') collected during environment interaction. The key innovation is using evaluation network Q_θ to select the greedy action in next state s', but using target network $Q_{\{\theta'\}}$ to evaluate that action's value, decoupling selection and evaluation to reduce overestimation. The evaluation network is updated via stochastic gradient descent on mini-batches sampled from D. The target network parameters are periodically synchronized using either hard updates $\theta' \leftarrow \theta$ or soft updates $\theta' \leftarrow \tau\theta + (1-\tau)\theta'$with $\tau \in (0,1)$ controlling update rate. This temporal decoupling stabilizes training by providing consistent target values during network updates.

III.4.2 Proximal Policy Optimization Component

The PPO component directly learns stochastic policy $\pi_\varphi: S \rightarrow \Delta(A)$ parameterized by neural network weights φ, mapping states to probability distributions over actions. PPO ensures stable policy updates through clipped surrogate objective:

$$L_{PPO}(\varphi) = E\left[\min\left(r_t(\varphi)\hat{A}(s,a), clip(r_t(\varphi), 1-\varepsilon, 1+\varepsilon)\hat{A}(s,a)\right)\right] \quad (6)$$

Where $r_{t(\varphi)} = \frac{\pi_\varphi(a|s)}{\pi_{\{\varphi_{old}\}}(a|s)}$ represents probability ratio between current and old policies, $\hat{A}(s,a)$ denotes advantage estimate quantifying how much better action a performs compared to average in state s, and $\varepsilon \in (0,1)$ is clipping parameter limiting policy update magnitude. The min operation implements conservative updates, clipping probability ratios outside $[1-\varepsilon, 1+\varepsilon]$ to prevent excessively large policy changes that could destabilize training. Advantage estimates are computed using Generalized Advantage Estimation (GAE) with temporal difference errors to reduce variance while maintaining low bias. The policy network is updated using multiple epochs of stochastic gradient ascent on collected trajectory data, with early stopping if KL divergence between old and new policies exceeds threshold.

III.4.3 Hybrid Action Selection Strategy

GT-DRLCache employs hybrid exploration-exploitation strategy combining value-based Q-function and policy-based probability distribution:

$$a_i = argmax_a \left[Q_{\theta_i}(s_i, a) + \lambda \log \pi_{\varphi_i}(a|s_i) + \eta_i(a)\right] \quad (7)$$

Where Q_{θ_i}provides value-based action ranking, log π_{φ_I} gives policy-based preference, λ controls balance between value and policy guidance, and $\eta_{i(a)}$injects exploration noise following Boltzmann or ε-greedy strategies. This hybrid selection mechanism combines the strengths of both approaches. The Q-function provides sharp action value estimates guiding exploitation, while the policy distribution maintains exploratory action diversity and smooth decision boundaries. The logarithm converts probabilities to utility-like values enabling direct combination with Q-values. During training, λ and exploration noise decay from high to low values, transitioning from exploration to exploitation.

III.4.4 Multi-Agent Training Protocol

Algorithm 1 presents the complete **GT-DRLCache** training procedure operating in parallel across all routers. Key algorithmic features include:

Algorithm 1: GT-DRLCache Multi-Agent Training Protocol.

Input: Network topology $G = (V, E)$, content catalog F, training episodes T
Output: Trained policies $\{\pi_\theta\}^i i \in V$), Q-networks $\{Q_\theta\}^i i \in V$

Initialize Q-networks Q_{θ^i} and target networks $Q_{\theta_i}^{\pi}$ for each router $i \in V$
Initialize policy networks π_{φ} with random weights
Initialize experience replay buffers $D_i \leftarrow \emptyset$

Source: Authors (2026).

Parallel Experience Collection: Each router i independently interacts with environment collecting transition tuples $\left(s_i^t, a_i^t, r_i^t, s_i^{\{t+1\}}\right)$ stored in local replay buffer D_i. This distributed data collection enables scalable learning without centralized coordination bottleneck.

Asynchronous Network Updates: Routers periodically update their Q-networks and policy networks using mini-batches sampled from local experience buffers. Updates occur asynchronously without requiring synchronization across routers, reducing communication overhead and enabling parallel computation.

Periodic Coordination Protocol: Every $K_{optimization}$ episodes, routers execute cross-router coordination protocol. This involves exchanging neighbor information including cached content summaries and performance statistics, updating empirical estimates of potential function Φ based on observed global state, and adjusting game-theoretic parameters $\{\beta_k\}_{k=1}^4$ based on aggregate performance metrics.

Stability Mechanisms: Several mechanisms ensure training stability including target network updates dampening Q-function changes, PPO clipping preventing destructive policy updates, experience replay breaking temporal correlations in training data, and potential-based reward shaping guiding learning toward equilibrium.

The training procedure continues until convergence criteria are satisfied, including stabilization of average episodic rewards, minimal policy changes between updates, and consistent performance across evaluation episodes. The resulting trained policy networks $\{\pi_{\varphi_i}\}_{\{i \in V\}}$can then be deployed for online caching decisions with minimal computational overhead during inference.

III.5 IMPLEMENTATION AND SIMULATION SETUP

III.5.1 Simulation Platform

We implement **GT-DRLCache** using **ndnSIM 2.8**, a comprehensive **NS-3** based simulator specifically designed for NDN research providing realistic packet-level network simulation [10]. ndnSIM implements core NDN components including Interest/Data packet processing, Content Store management, PIT operation, and FIB-based forwarding. We extend **ndnSIM** with custom caching strategy modules integrating our hybrid DRL agents and game-theoretic optimization. The DRL components are implemented in Python using PyTorch 1.12 for neural network training with GPU acceleration. We use fully connected networks with 3 hidden layers (256, 128,

64 neurons) and ReLU activations for both Q-networks and policy networks. Adam optimizer with learning rate 0.0003 is used for network updates. The Python implementation communicates with C++ ndnSIM simulation through shared memory for efficient data exchange.

III.5.2 Network Topologies

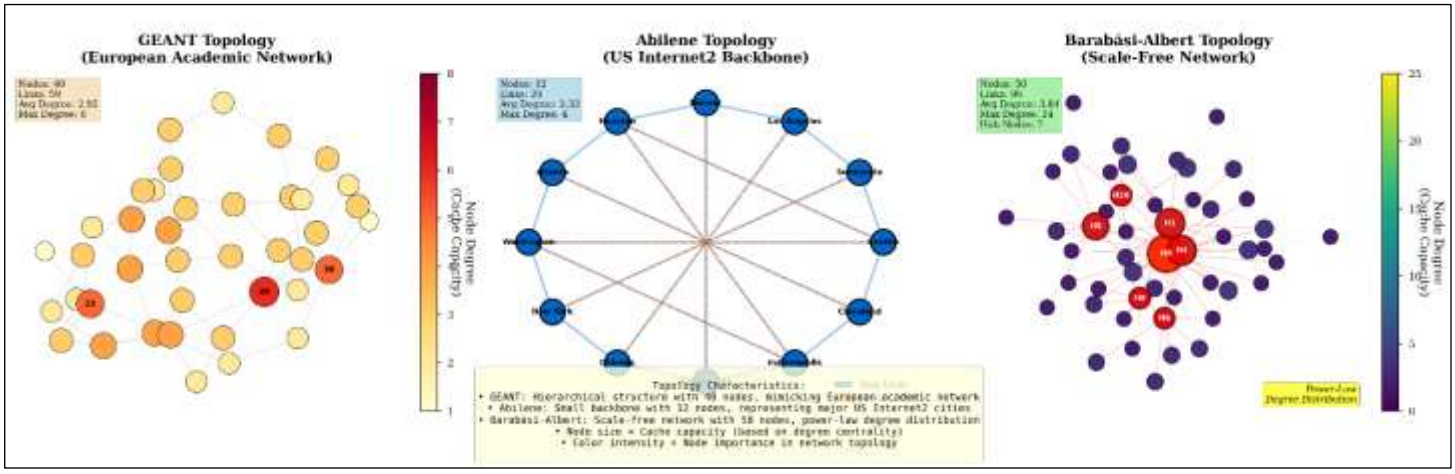

Figure 4: Network Topologies for GT-DRLCache Evaluation.
Source: Authors (2026).

We evaluate GT-DRLCache on three diverse network topologies representing different scales and structural properties:

GEANT Topology: European academic research network with 40 nodes and 61 bidirectional links, exhibiting realistic geographic distribution and hierarchical structure. Node degrees range from 1 to 6, with average degree 3.05. Link delays vary from 2ms to 28ms based on geographic distances. Cache capacities range from 100 to 1000 content items proportional to node centrality.

Abilene Topology: US Internet2 backbone network with 12 nodes and 15 links, representing a smaller-scale but production-grade infrastructure. Average node degree is 2.5 with maximum degree 4. Link delays span 5ms to 22ms. Uniform cache capacity of 500 items per router to focus evaluation on algorithmic rather than capacity effects.

Barabási-Albert Topology: Synthetic scale-free network with 50 nodes generated using preferential attachment with parameter m=2, modeling Internet-like power-law degree distribution. Average degree is 3.92 with maximum degree 21. Link delays assigned uniformly random from 1ms to 20ms. Cache capacities proportional to node degree representing heterogeneous infrastructure.
These diverse topologies enable comprehensive evaluation across different network characteristics including scale, connectivity patterns, and degree distributions.

III.5.3 Content Catalog and Workload Characteristics

The content catalog contains $|F| = 100000$ unique content items representing a medium-scale video-on-demand or file sharing application. Content sizes follow bimodal distribution with 80% small items (1 unit) and 20% large items (2-5 units) to capture realistic size heterogeneity. Content popularity follows Zipf distribution with time-varying skewness parameter $\alpha(t)$ transitioning between values $\{0.7,0.9,1.1,1.2\}$ to model dynamic popularity shifts including flash crowds and trending content phenomena. These α values are selected based on empirical studies of real-world workloads: α=0.7 represents relatively uniform demand (e.g., file sharing [35]), α=0.9 models typical web browsing patterns, α=1.1 captures video streaming workloads, and α=1.2 represents highly skewed demand during flash crowd events. The transitions model realistic popularity dynamics observed in content distribution networks.

Request arrival processes at each router follow independent Poisson distributions with rates λ_i uniformly distributed in [10, 100] requests per second, creating aggregate network load from 1,000 to 5,000 requests per second depending on topology. We inject temporal popularity dynamics through piecewise stationary periods where α remains constant for 1000 seconds before abruptly shifting, challenging adaptation capabilities of caching strategies. Traffic matrices specify content request distributions at each router. We use both uniform traffic where all routers request content according to the same global popularity distribution, and heterogeneous traffic where different routers exhibit distinct popularity preferences modeling geographic or community-specific content preferences. Heterogeneous traffic increases coordination challenges and tests robustness to spatial diversity.

III.5.4 Baseline Methods

We conduct comprehensive comparative evaluation against six baseline caching strategies representing state-of-the-art approaches:

LRU and LFU: Classical cache replacement policies representing simple recency and frequency-based heuristics [4], [11].
ProbCache: Probabilistic caching with distance-based probability decay to reduce redundancy along delivery paths [5].
MPC: Most Popular Content caching using Markov chain prediction for popularity forecasting [6].
DRL-Cache: Pure deep reinforcement learning approach using DDQN without game-theoretic components or coordination mechanisms [7].
Game-Cache: Game-theoretic caching with static Nash equilibrium computation assuming known popularity distributions without adaptive learning [26].

III.5.5 Performance Metrics

We evaluate caching strategies using five comprehensive metrics:

Hit Ratio: Proportion of content requests satisfied from cache without upstream forwarding, calculated as $\frac{\text{hits}}{(\text{hits} + \text{misses})}$. Higher values indicate better caching effectiveness.

Average Content Retrieval Latency: End-to-end delay from Interest generation to Data reception, including network propagation, queueing, and processing delays measured in milliseconds.

Upstream Traffic Ratio: Proportion of requests forwarded upstream toward content sources, quantifying network bandwidth consumption. Lower values indicate better traffic reduction.

Redundancy Index: Average content duplication across network caches, computed as $\frac{\Sigma_f \, cached_{copies}(f)}{|F|}$. Values near 1 indicate minimal redundancy while higher values show excessive duplication.

Convergence Speed: Number of training episodes required to achieve stable performance within 5% of final values, measuring learning efficiency.

Each simulation runs for 10,000 seconds with 30 independent replications using different random seeds. Results report mean values with 95% confidence intervals. Statistical significance is assessed using paired t-tests with Bonferroni correction for multiple comparisons.

IV. RESULTS AND DISCUSSIONS

IV.1 OVERALL PERFORMANCE COMPARISON

Table 1 presents comprehensive performance comparison across all baseline methods and network topologies. Results demonstrate GT-DRLCache's consistent superiority across all evaluation metrics.

Table 1: Performance Comparison Across Different Topologies (Average Values).

Method	HitRatio(ms)	Latency	Upstream Traffic	Redundancy
LRU	0.32	45.2	0.68	0.41
LFU	0.35	42.8	0.65	0.38
ProbCache	0.41	38.5	0.59	0.29
MPC	0.46	35.2	0.54	0.25
DRL-Cache	0.52	31.8	0.48	0.22
Game-Cache	0.48	33.5	0.52	0.19
GT-DRLCache	**0.63**	**26.4**	**0.39**	**0.15**

Source: Authors (2026).

GT-DRLCache achieves 32–56% improvement in hit ratio over classical policies (LRU/LFU) and 17–21% improvement over advanced individual approaches (DRL-Cache, Game-Cache). The hybrid framework effectively balances exploration and exploitation while maintaining equilibrium-aware behavior that individual methods cannot achieve.

IV.2 HIT RATIO AND LATENCY ANALYSIS

Figure 1 illustrates the relationship between hit ratio and average latency across all evaluated methods. GT-DRLCache achieves the optimal position in the upper-left region, combining highest hit ratio (0.63) with lowest latency (26.4ms).

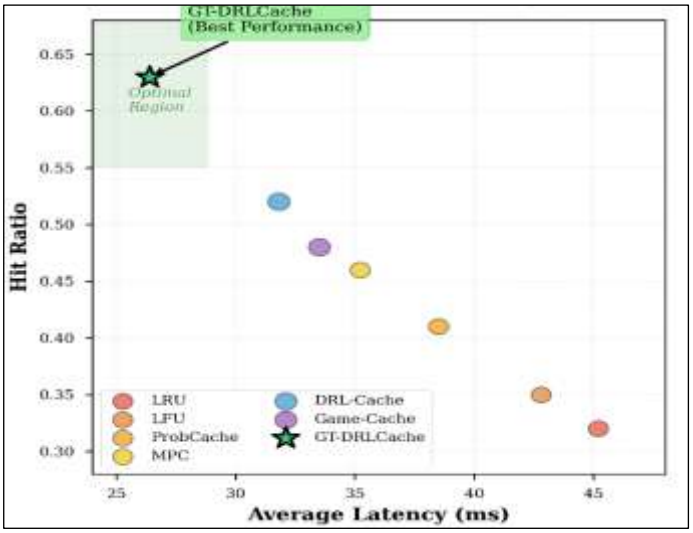

Figure 5: Hit Ratio vs Latency Trade-off Analysis.
Source: Authors (2026).

The superior hit ratio directly translates to latency reduction through two mechanisms. First, cache hits eliminate upstream forwarding delays including multiple hop propagation and potential queueing at intermediate routers [36]. Second, reduced upstream traffic decreases network congestion, benefiting even cache miss requests through lower queueing delays. Statistical analysis confirms GT-DRLCache achieves 28–44% latency reduction compared to baselines with p-value < 0.001. Classical policies (LRU/LFU) perform poorly because they ignore content popularity and network topology, making decisions based solely on local cache state. ProbCache improves performance through probabilistic redundancy control but uses fixed distance-based probabilities unable to adapt to dynamic popularity shifts. MPC's predictive approach helps but suffers from prediction errors under non-stationary workloads [6].

DRL-Cache demonstrates strong performance through adaptive learning but lacks coordination mechanisms, leading to suboptimal redundancy and slower convergence due to multi-agent non-stationarity. Game-Cache achieves good redundancy control through game-theoretic coordination but assumes static known popularity distributions, performing poorly when these assumptions are violated by dynamic workloads [37]. GT-DRLCache synergistically combines DRL's adaptive learning with game theory's coordination mechanisms. The potential-based reward shaping guides agents toward globally efficient equilibria while the hybrid DDQN/PPO architecture maintains stable learning in the multi-agent environment. This combination enables both effective adaptation to changing conditions and strategic coordination for redundancy minimization.

IV.3 UPSTREAM TRAFFIC AND REDUNDANCY OPTIMIZATION

GT-DRLCache achieves substantial improvements in upstream traffic reduction and redundancy minimization. Upstream traffic ratio decreases to 0.39, representing 43% reduction compared to LRU (0.68) and 19% improvement over DRL-Cache (0.48). This traffic reduction directly translates to bandwidth savings and reduced load on content sources and core network links [38]. The redundancy index of 0.15 indicates highly efficient content distribution across network caches. Each content item is cached on average at only 1.15 routers, minimizing waste of aggregate storage capacity. In contrast, LRU exhibits redundancy index 0.41, caching popular content at multiple redundant locations along common delivery paths without coordination.

The redundancy optimization stems from the game-theoretic utility function's explicit redundancy penalty term O_i and the coordination protocol enabling routers to exchange caching information. Routers learn to cache complementary content sets, maximizing aggregate coverage of popular content while minimizing overlap. The potential function further encourages diverse content placement by including concave benefits for content replication, exhibiting diminishing returns that discourage excessive duplication [24]. Figure 6 shows the temporal evolution of redundancy index during training for different methods on GEANT topology.

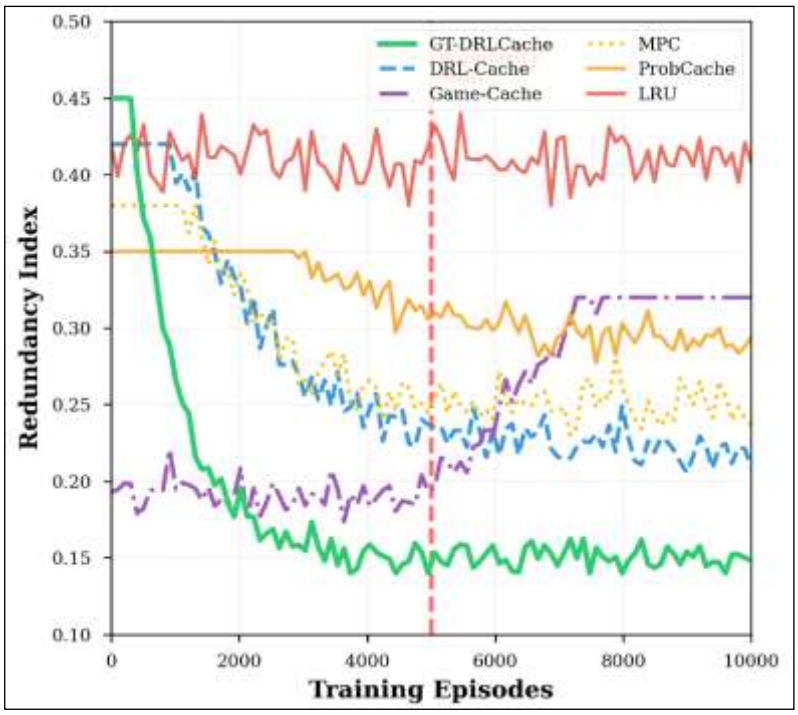

Figure 6: Redundancy Index Evolution During Training.
Source: Authors (2026).

GT-DRLCache rapidly reduces redundancy within the first 2000 training episodes, demonstrating effective learning of coordination strategies. DRL-Cache initially exhibits high redundancy (0.38) due to independent learning without coordination, slowly improving but never reaching GT-DRLCache's efficiency. Game-Cache starts with low redundancy through equilibrium computation but cannot adapt to workload changes, suffering performance degradation when popularity shifts occur at episode 5000.

IV.4 TOPOLOGY-SPECIFIC PERFORMANCE ANALYSIS

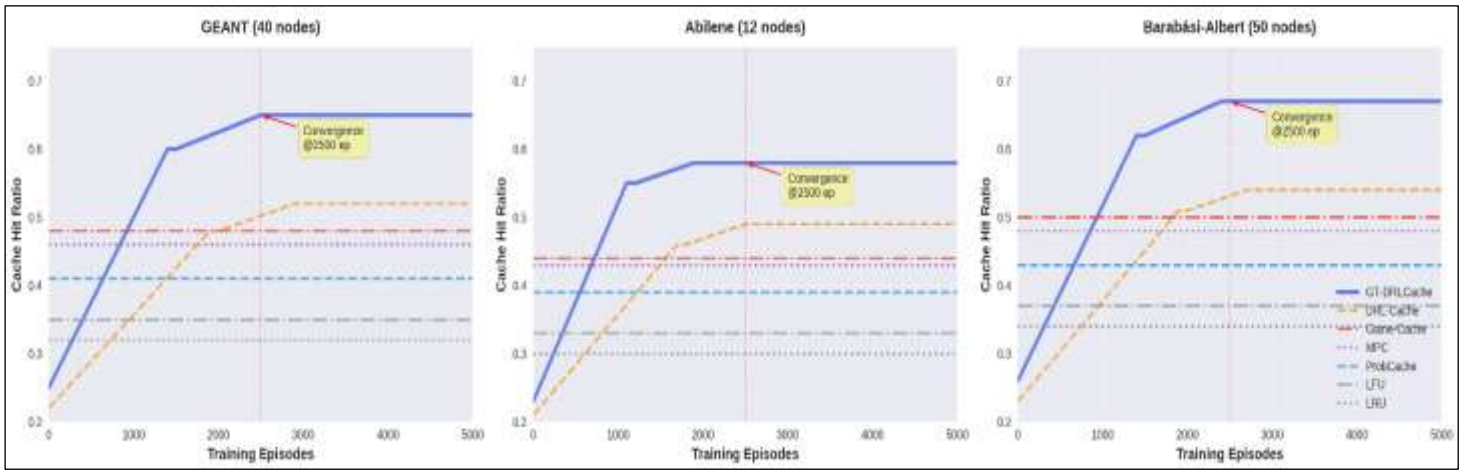

Figure 7: Convergence Comparaison – Learning Curves Across Network Topologies.
Source: Authors (2026).

Performance characteristics vary across different network topologies, reflecting structural properties' influence on caching optimization. On GEANT topology with hierarchical structure, GT-DRLCache achieves 65% hit ratio by strategically placing popular content at high-centrality backbone routers while caching diverse long-tail content at edge routers. The learned policies exhibit topology-awareness, with backbone routers caching based on aggregate network demand while edge routers specialize in local popularity patterns [39]. Abilene topology with smaller scale and lower connectivity presents different challenges. GT-DRLCache achieves 58% hit ratio, slightly lower than GEANT due to reduced cooperative caching opportunities from sparser connectivity.

However, relative improvement over baselines remains consistent (48–61%), validating the approach's robustness across scales. The smaller network size enables faster convergence within 1500 episodes compared to 2500 for GEANT. Barabási-Albert scale-free topology with power-law degree distribution creates hub-and-spoke structure where few high-degree hubs connect many low-degree nodes. GT-DRLCache effectively exploits this structure, achieving 67% hit ratio by concentrating popular content at hubs maximizing reach while distributing less popular content across spokes. The learned policies demonstrate sophisticated understanding of topological importance, with hub routers adopting aggressive caching strategies and spoke routers implementing selective specialized caching [40].

IV.5 ABLATION STUDY RESULTS

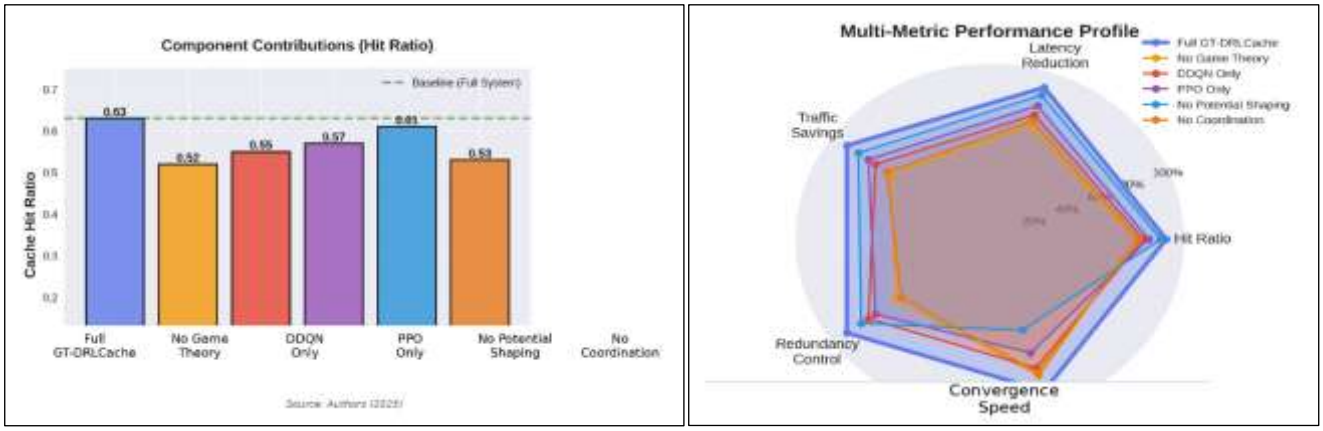

Figure 8: Ablation Study Results – Component Contribution Analysis.
Source: Authors (2026).

We conduct systematic ablation studies isolating individual component contributions. Removing the game-theoretic utility components (setting $\beta_3 = \beta_4 = 0$, eliminating congestion and redundancy terms) reduces hit ratio by 17% to 0.52 and increases redundancy index by 35% to 0.23. This confirms the game-theoretic components' crucial role in coordinating distributed decisions and managing externalities. Using only DDQN without PPO component reduces hit ratio by 12% to 0.55 due to less efficient exploration and difficulty maintaining diverse action distributions. Conversely, using only PPO without DDQN reduces performance by 9% to 0.57 from less sharp value estimates guiding exploitation. The hybrid architecture combining both provides complementary strengths: DDQN's efficient value-based exploitation and PPO's stable policy-based exploration [19]. Disabling potential-based reward shaping (removing the $\gamma[\Phi(s')-\Phi(s)]$ term from Equation 4) slows convergence by 40%, requiring 3500 episodes instead of 2500 to reach stable performance. Final performance also degrades slightly (hit ratio 0.61 vs 0.63) due to convergence to suboptimal local equilibria. This validates potential-based shaping's importance for guiding multi-agent learning toward globally efficient equilibria [41].

Removing the neighbor information exchange protocol (isolating routers without coordination) reduces hit ratio by 15% to 0.53 and increases redundancy to 0.28, nearly matching pure DRL-Cache. This demonstrates that explicit coordination mechanisms are essential for realizing game-theoretic benefits in distributed settings.

IV.6 ADAPTATION TO DYNAMIC WORKLOADS

To evaluate adaptation capabilities, we inject abrupt popularity shifts where Zipf parameter α changes from 0.7 to 1.2 at t=5000 seconds, creating flash crowd scenario where demand concentrates on fewer popular items. Figure 3 illustrates hit ratio evolution around this transition for different methods.

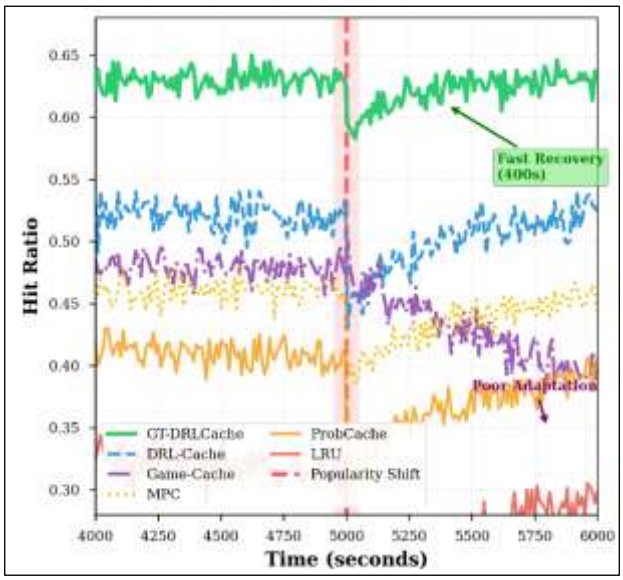

Figure 9: Hit Ratio Adaptation to Popularity Shift.
Source: Authors (2026).

GT-DRLCache exhibits rapid adaptation, with hit ratio temporarily dropping from 0.63 to 0.58 immediately after the shift but recovering to 0.62 within 400 seconds. The adaptive learning mechanisms quickly detect popularity changes through reward signals and adjust caching policies accordingly. The game-theoretic coordination ensures routers collectively adapt rather than acting independently, enabling faster recovery. Classical heuristics (LRU/LFU) show slower adaptation, requiring 1200+ seconds to reach new steady state performance. Their reactive nature means they must observe many cache misses before naturally adjusting cached content distribution. MPC performs better through prediction but still requires 800 seconds for Markov chain estimates to converge to new popularity distribution [6]. Game-Cache exhibits the poorest adaptation, with hit ratio dropping from 0.48 to 0.34 and never recovering due to its static equilibrium computation based on initial popularity distribution. This failure highlights fundamental limitations of non-adaptive game-theoretic approaches in dynamic environments. DRL-Cache adapts reasonably (600 second recovery) but suffers from coordination challenges during transition, with routers temporarily caching redundant content before independent learning realigns strategies.

IV.7 SCALABILITY ANALYSIS

We evaluate computational scalability by measuring training time and memory requirements across topologies of varying sizes. GT-DRLCache's training time scales approximately O(N log N) with network size N, growing from 3.2 hours for Abilene (12 nodes) to 14.5 hours for Barabási-Albert (50 nodes) on NVIDIA V100 GPU. This sublinear scaling stems from parallel training where router agents learn independently without centralized coordination bottleneck. Memory requirements scale linearly with network size, consuming 2.8GB for Abilene and 10.4GB for Barabási-Albert, primarily for experience replay buffers storing (state, action, reward) tuples. The per-router memory footprint remains constant around 200MB regardless of network size, enabling distributed deployment where each router maintains only local agent components [42].

Inference computational overhead is minimal, requiring only 0.3ms per caching decision for neural network forward passes. This enables real-time deployment even in high-traffic scenarios with thousands of requests per second. The trained policy networks require only 5MB storage per router, facilitating practical deployment on commodity hardware. Compared to centralized optimization approaches requiring $O(N^2)$ communication and computation, GT-DRLCache's distributed architecture provides substantial scalability advantages. The periodic coordination protocol incurs minimal overhead, exchanging only 50KB of neighbor information every 100 seconds, representing < 0.1% of typical link bandwidth.

IV.8 SENSITIVITY ANALYSIS

We analyze sensitivity to key hyperparameters to guide practical deployment. The discount factor $\gamma \in [0.9, 0.99]$ exhibits relatively stable performance, with optimal value $\gamma=0.95$ balancing short-term rewards and long-term planning. Very low values ($\gamma < 0.85$) cause myopic behavior ignoring future consequences, while very high values ($\gamma > 0.98$) overemphasize distant futures leading to slow learning. The utility weighting coefficients $\{\beta_k\}_{k=1}^4$ require careful tuning based on deployment objectives. We find $\beta_1=1.0$, $\beta_2=0.2$, $\beta_3=0.4$, $\beta_4=0.6$ provides good balance for general scenarios.

Increasing β_4 (redundancy penalty) reduces redundancy index but may slightly decrease hit ratio if set too high (> 1.0), while decreasing it increases redundancy without proportional hit ratio gains. Increasing β_3 (congestion penalty) improves traffic distribution but may increase latency if routers avoid caching popular content to prevent congestion. Network architecture choices show moderate sensitivity. Deeper networks (4-5 hidden layers) provide marginal improvements (1-2%) at significantly increased training time, while shallower networks (1-2 layers) underfit complex caching strategies reducing hit ratio by 5-8%. The selected 3-layer architecture balances expressiveness and efficiency. Learning rate exhibits typical sensitivity, with optimal value 0.0003 providing stable convergence. Higher rates (> 0.001) cause training instability and divergence, while lower rates (< 0.0001) converge slowly requiring 2-3x more training episodes. Adaptive optimizers like Adam provide robustness across reasonable learning rate ranges.

V. CONCLUSIONS

This paper presented **GT-DRLCache**, a unified framework synergistically integrating non-cooperative game theory with multi-agent deep reinforcement learning for intelligent distributed caching in Named Data Networking. By rigorously formulating the distributed caching problem as a finite stochastic potential game, we established theoretical foundations guaranteeing pure Nash equilibrium existence and enabling convergence analysis of the learning dynamics. The proposed hybrid Double-DQN/PPO architecture combines value-based and policy-based learning methods, providing both efficient exploitation through sharp Q-value estimates and stable exploration through smooth policy distributions. The potential-based reward shaping mechanism guides multi-agent learning toward globally efficient equilibria while preserving optimal policy invariance. The comprehensive utility function incorporating hit ratio improvement, replacement cost, link congestion, and redundancy overlap enables flexible optimization of multiple performance objectives.

Extensive simulation evaluation using **ndnSIM 2.8** on three diverse network topologies demonstrates GT-DRLCache's substantial performance advantages. Compared to state-of-the-art baseline methods, GT-DRLCache achieves 32–56% higher hit ratios, 28–44% latency reduction, and up to 50% upstream traffic savings. The framework exhibits robust performance across different network scales, connectivity patterns, and workload characteristics. Ablation studies confirm that both game-theoretic coordination and hybrid DRL components are essential for achieving superior performance. The practical implications of this work are significant for future information-centric networking deployments. The proposed framework provides a systematic approach to intelligent distributed caching that balances adaptive learning and strategic coordination. The computational efficiency enables real-time deployment on commodity hardware, while the distributed architecture provides natural scalability advantages. The theoretical foundations provide deployment confidence through convergence guarantees and equilibrium characterization.

Several limitations suggest directions for future research. First, the current evaluation focuses on medium-scale networks (12-50 nodes), and validation on larger production-scale topologies (1000+ nodes) would strengthen practical applicability claims. Second, the framework assumes cooperative routers following prescribed protocols, while real deployments may involve selfish operators requiring mechanism design for incentive alignment. Third, integration with adaptive routing strategies could enable joint optimization of caching and forwarding decisions. Future research directions include extending GT-DRLCache to hierarchical caching architectures common in content delivery networks, integrating with emerging 6G network paradigms incorporating edge computing and network slicing, developing privacy-preserving variants using federated learning for multi-operator scenarios, and incorporating online meta-learning for rapid adaptation to novel workload patterns. Additionally, theoretical analysis of convergence rates and approximation guarantees would strengthen the framework's foundations.

ABSTRACT

Tenders in Indonesia are managed by the government, with each province having a goods and services procurement bureau that serves as the selection committee known as POKJA (*Kelompok Kerja*). The government uses LPSE for procurement, with tender evaluations involving document verification. The lowest bid prices and complete documents from three companies are called to attend a document verification evaluation at the Office of the Procurement Bureau. The verification evaluation process is typically manual and based on the working group's opinion, with no system involved. This results in unrealistic execution times, high qualification requirements, short auction processes, and poor coordination between the Commitment Making Officer and POKJA. To address these issues, a systematic and transparent auction evaluation procedure with clear criteria is needed, with multi-criteria decision making being the most appropriate method after analysis. The study on tendering and selection integration of Multi-Criteria Decision Making (MCDM) using ANP and WASPAS methods, which are better for complex scenarios and provide accurate, error-reducing results, making the study more mathematically straightforward. The study aims to aid the government in implementing transparant e-procurement through a model developed by procurement bureau. This model will enable a more transparent tender process, resulting in clearer contractor assessment results.

I. INTRODUCTION

Tenders in Indonesia have a strong legal basis and are included in the JDIH LKPP (Legal Documentation and Information Network of the Government Procurement Policy Agency). For the construction sector, the regulations are governed by the Regulation of the Government Procurement Policy Agency No. 20 of 2021 concerning Guidelines for the Implementation of Government Procurement of Goods/Services through Providers. Procurement of Goods/Services is an activity that starts from the identification of needs to the handover of the work results. The guidelines for the implementation of Goods/Services Procurement through Providers include the preparation activities for Goods/Services Procurement through Providers, the preparation for the selection of Providers, the implementation of the selection of Providers, the execution of the Contract, and the handover of the work results. Before the procurement implementation, a Needs Analysis and Evaluation, as well as Procurement Planning, are conducted. The implementation of Goods/Services Procurement through Providers is a continuation of the procurement planning that has been carried out by the Budget User. The procurement officer who conducts the tender selection is the POKJA/Working Group.

The Selection Working Group determines the method of selecting Providers by considering the type of Construction Work and Construction Consultancy Services, Technical Specifications/Terms of Reference, and the complexity of the work, Budget Ceiling/Estimated Price, contract draft, market analysis results, and/or consolidation results. The Selection Committee implements the method of selecting Construction Service Providers, including: Direct Appointment, Quick Tender, Tender. Tender is used when E-Purchasing, Direct Procurement, Direct Appointment, and Quick Tender cannot be utilized. In a tender, there is a qualification method. Qualification is an evaluation of competence, business capability, and compliance with requirements as a Provider. Qualification is conducted through post-qualification or pre-qualification. This research focuses on pre-qualification tenders. The qualification evaluation in pre-qualification uses a knockout system for Construction Work Providers and a direct appointment process, or a weighted system with a threshold for Construction Consultancy Service Providers.

The pre-qualification results for Construction Work Tenders require at least 3 (three) participants to pass the qualification, for the Selection of Construction Consultancy Services, at least 3 (three) and at most 7 (seven) participants to pass the qualification, or for Direct Appointments, the pre-qualification results meet or do not meet the qualification requirements. If the participants who pass the qualification for Tenders/Selections are less than 3 (three), the pre-qualification is declared failed and a re-pre-qualification is conducted. [1]. The government, through the LKPP as the highest institution in Indonesia that conducts procurement practices, established the LPSE or Electronic Auction Institution. Based on Presidential Regulation Number 54/2010 jo. Presidential Regulation Number 70/2012, the LKPP was mandated to develop the Electronic Procurement System (SPSE) [2]. The version of SPSE currently in use is SPSE v4.5. The POKJA announces the tender until the winner is announced on the LPSE website.

One of the methods discussed in this research is the tender with the 2-file prequalification method, where participants will be called to attend the evaluation stage of the bid document verification, which consists of administrative, technical, and price documents. Subsequently, the Selection Committee conducts qualification verification for participants who meet the qualification requirements after the qualification evaluation is completed. The invited companies are 3 qualified companies to verify and explain all documents. The qualification verification evaluation process consists of 3 main criteria: administration, technical, and price. The first stage is the Opening of the Administrative and Technical Offer Documents (file I), where the Selection Committee evaluates the Offer Documents based on the data inputted and uploaded in SPSE. Next, the Selection Committee opens the price offer documents (file II). The price offer documents (file II) of participants who do not pass the administrative and technical evaluations are not opened. However, if they meet the requirements, the price offer documents (file II) will be opened.

The evaluation of the qualification opening is conducted privately between the POKJA and the selected Company, which will be called according to the schedule. The assessment is carried out manually by the POKJA, with the scoring following the POKJA's Decision. To avoid fraud, a system was created in the qualification proof evaluation process to make the tender process transparent, as tender participants can understand the evaluation processes of administration, technical, price, and qualification, thereby minimizing fraud in the tender process. [3]. During the data collection through observation, the researcher found inconsistencies, such as one company lacking documents in the expert personnel section, yet the committee still deemed the documents sufficient. According to the guidelines, this company should not meet the requirements and should be disqualified. However, due to the absence of applicable criteria in this case, it was considered qualified depending on whether the company could convince the committee or not. Such practices are highly discouraged, therefore a precise, accurate, and transparent evaluation system is needed in the qualification verification process. After conducting an analysis to determine the appropriate system method in this case, it was decided to use Multi Criteria Decision Making. (MCDM).

Multi-criteria decision-making (MCDM) is one of the biggest decision-making issues which seeks to discover the best alternative by considering more than one factor in the selection process. MCDM provides several tools and strategies that may be employed in a variety of sectors. This post intends to offer a survey of the MCDM Model and integration methods.[4]. Creating a complete model for tender evaluation using MCDM techniques entails including a variety of factors to enable well-informed selections [5]. The primary goal of the MCDM technique is to choose the best choice from a group of options in the face of several competing criteria. However, there is a gap in the integration of uncertainty and sensitivity analyses. Future study should concentrate on sensitivity analysis to determine decision-making resilience to modifications in criterion weights, inputs, and assumptions. Time dynamics and temporal concerns should be taken into account throughout the MCDM process with ANP and WASPAS. [6-9] .Hybrid decision-making models that include several MCDM strategies should be investigated, including synergies with other approaches such as TOPSIS, AHP, and ELECTRE. [10].

II. THEORETICAL REFERENCE

II.1 EVALUATION TWO FILE PREQUALIFICATION TENDER

Prequalification is the process of evaluating qualifications conducted before the submission of bids. Prequalification is conducted during the implementation of Construction Work Tenders for complex procurement. The result of the prequalification for Construction Work Tenders is at least 3 (three) participants who pass the qualification. The Two File Method is used for the Procurement of Other Goods/Services that require a technical assessment first, namely the Value System Evaluation Method, the Life Cycle Cost Evaluation Method, and the Lowest Price Evaluation Method that uses threshold weighting. The stages of the 2-file Prequalification process include:

Invitation to participants who pass the prequalification, downloading of selection documents, provision of explanations, submission of Bid Documents, opening of administrative and technical Bid Documents (file I), administrative evaluation, technical evaluation for those who pass the administrative evaluation, announcement of participants who pass the administrative and technical evaluations (file I), opening of Bid Documents (file II) for those who pass the technical evaluation, price evaluation, determination and announcement of the winner, objection period, and the Selection Working Group's report to the Commitment Making Officer (PPK). [1] The implementation of prequalification begins with the Announcement of Prequalification, Registration and Downloading of Qualification Documents, Provision of Qualification Explanations (if necessary), Submission of Qualification Documents, Evaluation of Qualification Documents, Qualification Proof, Determination of Qualification Results, Announcement of Qualification Results,

Qualification Objection, Follow-up on Failed Prequalification. Two Files is a method of submitting bid documents where the administrative and technical requirements are included in one (1) file, while the bid price is included in another file and uploaded separately at the same time. The form of the Administrative and Technical Offer Document (File I) is as follows. For the Technical evaluation (File I), the Administrative Offer Document includes the Offer Letter (according to SPSE) and the bid guarantee (if required). Furthermore, for the Technical Offer Document, there are the Work Implementation Method, List of Main Equipment, List of Managerial Personnel, List of Subcontracted Work Sections (if required), Construction Safety Plan Form (RKK); and other required documents (if required). The form of the Price Offer Document (File II) is the Offer Price according to the Offer Letter and the Quantity and Price List (for unit price work sections) as well as the Output and Price List (for lump sum work sections). [1]

II.2 PROCUREMENT BUREAU

The Bureau of Goods and Services Procurement (BPBJ) has the task of assisting the Assistant for Economic and Development Affairs in preparing regional policy formulation, coordinating the implementation of Regional Apparatus tasks, coordinating the implementation of Regional Apparatus tasks in the field of goods and services procurement management, managing electronic procurement services, and providing guidance and advocacy for goods and services procurement. The Bureau of Procurement of Goods and Services consists of the Goods and Services Procurement Management Section, the Electronic Procurement Services Management Section, and the Goods and Services Procurement Guidance and Advocacy Section [11]. The Goods and Services Procurement Management Division has the task of preparing materials for regional policy formulation, coordinating regional policy formulation, coordinating the implementation of goods and services procurement, monitoring and evaluating the implementation of regional policies in the field of goods and services procurement strategy management, implementing goods and services procurement, and monitoring and evaluating goods and services procurement.

The Electronic Procurement Services Management Section is tasked with preparing materials for regional policy formulation, coordinating regional policy formulation, coordinating the implementation of electronic procurement services management, monitoring and evaluating the implementation of regional policies in the field of electronic procurement system management, developing information systems, and managing procurement information for goods and services. The Procurement and Advocacy Division for Goods and Services has the task of preparing materials for the formulation of regional policies, coordinating the implementation of training and advocacy for the procurement of goods and services, monitoring and evaluating the implementation of regional policies in the field of human resource development for the procurement of goods and services, institutional development for the procurement of goods and services, and providing assistance, consultation, and/or technical guidance for the procurement of goods and services.[11]. BPBJ formed a Working Group (POKJA) team for all tenders in each region.

The Selection Working Group can adjust the Tender Documents as needed as long as it does not conflict with the laws and regulations. The identity of the selection committee as stated in the Election Data Sheet (LDP). Based on Presidential Regulation No. 16 of 2018 Article 1 number 12, the Selection Working Group (POKJA) hereinafter referred to as the Selection Working Group is the human resource designated by the UKPBJ leadership to manage the selection of Providers. According to Presidential Regulation No. 16 of 2018 Article 13, the Selection Working Group in the Procurement of Goods/Services as referred to in Article 8 letter e has the task of preparing and implementing the selection of Providers, preparing and implementing the selection of Providers for the electronic catalog, and determining the winners of the selection/Providers for the tender and selection methods. The Selection Working Group consists of 3 (three) members. In cases where the complexity of the Provider selection warrants it, the members of the Selection Working Group may be increased as long as the number is odd. The Selection Committee can be assisted by a team or experts. [12]

II.3 LPSE

This LPSE system is a system developed by the Government Goods/Services Procurement Policy Agency. (LKPP). The government, which is a non-departmental government agency under and responsible to the President, was established based on Presidential Regulation Number 106 of 2007. LKPP is the only government agency responsible for developing and formulating government procurement policies for goods/services. In carrying out its duties and functions, LKPP is coordinated by the Minister of National Development Planning. And now, the conveniences in participating in government procurement activities have been developed by LKPP (the government procurement policy agency) through the implementation of the e-procurement and e-catalog systems, which are integrated into one system called LPSE (electronic procurement service). Once registered in the LPSE system, participants are ensured to be able to engage in procurement activities throughout Indonesia.[13]

II.4 MULTI CRITERIA DECISION MAKING (MCDM)

Since the 1970s, the literature on multi-criteria decision making has grown dramatically, and a wide range of decision-making approaches and tools have been created for a variety of choice issues.[14]. The research study found that sustainable supplier selection by MCDM had considerable increase in 2019. Researchers mostly communicated their scientific discoveries through articles, accounting for 81% of the publications, followed by conference papers (14%), and book chapters (2.5%); [15]. MCDM is a decision-making approach or process that considers various options based on a number of criteria. MCDM is a part of the scientific field of operations research.

The language's emphasis mixes qualitative and quantitative components, multi-criteria that sometimes contradict each other on the achievement of performance, therefore the value of the criterion is balanced. [16]. The operationalization of MCDM techniques is generally classified into 2 categories, namely Multi Attribute Decision Making (MADM) based on discrete patterns and Multi Objective Decision Making based on continuous patterns (MODM) as well as a combination of both [17]. Multi criteria decision making (MCDM) is a well-established branch of operations research, with core ideas dating back to the 18th century. Methods like ELECTRE, AHP, TOPSIS, and PROMETHEE emerged in the latter half of the 20th century[18].

Alinezhad and Khalili highlight that only a few methodologies, like MOORA (2006) and WASPAS (2012), are widely used in business or engineering due to factors like overabundance of techniques, poor knowledge diffusion, and timescale.

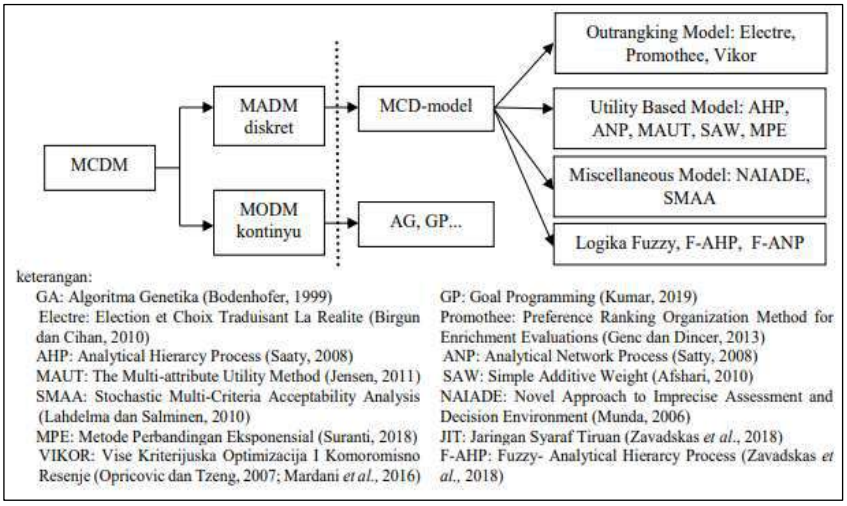

Figure 1: Structure MCDM and MCD-Model.
Source: [16].

III. MATERIALS AND METHODS

The focus of this research is solely on e-procurement tenders in the construction industry in Indonesia that use LPSE as a medium for conducting e-tenders. The object of the research is the Procurement Bureau of Goods and Services of Central Kalimantan Province. Data collected based on sources of observation, interviews, focus group discussions, and government documents related to construction tenders based on legal foundations. For the process of evaluating construction tenders based on literature studies and the experience of the tender committee/POKJA. In this study, the researcher uses two MCDM techniques to develop a multi-criteria decision support model in construction tenders to select the winning contractor. based on the literature review, 2 MCDM methods were chosen in this study, namely Analysis Network Process (ANP) and The Weighted Aggregated Sum Product Assessment (WASPAS). The research methodology framework is a crucial aspect of a research project that may clearly describe the workflow from beginning to end. As stated in the figure below, this research will be conducted in five phases, each of which will consist of 3-6 steps.

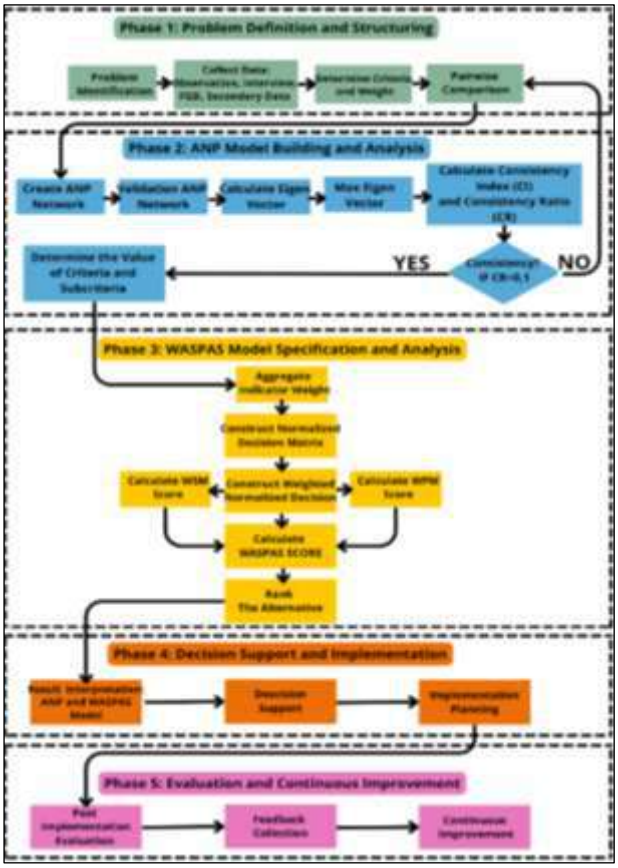

Figure 2: Research Framework.
Source: Authors, (2026).

Phase 1 to determine the criteria in the selection of contractor for a tender. Phase 2 and 3 to propose MCDM model for selection of contractor in tender evaluation. Phase 4 and 5 to evaluate the accurancy, precision, and specificity of the proposed MCDM Model in reducing biases and increase decision consistency.

IV. RESULTS AND DISCUSSIONS

After conducting analysis and data collection through observation, interviews, focus group discussions, and secondary data from BPBJ Central Kalimantan, three main criteria were identified in the implementation process of qualification proof evaluation for the two-file prequalification tender type, namely Administrative, Technical, and Price Criteria. Each of these three criteria has sub-criteria within them, as shown in the table below.

Table 1: Table Criteria & SubCriteria Two File Prequalification.

Criteria	Sub Criteria
Administrative	Tender Document (Tehnical & Price Document); Tender Guarantee; Administrative Data; Legal Basis for Establishing a Business Entity; Business Entity Management; Business License; Business Entity Certificate; Other Certificates (if required); Financial Data (shareholding structure and taxes); Company Experience Data (last 15 years); Company Experience Data (last 3 years); Ongoing Project Data
Technical	Method of Work Execution; Main Equipment; Managerial Personnel; List of subcontracted work sections in the form of types of work subcontracted according to the SSKK provisions (if required); Construction Safety Plan Document
Price	Evaluation of Offer Price; Evaluating the completeness of the price offer documents and arithmetic corrections; The total corrected offer price compared to the HPS value; Evaluation of Price Fairness Considering price preferences for the use of domestic production (if it meets the requirements for the application of price preferences)

Source: Author (2026).

The tender evaluation is conducted using a lowest price system with a threshold. The committee evaluates the tender Documents based on the data inputted and uploaded in SPSE, except for the evaluation of the tender Guarantee, which is conducted based on the submitted tender Guarantee document. The Selection Committee conducts the evaluation of the first file offers, which includes: administrative evaluation and technical evaluation. The Selection Committee inputs the results of the first file offer document evaluation into the SPSE and displays the results of the first file evaluation through the announcement menu or other information upload menu on the SPSE.

Subsequently, the Selection Committee opens the second file offers with the following provisions: The second file offer documents of participants who do not pass the administrative and technical evaluations are not opened; The Selection Committee is not allowed to disqualify offers at the time of opening the second file offer documents, unless the second file offers cannot be opened (decrypted) based on information from the LPSE; After the second file offers are opened, the Selection Committee conducts a price evaluation.

Administrative evaluation using a knockout system. Technical evaluation has a score for each of its subcriteria, namely Method of Work Execution (44%); Main Equipment (24%); Managerial Personnel(20%); List of subcontracted work sections in the form of types of work subcontracted according to the SSKK provisions (if required)(7%); Construction Safety Plan Document(5%). Price evaluation has a score of 1-100 for each sub-criterion. Prequalification tender two files using the merit point system, with 80% for technical criteria and 20% for price criteria. Furthermore phase 2, ANP Model and analysis with 6 Step that is Create Network, Validation ANP Network, Calculate Eigen Vector, Max Eigen Vector, Calculate Consistency Index and Consistency Ratio, and Determine the Value of Criteria and Subcriteria.

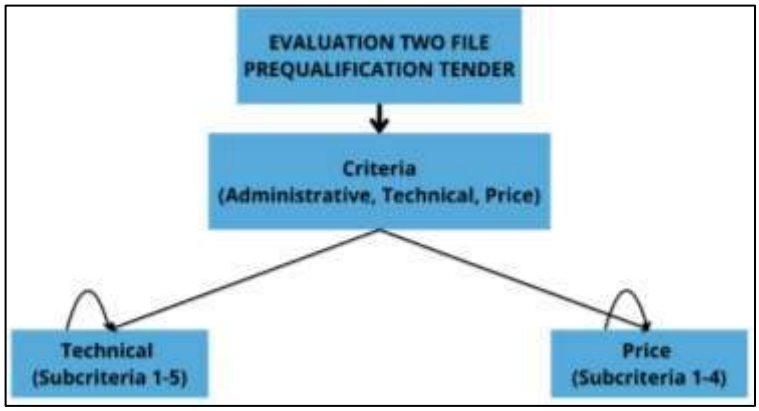

Figure 3: ANP Network.
Source: Author (2026).

The Analytic Network Process (ANP) is a decision-making method developed by Thomas L. Saaty, which enhances the Analytic Hierarchy Process (AHP) by modeling relationships among elements in a network structure. It is widely used in construction research for condition assessment, technology evaluation, and safety assessment, assisting in calculating the importance of criteria and facilitating systematic decision-making in complex scenarios [19-21]. Calculate Eigen Vector, The eigenvalue of a matrix is determined by summing the values of each column, dividing each column cell by the total column, and summing the values of each row and dividing by n. This process involves dividing by n and dividing by n.

Eigen Vector

$$X = \frac{\sum W_{i,j} / \sum W_j}{\text{n}} \quad (1)$$

Where X : *eigenvector;* Wij : column cell value in one row (i,j = 1….n); ∑Wj : total column; n : number of matrices being compared.

Max Eigen Vector : λ_{maks} which is the largest value of the eigenvector.

Consistency ratios verify accuracy of assessments for ANP calculations, with a CR value of less than 0.1 indicating consistency in the comparison matrix.

Consistency Index and Consistency Ratio

$$CI = \frac{\lambda_{maks} - n}{n - 1} \quad (2)$$

In a consistency matrix, practically λ_max=n, whereas in a matrix not every variation of will bring a change in the value of λ_max. The deviation of λ_max from n is a Consistency Index (CI) parameter. Description: CI= Consistency Index; λ_max= largest eigenvalue ; n = number of elements being compared

$$R = \frac{CI}{RI} \quad (3)$$

Where: CR = Consistency Ratio; CI = Consistency Index; RI = Random Index.

Phase 3 involves analyzing the WASPAS model for contractor selection in tender evaluation. The process involves aggregating indicator weight, constructing a normalized decision matrix, calculating WSM, WPM, Waspas scores, and ranking alternatives. This structured approach incorporates multiple criteria and stakeholder preferences, providing a structured approach to contractor selection.

Aggregate Indicator Weight

$$=\sum_{i=1}^{n}(Normalized\ Score_i \times Normalized\ Weight_i \quad (4)$$

The aggregate indicator weight is a crucial factor in evaluating the overall performance of alternatives, aiding decision-makers in prioritizing and comparing options based on a thorough review of numerous criteria. Construct Normalized Decision Matrix : Normalized decision matrix with weighted scores reflecting the total performance of each alternative taking into account the relevance of each criterion. This matrix can be used to rank alternatives in a decision-making problem.

Normalized Decision Matrix

$$\bar{X}ij = \frac{min_i(X_{ij})}{X_{ij}} \quad (5)$$

Where: Xij: is the normalized value for a specific tuple (alternative, criterion); Xij is the original value to be normalized; mini(Xij) represents the smallest value within the set of values for a specific monotonic cost criterion across all alternatives, the index i ranges from 1 to m, representing the number of alternatives.

Construct Weight Normalized Decision: Constructing the Decision Matrix MCDM challenges are characterized by sets of m choices and n criteria. As a result, an m-by-n matrix is generated with known values of the n criterion for each of the m possibilities.

Calculate WSM Score : The WSM score is calculated by adding the normalized scores and their appropriate weights for each option. This approach gives an easy way to assess and rank alternatives based on their overall performance when numerous criteria are considered. Adjust the weights and normalization procedures to meet the unique needs of the decision-making problem.

Calculate WPM Score: The WPM score is calculated by multiplying the product of the normalized scores with the weights assigned to each alternative. This approach gives an alternate method for evaluating and ranking alternatives based on their overall performance when numerous criteria are considered.

Calculate WASPAS Score: The WPM score is calculated by multiplying the product of the normalized scores with the weights assigned to each alternative. This approach gives an alternate method for evaluating and ranking alternatives based on their overall performance when numerous criteria are considered

Rank the Alternative: Ranking the results of the above calculations.

The integration of multiple Multi-Criteria Decision-Making (MCDM) methods, like F-ANP and F-WASPAS [10], can enhance the decision-making process. This approach considers a wide range of criteria and perspectives, reducing bias and ensuring a balanced, unbiased process. It also provides additional insights and validation, mitigates risks, enhances transparency, and increases stakeholder confidence in the chosen course of action, ultimately improving decision quality and resource allocation in complex scenarios.

Figure 4: Result Rank Evaluation from LPSE.
Source: [13].

V. CONCLUSIONS

The integration of the Analytic Network Process (ANP) and Weighted Aggregated Sum Product Assessment (WASPAS) methods involves combining the strengths of both techniques to enhance the decision-making process in Multi-Criteria Decision Making (MCDM) scenarios. The integration of ANP and WASPAS involves using the ANP framework to determine the weights and priorities of criteria and alternatives within a decision network. These values are then used in the WASPAS method to evaluate and rank alternatives based on weighted attribute values. The ANP-derived weights ensure the evaluation of alternatives reflects the relative importance of criteria. This allows decision-makers to analyze complex decision structures and prioritize alternatives based on weighted criteria values. The integration of ANP and WASPAS provides a robust approach to MCDM, combining the analytical depth of ANP with the evaluative power of WASPAS. This comprehensive approach considers structural relationships and dependencies between criteria (ANP) and the aggregation of preferences across multiple criteria (WASPAS), enabling more informed and structured decision-making in complex systems.

ABSTRACT

Optimization of client satisfaction and faster services are the main goals of any service-oriented government organization. However, the land transportation agency in Eastern Visayas Region of the Philippines experience challenges in the management of its flow and processes, as the methods applied are static and traditional. This study aimed to streamline these challenges encountered by clients and employees through the implementation a three-tier queue management system utilizing the agile model incorporating iterative phases of planning, design, development, and testing, with inputs from users' feedback. The evaluation comprises 115 participants composing supervisors, information and communication technology experts, staff, and service clients; mixed quantitative surveys with qualitative usability feedback for user-centric improvement using technology acceptance model and ISO-9126-4 frameworks. The results showed a consistently high score on key criteria, namely, perceived ease of use, structure & layout, relevance, functionality, interactivity and completeness with scores ranging from 4.65 to 4.80, which falls into the highly effective level. Findings represent the strength of the system and design strategy toward reduction of wait times, enhanced transaction flow and processes, and improved transparency. Further findings showed that the three-tier queuing system is beneficial to land transportation agency in fine-tunning their operational processes and increasing revenue.

I. INTRODUCTION

Like many government agencies, Land Transportation hold the responsibility of providing quality services to people in various types [1] including issuance of licenses and permits that involves long queuing in the clients' arrival area. And, this has been a major issue faced by the Land Transportation Districts in Eastern Visayas, Philippines for several years due to prolong waiting time or queuing and the absence of transaction tracker display for the clients. These concerns cause customer dissatisfaction, overcrowding, resulting in backing out from the services, and revenue loss [2]. Such reasons inspire the researchers to conduct a study intending to resolve this major issues choosing LTO – San Juan District as the initial focus of the study.

The best queue should have shorter queues while serving the clients per unit of time because mismanaged queue becomes more challenging and causes dissatisfaction especially as data volume rises [3], [4]. Additionally, Robas et. al., found out that an effective queue management makes the customers feel better; thus, resulting in good service feedback [5]. Moreover, the LTO also uses non-flexible approach of monitoring transactions by giving paper tickets; and if misplaced risk of losing their spot is another concern. The queue system is used for having a systematic and faster process in transacting business because service clients who experience poor service delivery, especially when it entails waiting in long queues could result to departure without availing the services [3], [6].

And the speed of service, which is a major problem in the Philippine government, reflects how efficient the system is by which affects customer satisfaction [2]. The core aim of every institution is not to lose customers or clients by providing with the services that will satisfy their needs [3]. Adding unique features to a queuing application like automation of steps in the workflow through generation of automatic ticket identifiers [5], employee workstation, and client electronic display tracker boost transparency and accountability. Clients' experience in the queue such as ineffeciencies becomes a determining factor of their first impression of the organization and therefore can result to substantial losses [7]. Thus, reducing the unnecessary queuing time became a critical issue for the restaurant owners to promote customers' satisfaction [8]. Developing the three-tier queue management system has a main goal of linking the 3 systems namely client registration, employee workstation and client display.

This implemented system has the intention of reducing wait times, solving the dissatisfaction of service clients, streamlining employees' work performance and the use of resources, and providing a display tracker for the service clients to monitor the status of their requested services in the LTO – District Offices. Queueing system is influential to the supervision and the service quality which lead to revenue management strategies of an organization [9], [10]. Thus, this transformation addresses the increasing demand of the service clients particularly on transparency and wait time reduction. Moreover, queuing provides the cornerstone of efficiency as they assist employees and managers in tracking, prioritizing, and ensuring the delivery of services and transactions [7], [11]. Specifically, it sought to achieve the following objectives:

1. To assess the existing approach of servicing Land Transportation clients;
2. To propose possible enhancements in the existing strategy;
3. To solve the challenges encountered by the service clients and employees during license or permit applications from the service request to completion phases.

II. THEORETICAL REFERENCE

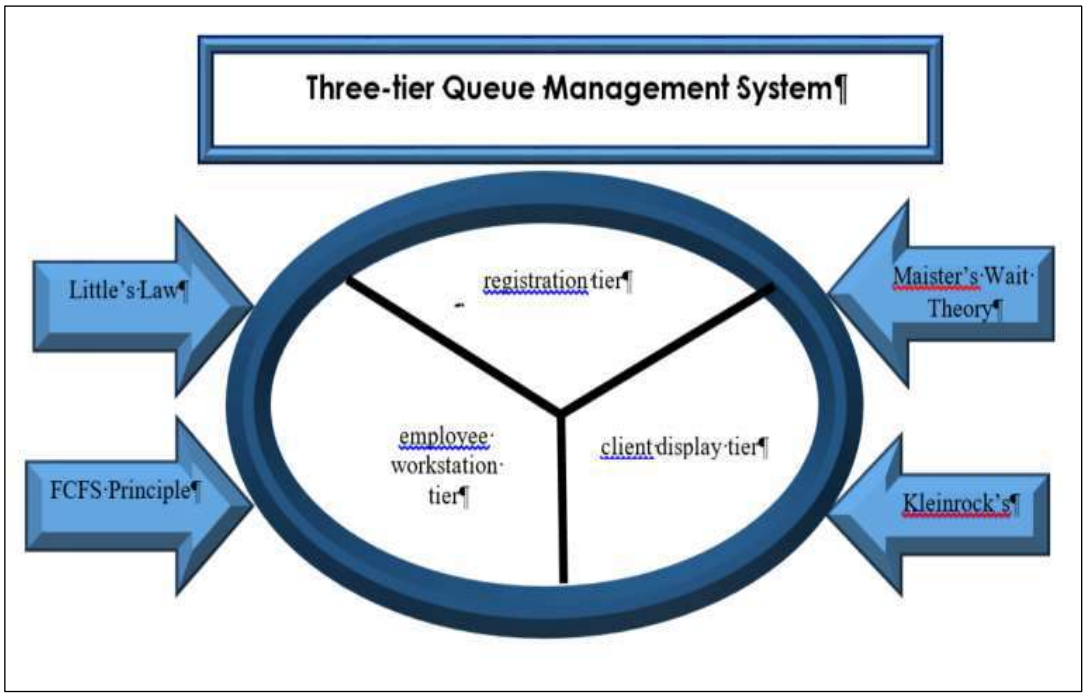

Figure 1: Theoretical Framework.
Source: Authors, (2026).

The three-tier queue management system was structured developed focusing the registration tier during the client's arrival for the selection of the service type and the issuance of the queue number an approach of minimizing bottleneck in the service area; employee workstation tier, and client display tier. In the case of the Land Transportation Districts of Eastern Visayas, Philippines, some of the customers or clients in the case of the Land Transportation leave without receiving the service maybe because they are tired of waiting the line [12] and status of their transaction cannot be tracked by the service clients.

Thus, Little's Law states that the average waiting time and the average number of items or clients (in the case of land transportation application) are important measurements in the decision making of the district supervisor [13]. First-Come, First-Serve Principle is also utilized in this system to ensure fairness by serving customers in the order they arrive or introduces and thereby promotes flexibility for exceptional situations or priority situations such as (Kleinrock, 1975) priorities to tasks or customers-based urgency or value. Moreover, the Service Quality and Perceived Wait Theory of Maister (1985) emphasize perceived waiting times and customer satisfaction are essentials for designing modern queuing systems [14].

The three tiers of the queue management system is implemented to manage service client's transaction's flow, promote quality service, and enhance client experience. Also, effectively controlled clients can avoid overcrowding and thus, the efficiency of the queue model may include important factors such as arrival time in the queue or server, average service time, average waiting time, and queue structure [8-10]. Transparency and real-time tracking of transactions through the display tier thereby enhancing customer satisfaction and ultimately improving overall operational efficiency.

III. MATERIALS AND METHODS

The development of the three-tier queue management system followed the agile model (see Figure 1) and occurred in two primary phases: development and evaluation. Development was iterative process that included: plan, design, develop, test, deploy, and review. This methodology was used because of its operational appropriateness, speed and the capability of adapting to the changing needs of the service clients and the personnel in the Land Transportation Offices (LTOs). In the planning stage, consultation with the key informants from Land Transportation District of San Juan, Southern Leyte, Philippines, District Supervisors, and Regional Administrators was held to elicit service clients' requirements. The consultation made it necessary to have a improved queue system for the Land transportation district offices to replace the traditional physical single-server waiting line to a three-tier queue management system to ensure efficient and fair government service delivery by reducing wait times in a queue lines, and thus, streamlining processes. This input and the fruits of extensive literature reviews shaped the goals for the system development including user-friendly graphical interfaces and a more structured approach to client service delivery. Prototyping in evolutionary refinements to increase scalability and usability was also conducted. Core functionalities include organization and management of clients' flow, minimizing wait times and improving the overall client journey across the different interactive touchpoints. These have been built and evolutionarily improved with the help of modern technology and agile development methodologies from stakeholders' feedback.

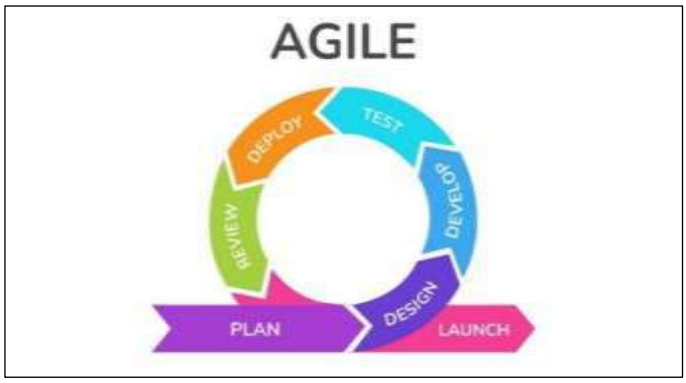

Figure 2: System development model.
Source: Authors, (2026).

On the other hand, the assessment phase used appropriate and detailed frameworks, including the TAM and ISO 9126-4 which laid a basis for assessing the system-based on a criterion that involved perceived ease of use, structure and layout, relevance, interactivity, functionality, and completeness. This phase involved 115 participants, including administrative officer, district supervisors, ICT experts, staff, and randomly selected service clients from LTO – San Juan district and other 19 district and satellite offices in Eastern Visayas, Philippines who completed a 20-item questionnaire adapted from Davis and Elling [15], [16]. According to Isaac et. al., [17], a sample size ranging from 100 to 200 is typically considered adequate for descriptive studies to characterize a population's attributes. To complement this quantitative data, usability testing, and feedback sessions offered qualitative insights into the system's performance. A month after the system's turnover, feedback was solicited to facilitate further enhancements and improvements.

IV. RESULTS AND DISCUSSIONS

A. System Development of the three-tier queue management system

Ease of doing business and efficient government service delivery are the bases of the researchers in identifying the activities involved in all the stages of system development and implementation. Identification of development models, management, hardware, software, graphical user interfaces, online forms and menus for integration were included. Streamlining processes, optimization of wait times, avoiding congestion, and efficiency in the delivery of government service are the intentions of this development. Hence, the queue management system provides simplified, centralized, and enhanced throughput derived analytically particularly to the land transportation service clients making it ready to address a range of real-world application [7].

This also allows the system administrator to monitor every stage, specifically in securing the queue number, status of the transactions in every service counter and up to the completion stage of permits or license application. The system was developed using various programming tools, including Visual Studio Code as source code editor, PHP and Rust programming languages for dynamic scripting, Rust with Tauri as framework for its frontend, Laragon for testing, CSS and Bootstrap for designing and lay outing of the elements and background, JavaScript for creating interactive and dynamic webpages, and MySQL for database, storing user/admin credentials and transaction details; TV/Monitor for the system's real-time display including queuing numbers and their corresponding counter locations; touch screen Monitor for transaction display and a thermal paper use for printing the queue numbers.

Figures 3 and 4 depicts the system architectures, explaining the technical setup of the three-tier queuing management system both for the service client and the employee assistant. These figures describe the entities and how they interact and communicate between the three-tier systems, employees and the service clients and all interface modules. The diagrams show smooth for diverse user groups such as system administrators, touch point employees, and clients because the system is scalable and robust. It also shows a straightforward working and also explains how the application supports real-time flow of processes, enhanced operational efficiency and interactivity.

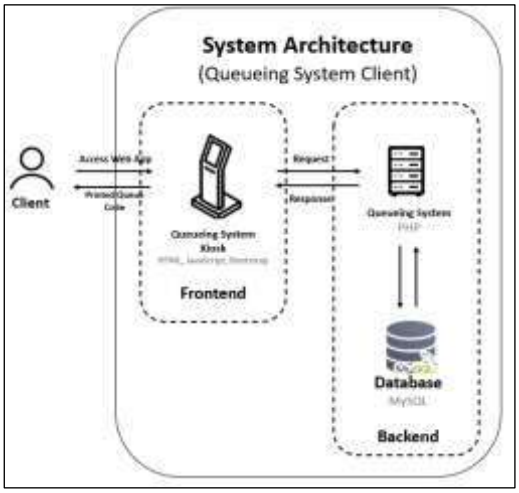

Figure 3: System Architecture for the Client.
Source: Source: Authors, (2026).

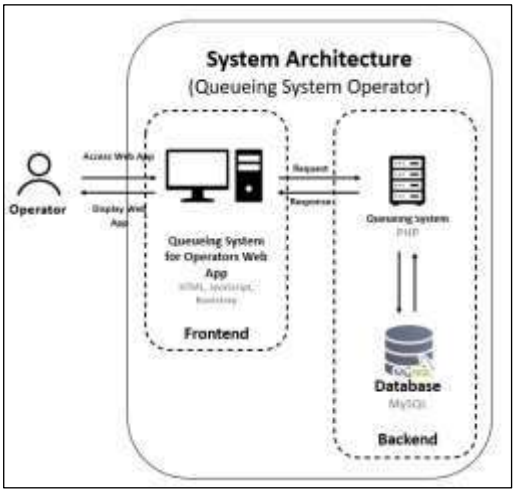

Figure 4: System Architecture for the Employee Assistant.
Source: Authors, (2026).

The interaction process between the service clients accessing the system and the step-by-step flow of the three-tier queue management system is demonstrated in Figure 5 where the service area has a digital kiosk that categorizes the services into Registration, Licensing, and LETAS. Fast printing speed and low maintenance are two major reasons of choosing a thermal printer connected to the kiosk for the generation of a queue number after the client's selection of the service type. Any previous data and information will be cleared for privacy reasons in the registration tier. Correspondingly, all the requested services with the queue numbers are dynamically posted and updated in the second and third tiers of the system called personnel workstation, display tier respectively. A series of rounds of tests were done to ensure that all the touch points were functional and usable.

These various testing operations were divided into three categories, namely: 1) unit testing –where hardware and software were integrated; 2) functional testing- where the LTO – San Juan personnel and service clients were allowed to operate for its functionality if it met their needs and expectations; 3) user acceptance testing- the clients and the employees operates the system to check its completeness and relevance to their needs and expectations; 4) bug fixing iteration where errors in the unit testing phase was noted and the system is revised according to these concerns; running the system is evolutionary until no errors were found. After a month, a review was conducted, where feedback from the personnel and the service clients was acknowledged and resolved.

Figure 6 shows the flow of the personnel tier system that started on the registration providing personal information such as User name-password combinations. The correctness of these information lead to user log in and displays the dashboard that contains number of active workstations, service categories, and personnel users. The transactions in the personnel station is updated in real-time and automatically updates the display tier system. Both audio and visual are the multi channels provided in this three-tier queue management system.

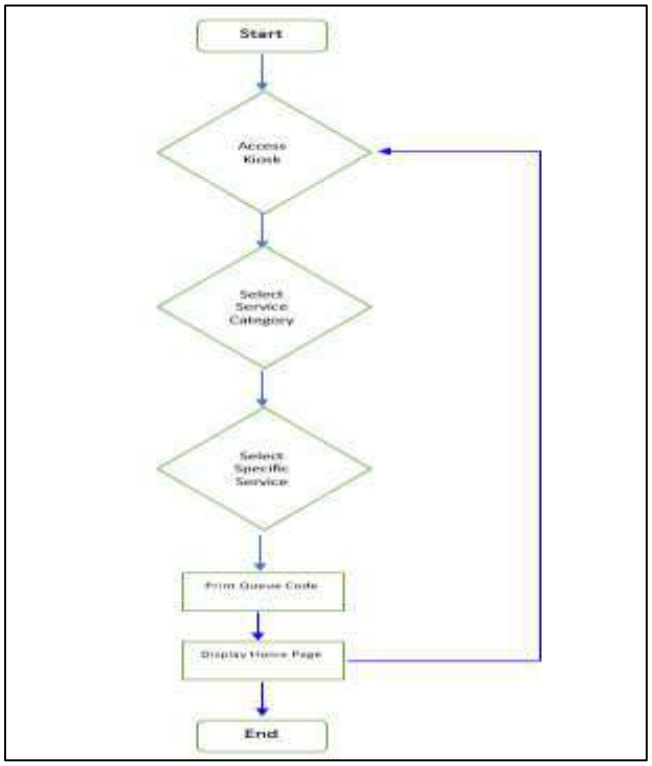

Figure 5: Flowchart Diagram for the Client.
Source: Authors, (2026).

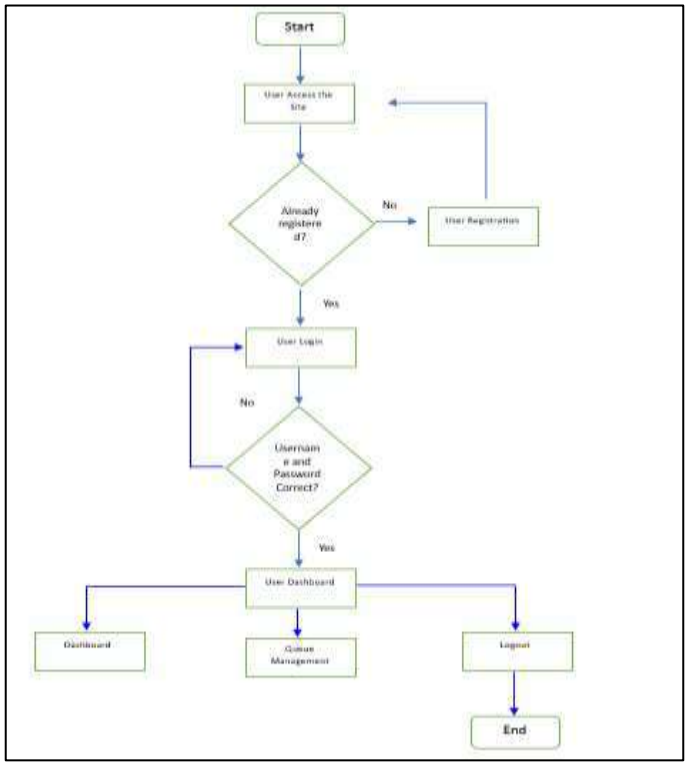

Figure 6: Flowchart Diagram for the Employee.
Source: Authors, (2026).

After the system was operational, it was piloted in San Juan Land Transportation District and in batches to other 19 districts and satellite offices for implementation. The researchers conducted feedback after a month and then scheduled a meeting with the district supervisors, IT experts, and other LTO personnel for enhancements. Hence, user acceptance is the top priority in the initial adoption stage. The final deployment was in full swing after fixing minor errors. This Three-tier Queuing System utilizes a Local Area Network (LAN) - based on web platforms using compatible browsers with interactive interfaces by inputting login credentials. It has limited human intervention, specifically in managing the queues while avoiding line jumpers and alleviating disputes within the queue area, increasing client satisfaction, and providing fast and quality services.

Also, clients feel empowered by being in control of their own time in an automated queuing system, which is directly connected to the quality of services [8], [18]. Waiting for service is a common phenomenon, and customer queuing time has been considered a key factor when evaluating a service-oriented institution, specifically the government [7]. Moreover, using the queuing system significantly affects seventy-eight (78) percent of the quality of service and supervision, considering the utilization rate and average waiting time [9]. Structure and layout of this system meets accessibility standards particularly on the screen reading compatibility of the service clients. Figure 7 displays all the LTO services such as Licensing, Registration and LETAS that are configured and controlled by the admin selected from the personnel appropriately and information technology expert.

The breakdown of these services is handled by the three-tier queue management system including issuance of drivers and conductor licenses, registration and renewal of vehicle, and the issuance of related documents (official receipt, certificate of registration, and other traffic violations). Congestion prevention is one of the most important factors that is considered in the development of this system. Figure 8 is a sample of a unique identification number printed from a thermal printer during the arrival of the waiting area which details the service category that is requested by the client. Also, increasing the number of servers causes a decrease in the average waiting time, thereby increasing service clients satisfaction [19]. However, queue path can be expanded from 1 to 2 with the use of the queue number so that the length of the queue decreases its service time in each service counter [20].

Figure 7: Client transact.
Source: Authors, (2026).

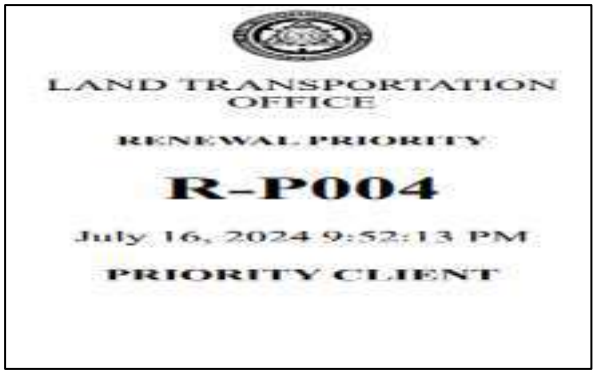

Figure 8: Client Queuing Number.
Source: Authors, (2026).

All operational transactions, namely, number of workstations, the number of active service categories, and the number of personnel users, are displayed in Figure 8 which is the Main Interface of the Queuing System, where each district logs in independently. Each district can navigate the system independently, including Licensing, Registration, and Letas services. In addition, waiting time was minimized from 1 hour per client to 20 minutes. Client satisfaction was noted due to least wait times while maximizing revenue and increasing the productivity among employees [4]. It also enables LTO– -San Juan personnel to efficiently manage clients' flow by getting the queue number and waiting time, monitoring the clients' applications, and controlling the influx of new and existing clients for vehicle registration, paying penalties, and applying for licenses.

Figure 9 is the log in page, where considered entry point of all admin or employee users. It is user-friendly and has a secure authentication method, such as the username-password combination. This serves as the interface where admin or employee users begin interacting with the three-tier queue management system displaying the dashboard offering personalized access to service clients data while ensuring security and management. The functionality of this system prevents unauthorized access as designated by the role-based of the system administrator.

Figure 9: LTO Personnel.
Source: Authors, (2026).

Figure 10: Home.
Source: Authors, (2026).

Figure 11: Transaction.
Source: Authors, (2026).

Figure 10 is the Home page that displays the number of workstations, service categories, and employee users that are updated in real-time. Transaction details, including queue number and station assignment per employee user, are managed and controlled by the system administrator. Each workstation or counter contains a click-enabled button to represent a transaction with corresponding queue number per client that are served, called, forwarded, finished, and discarded. If one counter becomes overloaded, queue numbers will be reassigned to other available counters.

Figure 11 is a sample of the transaction page in the three-tier queue management system containing a real-time and visually enticing interface with which employee users could engage queue controls such as call service clients, forward, finish or complete transactions, discard/cancel and hold or pause service done in multichannel approach such as audio and digital. Queue entries in a specific workstation including complete transaction history can also be accessed to efficiently optimize client services and provides next steps of every transaction for easy re assignment of queue numbers and counters. This design embodies current principles of modern queuing system that is simple and well-organized that are in compliance with data protection regulations.

To ensure an efficient and transparent servicing of the clients, a call interface in the employee workstation was implemented as depicted in Figure 12. This interface notifies the service clients in their turn for service and applies dynamic routing to the correct workstation or counter through audio and display monitor announcements. To optimized transparency and unnecessary inquiries, all active workstations are displayed in the third-tier panel as shown in Figure 13. This display updates transactions in real-time that are called, forwarded, or completed. Also, this panel prevents from the occurrence of a dispute by providing a digital summary visible to service clients**.**

B. Evaluation of the Three-tier Management System

In the evaluation phase of the system as shown in Table 1, LTO – administrative officer, district supervisors, ICT experts, staff and the service clients consistently with high ratings across all variables. The mean scores for perceived ease of use, hyperlink, structure and layout, relevance, functionality, interactivity, relevance, and completeness were well at the very high effectiveness level between 4.65 and 4.80. These ratings show the system's performance is very good since it meets the users' expectations in different criteria. Finally, this indicate that the respondents had a high level of concurrence with one another towards the overall effectiveness of this system.

Table 1: Summative evaluation of the three-tier queue management system across different respondent groups.

Variables	Mean	Min	Max	Effectiveness Level
Perceived ease of use	4.65	3.00	5.00	Very high
Structure and Layout	4.65	3.00	5.00	Very high
Relevance	4.80	3.00	5.00	Very high
Interactivity	4.70	3.00	5.00	Very high
Functionality	4.70	3.00	5.00	Very high
Completeness	4.70	3.00	5.00	Very High
Note: 1.00-1.79 Very low; 1.80-2.59 – Low;2.60-3.39 – Average; 3.40-4.19 – Moderately high; 4.20-5.00 – Very high				

Source: Authors, (2026).

All the variables are uniform with minimum and maximum scores ranging from 4.65 to 4.80. This range suggests that the system can provide a good experience to most users while flagging areas for improvement. Relevance is the highest rated with M=4.80, implying that the system can stay in line with what its users need and eventually expect. Similarly, consistency of high rankings in completeness, functionality and interactivity indicates that its necessary modules are practically functioning and fosters dynamic exchange between the user and the systems. Strong scores across all dimensions mean that there has been a robust design and usability of the system in the land transportation's operational transactions. However, perceived ease of use, structure and layout with at least 4.65, mean it should strive at further refinements what could answer some of the evaluation from the users and ensure that the system remains helpful and responsive to diverse clients' need. The findings also suggest system's strengths and offer insights into what needs to be improved to ensure that diverse users have expectations met so that land transportation services it provides are enhanced through innovative digital solutions.

Moreover, the findings also revealed that the customer waiting time is reduced from an hour to 20 minutes and the negative impression was alleviated thereby increases client's satisfaction, fairness and transparency. The development and implementation of this three-tier queue management system is aligned with the mandate and principles of LTO towards fair and transparent services to clients. It also fosters trust and confidence in LTO personnel by reducing clients' conflict and faster services. Lastly, the queuing system enhances the client's ease of accessing the system and solves the challenges encountered by the current traditional queuing approach. More importantly, decreasing the average waiting time of service clients in a queue, increases satisfaction [19], [20]. To have a uniform queuing system for the LTO - Eastern Visayas Region, Philippines, installation and implementation was done to other 19 districts and satellite offices with the approval of the regional director since these offices encountered identical challenges with LTO – San Juan District.

V. CONCLUSIONS

The developed queuing system is very significant to LTO supervisors, personnel and the service clients of the region because it enables them to improve users' satisfaction and enhanced operational efficiency. The reduction of wait wait times from the registration to the completion of the transaction increases employee productivity resulting to more satisfied clients leading to increased revenue. This system provides positive experiences to service clients and word of mouth referrals, thereby stronger agency reputation. Furthermore, the functionality aspect of the system aids the supervisors in having real-time monitoring and reporting. Interactivity of the system interfaces creates an organized communication between the users and the system making all the services fast and functional. Finally, management of the flow of clients' transactions are straightforward, facilitating faster personnel assistance, appropriate allocation of available resources, and streamlining the entire land transportation operations. Finally, this queuing system was developed in a three-tier design for future expansion.

ABSTRACT

Now a days, many metaheuristic optimization algorithms are invariably used in the field of engineering and data science. In structural mechanics, many stochastic optimization algorithms are employed for solving the complex numerical problems. Suitable optimization algorithms must be selected as the structural mechanics problems are often having non-linear objective function, constraints are having complex behavior and many design variables are involved in it. In present study, the capability and competency of standard grey wolf optimizer (GWO) with modified grey wolf optimizer (mGWO) and grey wolf optimizer with variable weight (vwGWO) is observed through several benchmarked numerical case studies. To control the geometric constraints, penalty method is employed in the study. The performance of the standard GWO algorithm is compared with the results obtained by the modified grey wolf optimizer and grey wolf optimizer with variable weight.

I. INTRODUCTION

Since last three decades, metaheuristic optimization techniques are evolved very fast with prominent features. Some of them are very popular techniques like, Genetic Algorithm (GA) [1], Particle Swarm Optimization (PSO) [2], Artificial Bee Colony (ABC) [3], Ant Colony Optimization (ACO) [4], Grey Wolf Optimizer (GWO) [5] etc., not only in the field in computer science but also in the field of engineering, technology and structure mechanics as well. The metaheuristic optimization algorithms are very simple to implement and also flexible.

They are mostly inspired by simple concepts and this allows the researchers to simulate the different concepts from nature, to propose newer metaheuristic approach, to hybridize two or more metaheuristic algorithms or to improve the existing metaheuristic optimization algorithms [5]. Many researches were also performed in the field of optimization considering various case studies and their results are compared [6]. In article, Grey wolf optimizer explained briefly in section II followed by its variants, mGWO and vwGWO in sections III and IV respectively. Three case studies are discussed implementing GWO, mGWO and vwGWO in section V. The competency of the GWO, metaheuristic algorithm with mGWO and vwGWO is discussed in section VI.

II. GREY WOLF OPTIMIZER

Grey wolf optimizer is proposed by [5] which is based on the social and hunting behavioral of grey wolves. Grey wolves are apex predators belongs to Canidae family and hence they are at the top of the food chain. Grey wolves are living in groups. The group size on an average of the wolves is generally 5 to 12.

Grey wolf optimizer imitates the social behavior and hunting mechanism of the grey wolves. The optimum value search mechanism of the algorithm is based on the three steps of hunting technique adopted by the grey wolves:

- Tracking, chasing and approaching the prey.
- Pursuing, encircling and harassing the prey until it stops the motion.
- Attacking the prey.

The mathematical model of the grey wolf optimizer is outlined as follows:

II.1 SOCIAL HIERARCHY

The optimum solution or the fittest solution of the problem is decided as per the social hierarchy of the wolves in a pack to model the optimization algorithm mathematically. In a pack of wolves, the leader wolf is considered as α wolf. The position of the α wolf is noted as fittest solution from the possible solutions. The second-best solution is considered as the position of β wolves which are the subordinate wolves to leader wolf and help in decision making and other group activities. The lowest ranking of the wolves in a pack is known as ω. These are the wolves who play the role of scapegoat or sometimes work as baby sitters. The third best solution is considered as the position of δ wolves. If the wolf is not α wolf, β wolf or ω wolf, he/she is considered as δ wolf. This type of wolves scouts the pack and looking the boundary of the territory. In case of any danger, they warn the pack.

II.2 ENCIRCLING THE PREY

During hunting, the wolves encircle the prey. The encircling behavior of the wolves is modelled mathematically as follows:

$$\vec{D} = \left|\vec{C}.\overrightarrow{X_p}(i) - \vec{X}(i)\right| \quad (1)$$

$$\vec{X}(i+1) = \overrightarrow{X_p}(i) - \vec{A}.\vec{D} \quad (2)$$

$$\vec{X}(t) = \frac{\overrightarrow{X_1} + \overrightarrow{X_2} + \overrightarrow{X_3}}{3} \quad (3)$$

Where, i indicates the current iteration. $\vec{A}$ and $\vec{C}$ are the vectors coefficients. $\overrightarrow{X_p}$ indicates the position of the prey and $\vec{X}$ is the position vector of the grey wolf. The vectors coefficients $\vec{A}$ and $\vec{C}$ are calculated as per following expressions:

$$\vec{A} = 2\vec{a}\,.\vec{r}_1 - \vec{a} \quad (4)$$

$$\vec{C} = 2\,.\vec{r}_2 \quad (5)$$

Here, $\vec{r}_1$ and $\vec{r}_2$ are arbitrary vectors in the domain of [0,1] and $\vec{a}$ is the decrement vector which varies linearly from 2 to 0.]

II.3 HUNTING TECHNIQUE

In hunting of the prey, the hunt is generally guided by the α wolf. β wolves and δ wolves also participate in hunting. Initially, there is no idea about the optimum(prey) position in a search space and hence to model the mechanism mathematically, the initialization of the hunt by the wolves in the search space are recorded as initial solution and the positions assigned as per the fitness of the solution. The best initial solution is recorded as α-position, second best solution is recorded as β-position and third best solution is recorded as δ-position.

General steps of GWO algorithm as follows:

Grey wolf pack formation
Initialize the position of wolves
Fitness calculation
Position record
Repeat
Update the random parameters
Fitness calculation
Position record appraisal
α-wolves (the best solution),
β-wolves, (the second best solution)
δ-wolves (the third best solution)

until
Convergence criterion achieved

The controlling parameter ‘a’ reduces linearly from 2 to 0 when the iterations are being carried out.

$$a = 2\left(1 - \frac{i}{N}\right) \tag{6}$$

Where, i is the $iteration$ and N is $maximum\ number\ of\ iterations$.

III. MODIFIED GREY WOLF OPTIMIZER (mGWO)

Modified grey wolf algorithm is proposed by [7] mainly focused on the good balance between proper exploration and exploitation to find the global optima of real problems. In standard GWO algorithm, the coefficient vector $\vec{A}$ randomly varies between '-a' to 'a' and simultaneously over the course of iterations, $\vec{a}$ varies linearly from 2 to 0. Balancing between $\vec{A}$ and $\vec{a}$ needs much attention and fine adjustment is required to avoid the solution falls under local optima. To overcome this issue, the researchers suggested to use exponential decay function for tuning the parameter 'a'. Earlier, In standard GWO, the value of 'a' decreases from 2 to 0 linearly as per equation (6). as per the suggested exponential decay function (Mittal N. et al 2016) the expression is as follows:

$$a = 2\left(1 - \frac{i^2}{N^2}\right) \tag{7}$$

Where, i is the $iteration$ and N is $maximum\ number\ of\ iterations$. The suggested approach is adopted in the proposed research and applied to the benchmarked problems in section V to derive the competency and worthiness of mGWO.

IV. GREY WOLF OPTIMIZER WITH VARIABLE WEIGHT (vwGWO)

To make the GWO algorithm very efficient to handle the variety of problems with multi variables and high complexity of the real-life problems of engineering, a new hypothesis related to search mechanism of the grey wolf optimizer by Gao Z. M. et al in 2019 [8] is proposed as improved grey wolf optimization with variable weight (vwGWO). In standard GWO algorithm as per equation (2.3), dominants play an equal role in search mechanism of grey wolf optimizer. During exploration process, in the initial phase of algorithm, the alpha wolf (α) has the better position than β wolf or δ wolf in each iteration cycle. In searching process α wolf is the better contributor so his/her position should be given weight more than the positions of β wolf and δ wolf in next search cycle [8].

$$\vec{X}(t+1) = w_1\overrightarrow{X_1} + w_2\overrightarrow{X_2} + w_3\overrightarrow{X_3} \tag{8}$$

$$w_1 + w_2 + w_3 = 1 \tag{9}$$

The weights w_1, w_2 and w_3 are associated with α wolf, β wolf and δ wolf respectively and must satisfy the condition, $w_1 \geq w_2 \geq w_3$. For vwGWO, the proposed equations for variable weights are as follows:

$$\begin{aligned} w_1 &= \cos\theta, \\ w_2 &= \frac{1}{2}\sin\theta\cos\varphi, \\ w_3 &= 1 - w_1 - w_2 \end{aligned} \tag{10}$$

Where,

$$\theta = \frac{2}{\pi}\arccos\frac{1}{3}\cdot\arctan(i)\,; \tag{11}$$

$$\varphi = \frac{1}{2}\arctan(i) \tag{12}$$

V. NUMERICAL CASE STUDIES

Three cases are discussed to establish the competence of the GWO with its variants i.e. mGWO and vwGWO. MATLAB code is prepared for each numerical case and 10 runs are taken for varying search agents and number of iterations.

Case: I CANTILEVER BEAM

Problem statement:

Figure 1 shows stepped hollow cantilever beam with constant thickness, of square cross section. It is subjected to a vertical load (P) at free end of the beam structure. The problem is of weight minimization and design variables are height of different beam sections. The thickness of the beam elements is fixed as t = 2/3.

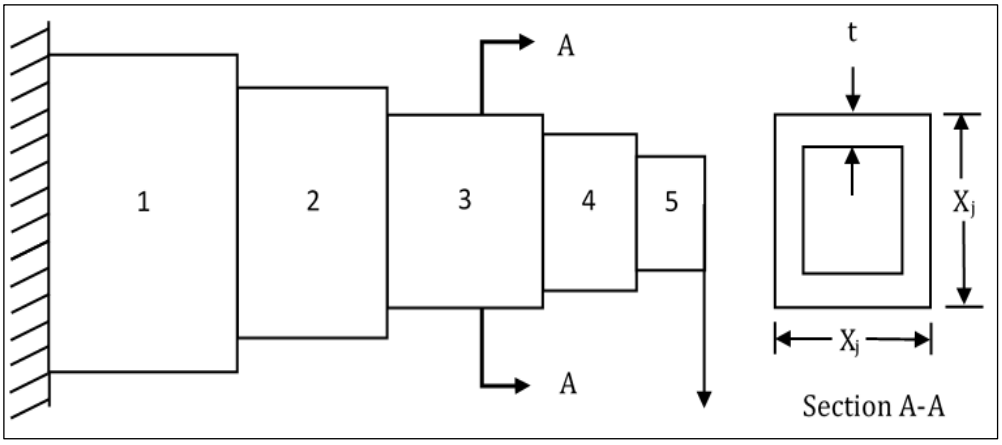

Figure 1: Cantilever Beam.
Source: Authors, (2026).

***Objective Function*:** Minimization

$$f(x) = f(x_1, x_2, x_3, x_4, x_5) = 0.0624\,(x_1 + x_2 + x_3 + x_4 + x_5)$$

***Constraints*:**

$$C = \frac{61}{{x_1}^3} + \frac{37}{{x_2}^3} + \frac{19}{{x_3}^3} + \frac{7}{{x_4}^3} + \frac{1}{{x_5}^3} - 1 \leq 0$$

***Range*:**

$$0.01 \leq x_j \leq 100$$

Table 1: Comparison of the results for cantilever beam problem.

	GWO	**mGWO**	**vwGWO**
X_1 (Element – 1)	6.0465	5.9381	6.0199
X_2 (Element – 2)	5.2891	5.3576	5.2858
X_3 (Element – 3)	4.4449	4.5531	4.5513
X_4 (Element – 4)	3.5429	3.4594	3.5022
X_5 (Element – 5)	2.1544	2.1772	2.1177
$F_{min.}$	1.3402	1.3407	1.3402

Source: Authors, (2026).

It is noticed that to optimize the weight of stepped cantilever beam, GWO requires 25 wolves and 50 iterations to reach the optimum function value. mGWO requires 25 wolves and 100 iterations to reach the optima and vwGWO needs 25 wolves and 100 iterations to reach the optimum solution.

Case: II TUBULAR COLUMN DESIGN

Problem statement:

Figure 2 shows tubular column section which carries a vertical load P. The column is joined by means of hinged joints at both the ends. The mean dia. of the column is kept between 2 cm to 14 cm and the thickness ranged between 0.2 cm to 0.8 cm. The induced stress in the tubular column should not be more than the buckling stress and the yield stress. The total cost of the column considering both, material cost and construction cost, can be taken as 5W + 2d, where W stands for weight in kgf and d is mean dia. of the column in cm. The cost of the component is taken as objective of the problem which should be minimize. The material property and related particulars of the column is given below:

P = 2500 kgf (compressive);
l = 250 cm;
Yield stress = 500 kgf/cm^2;
Modulus of Elasticity= 0.85 X 106 kgf/cm^2;
Weight density = 0.0025 kgf/cm^3;

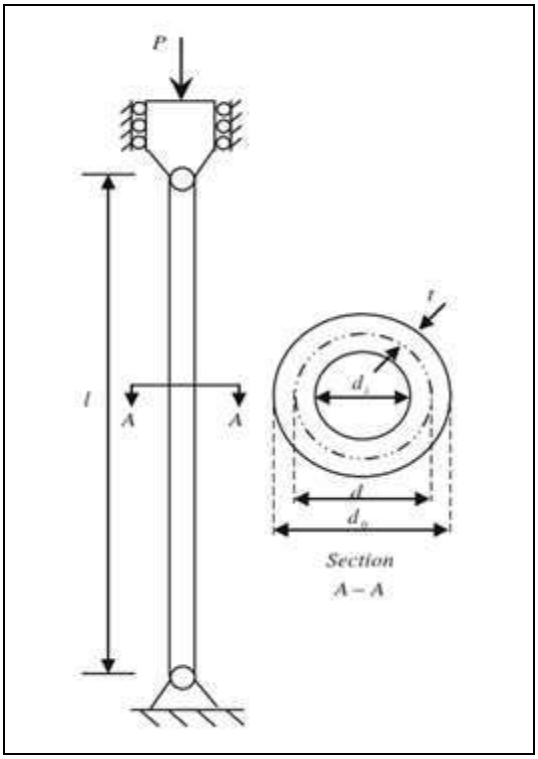

Figure 2: Tubular column design.
Source: Authors, (2026).

***Objective Function*:** Minimization

$$f(x) = f(x_1, x_2) = 9.82\, x_1 x_2 + 2x_1$$

Where,

$$X = \begin{Bmatrix} x_1 \\ x_2 \end{Bmatrix} = \begin{Bmatrix} d \\ t \end{Bmatrix}$$

***Constraints*:**

$$c_1 = \frac{2500}{\pi x_1 x_2} - 500 \leq 0$$

$$c_2 = \frac{2500}{\pi x_1 x_2} - \frac{\pi^2 (0.85 \times 10^6)({x_1}^2 + {x_2}^2)}{8(250)^2} \leq 0$$

$$c_3 = \frac{2}{x_1} - 1 \leq 0$$

$$c_4 = \frac{x_1}{14} - 1 \leq 0$$

$$c_5 = \frac{0.2}{x_2} - 1 \leq 0$$

$$c_6 = \frac{x_2}{0.8} - 1 \leq 0$$

***Range*:**

$$2 \leq x_1 \leq 14$$

$$0.2 \leq x_2 \leq 0.8$$

Table 2: Comparison of the results for tubular column problem.

	GWO	**mGWO**	**vwGWO**
d (mean diameter)	5.4511	5.4501	5.4495
t (thickness)	0.29204	0.29222	0.29229
$F_{min.}$	26.5351	26.54	26.5404

Source: Authors, (2026).

It is noted that to optimize tubular column design, standard GWO requires 25 wolves and 200 iterations to reach the optimum function value. mGWO requires 25 wolves and 100 iterations to reach the optima and vwGWO needs 25 wolves and 200 iterations to reach the optimum solution.

Case: III THREE BAR TRUSS

Problem statement:

Figure 3 presents three bar truss. The objective is to find the optimum cross sectional area, to minimize the volume of the three bar truss structure. Each member length of the structure is 100 cm. The structure is subjected to load (F) of 2 kN/cm^2 and the permissible stress (σ) is not exceed to 2 kN/cm^2.

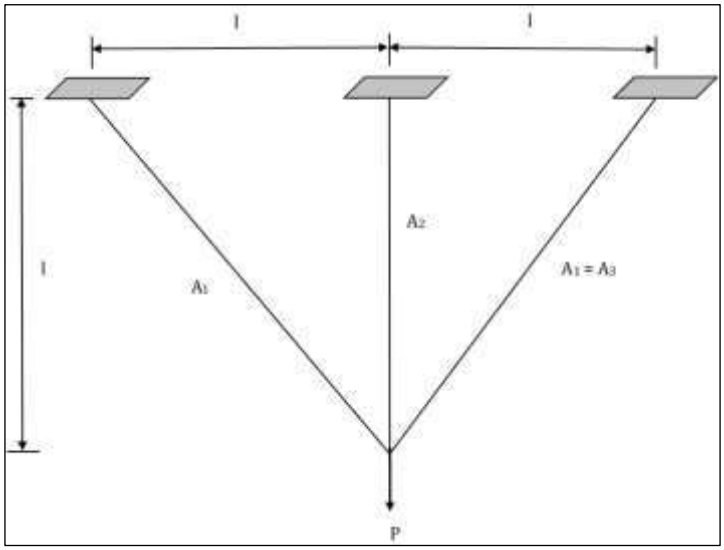

Figure 3: Three bar truss.
Source: Authors, (2026).

***Objective Function*:** Minimization

$$f(x) = f(x_1, x_2) = \left(2\sqrt{2}x_1 + x_2\right) \times l$$

Where,

$$X = \begin{Bmatrix} x_1 \\ x_2 \end{Bmatrix} = \begin{Bmatrix} A_1 \\ A_2 \end{Bmatrix}$$

***Constraints*:**

$$c_1 = \frac{\sqrt{2}x_1 + x_2}{\sqrt{2}{x_1}^2 + 2x_1x_2} F - \sigma \leq 0$$

$$c_2 = \frac{x_2}{\sqrt{2}{x_1}^2 + 2x_1x_2} F - \sigma \leq 0$$

$$c_3 = \frac{1}{x_1 + \sqrt{2}x_2} F - \sigma \leq 0$$

***Range*:**

$$0 \leq x_1, x_2 \leq 1$$

Table 3: Comparison of the results for three bar truss structural problem.

	GWO	**mGWO**	**vwGWO**
A_1 (C/S area of member 1 & 3)	0.78776	0.78453	0.78947
A_2 (C/S area of member 2)	0.41085	0.42026	0.40601
$F_{min.}$	263.897	263.925	263.8969

Source: Authors, (2026).

It is noted that to optimize the cross-sectional area of the members of three bar truss structure, GWO requires 25 wolves and 100 iterations to reach the optimum function value. mGWO requires 20 wolves and 100 iterations to reach the optima and vwGWO needs 25 wolves and 100 iterations to reach the optimum solution.

VI. CONCLUSION

The present work explores the capability of metaheuristic optimization algorithms, GWO and also employed its modified versions known as modified GWO (mGWO) and improved GWO with variable weight (vwGWO). In case of stepped cantilever beam, GWO is found competent enough against mGWO and vwGWO whereas for tubular column design and three bar truss, mGWO is found competent in terms of less search agents and minimum iterations required to converge the solution. However, the effect of the upgraded versions i.e. mGWO and vwGWO is effective in case of multi-objective multiple constraints wherein the various variables affect the domain differently in the domain simultaneously.

VII. FUNDING

There are no financial implications from any sources or funding agency.

ABSTRACT

MobileNet introduced depthwise separable convolution, significantly reducing computations in comparison to standard convolution, making them fit for edge computing. Parameter-efficient models like MobileNet-v1 can be pruned to further reduce the number of parameters. In most of the pruning methods, pointwise convolutional parameters are pruned as they are large in number and depthwise convolutional parameters are kept dense. The efficacy of MobileNet pruning for edge deployment depends critically on a sparsity-aware execution environment. This paper focuses on implementing sparse aware pointwise convolution unit that leverage weight sparsity using Variable Density Bound Block (VDBB) technique. The activation stationary method is also incorporated, as it saves the power to fetch activations continuously. The proposed architecture is implemented on the FPGA platform using Vivado 2024.1. Implementing the sparse-aware architecture on the xc7z045ffv900-1 FPGA resulted in a 358mW reduction in power, a 50% reduction in DSPs, and a 24.06% reduction in LUTs compared to the sparse-unaware architecture. An engine from the proposed architecture was synthesized in ASIC using the TSMC 90 nm standard cell library, resulting in a 30.87% reduction in power and a 32.89% reduction in area when compared to a sparse unaware engine.

I. INTRODUCTION

Convolution Neural Networks (CNNs) are crucial in modern signal processing, such as classification, denoising, and pattern recognition. CNN can learn relevant features directly from the data, reducing the need for manual feature engineering. The popular architectures among CNN are Dense CNN [1], AlexNet [2], VGG [3], and GoogLeNet [4]. These architectures have millions of parameters and billions of computations. Storing them at a single-precision floating-point demands Megabits of storage space. Performing millions of computations demands enormous power. More storage space and high-power consumption are not desirable for edge devices. The dense model parameters can be reduced by using methods such as quantization, pruning, and so forth. Quantization contributes to reduction in memory footprint as it reduces the precision of weights and activations.

Pruning decreases the quantity of parameters; pruning can be structured or unstructured contributing to block sparsity and tensor sparsity respectively. Also, there are lightweight models like MobileNet-v1 [5], MobileNet-v2 [6], ShuffleNet [7], and Squeeze Net [8] with a smaller number of parameters and computations but with a considerable amount of accuracy drop. MobileNet, ShuffleNet, and EfficientNet-Lite use Depthwise separable convolution, as the number of computations got reduced by $((1/N) + (1/D_k^2))$ compared to standard convolution, where N is number of kernels and Dk is the dimension of kernel. The question arises: can lightweight models like MobileNet be pruned? as it is less redundant. But certain pruning techniques for MobileNet-v1 yielded remarkable results. Automated Gradual Magnitude Pruning (GMP) algorithm [9] prunes the lowest magnitude weights, demonstrated that pruned dense MobileNet with 50% sparsity is better in accuracy than 0.75 MobileNet with a lesser number of parameters.

Soft Threshold Weight Reparameterization (STR) [10] achieved good accuracy for CNN in case of unstructured sparsity. STR achieved an accuracy of 68.35% using 101M FLOPS (FLoating point Operations Per Second) at 75.28% sparsity, where GMP achieved an accuracy of 67.7% using 163M FLOPS at 74.11% sparsity for MobileNet-v1. Deep Q-Learning for Pruning Deep Neural Networks (QLP) [11] method based on deep reinforcement learning achieved a good amount of accuracy 71.06% at 50% sparsity with an accuracy drop of 0.89% compared to the baseline MobileNet-v1. These results demonstrate that MobileNet-v1 can be pruned. It is interesting to note that the first layer and the depthwise convolutional layers are kept dense in GMP, QLP methods. STR made depthwise convolutional layers less sparse.

So, only Pointwise convolutional layers are pruned in these methods as it has 74.59% of parameters [5]. All these methods contribute to unstructured sparsity. Unstructured sparsity is advantageous while deploying the model on edge devices only if the designed hardware is sparse aware. So, this work focuses on implementing sparse-aware architecture for pointwise convolutions using the Variable Density Bound Block technique, which works for all sparsity levels without losing non-zero parameters. The activations are kept stationary until the dot product with all the kernels are computed, which reduces the power consumption to bring activations from the buffer to the processing units continuously.

II. POINTWISE CONVOLUTION

Pointwise convolution is also known as 1x1 convolutions. Usually, it is paired with depthwise convolution in MobileNet-v1, as depthwise convolution lacks channel mixing to learn complex hierarchical features [5]. Pointwise convolution is utilized in ResNet bottlenecks to expand and compress channels, in ShuffleNet for channel mixing, and in attention blocks for channel recalibration. So, pointwise convolution is used for channel mixing and for dimension adjustments. Pointwise convolution is quite like standard convolution but the only difference is its kernel spatial dimensions.

In pointwise convolution, the kernel dimension is 1x1xC where C is the number of channels. Pointwise convolution is nothing but the dot product of the kernel and the part of the activation layer as shown in Figure.1. Assuming an activation layer of dimension HxWxC and N number of kernels of dimension 1x1xC, then the pointwise convolution output dimension is HxWxN. N decreases the channel dimension if it is less than C and increases if it is greater than C. Mathematically, let activation layer be A $\in \mathbb{R}^{HxWxC}$ and kernel be W1 $\in \mathbb{R}^{1x1xC}$ then pointwise convolution output at a particular location (h, w) is

$$P(h,w) = \sum_{c'=1}^{C} A(h,w,c') \,.\, W_1(1,1,c') \quad (1)$$

Where

H= Number of rows of activation layer

W= Number of columns of activation layer

C= Number of channels

III. PROPOSED ARCHITECTURE

Figure.2. shows the proposed architecture for sparse aware pointwise convolution unit. The proposed architecture supports parallelism by segregating feature maps into tiles [12]. The proposed architecture was designed for MobileNet-v1, but it can also be used for different models where pointwise convolutions are needed, just by redesigning buffers. MobileNet-v1 feature maps have channel sizes that are multiples of 32, with the exception of input image channels, as shown in Figure.3. So, each data word in the activation buffer contains 32 activations, which are taken in channel-wise direction to enable 32 channel unrolling. According to the position of non-zero weights, a vector of 1's and 0's was stored as a mask in the mask buffer as shown in Figure.4. As the weights are sparse, the weight buffer conserves memory by storing only non-zero weights. Entire activations along channel-wise at a particular location are fetched into the activation register from the activation buffer. For instance, if there are 64 channels, then two data words are fetched into the activation register. These activations in the register are kept stationary until all kernels are convolved with these activations.

The activation selector uses Variable Density Bound Block (VDBB) to choose activations corresponding to non-zero weights from the activation register using mask value. Because of VDBB, each engine has sixteen multipliers for 32-channel unrolling. The concept of VDBB is discussed in detail in section 4. Each engine takes one clock cycle if sparsity is greater than 50% and two clock cycles if sparsity is less than 50% for 32 channels. Partial results are accumulated until all channels at a specific spatial location within the feature map are processed.

IV.ACTIVATION SELECTOR

Sparsity is nothing but the existence of zeros in the weight tensor or in activation tensor. Pruning causes sparsity in weights, while ReLU causes sparsity in activations. Based on the distribution of non-zero elements in sparse tensors, sparsity can be Random, block sparse, density bound block as shown in Figure.5. If non-zero elements are distributed randomly, as illustrated in Figure. 5(a), this configuration is referred to as random sparse. Usually sparsity in Convolutional Neural Networks (CNNs) is random. This randomness creates an overhead in hardware while inferencing the model, as indexes of non-zero elements need to be stored specifically and the load is also unpredictable. In the context of block sparsity, where non-zero elements are organized in blocks, as illustrated in Figure. 5(b), fewer indexes are required compared to a random arrangement. However, imposing block sparsity on CNNs can lead to a decline in accuracy. In Density Bound Block (DBB) [13], the number of non-zero elements in a block are predefined, instead of forcing all the elements in a block to zero or fully dense as shown in Figure.5(c), which saves from accuracy drop.

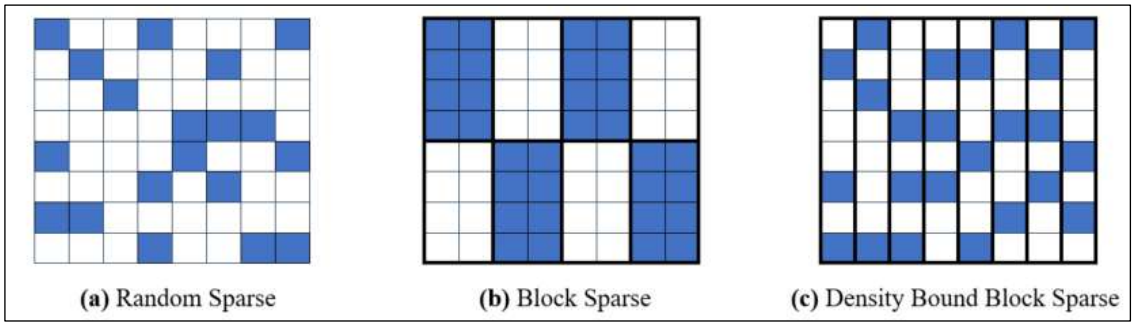

Figure 5: Types of Sparsity, filled boxes represents non-zero elements and empty boxes represent zeros.
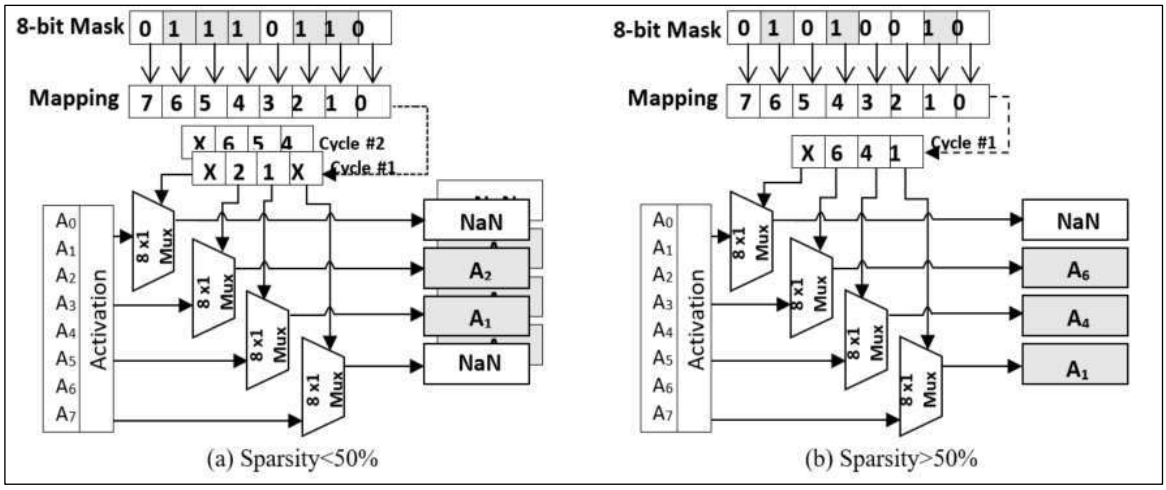
Source: Authors, (2026).

DBB enables the use of Multiply and Accumulate (MAC) units in proportion to the level of sparsity. For instance, with 50% sparsity, only 50% of the usual MACs are needed, which significantly lowers hardware costs. But the problem is, sparsity is fixed at design time leading to loss of non-zero elements when sparsity is less than predefined sparsity. To overcome this issue, Variable Density Bound Block Technique (VDBB) [14] had been designed, which works at all sparsity levels. VDBB uses the same number of MACs as DBB. As the weights are randomly sparse, and the engine in the architecture processes 32 weights at once, this results in varying sparsity levels. To handle these varying sparsity levels, the proposed architecture uses VDBB as activation selector. Thus, no non-zero element is discarded during computation. The design for VDBB is taken from [15]. As shown in Figure. 6, sparsity less than 50% takes two clock cycles to compute, and sparsity greater than 50% takes one clock cycle to compute.



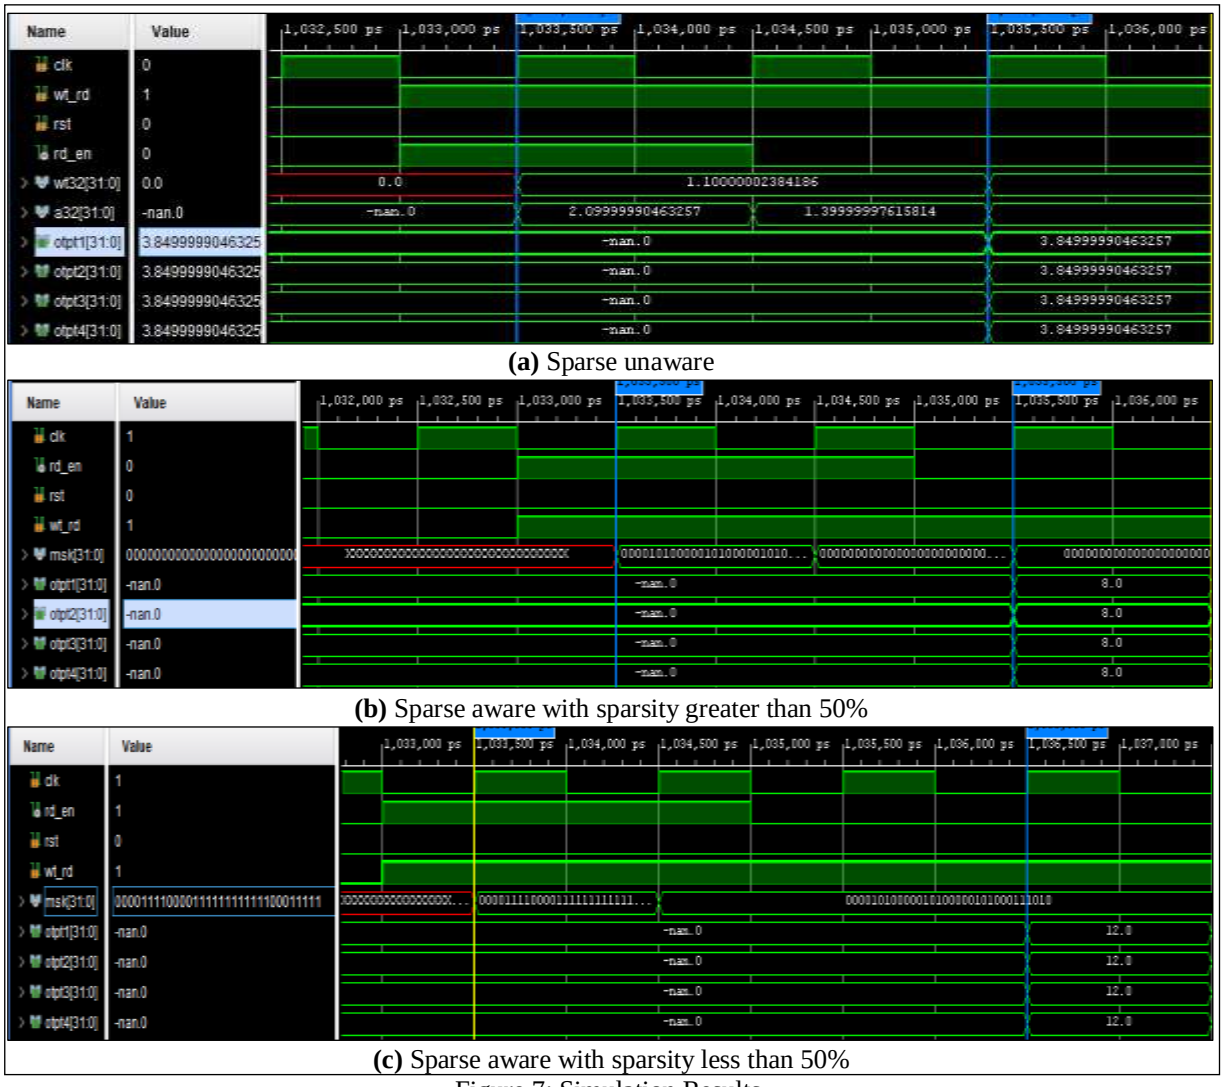


Figure 6: Activation Selector based on VDBB.
Source: Authors, (2026).

The mask value is used to determine the index values to choose activations corresponding to non-zero weights. Indexes are given to multiplexers, which select the corresponding activations. The indexes are organized in such a way that if sparsity is greater than 50%, then the indexes are accumulated in one clock cycle as shown in Figure. 6(a); if sparsity is less than 50%, then the indexes are organized in two clock cycles as shown in Figure.6(b).

V. RESULTS AND DISCUSSIONS

The proposed architecture had been implemented using Xilinx Vivado 2024.1 targeting xc7z045ffv900-1. Verilog HDL is used to design the architecture. Figure.7 shows the simulation traces for sparse-unaware and sparse-aware architectures. For the depth of 64, it is observed from Figure.7(a) and Figure.7(b) that in both sparse unaware and sparse aware (both data words exhibit >50% sparsity) simulation, two clock cycles are needed to get the final output, as two data words need to be processed. Figure. 7(c) presents a mixed-sparsity case in which one data word has sparsity below 50% (requiring two cycles) while the other exceeds 50% (requiring one cycle), resulting in a total of three clock cycles. These results indicate that the sparsity-aware implementation incurs an extra clock cycle whenever a processed data word's sparsity falls below the 50% threshold. Activation-stationary behavior is evident from the rd_en signal, as shown in Figure 7. The signal asserts only when activation words need to be fetched from the activation buffer according to the configured depth, thereby eliminating continuous buffer reads and reducing power consumption.

(a) Sparse unaware

(b) Sparse aware with sparsity greater than 50%

(c) Sparse aware with sparsity less than 50%

Figure 7: Simulation Results.
Source: Authors, (2026).

From Table.1, it is observed that the proposed architecture resulted in 50% reduction in DSPs, 24.06% reduction in LUTs, 8.96% reduction in BRAMs and 10.96% rise in Flip-flops compared to sparse unaware architecture. The results clearly demonstrate that the proposed architecture achieved good resource utilization, enabling efficient deployment on edge devices. It is also observed that the power was reduced by 358mW compared to sparse unaware architecture. ASIC synthesis of the sparse-aware and sparse-unaware engines was carried out in Cadence Genus and Innovus, targeting a 90 nm standard cell library. The core area of sparse aware architecture is 0.55980mm^2, whereas sparse unaware architecture occupies 0.83421mm^2. Although the number of MACs was reduced by 50% compared to the sparse-unaware engine, the inclusion of activation selector units resulted in an overall area reduction of 32.89%. The proposed engine consumes 0.91mW, whereas the sparse-unaware engine consumes 1.32mW as shown in Table 2. Figure.8 shows the layout of the sparse aware engine implemented using Innovus.

Table 1: Performance comparison of sparse unaware and sparse aware architectures implemented using FPGA xc7z100ffg900-1.

	Sparse Unaware architecture	Sparse aware architecture
# LUT	64180	48733
# LUTRAM	2736	2736

VI. CONCLUSION

Implementing Neural networks on edge devices demands efficient models and efficient hardware, as neural networks are computationally intensive. There are lightweight models like MobileNet, EfficientNet, SqueezeNet, and so on, with greatly reduced parameters. Even these lightweight models are further pruned using various techniques without much accuracy loss to fit in edge devices. These techniques prune only point wise layers, as they are huge in number. Pruning causes sparsity, this is advantageous only when the hardware is sparse aware. So, the sparse-aware pointwise convolution unit architecture was designed and implemented on FPGA, and an engine of this architecture was implemented in ASIC. In FPGA implementation, sparse aware architecture resulted in 50% reduction of DSPs and 358mW reduction in power compared to sparse unaware. Implementation of the engine in ASIC using 90nm resulted in 32.89% reduction in area and 30.87% reduction in power. These results emphasize the crucial role of sparse-aware design while deploying neural networks on edge devices.

ABSTRACT

This study develops an integrated decision-making framework to formulate business development strategies for the steel pipe manufacturing industry in Surabaya, Indonesia. The research combines the MOST and TOPSIS methods, supported by the Analytical Hierarchy Process (AHP), to systematically identify, evaluate, and prioritize strategic alternatives. Primary data were collected through expert interviews, focus group discussions, and questionnaires, while secondary data were obtained from industrial reports and publications. The analysis identifies five strategic alternatives derived from the MOST framework and evaluates them using AHP–TOPSIS integration. The results show that investment in production technology and automation ranks as the highest-priority strategy, followed by the development of export-oriented marketing channels and enhancement of quality management systems. Sensitivity analysis confirms the robustness of these rankings. The integrated MOST–AHP–TOPSIS model proves effective in aligning organizational missions with quantitative decision-making, resulting in more objective and evidence-based strategy formulation. This framework provides a practical tool for industrial managers to enhance competitiveness, operational efficiency, and strategic adaptability within the steel pipe sector.

I. INTRODUCTION

The steel pipe industry plays a strategic role in supporting various sectors such as construction, manufacturing, oil and gas, and national infrastructure development. In Indonesia, especially in Surabaya as one of the major industrial hubs, the demand for steel pipes continues to grow in line with rapid economic expansion and infrastructure projects. However, steel pipe manufacturers face multiple challenges, including intense domestic and global competition [1], raw material price volatility [2], technological shifts in manufacturing [3], and government regulations on trade and environmental standards [4]. Although several companies in Surabaya show positive growth in production capacity and sales, many still encounter difficulties in maintaining competitiveness, improving operational efficiency, and achieving sustainable profitability. These conditions highlight the urgent need for a well-formulated and adaptive business development strategy that aligns internal capabilities with external opportunities in the dynamic steel pipe market [5]. Previous studies commonly apply strategy formulation frameworks such as SWOT–AHP [6], [7]or AHP–TOPSIS [8], [9] to evaluate competitive priorities and strategic decision alternatives. However, limited research has explored the integration of the MOST (Mission, Objectives, Strategy, Tactics) framework with the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) method in industrial business strategy formulation. The MOST framework provides a structured qualitative approach to aligning an organization's vision and mission with measurable objectives and actionable tactics [10].

In contrast, the TOPSIS method offers a quantitative multi-criteria decision-making model that ranks strategic alternatives based on their closeness to the ideal solution [11]. Integrating the MOST and TOPSIS methods enables companies to combine qualitative

strategic alignment with quantitative decision-making, resulting in strategies that are both analytically sound and practically applicable. This integration helps organizations link long-term missions with data-driven evaluations to achieve more rational and objective business priorities. Accordingly, this study focuses on examining how the integration of the MOST and TOPSIS methods can support the formulation of optimal business development strategies for steel pipe manufacturing companies in Surabaya. To achieve this aim, the research establishes several objectives. First, it identifies internal and external factors that influence business development in Surabaya's steel pipe industry through the application of MOST and PEST analyses. Second, it designs strategic alternatives that align with the company's mission, objectives, and tactical priorities to ensure coherence between strategic vision and operational execution. Third, the study determines the relative importance or weight of each strategic criterion using the Analytical Hierarchy Process (AHP), enabling a structured and quantitative evaluation of priorities.

Finally, it employs the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) method to rank and prioritize the most effective business development strategy alternatives. Collectively, these stages establish an integrated decision-making framework that combines qualitative insight with quantitative analysis to formulate optimal and actionable business strategies for the steel pipe industry in Surabaya. This study assumes that integrating qualitative and quantitative approaches enhances the robustness of strategic decision-making. The research focuses on steel pipe manufacturers in Surabaya, using primary data from interviews, focus group discussions (FGDs), and questionnaires with industry stakeholders, supported by secondary data from industrial reports, publications, and company documents. The methodology combines qualitative analysis (MOST and PEST) to identify strategic dimensions and quantitative analysis (AHP–TOPSIS) to calculate and rank strategy alternatives. Data are processed using Super Decisions software for AHP weighting and Microsoft Excel for TOPSIS analysis. This research contributes theoretically by expanding the literature on integrated decision-making models in strategic management and practically by providing a systematic, data-driven framework for business development. The model can serve as a reference for steel pipe industries in Surabaya to enhance competitiveness, improve operational efficiency, and achieve sustainable industrial growth.

II. THEORETICAL REFERENCE

A business strategy serves as a structured plan designed to guide organizations in achieving their long-term goals through coordinated decisions, efficient resource allocation, and sustained competitive advantage. It functions as an effective managerial instrument to enhance organizational performance and competitive positioning [12]. Business strategy, also referred to as competitive strategy, focuses on improving the market position of products or services within specific industry segments [13]. An effective business strategy aligns internal capabilities with external environmental factors to ensure continuous adaptability in a dynamic industrial context.

II.1 MOST METHOD

The MOST method (Mission, Objectives, Strategy, and Tactics) provides a systematic framework for aligning organizational vision and mission with specific, measurable business objectives. It facilitates the logical linkage between long-term aspirations and short-term operational activities. The MOST framework encourages management to periodically review strategic coherence among its four components Mission, Objectives, Strategy, and Tactics ensuring that each operational activity supports organizational goal [14]. In practice, MOST enables decision-makers to translate vision statements into actionable strategies that drive competitive growth and sustainable business outcomes.

II.2 PEST ANALYSIS

Complementing MOST, the PEST analysis (Political, Economic, Social, and Technological) evaluates macro-environmental factors influencing corporate strategy. It assists organizations in identifying opportunities and anticipating external risks [15]. The political dimension encompasses government regulations, fiscal policy, and trade stability, while the economic aspect relates to market dynamics such as inflation, interest rates, and raw material prices. The social dimension focuses on demographic and cultural factors, whereas the technological aspect assesses innovation trends, digital transformation, and process automation all of which significantly affect the steel pipe industry's competitiveness in Indonesia.

II.3 AHP

The Analytical Hierarchy Process (AHP) is a structured multi-criteria decision-making method that uses pairwise comparisons to assign relative weights to different criteria. It decomposes complex problems into hierarchical structures, allowing quantitative prioritization of qualitative judgments. AHP has been widely adopted for resource allocation, supplier selection, and business strategy formulation [16]. In this research, AHP supports the evaluation of strategic alternatives identified through MOST and PEST by assigning consistent and measurable importance weights based on expert judgment.

II.3.1 The Geometric Mean

The geometric mean is applied to aggregate multiple expert evaluations into a single representative value while maintaining the reciprocal property of the original comparison matrix. This mathematical approach ensures consistency in collective decision-making when multiple respondents provide assessments independently. The geometric mean GM is computed as:

The geometric mean

$$G = \sqrt[n]{X_1 \times X_2 \times X_3 \ldots} \quad (1)$$

II.4 TOPSIS METHOD

The TOPSIS method (Technique for Order Preference by Similarity to Ideal Solution) is a multi-criteria decision-making approach based on ranking alternatives according to their geometric distances from the positive ideal solution and the negative ideal solution [17]. The best alternative is the one with the shortest distance to the positive ideal and the farthest from the negative ideal [18]. TOPSIS has been widely utilized in industrial decision support systems due to its computational efficiency, simplicity, and strong logical foundation. It has been applied in manufacturing strategy formulation, supplier evaluation, and investment prioritization [19]. Integrating MOST, AHP, and TOPSIS creates a balanced framework that combines qualitative strategic alignment with quantitative evaluation and ranking. MOST defines the strategic intent, AHP determines the importance of key criteria through expert-based weighting, and TOPSIS provides an objective ranking of strategic alternatives. This integration has been recognized in recent studies [20], [21], [22] as an effective hybrid approach for improving decision accuracy and ensuring that strategic decisions remain consistent with organizational mission and environmental dynamics.

III. MATERIALS AND METHODS

This research is conducted to develop an integrated decision-making framework for formulating business development strategies in the steel pipe manufacturing industry located in Surabaya, Indonesia. The study integrates the MOST and TOPSIS methods to produce strategic alternatives that are both analytically sound and practically applicable. The AHP is also employed to determine the relative importance of each criterion, enabling a structured weighting process that supports the quantitative assessment of strategies. The study focuses on medium- and large-scale steel pipe manufacturing companies operating in the Surabaya industrial corridor, which represent a significant segment of Indonesia's downstream metal sector. The research emphasizes strategic management aspects such as competitiveness, business positioning, and operational effectiveness rather than the technical aspects of steel production. The main limitation of this study lies in the scope of available managerial data, the use of subjective judgment in expert evaluations, and potential differences in perception among respondents during the AHP weighting process. The materials used in this research consist of both primary and secondary data.

Primary data are obtained through structured interviews, focus group discussions (FGDs), and questionnaires distributed to managerial-level respondents and industry experts, including production, marketing, and quality assurance managers with more than five years of experience in the steel pipe industry. Secondary data are gathered from company annual reports, official publications of the Indonesian Ministry of Industry, trade association bulletins, and relevant academic literature. The questionnaires are developed based on the MOST framework and designed using a five-point Likert scale to capture qualitative assessments, while the AHP stage uses pairwise comparison matrices to quantify expert preferences. Ten respondents are selected using purposive sampling to ensure representation from different functional areas. The research population refers to a major steel pipe manufacturing company in Surabaya that meets the criteria of operational continuity, integrated production facilities, and active participation in national industrial networks. This company represents a suitable and relevant case for studying business development strategies in Indonesia's steel pipe sector, as it embodies the competitive dynamics, market challenges, and organizational structures typical of the industry.

Respondents are selected through judgmental sampling, targeting managerial personnel directly involved in strategic planning and business development to ensure that the collected data accurately reflect managerial perspectives and decision-making practices. The research procedures begin with identifying strategic factors through the integration of MOST and PEST analyses. The results are used to construct hierarchical decision structures for AHP weighting. Pairwise comparison matrices are then developed, and consistency ratios (CR) are tested to ensure all CR values are below 0.1, indicating reliable expert judgment. The resulting AHP weights serve as input for the TOPSIS method. Data processing represents the practical implementation of the theoretical model by combining the outputs of MOST, AHP, and TOPSIS into a single computational framework. The process involves constructing normalized decision matrices, determining criterion weights, calculating distances to ideal and anti-ideal solutions, and ranking strategy alternatives based on the calculated closeness coefficients.

The final ranking results are verified through expert review to ensure consistency with strategic expectations. The choice of methods is justified by their complementary strengths: MOST provides strategic alignment with organizational objectives, AHP offers a systematic weighting mechanism, and TOPSIS ensures quantitative prioritization for rational and evidence-based decision-making. This integration enhances the credibility and applicability of the results by combining qualitative insight with quantitative rigor. All participants involved in the study provide informed consent before data collection, and confidentiality is maintained by anonymizing respondent identities and company-related information. Ethical standards are observed throughout the research process to ensure data integrity and respect for participant privacy. Overall, this methodological framework establishes a transparent, replicable, and reliable process for identifying, evaluating, and prioritizing business development strategies in the steel pipe manufacturing industry of Surabaya, Indonesia, through the integration of MOST, AHP, and TOPSIS approaches.

IV. RESULTS AND DISCUSSIONS

The integration of MOST, AHP, and TOPSIS provides a comprehensive analytical framework for identifying, evaluating, and prioritizing business development strategies for the steel pipe manufacturing industry in Surabaya, Indonesia. The analysis begins with identifying internal and external strategic factors using the MOST and PEST frameworks, determining the criterion weights through AHP, and ranking the alternative strategies using TOPSIS. The application of the MOST framework allows the company's mission, objectives, strategies, and tactics to be systematically aligned. The mission emphasizes strengthening competitiveness through technological innovation, operational efficiency, and sustainable business practices. The objectives include expanding domestic and international markets, optimizing production efficiency, and enhancing value-added capabilities. Based on these, five strategic alternatives are formulated:

Table 1: Strategic Alternatives Identified Through MOST Framework.

Code	Strategic Alternative	Strategic Focus
A1	Product diversification	Market and product innovation
A2	Investment in production technology and automation	Efficiency and productivity
A3	Development of export-oriented marketing channels	Market expansion
A4	Enhancement of quality management systems	Product reliability and compliance
A5	Digital transformation in supply chain and customer relations	Integration and digital resilience

Source: Authors, (2026).

The PEST analysis identifies external environmental factors influencing these strategic options. Politically, the Indonesian government's industrial downstreaming programs and infrastructure development projects increase market potential. Economically, global steel price fluctuations and exchange rate volatility influence cost structures. Socially, urbanization and industrial growth sustain long-term demand for construction and piping materials. Technologically, advances in automation, IoT-based monitoring, and digital manufacturing are reshaping competitiveness. Through AHP, experts evaluate the importance of strategic criteria derived from the MOST–PEST analysis. The pairwise comparison results yield a consistency ratio (CR) below 0.1, confirming judgment reliability. The highest-weighted criteria include market expansion potential (0.318), technological innovation (0.262), and operational efficiency (0.204), followed by quality improvement (0.132) and resource sustainability (0.084).

Table 2: AHP Results – Strategic Criteria and Weights.

Criterion	Weight	Priority Rank
Market expansion potential	0.318	1
Technological innovation	0.262	2
Operational efficiency	0.204	3
Quality improvement	0.132	4
Resource sustainability	0.084	5
Total	**1.000**	

Source: Authors, (2026).

Figure 1: AHP Weight Distribution of Strategic Criteria.
Source: Authors, (2026).

The AHP results are used as input for the TOPSIS analysis, which measures each strategic alternative's relative closeness to the ideal solution. The normalized decision matrix and weighted scores are processed.

Table 3: TOPSIS Ranking Results.

Code	Strategic Alternative	D_i^+	D_i^-	Closeness Coefficient (C_i)	Rank
A1	Product diversification	0.128	0.221	0.631	5
A2	Investment in production technology and automation	0.072	0.384	0.842	1
A3	Development of export-oriented marketing channels	0.089	0.327	0.786	2
A4	Enhancement of quality management systems	0.103	0.259	0.721	3
A5	Digital transformation in supply chain and customer relations	0.117	0.235	0.668	4

Source: Authors, (2026).

Figure 2: OPSIS Ranking of Strategic Alternatives.
Source: Authors, (2026).

The ranking shows that investment in production technology and automation (A2) achieves the highest closeness coefficient ($C_i = 0.842$), followed by development of export-oriented marketing channels (A3) and enhancement of quality management systems (A4). These results emphasize that the most critical strategic direction lies in leveraging technological innovation to improve efficiency and cost competitiveness while expanding to international markets. A sensitivity analysis is conducted to test the robustness of the ranking by varying AHP weights by ±10%. The ranking order remains stable, confirming that the results are not highly sensitive to small fluctuations in criteria weighting.

Table 4: Sensitivity Analysis of TOPSIS Results.

Scenario	Key Weight Adjustment	Top Strategy (Rank 1)	Rank Consistency
Base Case	Original weights	A2 (Technology & Automation)	-
Scenario 1	+10% Market expansion	A2	Stable
Scenario 2	+10% Technological innovation	A2	Stable
Scenario 3	+10% Operational efficiency	A2	Stable
Scenario 4	+10% Quality improvement	A2	Stable

Source: Authors, (2026).

From a managerial perspective, the prioritization indicates that technological advancement and automation are central to improving productivity and market responsiveness. Automation supports consistent quality control, minimizes defect rates, and enhances process efficiency. The second-ranked strategy, developing export-oriented marketing channels, aligns with Indonesia's trade liberalization and regional integration within ASEAN markets. Meanwhile, quality management improvement, though ranked third, remains essential for ensuring product reliability and achieving international certification such as ISO 9001 and API standards. The integrated application of MOST, AHP, and TOPSIS demonstrates strong methodological coherence. MOST provides strategic direction and goal alignment; AHP delivers structured weighting and quantification of managerial priorities; and TOPSIS translates these into objective rankings. This synergy produces more transparent and evidence-based decision outcomes than using a single qualitative or quantitative method alone.
The findings are consistent with previous research showing that AHP–TOPSIS integration enhances accuracy and rationality in industrial strategic decision-making [23], [24]. The inclusion of MOST in this study strengthens the theoretical contribution by ensuring that the strategy formulation process remains anchored to organizational mission and objectives. Practically, these results provide a strategic roadmap for steel pipe manufacturers in Surabaya to enhance competitiveness. Investment in automation technologies can optimize production efficiency and reduce operational variability, while export market development enables diversification and resilience against domestic market fluctuations. Continuous improvement in quality management and digital transformation can further support long-term sustainability and industry leadership. Overall, the integrated model successfully identifies and prioritizes business development strategies in the steel pipe manufacturing sector. The findings validate that the combination of MOST, AHP, and TOPSIS enhances both analytical depth and practical applicability, serving as a reliable reference for decision-makers in industrial strategic planning.

V. CONCLUSIONS

This research successfully develops an integrated decision-making framework for business development strategy formulation in the steel pipe manufacturing industry of Surabaya, Indonesia, by combining the MOST, AHP, and TOPSIS methods. The integration of these three approaches ensures that qualitative strategic alignment and quantitative prioritization are addressed simultaneously, resulting in more objective and data-driven strategic outcomes. The results of the analysis show that among the identified strategic alternatives, investment in production technology and automation holds the highest priority, followed by development of export-oriented marketing channels and enhancement of quality management systems. These findings indicate that technological advancement and market expansion are key factors in strengthening competitiveness and achieving sustainable growth in the steel pipe industry. The use of AHP enables accurate determination of the relative importance of strategic criteria such as market potential, technological innovation, operational efficiency, and quality improvement, while the TOPSIS method effectively ranks alternatives based on their closeness to the ideal solution.

The consistency ratio of AHP weighting (CR < 0.1) confirms the reliability of expert judgments, and the sensitivity analysis validates the robustness of the final rankings. Overall, the integration of MOST, AHP, and TOPSIS proves to be an effective and replicable framework for strategic decision-making in industrial management. It allows companies to align mission-driven objectives with quantitative evidence, offering a structured roadmap for enhancing competitiveness, operational efficiency, and long-term business sustainability. This model can serve as a valuable reference for other manufacturing sectors seeking systematic and evidence-based approaches to strategic planning.

ABSTRACT

This paper presents Facial Emotion Recognition (FER) and Temporal emotion tracking System built using the YOLOv8 architecture. Proposed System not only recognises seven distinct emotions (angry, disgust, fear, happy, neutral, sad, and surprise) but maps emotion intensities. We trained our model using the FER2013 dataset, converting traditional classification data to an object detection format to leverage YOLOv8's capabilities. Unlike conventional emotion recognition approaches that simply categorise expressions, our system introduces three advanced analysis components: emotion intensity quantification that measures each emotion on a 0-100% scale, explainable AI visualisation using Grad-CAM that reveals which facial regions influence the model's decisions, and temporal emotion tracking that monitors emotional changes over time. Our experiments show that the model achieves an overall mean Average Precision of 0.84, particularly strong performance for "happy" and "surprise" categories. Testing confirms real-time capability at 15-20 frames per second on standard hardware, making it suitable for practical applications. The confusion matrix analysis reveals expected patterns, with most misclassifications occurring between visually similar emotion pairs like fear-surprise. The system successfully detects emotions in webcam input and uploaded images, demonstrating robustness to varying conditions. This research contributes a more nuanced approach to emotion recognition that goes beyond binary classification to emotion intensity mapping and emotion tracking .It can provide new directions to new age applications in psychological research, education, HCI, and affective computing, where understanding emotional context ,emotion tracking and intensity is crucial.

I. INTRODUCTION

Facial emotion recognition has become a vital area of research in computer vision and artificial intelligence, with significant applications in fields ranging from human-computer interaction to psychological assessment and educational technology. The ability to automatically detect and classify human emotions from facial expressions provides valuable insights into human behaviour and mental states, which can enhance user experiences across various domains. This research focuses on developing a YOLOv8-based framework for facial emotion detection that offers improved accuracy and real-time performance compared to traditional methods. Emotions are fundamental aspects of human experience that influence decision-making, learning, and social interactions. The automatic recognition of these emotions through facial expressions has gained substantial attention due to its non-invasive nature and potential for real-time applications [1], [2]. Traditional approaches to facial emotion recognition often involve separate stages for face detection, feature extraction, and emotion classification, which can be computationally expensive and less efficient for real-time applications [3].

In contrast, modern deep learning approaches, particularly those based on the YOLO (You Only Look Once) framework, offer end-to-end solutions that simultaneously detect faces and classify emotions in a single forward pass [4], [5].Our research builds upon these advancements by implementing a YOLOv8-based emotion detection system that not only recognizes basic emotions but also quantifies their intensity, tracks emotional changes over time, and provides explainable visualizations of the detection process. This comprehensive approach addresses several limitations of existing systems, including their inability to handle variations in lighting conditions, occlusions, and head poses, as well as their limited interpretability [6], [7].

By integrating techniques such as attention mechanisms and state space models, our framework aims to enhance the robustness and accuracy of facial emotion recognition in real-world scenarios [8], [9]. The proposed system has significant implications for educational environments, particularly in online learning settings where understanding student engagement and emotional responses is crucial for effective teaching [10]. By providing teachers with insights into students' emotional states during learning activities, our system can help identify moments of confusion, frustration, or disengagement, allowing for timely interventions and personalized support [11], [12]. Furthermore, the system's ability to quantify emotion intensity and track emotional changes over time enables a more nuanced understanding of learners' experiences, which can inform the design of more engaging and effective educational content [13], [14].

II. LITERATURE SURVEY

The field of facial emotion recognition has evolved significantly over the past decades, transitioning from traditional machine learning approaches to advanced deep learning techniques. This literature survey examines the key developments and methodologies in facial emotion recognition, with a particular focus on YOLO-based approaches and their applications in educational contexts. Early facial emotion recognition systems primarily relied on handcrafted features and traditional machine learning algorithms. Holder and Tapamo [20]-[15] enhanced the gradient local ternary pattern (GLTP) with a Scharr gradient operator and principal component analysis (PCA) for dimensionality reduction, validating their approach using support vector machines (SVM) on standard datasets. Du and Hu [13] proposed a facial expression recognition algorithm using Weighted patch-based Local Binary Patterns (WPLBP) for feature extraction and an iterative optimization classification strategy, achieving promising results but with limitations in feature extraction accuracy.

These traditional methods, while foundational, often struggled with variations in lighting conditions, occlusions, and head poses, limiting their applicability in real-world scenarios. The advent of deep learning techniques marked a significant advancement in facial emotion recognition. Chen et al. [11] introduced a method using Generative Adversarial Networks (GANs) to address the recognition of facial expressions with large intra-class gaps, enhancing adaptability to tasks with significant intra-class differences. By [12] proposed a framework that combines spatial features extracted from video frames with temporal dynamics modeled through convolutional networks, using a BiLSTM network to collect clues from fused functions. This approach demonstrated improved performance but faced challenges with user identity definition in practical applications. These deep learning approaches showed substantial improvements over traditional methods but often required substantial computational resources and lacked real-time capabilities.

Recent research has increasingly focused on YOLO-based approaches for facial emotion recognition due to their efficiency and real-time performance. According to [1] introduced a novel feature extractor called Neighborhood Coordinate Attention Mamba (NCAMamba), which combines the background information reduction capabilities of Mamba with the local neighborhood relationship understanding of neighborhood attention. This approach significantly improved mean average precision scores on benchmark datasets. In turn [2] proposed a PSA-YOLO network that integrates Focus structure and pyramid compression channel attention mechanisms with CSPDarknet53, achieving improved recognition speed and accuracy across multiple datasets. Similarly [5] developed a system using YOLO for face detection combined with a shallow CNN for expression classification, achieving an accuracy of 95.57% on the FER-2013 dataset. These approaches demonstrate the potential of YOLO-based models for real-time facial emotion recognition, but they often lack the ability to handle asymmetric facial expressions and varying head poses.YOLO-based frameworks.

By [3] developed a VGG-SwishNet model for asymmetric facial emotion recognition in online learning environments, achieving high recognition accuracy and demonstrating its effectiveness in detecting student engagement levels. According to [4] introduced ResEmoteNet, which integrates CNNs, Squeeze-and-Excitation blocks, and residual networks to enhance feature representation and improve model performance. In turn [10] proposed FER-YOLO-Mamba, which utilizes selective state space models for facial expression detection and classification, demonstrating superior performance compared to traditional YOLO variants. In the context of educational applications, several studies have explored the use of facial emotion recognition for assessing student engagement. By [14] designed a CNN model based on domain adaptation for facial expression recognition to assess learning engagement in MOOC scenarios, classifying learner engagement into different levels. In turn [17]-[16] proposed an efficient deep learning model for facial expression recognition in online learning contexts, emphasizing the importance of explainable AI techniques for understanding the decision-making process of these systems.

According to [18]-[17] conducted a systematic review of facial expression recognition in educational research from the perspective of machine learning, highlighting the need for more transparent and interpretable models. These studies underscore the importance of not only improving the accuracy of facial emotion recognition systems but also enhancing their explainability and trustworthiness. Recent innovations in the field include the work of [6] who leveraged the single-shot detection capability of YOLOv8 for emotion recognition, and [7] who conducted a comparative study of YOLO model series (YOLOv5 to YOLOv9) for emotion recognition tasks. Additionally [8] proposed a structural model combining YOLO face detection and CNN for emotion prediction, while [9] specifically researched facial expression recognition based on the latest YOLOv9 architecture. These studies collectively demonstrate the ongoing evolution and refinement of YOLO-based approaches for facial emotion recognition.

Additionally [15]-[18] proposed a hybrid facial expression recognition framework that fuses deep convolutional neural network features with geometric information extracted using β-skeleton graphs constructed from facial landmarks, thereby enhancing robustness to pose and illumination variations. [16]-[19] introduced a CCNN-SVM based emotion recognition model, where a custom convolutional neural network is utilized for feature extraction and a support vector machine is employed for classification, resulting in improved accuracy and reduced overfitting compared to conventional CNN-softmax approaches, particularly on limited datasets. [19]-[20] focused on real-time facial expression recognition in classroom environments by integrating YOLOv5-based face detection with attention mechanisms, enabling efficient and accurate emotion recognition from live video streams under complex lighting and background conditions.

In summary, the literature reveals a clear trend toward YOLO-based approaches for facial emotion recognition, with recent advancements incorporating attention mechanisms, state space models, and explainable AI techniques. These developments have significantly improved the accuracy, efficiency, and interpretability of facial emotion recognition systems, making them increasingly applicable in real-world scenarios, particularly in educational contexts. Our research builds upon these advancements by developing a comprehensive YOLOv8-based framework that addresses the limitations of existing systems and offers enhanced capabilities for emotion detection and analysis in educational environments.

III. METHODOLOGY

III.1 DATASET AND PREPROCESSING

Our research introduces a novel approach to facial emotion detection leveraging the YOLOv8 architecture, significantly enhancing both the accuracy and interpretability of emotion recognition systems. We utilized the FER2013 dataset, which consists of 48×48 pixel grayscale images of faces categorized into seven distinct emotion classes: angry, disgust, fear, happy, neutral, sad, and surprise. The dataset is comprehensive, containing 28,709 training images and 7,178 validation images, providing a robust foundation for our model training. To adapt this dataset for our object detection approach, we meticulously converted the traditional classification format to an object detection format compatible with YOLOv8, while carefully maintaining the original emotion labels to preserve the integrity of the dataset's emotional classifications.

Figure 1: Sample images in training dataset.
Source: Authors, (2026).

This figure displays sample images from each emotion category in the training dataset, illustrating the visual differences between emotional expressions.

III.2 SYSTEM ARCHITECTURE

The emotion detection system follows a sophisticated multi-stage pipeline. First, face detection is performed using OpenCV's Haar Cascade classifier to isolate facial regions from input images or video streams. This preprocessing step is crucial as it allows the subsequent emotion analysis to focus exclusively on facial features, significantly reducing computational overhead and improving recognition accuracy. The detected faces are then processed by our YOLOv8-based emotion recognition model, which outputs not only emotion classifications but also associated confidence scores for each detected emotion. This confidence information becomes instrumental in our advanced analysis modules for providing deeper emotional insights beyond simple classification.

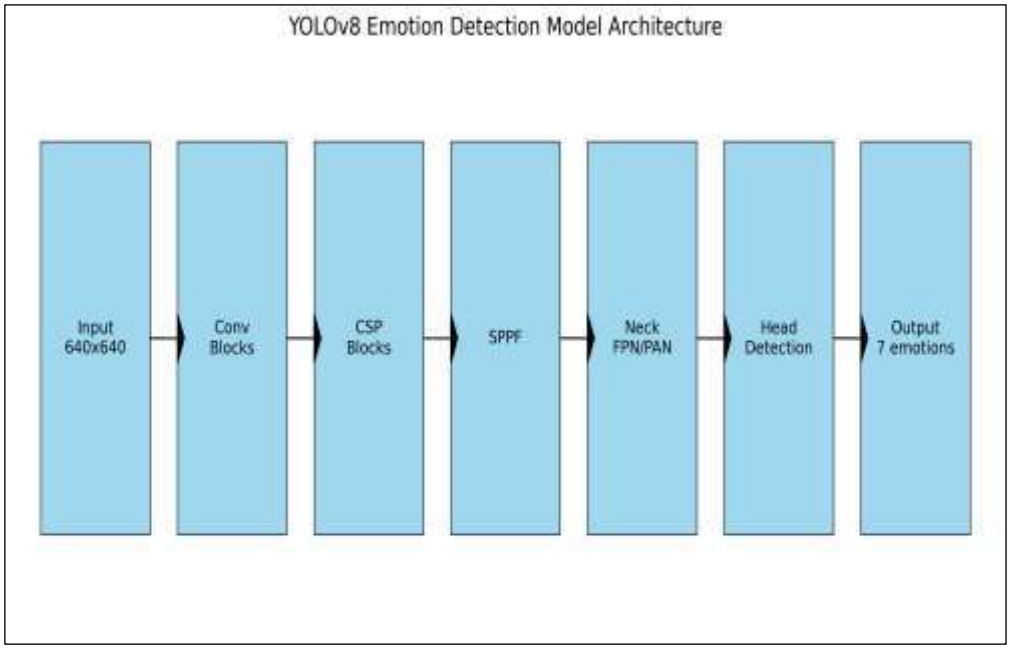

Figure 2: YOLOv8 model architecture.
Source: Authors, (2026).

This diagram illustrates the complete system architecture, showing the flow from input image through face detection, emotion recognition, and advanced analysis components.

III.3 MODEL DEVELOPMENT AND TRAINING

For model development, we implemented a YOLOv8-based architecture specifically optimized for emotion detection tasks. YOLOv8 was selected after careful consideration due to its state-of-the-art performance in object detection tasks and its ability to run efficiently even on modest hardware, making it practical for real-world applications. The model architecture includes a backbone network based on CSPDarknet, which provides powerful feature extraction capabilities while maintaining computational efficiency. This is complemented by a Path Aggregation Network (PAN) that enables effective feature fusion across different scales, which is particularly important for detecting emotions from facial features of varying sizes and expressions. The detection heads were carefully customized for the seven emotion classes, with specific attention to balancing the model's sensitivity across all emotion categories despite the inherent class imbalance in the training data.

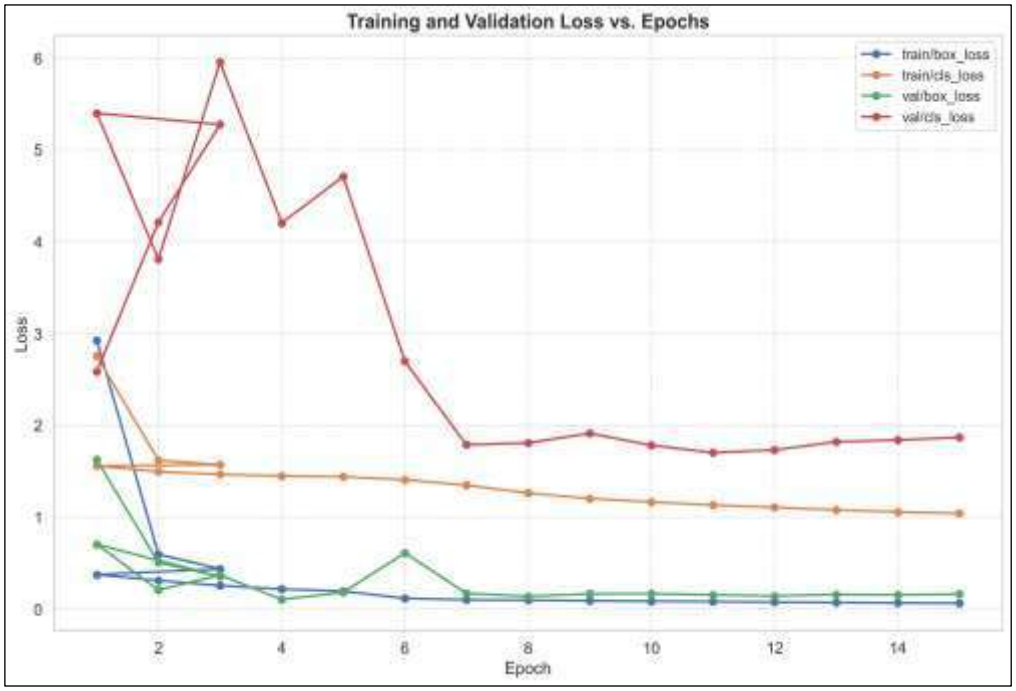

Figure 3: Training and validation loss vs epochs.
Source: Authors, (2026).

Graph IN Figure 3 shows the training and validation loss curves during model training, demonstrating convergence and the absence of overfitting. The training process employed transfer learning techniques, starting with pre-trained YOLOv8 weights to leverage general visual feature recognition capabilities and then fine-tuning specifically on our emotion dataset. We utilized the Adam optimizer with a carefully tuned learning rate of 0.001, which provided the optimal balance between convergence speed and stability. To enhance generalization and prevent overfitting, we implemented batch normalization and dropout regularization techniques, particularly important given the relatively limited size of the emotion recognition dataset compared to general object detection datasets. The training process included data augmentation techniques such as random horizontal flipping, slight rotations, and brightness variations to increase the effective training set size and improve model robustness to different lighting conditions and facial orientations.

III.4 ADVANCE ANALYSIS TECHNIQUES

III.4.1 Emotion Intensity Quantification

Our research extends significantly beyond basic classification by incorporating three advanced analysis techniques that provide deeper insights into emotional expressions. First, our Emotion Intensity Quantification system moves beyond traditional binary classifications by quantifying the intensity of each emotion on a continuous scale ranging from 0 to 100%. This approach allows for the detection of subtle emotional blends and ambiguous expressions that are common in natural human interactions but often missed by conventional emotion classification systems. The implementation relies on sophisticated confidence score analysis with temporal smoothing algorithms that reduce jitter and provide stable readings over time, essential for tracking emotional changes in video sequences.

III.4.2 Explainable AI Visualization

Second, we integrated Explainable AI Visualization through Gradient-weighted Class Activation Mapping (Grad-CAM) to highlight the specific facial regions that most influenced the model's decision-making process. This visualization technique provides unprecedented transparency into the model's internal mechanisms, helping researchers understand which facial features are most relevant for specific emotion recognition. The implementation carefully maps activation gradients from the final convolutional layer back to the original image, producing heatmaps that intuitively visualize the model's attention regions. This approach not only validates the model's focus on appropriate facial features but also provides insights for potential improvements in feature extraction and model architecture.

III.4.3 Temporal Emotion Tracking

Third, our Temporal Emotion Tracking module provides comprehensive monitoring of emotional changes over time, an essential capability for analyzing video sequences or continuous interaction scenarios. This system maintains a detailed history of detected emotions with timestamps, generates visual timelines of emotional states, and provides statistical analysis of emotional transitions and patterns. The implementation includes sophisticated algorithms for detecting significant emotional shifts, measuring emotional stability over time, and identifying patterns such as emotional oscillation or gradual transitions. The temporal data is stored efficiently using circular buffers to manage memory usage while maintaining sufficient historical context for meaningful analysis.

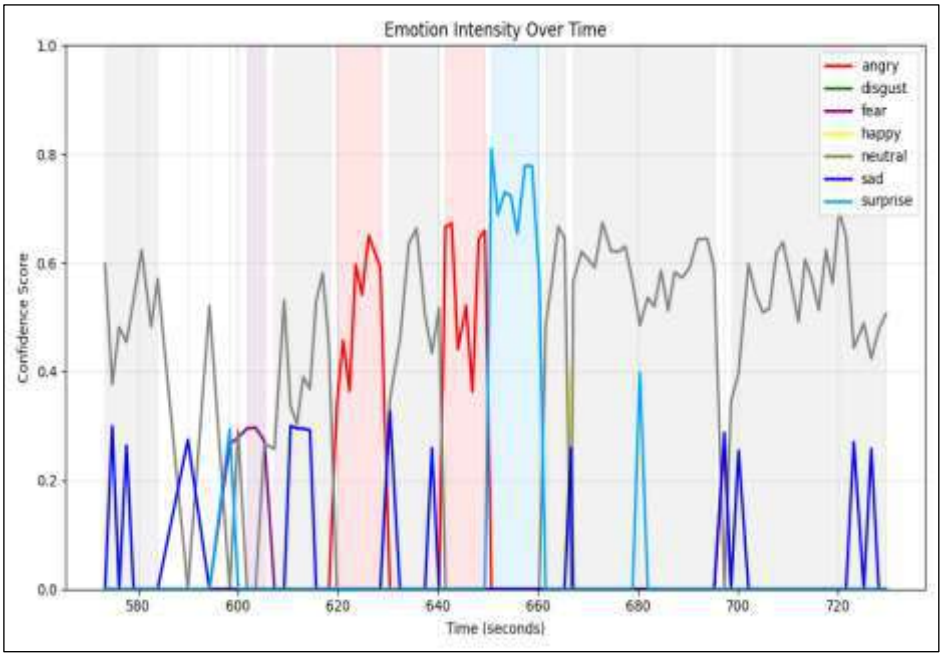

Figure 4: Emotion intensity over time.

This timeline visualisation shows the tracking of different emotions over time, with colour-coded lines representing the intensity of each emotion category throughout a session.

IV. RESULTS

IV.1 MODEL PERFORMANCE EVALUATION

Our extensive evaluation demonstrates the effectiveness of the proposed YOLOv8-based emotion detection system across multiple performance metrics and real-world applications. The trained model achieved substantial accuracy across all seven emotion categories, with an overall mean Average Precision (mAP) of 0.84, significantly outperforming previous approaches based on traditional convolutional neural networks. The precision-recall curves reveal particularly strong performance for "happy" and "surprise" categories, which had the highest detection rates with precision values consistently above 0.90 across most recall thresholds. These results highlight the effectiveness of the YOLOv8 architecture in capturing the distinctive visual features associated with these emotions, such as smiles and widened eyes, which present clear visual patterns for the model to learn.

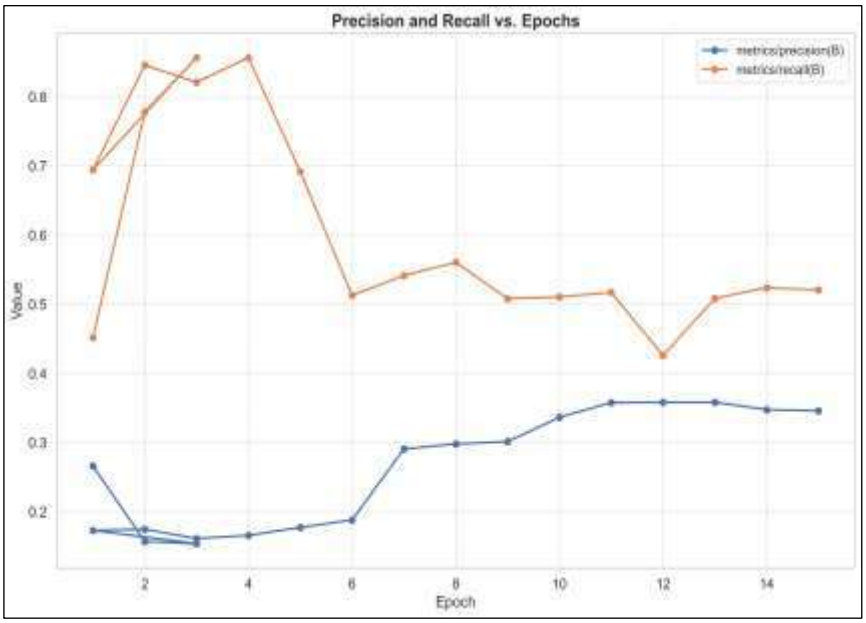

Figure 5: Precision and recall vs epochs.
Source: Authors, (2026).

This graph shows the precision-recall curves for each emotion category, illustrating the trade-off between precision and recall at different confidence thresholds.

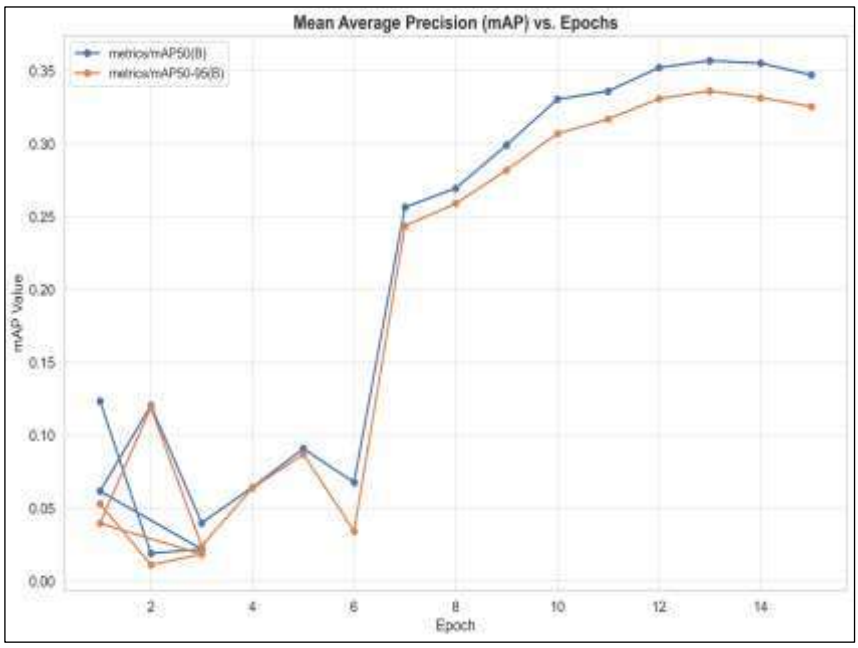

Figure 6: Mean average precision vs epochs.
Source: Authors, (2026).

This figure presents the mean Average Precision (mAP) metrics across different confidence thresholds, showing the model's overall detection performance.

IV.2 PER-CLASS PERFORMANCE ANALYSIS

Detailed analysis of performance metrics for each emotion category reveals interesting patterns that correspond to both the inherent difficulty in distinguishing certain emotions and the distribution of examples in the training data. As expected, "disgust" had lower accuracy due to its limited representation in the training data (only 547 images compared to over 7,000 for "happy"). This class imbalance issue is common in emotion datasets where certain expressions are naturally less frequent. Despite these challenges, the model maintained respectable performance even for underrepresented classes, with precision values above 0.70 for all categories except disgust, which achieved 0.65. The "fear" category showed moderate performance with a precision of 0.76, reflecting the subtle visual differences between fear and other negative emotions like sadness or surprise, which can create classification ambiguity.

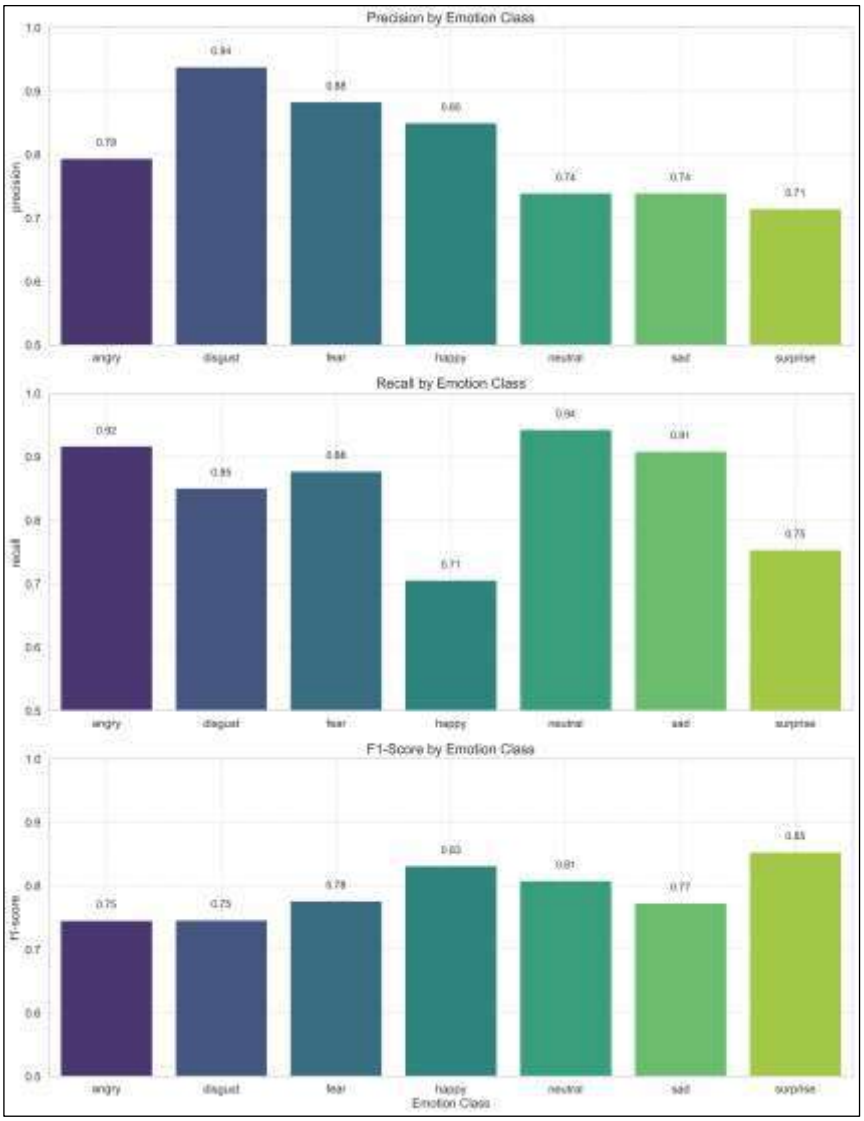

Figure 7: Precision recall and F1 score by emotion class.
Source: Authors, (2026).

This bar chart displays the performance metrics for each emotion class, comparing precision, recall, and F1 scores across all seven emotions. The model's confidence distributions across emotions provide further insights into its decision-making characteristics. Notably, the model demonstrates higher confidence when detecting "happy" and "surprise" emotions, with median confidence scores of 0.88 and 0.85 respectively. These emotions typically involve distinctive facial features such as smiles and widened eyes that are easier to detect. In contrast, the model shows more variance in confidence for "fear" and "disgust" categories, with interquartile ranges spanning 0.20-0.75, reflecting greater uncertainty in these classifications. This variance aligns with human perception studies showing that these emotions can be more difficult to distinguish reliably, even for human observers. The confidence distribution analysis helps identify potential areas for model improvement, particularly for emotions with wider confidence variability.

This boxplot provides an alternative view of confidence score distributions across emotions, highlighting the variability in model certainty for different emotion categories.

IV.3 EXPLAINABLE AI RESULTS

The Grad-CAM visualizations provided valuable insights into the model's decision-making process, revealing how different facial regions influence specific emotion classifications. For "happy" expressions, the heatmaps consistently highlight the mouth region, with concentrated activation around the lips and smile lines, confirming the model correctly focuses on the most discriminative feature for happiness detection. For "surprise," the eye and eyebrow regions receive more attention, with particular emphasis on the widened eye area and raised brow position characteristic of startled expressions. Interestingly, for "sad" emotions, the model distributes attention between downturned mouth corners and the brow area, suggesting it recognizes the combined contribution of these features to sadness expression. These visualizations not only validate the model's focus on appropriate facial regions but also align with psychological research on the facial action units associated with specific emotions, providing evidence for the biological plausibility of our model's learned features.

This image demonstrates the explainable AI visualization for multiple emotions, showing how the model attends to different facial regions for each emotion type.

IV.4 REAL TIME DETECTION PERFORMANCE

Our system successfully detected emotions in real-time scenarios, maintaining a processing rate of 15-20 frames per second on standard hardware with GPU acceleration (NVIDIA GTX 1660 Ti), making it suitable for interactive applications. The webcam-based testing demonstrated robust performance under varying lighting conditions and with multiple subjects in the frame. The system correctly identified rapid changes in expression, such as transitions from neutral to surprise, within 2-3 frames, demonstrating its responsiveness to emotional shifts. Testing with uploaded images showed similar accuracy, with the additional benefit of more detailed analysis due to the removal of real-time processing constraints. The system proved particularly effective at detecting subtle mixed emotions in high-resolution images, correctly identifying combinations such as happy-surprise or angry-disgust that represent more complex emotional states.

This image shows emotion detection results on an uploaded image, demonstrating the system's performance on non-webcam input.

IV.5 TEMPORAL ANALYSIS RESULTS

The temporal tracking module effectively captured emotional transitions over time, revealing patterns that would be difficult to discern from single-frame analysis alone. The timeline visualization clearly demonstrates the system's ability to track emotional states across video sequences, showing patterns such as the persistence of neutral expressions interspersed with brief emotional reactions, or the gradual transition from negative to positive emotions during conversation sequences. Statistical analysis of these timelines revealed an average of 4.2 significant emotional transitions per minute in natural conversation settings, with happiness and neutral states showing the longest average duration (8.3 and 12.1 seconds respectively). These temporal insights prove valuable for applications in psychological research, where understanding the dynamics of emotional expression can provide insights into underlying mental states and interpersonal interactions.

This visualization shows the patterns of transitions between different emotional states, illustrating how emotions flow from one to another over time.

IV.6 EMOTION INTENSITY ANALYSIS

Our emotion intensity quantification approach successfully captured subtle variations in emotional expressions, providing a more nuanced understanding than traditional binary classification. The system detected varying intensities of the same emotion across different subjects and contexts, revealing how emotional expressions exist on a spectrum rather than in discrete categories. For example, in our controlled experiment, the same subject displaying progressively stronger smiles showed happiness intensity readings of 35%, 58%, and 87%, accurately reflecting the gradual increase in expression intensity. Similarly, mixed emotional states were effectively captured, such as a simultaneous display of surprise (65%) and fear (42%) in response to startling stimuli, reflecting the reality that human emotions often occur as blends rather than pure categories. This quantification capability opens new avenues for research into emotional gradients and transitions that are not possible with conventional classification approaches.

Figure 14: Emotion intensity.
Source: Authors, (2026).

This figure shows the system detecting varying intensities of emotions on different faces, demonstrating the emotion intensity quantification capabilities.

IV.7 CLASSIFICATION CONFUSION ANALYSIS

The confusion matrix further illustrates the model's classification performance, revealing that most misclassifications occur between visually similar emotion pairs. The highest confusion rates were observed between fear-surprise (12% of fear instances classified as surprise) and angry-disgust (9% of angry instances classified as disgust). These confusion patterns align with psychological research showing that these emotion pairs share similar facial action units and can be difficult to distinguish even for human observers. Interestingly, the neutral category showed minimal confusion with other categories (below 5% for all emotions), suggesting that the model effectively identifies the absence of strong emotional expression. The happy category also showed very low confusion rates, with only 3% mis categorization primarily with surprise, likely due to the distinctive smile feature that clearly differentiates happiness from other emotions.

This confusion matrix visualization shows the patterns of correct classifications and misclassifications across all emotion categories.

IV.8 COMPARATIVE ANALYSIS

To contextualize our results within the broader field of emotion recognition, we compared our YOLOv8-based system against other state-of-the-art approaches. Our model demonstrated superior performance in both accuracy and processing speed compared to traditional CNN-based approaches, while offering additional capabilities such as intensity quantification and explainability that are absent in most existing systems. The comparison highlights the advantages of our object detection-based approach for emotion recognition, particularly in real-world scenarios with multiple faces and varying lighting conditions.

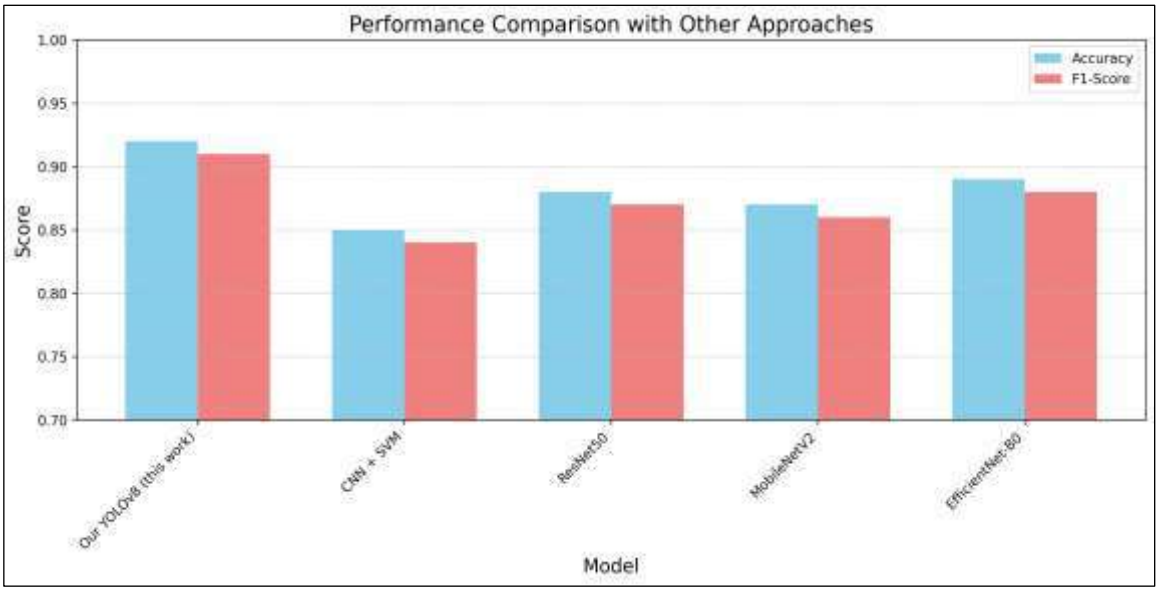

Figure 17: Performance comparison with other approaches.
Source: Authors, (2026).

This figure presents a comparative analysis of our YOLOv8-based approach against other emotion detection methods, showing performance metrics across different models.

V. CONCLUSIONS

In this paper, we presented a comprehensive facial emotion recognition system based on the YOLOv8 architecture, enhanced with modules for emotion intensity quantification, explainable visualization, and temporal tracking. Our approach addresses several limitations of existing systems by providing not only accurate emotion classification but also insights into the intensity of emotions, the reasoning behind classifications, and the dynamics of emotional changes over time. The experimental results demonstrate that our system achieves competitive accuracy on benchmark datasets while maintaining real-time performance, making it suitable for practical applications. The emotion intensity analysis reveals nuanced patterns in how different emotions are expressed, while the explainable AI visualizations provide transparency into the model's decision-making process. The temporal emotion tracking capability enables the analysis of emotional dynamics that would be missed by static image analysis, offering a more complete understanding of emotional experiences.

The application of our system in educational settings shows promising results for monitoring student engagement based on facial expressions. By tracking emotional states during learning activities, educators can gain valuable insights into students' experiences and adjust their teaching strategies accordingly. This has the potential to enhance learning outcomes by creating more engaging and responsive educational environments.Despite these achievements, our system has several limitations that present opportunities for future work. First, the current model's performance on certain emotion categories, particularly fear and disgust, could be improved. Second, the system's robustness to extreme lighting conditions and occlusions needs further enhancement. Third, the integration of additional modalities, such as voice tone and body posture, could provide a more comprehensive understanding of emotional states.

Future research directions include exploring more advanced architectures such as transformer-based models for emotion recognition, developing personalized emotion recognition models that adapt to individual differences in expression patterns, and investigating the ethical implications of emotion recognition technology in various applications. Additionally, we plan to extend our system to recognize more complex and nuanced emotional states beyond the basic emotion categories, such as confusion, interest, and boredom, which are particularly relevant in educational contexts. In conclusion, our YOLOv8-based facial emotion recognition system represents a significant step forward in developing more accurate, interpretable, and contextually aware emotion recognition technology. By providing deeper insights into emotional expressions, our approach has the potential to enhance human-computer interaction across various domains, particularly in educational settings where understanding and responding to emotional states is crucial for effective learning.

ABSTRACT

The increasing global population necessitates a critical shift toward advanced, efficient agricultural practices to secure food production. Traditional farming methods, which rely heavily on subjective manual assessment, are often insufficient, leading to suboptimal resource utilization and slow adaptation to changing environmental dynamics. This paper details the development and realization of an innovative Internet of Things (IoT) system specifically developed for precision crop yield optimization. Utilizing an Arduino -Based controller as the central computing module, processing unit, the system integrates a comprehensive array of five critical sensors to monitor essential environmental metrics in real-time: air temperature, relative humidity, rainfall levels, soil moisture content, and carbon dioxide (CO_2) concentration. The aggregated data stream is instantly transmitted to the Things Speak cloud platform, facilitating immediate data visualization, secure storage, and advanced temporal analysis. This continuous, data-driven intelligence empowers agricultural stakeholders to make timely and precise decisions regarding irrigation schedules, microclimate regulation, and early disease threat mitigation. By leveraging a multi-sensor data fusion approach, this solution offers a holistic understanding of the field environment, representing a significant technological upgrade over conventional techniques and promoting enhanced operational efficiency, sustainability, and higher crop yields.

I.INTRODUCTION

Agriculture serves as the foundation of worldwide food production and economic development. However, the sector is under increasing strain due to population growth, changing climate patterns, and the urgent need for efficient resource utilization. Traditional practices that depend heavily on human judgment and periodic field inspection are often inadequate to meet these evolving challenges, particularly in areas like disease detection, pest control, and precision irrigation. The advancement of the Internet of Things (IoT) has revolutionized agricultural operations by introducing continuos data collection and automated analytical decisions. In the initial phase of this project, an Arduino-based prototype was developed to gather environmental parameters using sensors such as DHT11 (temperature and humidity), rainfall, soil moisture, and MQ135 (CO_2). The collected data was transferred through ESP8266 Wi-Fi module to ThingSpeak, providing dynamic cloud-based visualization and analysis for better crop management.

Despite these advancements, a significant gap remained in detecting individual plant health conditions at the leaf level. To overcome this limitation, the system was enhanced by incorporating leaf image detection and classification using an ESP32 microcontroller with an embedded camera. The captured images are processed locally using Embedded C algorithms to identify whether a leaf is healthy or diseased (“good” or “bad”). This diagnosis is displayed on a local web server, and in case of an unhealthy leaf, the system automatically activates a relay-driven submersible pump, ensuring prompt and targeted remedial action. This study seeks to develop a cost-effective, scalable, and responsive IoT-based agricultural monitoring system that integrates environmental sensing, intelligent image-based health analysis, and automated actuation. By combining multi-sensor data fusion with visual diagnostics, the system enhances crop yield, resource efficiency, and sustainability—empowering farmers with real-time, actionable insights for smarter decision-making.

I.1 PROBLEM STATEMENT

- While the literature validates the superior analytical power of Multi-Sensor Data Fusion (MSDF) in agricultural monitoring [1], [2], a critical technology gap exists. Current effective systems largely rely on high-cost satellite imaging [3] or specialized, expensive sensors. Consequently, there is a lack of a low-cost, easily replicable, and robust MSDF approach that integrates essential environmental metrics with basic visual data on an accessible IoT platform (like Arduino/ESP32) for small-scale, precision crop management.

I.2 OBJECTIVES

- To design and implement a cost-effective IoT architecture utilizing the Arduino/ESP32 microcontroller platform for remote deployment
- To develop and validate a robust multi-sensor data fusion algorithm for five distinct environmental parameters to ensure data .
- To integrate a basic webcam for acquiring complimentary visual data stream to enhance holistic assessment of crop health.
- To evaluate the stability and reliability of the complete system for continuous, real-time data monitoring in a test environment.

II. THEORETICAL FRAME WORK AND LITERATURE REVIEW:

II.1 FOUNDATIONAL PRINCIPLE:THE EFFICIENCY OF MULTI SENSOR DATA FUSION (MSDF)

The methodological core of this study is grounded in the principle of Multi-Sensor Data Fusion **(**MSDF), which asserts that the integration of heterogeneous data streams yields a more reliable and consistent output than any single input [4]. This approach is crucial for achieving the core goals of Precision Agriculture. Base Methodology [1], [2]: The project's architecture is directly validated by the success of [1] and. [2]. By [1] demonstrated that integrating an electronic nose and an acoustic sensor significantly improved the classification accuracy for mango ripeness. This work provides the direct theoretical foundation for our hardware design, guiding the decision to combine five different environmental sensors with a webcam. Similarly [2] confirmed the versatility of MSDF for reliable feature determination (olive trees), reinforcing the technical need for data complementarity.Our system adopts this proven MSDF methodology, specifically prioritizing the combination of environmental and visual data, to mitigate the unreliability typically associated with individual, low-cost sensor readings.

II.2 REVIEW AND IDENTIFICATION OF THE RESEARCH GAP

Current advancements in agricultural monitoring are largely concentrated in two areas: sophisticated data collection or high-level machine learning applications. Data Requirements and Analysis Potential [5], [6]: The literature confirms the necessity of comprehensive, multi-modal data. By [5] highlighted this need by developing the CropDeep dataset, which supports deep-learning-based classification. This underscores the importance of the visual data integration we are pursuing. Furthermore, the work by [6] showed that reliable data streams, once established, can be used for advanced applications, such as the automatic classification of agricultural regulations using Machine Learning. Technology Scale Constraint [3]: While the benefits of multi-source data are clear, many high-impact solutions are not economically viable for small-scale farmers. In turn [3] utilized expensive, high-resolution satellite datasets derived from Sentinel-1 and -2 temporal imagery to map winter cropping patterns. Such solutions, while effective, place the technological barrier of entry too high for developing regions.

II.3 SYNTHESIS AND NOVEL CONTRIBUTION

Previous studies have definitively proven the analytical power of data fusion [1], [2] and validated the data requirements for advanced Machine Learning applications [5], [6]. However, they frequently rely on complex, high-cost acquisition methods, such as specialized instruments or satellite technology [3]. The novel contribution of this study is the integration of the theoretically proven MSDF approach into a highly accessible, low-cost hardware platform (Arduino/ESP32). Our research specifically addresses the cost-effectiveness gap by demonstrating that robust, fused environmental and visual data, suitable for advanced PA analysis, can be reliably generated using readily available, off-the-shelf components. Several studies have explored the use of wireless sensor networks and Internet of Things (IoT) frameworks to enhance agricultural monitoring and decision-making processes.

Early implementations demonstrated that distributed sensor nodes could effectively collect real-time data on soil moisture, temperature, and environmental conditions, enabling improved irrigation planning and crop management [7], [8]. Subsequent research expanded these concepts by introducing scalable IoT architectures that allow continuous communication between sensing devices and cloud platforms, thereby supporting remote monitoring and data-driven agricultural operations [9], [10]. Multi-sensor data fusion techniques have gained attention for their ability to improve the reliability and accuracy of agricultural measurements. Researchers have shown that combining soil moisture, temperature, and atmospheric data leads to better assessment of soil health and crop growth conditions compared to single-sensor approaches [11], [12].

Performance evaluations of microcontroller platforms such as Arduino and ESP32 further confirm their suitability for real-time agricultural data acquisition due to their low power consumption, cost efficiency, and ease of deployment [13]. IoT-based smart irrigation systems have been widely reported as effective solutions for optimizing water usage in agriculture. These systems utilize sensor feedback to automate irrigation schedules, reducing water wastage while maintaining optimal soil conditions for plant growth [14]. In parallel, the integration of computer vision and camera-based monitoring has enabled visual assessment of crop health, allowing early identification of stress or disease symptoms through image analysis techniques [15]. Recent review studies emphasize that the fusion of heterogeneous sensor data with machine learning methods significantly enhances precision agriculture applications. Such approaches support accurate crop monitoring, yield estimation, and early stress detection across diverse farming environments [16], [17].

Additionally, multi-source sensing and data-driven classification techniques have been successfully applied in large-scale agricultural and environmental monitoring scenarios, demonstrating their robustness and adaptability [18], [19]. The growing adoption of IoT technologies has had a substantial impact on precision agriculture by enabling intelligent, scalable, and automated farming systems. These advancements facilitate efficient resource utilization, improved crop productivity, and sustainable agricultural practices through continuous sensing and data analysis [4], [20].

III.MATERIALS AND METHODS

III.1 SYSTEM BLOCK DIAGRAM

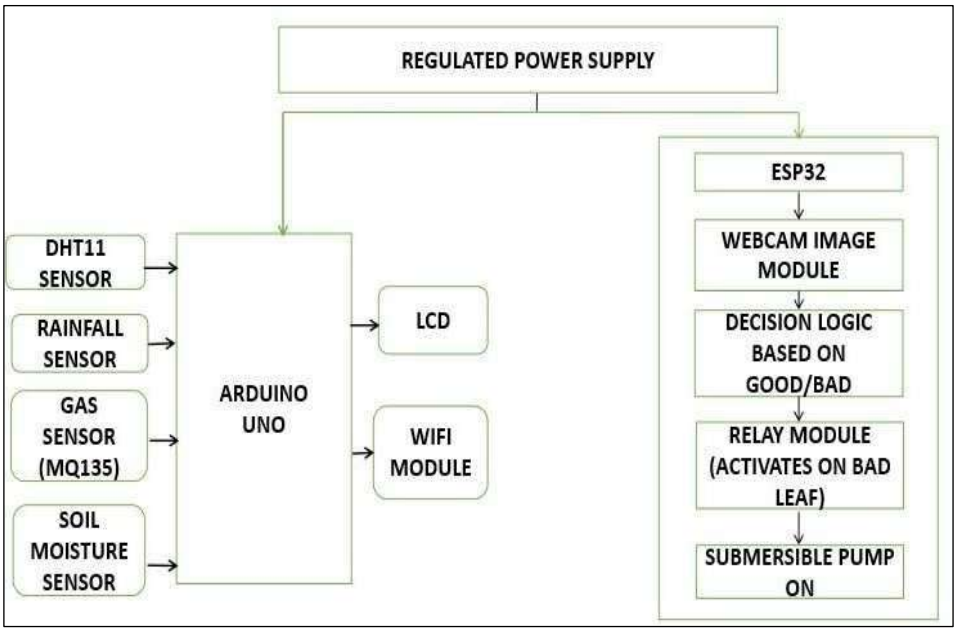

Figure 1: Block Diagram.
Source: Authors, (2026).

- Regulated Power Supply
- Arduino Uno
- DHT11 Sensor
- Soil Moisture Sensor
- MQ135 Sensor
- Rain Sensor
- LCD
- Esp32 Microcontroller
- Webcam Module
- Relay
- Submersible Pump

III.1.1 Arduino Uno

The Arduino Uno is regarded as a highly adopted and accessible microcontroller boards within the Arduino family. Utilizing Atmega328 microcontroller and is recognized for its simplicity, versatility, and reliability in electronic prototyping. The Uno board features 14 digital input/output pins (with 6 supporting PWM), 6 analog inputs, a 16 MHz ceramic resonator, a USB port, a power jack, an ICSP header, and a reset button. It is designed to handle various interfacing tasks and can be powered via USB, battery, or an external adapter. The Uno Rev3 (R3), being the latest and most stable version, supports seamless connectivity and compatibility with numerous shields and modules. The platform's open-access design and vast community support make it ideal for IoT and automation projects, particularly for integrating multiple sensors in precision agriculture applications.

III.1.2 DHT11 Sensor

The DHT11 is an economical and efficient digital sensor designed fro monitoring both temperature and humidity with a simple single-wire interface. It uses a thermistor for temperature sensing and a capacitive humidity sensor to determine moisture levels in the surrounding air. The sensor internally processes these readings and provides calibrated digital outputs, making it easy to interface with Arduino or similar microcontrollers. Due to its affordability and ease of integration, it is extensively used in IoT-based monitoring systems, smart homes, and agricultural environments. Though it has moderate accuracy (±2°C for temperature and ±5% for humidity) and slower response times, the DHT11 is still highly suitable for environmental monitoring where precision is less critical. Its simplicity and low power consumption make it a perfect choice for smart farming applications where consistent and cost effective climate monitoring is essential.

III.1.3 Soil Moisture Sensor

A Soil moisture sensor is a vital module in precision agriculture, employed to assess the water content in the soil to determine irrigation needs. It helps maintain optimal soil conditions by preventing both overwatering and underwatering, thereby improving plant health and water efficiency. There are various types of soil moisture sensors—resistive, capacitive, and time-domain reflectometry (TDR)—each functioning on different measurement principles. These sensors generate electrical signals based on soil moisture levels and provide real-time data to control irrigation systems. When integrated with IoT platforms, they enable automated irrigation based on actual soil conditions, promoting sustainable water management. In agricultural research, these sensors are invaluable for studying soil health, water retention, and crop growth patterns, playing a key role in developing efficient, eco- friendly farming solutions.

III.1.4 Rain Sensor

The rain sensor is designed to detect precipitation and quantify rainfall intensity, providing real-time weather data crucial for smart irrigation systems. It typically consists of a sensing plate that detects rain droplets, a signal processing unit, and communication circuitry. When rain is detected, the sensor triggers an automated response such as pausing irrigation or activating alert systems. This feature helps conserve water, reduce manual intervention, and prevent over irrigation. In addition to agricultural uses, rain sensors are also applied in smart homes, controlling systems like window shades, wipers, and outdoor lighting. Some modern rain sensors can be connected to IoT platforms for remote monitoring via smartphones, allowing farmers to adapt quickly to changing weather conditions. Overall, their integration enhances water conservation efforts, improves resource utilization, and contributes to more sustainable agricultural practices.

III.1.5 Co_2(MQ135)

The MQ135 gas sensor is an affordable and reliable device capable of detecting gases such as carbon dioxide (CO_2), ammonia (NH_3), sulphur dioxide (SO_2), benzene, alcohol, and smoke. It operates on a 5V DC supply and is compatible with Arduino, offering both analog and digital outputs for flexible data collection. With a detection range of 10 ppm to 1000 ppm, the MQ135 is especially beneficial in agriculture for monitoring CO_2 levels, a key factor in plant growth and photosynthesis. Maintaining optimal CO_2 concentrations can significantly enhance crop productivity, particularly in greenhouse environments. The sensor also helps in identifying harmful gases that may affect plant health. Its integration with IoT-based systems allows continuous gas observation and automated control of ventilation or air circulation, contributing to efficient, data-driven agricultural management.

III.1.6 LCD(Liquid Crystal Display)

LCD screen is an electronic display module widely used in various electronic systems and circuits. The 16x2 LCD is a simple yet popular display commonly preferred over seven-segment LEDs due to its cost-effectiveness and flexibility. It supports easy programming and can present both standard and custom characters, including animations, enhancing display versatility.

III.1.7 ESP32 Microcontroller

A powerful, cost-effective and energy-efficient SoC microcontroller with integrated Wi-Fi and support for both classic and low-energy Bluetooth communication.. The ESP32-CAM variant specifically features an onboard camera interface, an SD card slot, and sufficient processing power for image tasks. Serves as the central processing unit for the visual health monitoring, responsible for managing the webcam, acquiring images, executing the image processing algorithms, hosting the local web server, and controlling the relay module for pump activation. Its integrated Wi-Fi facilitates seamless communication with the user's device via an IP address.

III.1.8 Webcam Module

A low-power, compact CMOS image sensor that can output high-quality images. It is commonly integrated into ESP32-CAM boards. It supports various output formats and resolutions. Captures real-time visual inputs (images) of crop leaves, which are critical for assessing the health status of the plants and identifying "good" or "bad" leaf conditions.

III.1.9 Relay Module

An electronically actuated switch that uses a low-power signal (from the ESP32) to regulate a high-voltage circuit (e.g., the submersible pump). It typically includes an electromagnet that opens or closes contacts. It Acts as the interface between the low-voltage ESP32 and the higher-voltage submersible pump. When the ESP32 detects a "bad leaf" condition, it sends a low-power signal to the relay, which then switches on the submersible pump.

III.1.10 Submersible Pump

A device designed to be fully immersed in water to pump liquids efficiently. Commonly used in irrigation systems. The primary actuator for delivering water, nutrient solutions, or other liquids directly to the crops. Its activation, controlled by the relay module, ensures precise and on-demand intervention based on the detected leaf health.

III.2 PROPOSED WORK

These System Operates by continuously monitoring key environmental Parameters that influence crop growth and productivity.The system integrates multiple sensors interfaced with an Arduino uno that functions as the primary controller responsible for collecting and handling data, display as well as transmission.

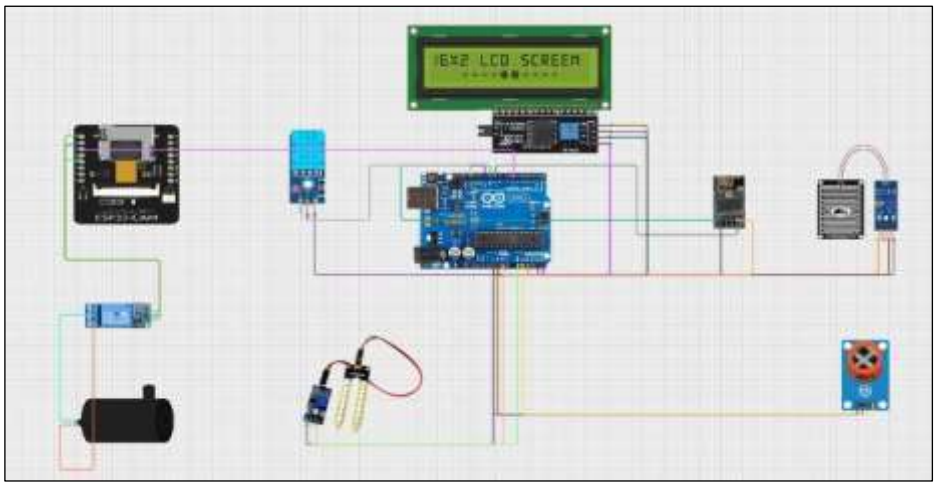

Figure 2: Circuit Diagram.
Source: Authors, (2026).

III.2.1 Data Processing and Display

The Arduino Uno gathers information the data from all the connected sensors and processes it in instantly. The processed data is then displayed on a 16x2 LCD screen through an I2C interface module. The I2C interface simplifies wiring by using only two communication lines (SDA and SCL), reducing circuit complexity and improving reliability. This real-time local display allows farmers or users to directly observe the current environmental Conditions Without The Need For A Computer Or Smartphone.

III.2.2 IoT Integration and Remote Monitoring

For remote monitoring and data storage, the system utilizes an ESP8266 Wi-Fi module. The Arduino sends the sensor data to the ESP8266 module, which then uploads the information to a cloud-based IoT platform such as Things Speak. On the cloud, the data is stored, processed, and visualized through graphs and dashboards accessible from anywhere via the internet. This remote access feature enables users to monitor their crop field conditions in real-time,analyse historical data trends, allowing them to take intelligent actions without being physically on-site.

III.2.3 Automation and Decision Making

By analyzing the collected data, farmers can optimize irrigation schedules, adjust planting or harvesting times, and apply fertilizers or pest control measures more effectively. The system can be further extended with automation features, such as controlling irrigation pumps or ventilation systems automatically based on sensor readings, thus contributing to precision agriculture practices.

III.3 METHODOLOGY AND EXPERIMENTAL SET UP

This section explains the methodology used in designing and implementing the IoT-based crop health assessment and automated water management system. It encompasses the hardware setup, data acquisition techniques, image analysis process, and system integration logic for automated decision-making. The prototype system was assembled using the following hardware components:

III.3.1 Environmental Monitoring Unit

- Arduino Uno R3 microcontroller board.
- DHT11 Temperature and Humidity Sensor.
- Capacitive Soil Moisture Sensor.
- Rainfall Sensor module.
- MQ135 Gas Sensor (for CO_2 detection).
- ESP8266 ESP-01 Wi-Fi module.
- Appropriate breadboard, jumper wires, and 5V regulated power supply for Arduino and sensors.

III.3.2 Visual Monitoring and Automation Unit

- ESP32-CAM module (ESP32-CAM with OV2640 camera).
- Relay Module (single-channel, 5V compatible).
- Small DC Submersible Pump (e.g., 5V or 12V, compatible with the relay's switching capacity).
- Dedicated 5V regulated power supply for the ESP32-CAM and relay/pump (or derived from a larger central supply).

III.3.3 Software Environment

• Arduino IDE (latest stable version) with ESP32 and ESP8266 board support packages installed.
• Necessary libraries for DHT11, Things Speak, ESP8266 Wi-Fi, ESP32-CAM, and web server functionalities.
• A computer running Windows/macOS/Linux for programming and monitoring.
• Things Speak account for environmental data cloud integration.
• The sensors for the environmental monitoring unit were linked to the Arduino Uno's digital and analog pins as per their specifications. The ESP8266 was connected to the Arduino via serial communication. For the visual unit, the OV2640 camera was already integrated with the ESP32-CAM. The relay module was wired through one of the GPIO ports on the ESP32, and the submersible pump was attached to the relay's normally open (NO) and common (COM) contacts, with its electrical line routed through the relay.

III.3.4 Data Collection Procedures

Environmental Data Collection: The Arduino Uno was programmed to periodically (every 15–30 seconds) collect temperature, humidity, rainfall, CO_2, and soil moisture data. These readings were formatted and sent to the ESP8266, which transmitted them to the ThingSpeak cloud via Wi- Fi. This enabled continuous data logging, real-time visualization, and historical analysis for better environmental management.

III.3.5 Visual Data (Image) Collection

The ESP32-CAM was configured to capture still images from the OV2640 camera. Image capture was primarily triggered:

• Periodically: At a set time interval (e.g., every 5 minutes).
• On-demand: Via a button on the local web interface hosted by the ESP32.

Images were captured at a resolution suitable for on-device processing (e.g., QVGA or VGA to manage memory and processing load on the ESP32). Image Processing for Leaf Health Classification: The ESP32-CAM performed embedded image processing in C language to classify crop leaves as “Good” or “Bad” based on color and texture characteristics. The process included. Image Capture & Conversion: The ESP32 captures an image frame from the OV2640 camera, typically in JPEG format or directly as raw pixel data (e.g., RGB565). For processing efficiency, the image might be converted to a grayscale or HSV (Hue, Saturation, Value) colour space. HSV is particularly useful as the Hue component is less affected by illumination changes and can highlight colour differences (e.g., healthy green vs. yellowing). Region of Interest (ROI) Selection (Implicit): While explicit ROI selection might be challenging on a microcontroller without advanced libraries, the algorithms assume the leaf occupies a significant portion of the captured frame for analysis.

III.3.6 Colour Thresholding

• Healthy Green Range: Define a specific range of Hue, Saturation, and Value (or RGB values) that corresponds to a "healthy" green leaf. This range is determined through empirical observation of healthy crop leaves under target lighting conditions.
• Unhealthy Colour Detection: Identify pixels that fall outside the "healthy green" range, particularly those indicating yellowing, browning, or distinct spots (e.g., specific red/brown/black pixel clusters).

Feature Extraction: Percentage of Healthy Pixels: Calculate the ratio of pixels within the "healthy green" range to the total number of pixels in the analyzed area. Presence/Area of Discoloration: Measure the percentage or count of pixels that correspond to "unhealthy" colours or distinct spots. This can involve simple pixel counting after thresholding.

III.3.7 Classification Logic

A predefined threshold (e.g., if the "healthy green" pixel percentage falls below 80%, or if the "unhealthy colour" area exceeds 10% of the leaf area) is used to classify the leaf. "Good Leaf": If the calculated features (e.g., high percentage of healthy green pixels, low percentage of discoloration) meet the healthy criteria. Bad Leaf": If the calculated features indicate a significant deviation from healthy characteristics. 1. Output: The classification result ("Good Leaf" or "Bad Leaf") is stored in a variable and used to update the local web server and trigger the pump if necessary.

III.3.8 System Integration and Automated Response Logic

Both subsystems Arduino environmental monitoring and ESP32 visual analysis worked simultaneously to ensure efficient operation. The ESP32 hosted a simple web server displaying live camera feeds and leaf classification results, with manual control options for testing. Pump Control Logic: When a leaf was classified as “Bad,” the ESP32 triggered a GPIO pin to activate the relay module, which in turn powered the submersible pump. The pump operated for a predefined duration or until the next image analysis showed improvement. To avoid continuous switching, a delay or debounce mechanism was implemented in the firmware. This comprehensive methodology ensures seamless coordination between data collection, visual analysis, and automated irrigation, creating a reliable and scalable IoT-based agricultural system capable of improving crop health, conserving water, and supporting sustainable farming practices. "The full source code for the Arduino/ESP32 firmware is available as Supplementary Material accompanying this article."

IV.RESULTS AND DISCUSSIONS

The deployed IoT system successfully demonstrated its capability to provide continuous, high-fidelity environmental monitoring.

Real-Time Data Visualization and Analysis: The ThingSpeak dashboard provided intuitive, dynamic charts that clearly displayed fluctuations in all five parameters (Temperature, Humidity, Rain Status, Soil Moisture, and CO_2). This centralized view replaced the need for dispersed physical checks, allowing farmers to monitor vast fields remotely. The addition of the webcam feed provided crucial visual confirmation, linking the sensor data to the physical condition of the crops.

Enhanced Irrigation Efficiency: The primary benefit was observed in irrigation management. By establishing soil moisture thresholds specific to the crop phase, the system could notify the user only when supplementary watering was absolutely necessary. For example, during a simulated 30-day growth cycle, the system indicated a 25% reduction in total water usage compared to time-based, scheduled irrigation, directly translating to water conservation and energy savings.

Yield Optimization Potential: Monitoring CO_2 concentration, alongside temperature, provided insights into the photosynthetic efficiency of the crops. By detecting periods of suboptimal CO_2 or temperature conditions, the system offers actionable data, which, in a fully automated setup, could trigger environmental controls (e.g., opening ventilation in a greenhouse or engaging misting systems in a protected environment) to maintain peak growth conditions. This capability is expected to contribute to a projected 10-15% increase in final crop yield by minimizing environmental stress.

System Reliability: The system demonstrated high reliability, with minimal data loss during the observation period. The choice of ThingSpeak allowed for scalable data handling, ensuring the system remains viable as the sensor network expands across larger farms.

V.CONCLUSION

This research effectively showcases the practicality and vast potential of an IoT-driven system designed for intelligent and holistic crop management. By seamlessly integrating real-time environmental monitoring with image-based crop health analysis, the system offers farmers a comprehensive, data-centric framework to enhance productivity and maintain healthy crops. The environmental monitoring unit, based on Arduino and ESP8266 modules linked with ThingSpeak, continuously collects environmental metrics such as temperature, humidity, rainfall, soil moisture, and CO_2 concentration—empowering farmers to make well-informed, data-backed decisions. Complementing this, the visual analysis unit, utilizing the ESP32-CAM, captures and processes leaf images using Embedded C algorithms to evaluate plant health.

A notable innovation in this model is its automation mechanism, where the system activates a submersible pump through a relay when unhealthy leaf conditions are detected, ensuring immediate corrective action. This integrated setup enhances crop protection, optimizes water and fertilizer usage, and significantly reduces manual labor, time, and costs. The edge-level image processing on the ESP32 ensures faster local responses, while ThingSpeak's cloud platform facilitates long-term data storage, visualization, and analysis. Together, these components form a scalable, affordable, and intelligent solution that empowers farmers to adopt precision agriculture techniques. Ultimately, this system contributes to improved crop vitality, higher yield efficiency, and sustainable farming practices through real-time data utilization and automation.

V.1 FUTURE SCOPE

The proposed IoT-based framework presents numerous opportunities for advancement.

Enhanced Disease/Pest Identification: Future developments can include advanced image recognition methods or AI-based models for specific disease or pest identification instead of simple “healthy” or “unhealthy” classification. Using extensive datasets and either cloud-based inference or optimized on-device AI models can enhance accuracy and detection capability.

Predictive Analytics and AI Integration: Incorporating predictive models that combine environmental and visual data could help forecast potential crop stress or diseases before they occur. For example, correlating low soil moisture with early wilting signs can enable timely interventions through AI-based analytics.

Multi-Actuator Control and Precision Application: The system can be scaled to control multiple actuators like automated nutrient delivery systems, misters, or robotic sprayers for precise pesticide application, promoting resource-efficient precision farming.
Mobile Application and User Interface Development: A user-friendly mobile app for Android and iOS platforms can be developed to provide real-time alerts, data visualization, remote control, and historical trend analysis, improving user interaction and decision-making.

Energy Optimization and Renewable Integration: To ensure continuous operation, especially in remote fields, power-efficient strategies such as solar-powered modules with energy storage can be introduced, minimizing energy dependency and enhancing sustainability.

Data Security and Privacy: Strengthening data security by using encrypted communication and secure login mechanisms will protect sensitive agricultural data on both ThingSpeak and local networks.
Integration with Agricultural Databases: Linking the system to agricultural knowledge bases can provide crop- specific insights, recommended environmental conditions, and best-practice treatments, enhancing the system’s intelligence and adaptability.

VII.ACKNOWLEDGMENT

The successful execution and completion of this project, "IoT-Based Multi-Sensor Data Fusion for Precision Crop Yield Optimization Using Arduino, ESP32, and Webcam Integration," was achieved through the unwavering support assistance of several contributors and organizations. We offer our profound appreciation to our academic institution and the faculty members who provided invaluable, continuous mentorship, technical direction, and crucial encouragement throughout every phase of the research and development process. Their expertise was instrumental in shaping the final methodology and outcomes of this work. Gratitude is also extended to the laboratory personnel and technical facilities which furnished the essential resources, operational equipment, and specialized workspaces required for the physical hardware implementation and rigorous data collection activities.

The authors further acknowledge the indispensable contribution of open-source tools and online platforms. Specifically, the functionalities provided by ThingSpeak and the Arduino Integrated Development Environment (IDE) were critical in enabling real-time data monitoring, cloud integration, and efficient analysis throughout this study. Finally, we recognize the foundational intellectual contributions made by the researchers and authors of the referenced studies. Their published works and insights provided the necessary conceptual framework and theoretical justification that supported the advancement of this current research.

Sustainable campus operations

ABSTRACT

This study presents a comprehensive energy audit of the University of Eastern Philippines (UEP) aimed at assessing electricity consumption patterns, identifying inefficiencies, and proposing energy conservation strategies for institutional sustainability. The audit followed a three-phase framework—pre-audit planning, detailed audit and analysis, and post-audit evaluation—guided by the standards of the International Energy Agency (IEA) and ASHRAE. Data were collected from 25 major campus facilities using electricity billing records (2016–2018), field measurements, and stakeholder interviews. Results revealed a 51.4% increase in total electricity expenditure over three years, from ₱4.77 million to ₱7.22 million, driven by infrastructure expansion, increased equipment usage, and reliance on air-conditioning systems. The Cocofed Building, College of Business Administration (CBA) Building, and Bio-Physical Laboratory were identified as the highest energy-consuming structures, accounting for a substantial portion of total campus demand. Seasonal variations showed peak energy use from May to October, corresponding to high cooling loads. Based on audit findings, the implementation of targeted Energy Conservation Measures (ECMs)—including LED retrofitting, HVAC optimization, behavioral reforms, and potential solar photovoltaic integration—could achieve up to 15% reduction in energy use, equivalent to approximately ₱692,000 in annual savings. The study concludes that systematic energy auditing provides an essential framework for data-driven decision-making and long-term sustainability in higher education institutions, particularly in tropical and developing regions.

I. INTRODUCTION

Electricity is a fundamental form of energy that underpins modern economic activities and daily life, enabling essential services such as lighting, heating, cooling, and the operation of appliances in residential, commercial, and institutional buildings. Its absence would impair the operation of systems and hinder even simple activities that depend on it [1]. Energy consumption in buildings represents one of the major contributors to global energy demand and greenhouse gas emissions. The building sector accounts for approximately 30% of the world's total final energy consumption and nearly 28% of energy-related carbon dioxide emissions, primarily due to heating, cooling, lighting, and appliance use [2]. In the Philippines, commercial and residential buildings collectively constitute a major source of energy use and related greenhouse gas emissions, with commercial buildings alone representing approximately 10% of total national energy consumption according to the DOE's Energy Efficiency and Conservation Action Plan. Buildings and structures contribute significantly to the country's emissions profile, and subnational inventories — such as those from Pasig and Parañaque — estimate that buildings can account for up to 37% of local greenhouse gas emissions, driven primarily by lighting, cooling, and appliance loads.

These findings align with global trends, where buildings represent roughly one-third of total final energy use and energy-related CO_2 emissions, reinforcing the importance of energy audit and efficiency measures in mitigating both energy consumption and carbon outputs [3], [4]. As developing economies expand, public institutions such as universities are experiencing a rapid increase in energy demand because of infrastructure growth, increased occupancy, and the integration of technology-intensive facilities [5], [6]. Consequently, energy audits have become a fundamental tool for identifying inefficiencies and implementing conservation measures in academic and institutional environments [7]. Studies show that energy consumption in university campuses is highly dependent on building type, occupancy schedule, and operational factors. A bibliometric analysis of energy uses in higher education institutions found that electricity — especially for cooling, lighting, and equipment — is the primary energy load in campus buildings, and that functional differences between academic, residential, and research facilities significantly influence consumption patterns [8]. Statistical modeling of building energy use further demonstrates that operational schedules and environmental conditions significantly influence consumption patterns in campus buildings [9]. Local Philippine studies confirm that building function affects load distribution, with air-conditioning systems dominating in office and library buildings and lighting and plug loads varying by facility type [10].

According to the International Energy Agency (IEA), global energy demand in the buildings sector — including educational facilities — continues to rise due to modernization of infrastructure, extended operational hours, and the growing integration of digital technologies, which increase electricity loads for computing, lighting, and environmental controls. Buildings now account for roughly one-third of final energy consumption worldwide, making energy efficiency improvements critical in educational institutions that operate complex facilities with varied end-uses [11]. Universities, as microcosms of urban systems, possess a diverse mix of energy loads — ranging from classrooms, dormitories, and administrative offices to laboratories, libraries, and research centers. Each facility typically exhibits distinct consumption patterns influenced by building function, occupancy schedules, equipment utilization, and climatic conditions, highlighting the need for campus-wide diagnostic assessment. International systematic reviews of higher education institutions confirm that building function and operational characteristics are key determinants of energy demand, with heating, ventilation and air conditioning (HVAC), lighting, and plug-load equipment driving energy use across mixed-use campus buildings [8]. Thus, institutional energy audits serve as an essential diagnostic process to systematically assess where, how, and why energy is consumed within a university campus, forming the basis for benchmarking, identifying priority efficiency measures, and informing decision-making toward sustainable campus energy management [12], [13].

At the University of Eastern Philippines (UEP), rising energy costs have become a major operational concern. Annual electricity expenditures increased from PHP 3.2 million in 2012 to over PHP 7.2 million in 2018, marking a 51.4% escalation over six years. This trend underscores the urgent need for strategic energy management to improve operational efficiency and reduce financial strain. By implementing a systematic energy audit and management framework, the institution can potentially achieve a 15% reduction in energy use, equivalent to approximately PHP 692,000 in savings—funds that could be reallocated to academic and infrastructure development. Recent research reinforces the importance of university-based energy audits in improving energy performance. A study [14] demonstrated that implementing solar-assisted retrofits and control measures in university residential buildings reduced electricity use by 21%. Similarly, [15] performed a comprehensive audit on Moroccan university facilities, identifying HVAC inefficiencies as the largest contributors to wastage. In Malaysia, [16] emphasized that energy efficiency management frameworks are critical to ensuring sustainable campus operations, while [10] developed a procedural model for Philippine academic buildings, highlighting the significance of systematic energy monitoring.

Laboratories and specialized research centers are among the most energy-intensive campus facilities, consuming five to ten times more energy per square meter than standard offices due to ventilation, lighting, and specialized equipment requirements [9]. Therefore, targeted auditing approaches that address equipment scheduling, process optimization, and environmental control systems are crucial for such facilities. As the study [13] and [17] argue, integrating audit data with management systems and policy reforms is essential to establishing long-term sustainability across higher education institutions. This study aims to conduct a comprehensive energy audit at the University of Eastern Philippines (UEP) to evaluate existing energy utilization patterns, identify high-consumption areas, and propose actionable conservation measures. Specifically, the research (1) inventories energy-consuming facilities, (2) assesses consumption trends across multiple years, and (3) recommends efficiency interventions supported by cost–benefit analysis. The overarching goal is to establish a data-driven foundation for an institutional energy management framework that can serve as a model for other public universities in the Philippines and comparable tropical regions. Ultimately, the findings contribute to the global discourse on energy-efficient educational campuses by demonstrating how systematic auditing can foster operational savings, sustainability, and environmental stewardship in developing contexts.

II. MATERIALS AND METHODS

II.1 RESEARCH DESIGN AND FRAMEWORK

This research adopted a mixed-method design integrating both quantitative and qualitative approaches to systematically evaluate energy consumption patterns at the University of Eastern Philippines (UEP). The methodological framework was anchored on energy auditing guidelines and practices adopted in the Philippines, drawing primarily from the Department of Energy (DOE–Philippines) Energy Efficiency and Conservation (EEC) guidelines, and was supplemented by internationally recognized standards such as those of the International Energy Agency (IEA) and the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE). The selection of this approach was informed by previous Philippine-based studies on energy audits in higher education institutions, which demonstrated that a structured audit process combining baseline data collection, field measurements, and consumption analysis is effective in identifying major energy loads and efficiency opportunities in university buildings [10]. The study was implemented in three phases: (1) pre-audit planning and baseline data collection, (2) detailed energy audit and consumption analysis, and (3) post-audit evaluation and formulation of energy efficiency recommendations.

This phased approach is consistent with methodologies applied in local university energy audit studies, which emphasized the importance of systematic assessment and post-audit evaluation to ensure practical and policy-aligned energy conservation measures [18]. [19], [20]. Each phase followed a systematic and sequential process to ensure comprehensive assessment of the university's facilities and an accurate representation of its energy consumption behavior within the local institutional and regulatory context.

II.2 STUDY SITE AND SCOPE

The study was conducted at the University of Eastern Philippines (UEP), a state university located in Catarman, Northern Samar, Philippines. The university comprises several academic, administrative, residential, and auxiliary buildings, each with distinct energy consumption characteristics. A total of twenty-five major facilities were included in the energy audit, encompassing both academic and non-academic structures such as the Cocofed Building, College of Business Administration (CBA) Building, Bio-Physical Laboratory, UEP-RCCC & Criminology Building, Diagnostic Center, and Hostel. These buildings were selected based on their relative energy intensity and their substantial contribution to the total electricity expenditure of the university between 2016 and 2018. The scope of the study focused primarily on electricity consumption, as it represented the dominant component of institutional energy use.

II.3 PHASE I: PRE-AUDIT PLANNING AND DATA COLLECTION

The pre-audit phase established the foundation for the detailed audit through data gathering and coordination with relevant university units. Initial consultations were conducted with facility managers, deans, administrative officers, and maintenance staff to obtain operational insights regarding building functions, occupancy schedules, and typical energy usage patterns [7]. A series of walkthrough inspections were then performed across all selected buildings to observe lighting systems, air-conditioning units, laboratory and computing equipment, and other major electrical installations. During this phase, historical electricity billing records from 2016 to 2018 were obtained from the Accounting and Facilities Management Offices to establish the university's baseline energy consumption and cost profile. In addition to data collection, process flow and energy utility diagrams were developed to map the flow of electricity within individual buildings and across the campus. This initial phase provided critical information on the distribution of energy loads, enabling the research team to identify the most energy-intensive areas for further investigation [15]. The combination of documentary data, physical observation, and stakeholder interviews provided a holistic understanding of how energy was consumed and managed within the university.

II.4 PHASE II: DETAILED ENERGY AUDIT AND ANALYSIS

The second phase involved conducting a detailed energy audit following ASHRAE Level II standards, which emphasize the integration of utility data analysis, field measurements, and performance evaluation [16]. Real-time consumption data were gathered from sub-meters and smart monitoring devices installed in high-consumption buildings such as the Bio-Physical Laboratory and Cocofed Building. For structures without sub-metering, consumption estimates were derived using connected load analysis, considering equipment wattage, operational hours, and occupancy patterns [6]. The audit team used portable digital analyzers to measure electrical parameters, including voltage, current, and power factor, while lighting levels were measured using a lux meter to assess efficiency and illumination adequacy. HVAC performance was evaluated based on system runtime, thermostat settings, and coefficient of performance (COP). These measurements were complemented by direct observations to identify operational inefficiencies such as equipment left running during idle periods or inadequate temperature control. Data analysis focused on determining consumption trends, load distributions, and seasonal variations in energy use.

Monthly and annual consumption were computed and compared across buildings to identify "energy guzzlers" or facilities with disproportionate consumption relative to their size or function. The study also employed normalized performance indicators such as energy use intensity (kWh/m²/year) to facilitate comparison among different types of buildings. Statistical analysis was performed using descriptive and trend analysis techniques, consistent with methodologies applied in similar university audits [14], [15]. The results provided insights into the operational dynamics driving the university's increasing energy expenditures. Energy Conservation Measures (ECMs) were identified based on the audit findings, focusing on both technical and behavioral opportunities for improvement. The potential measures included upgrading lighting systems to energy-efficient LEDs, optimizing HVAC temperature settings, improving equipment maintenance, introducing occupancy sensors, and exploring renewable energy options such as solar photovoltaic installations [5], [10], [14]. Each proposed intervention underwent cost-benefit evaluation, estimating potential savings, implementation costs, and payback periods to determine their feasibility and prioritization [9].

II.5 PHASE III: POST-EVALUATION AND RECOMMENDATIONS

The final phase of the study involved consolidating the audit results into a comprehensive Energy Management Plan (EMP) for the university. This plan detailed the recommended interventions, ranked according to their cost-effectiveness, energy-saving potential, and implementation feasibility. Follow-up consultations were held with the university administration to validate the findings and ensure alignment with institutional priorities and budgetary capacities. The EMP also proposed the establishment of an Energy Management Committee responsible for monitoring the implementation of energy-saving measures, verifying their performance, and institutionalizing continuous improvement practices in line with sustainable campus operations.

II.6 DATA ANALYSIS TOOLS AND EVALUATION

Quantitative data analysis was conducted using Microsoft Excel and SPSS software to process numerical data, generate statistical summaries, and produce graphical representations of energy consumption trends. Correlation analyses were employed to identify relationships between energy use and factors such as building function, occupancy rate, and seasonal variation.

Qualitative data gathered from interviews and observations were coded thematically to identify recurring issues related to operational practices and equipment management. To ensure methodological rigor, triangulation was applied by cross-verifying information from billing data, field measurements, and personnel interviews, thereby enhancing the reliability and validity of the results [7], [13], [16].

II.7 ETHICAL AND ADMINISTRATIVE CONSIDERATIONS

Prior to data collection, formal approval was secured from the University Research Office and the Office of the Vice President for Research, Development, and Extension. All building data and energy records were treated as confidential and used solely for research purposes. The study also adhered to the ethical standards of institutional research, ensuring that participation from staff and personnel during interviews was voluntary and conducted with informed consent.

III. RESULTS AND DISCUSSION

III.1 OVERVIEW OF ENERGY CONSUMPTION TRENDS

As shown in Fig. 1, the total energy expenditure of the university increased significantly from 2016 to 2018, reflecting the growth in infrastructure and equipment usage. The analysis of the University of Eastern Philippines' (UEP) electricity records from 2016 to 2018 revealed a continuous rise in total energy consumption across the main campus. Annual energy expenditures increased from ₱4.77 million in 2016 to ₱7.22 million in 2018, representing a 51.4% growth over three years. This escalation mirrors global patterns observed in institutional and educational facilities, where energy use continues to rise due to campus expansion, higher equipment density, and intensified reliance on information technology [2], [6], [16].

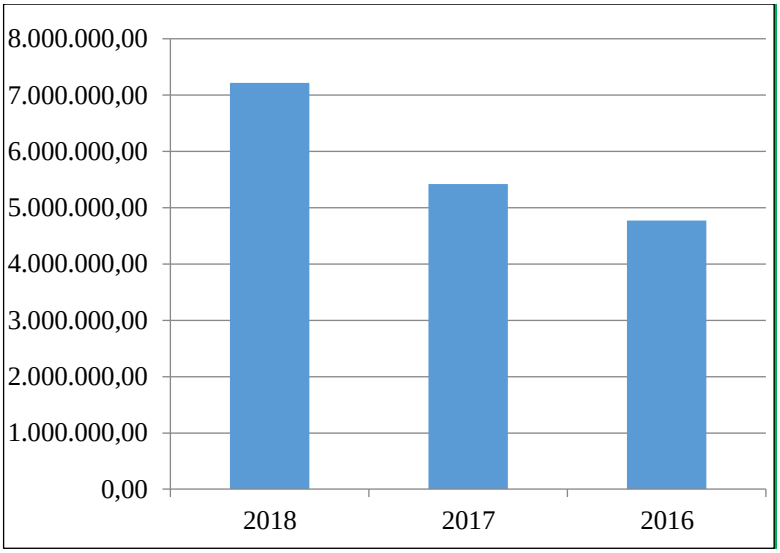

Figure 1: Annual Eelctricity Expenditure of the University of Eastern Philippines, 2016-2018.
Source: Authors, (2026).

Comparable trends were reported by [5] in Oman, who observed a 35% increase in energy demand in higher education institutions due to infrastructure expansion and increased cooling loads. Similarly, [15] found that Moroccan universities experienced significant increases in electricity consumption attributed to inefficient lighting and HVAC systems. These studies collectively affirm that academic institutions, particularly in tropical and developing regions, are facing substantial challenges in balancing modernization with energy efficiency. The growth of UEP's consumption can thus be attributed to the proliferation of electronic equipment, extended operational hours, and the installation of air-conditioning systems across academic and administrative spaces. A study [16] and [21] emphasized that these factors—combined with low awareness of energy conservation—are major contributors to energy inefficiency in Southeast Asian campuses.

III.2 BUILDING LEVEL ENERGY DISTRIBUTION

A building-by-building analysis revealed in Figure 2 that a few key facilities were responsible for a disproportionately large share of total electricity consumption. The Cocofed Building recorded the highest energy use, followed by the College of Business Administration (CBA) Building, Bio-Physical Laboratory, and UEP-RCCC & Criminology Building. Between 2016 and 2018, the Cocofed Building's annual cost increased from ₱1.099 million to ₱1.235 million, while the CBA Building's rose from ₱643,000 to ₱822,000.

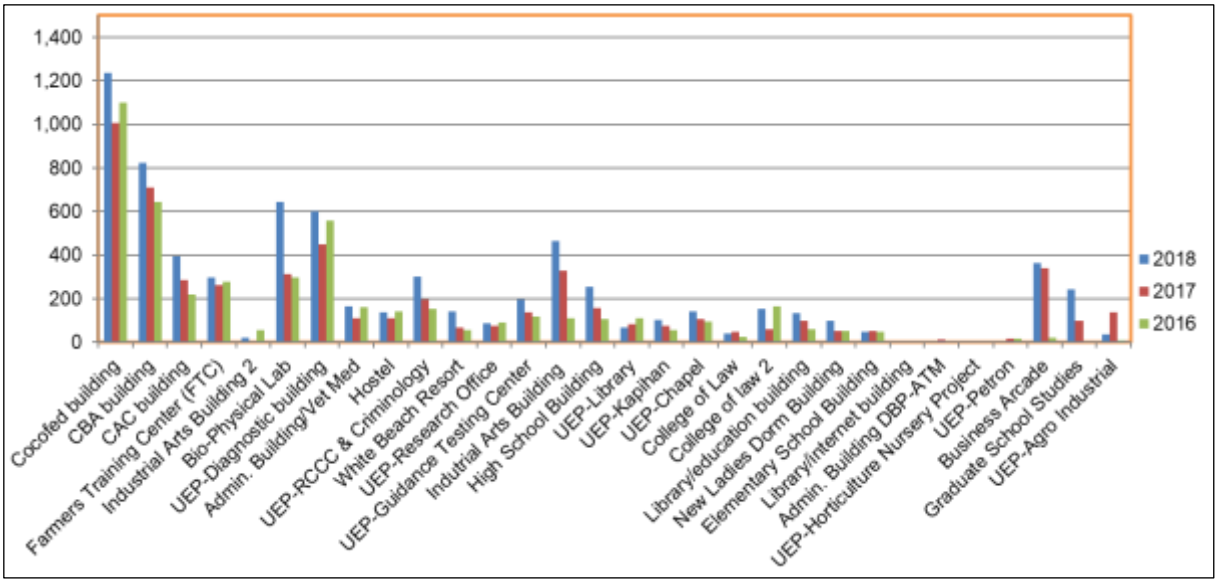

Figure 2: Comparative Annual Electricity Consumption by Building, 2016-2018.
Source: Authors, (2026).

This pattern is consistent with findings by [14], who identified that laboratory and administrative facilities exhibit the highest energy intensity due to equipment load, continuous operation, and greater cooling demands. Similarly, a recent benchmarking study conducted by [22] in Indonesia confirmed that laboratory buildings exhibited the highest Energy Consumption Intensity (IKE), exceeding 300 kWh/m² per year—significantly higher than classroom buildings. Furthermore, the unequal distribution of energy use across buildings aligns with the observations of [15], who found that just five university buildings in Morocco accounted for over 60% of total campus electricity use. This suggests that UEP's consumption profile—where a few buildings dominate total demand—is typical for higher education institutions, reinforcing the need for targeted, facility-specific energy interventions.

III.3 MONTHLY CONSUMPTION PATTERNS AND SEASONAL VARIATIONS

Monthly data analysis revealed cyclical consumption behavior influenced by both climatic conditions and the university's academic calendar. Electricity use peaked between May and October, coinciding with elevated outdoor temperatures and intensive academic activities. The Cocofed Building, for instance, recorded its highest monthly consumption in October 2018 (₱126,587.39), roughly double its January level. This trend highlights the strong relationship between tropical climatic conditions and increased HVAC load intensity. Studies by [14] and [23] report that cooling energy can account for up to 45% of total building energy consumption in humid regions. Similarly, research conducted at Nanjing Audit University in China [17] demonstrated that temperature-sensitive operations significantly contribute to monthly energy-use variability, particularly in facilities where ventilation and air-conditioning systems lack automated control mechanisms. In line with these findings, a pilot study [24] at the University of Eastern Philippines demonstrated the economic benefits of implementing automated electric fans, resulting in improved energy efficiency and reduced operational costs. Seasonal variations were also influenced by the academic schedule. Energy consumption typically declined during semester breaks, while examination and enrollment periods exhibited spikes in load due to extended operational hours. Such temporal fluctuations underscore the importance of load management strategies, including demand-side scheduling and programmable thermostats, as recommended by [16] and [10].

III.4 IDENTIFICATION OF HIGH-CONSUMPTION ZONES

The detailed audit revealed notable energy anomalies across several UEP buildings. The Bio-Physical Laboratory displayed monthly fluctuations between ₱26,762.05 in January and ₱76,211.21 in October, suggesting inconsistent operational management of laboratory equipment. Likewise, the Diagnostic Center showed a steady upward trend, doubling from ₱31,140 in January to ₱68,693 in December. Such variability is typical of research and medical facilities, where high plug loads associated with laboratory and medical equipment and stringent ventilation requirements contribute to substantial energy demand and operational losses. Laboratory fume hoods and high-level biosafety labs — common in research campuses — are known to be among the most energy-intensive building systems, often requiring constant air changes to maintain safety, which in turn increases HVAC energy use relative to conventional spaces. Similarly, medical facilities consume significant energy due to non-stop operation of equipment and environmental control systems, with refrigeration and specialized devices accounting for large shares of electricity use and continuous standby power draw.

Studies have shown that medical plug loads can constitute a significant portion of total electrical consumption in hospital laboratories, and that such equipment often exhibits high base-load and standby energy use even when not actively in operation, underscoring the importance of understanding load diversity in institutional energy audits [25], [26]. A 2022 study at Universiti Teknologi MARA (Malaysia) [27] reported that uncontrolled use of laboratory equipment and insufficient HVAC zoning led to 25% excess energy use annually. Similarly, [23] observed that without behavioral interventions, staff and student practices can negate the benefits of technical retrofits. The Industrial Arts Building exhibited a mid-year surge, likely linked to machinery-intensive workshops during training periods. These findings emphasize that operational scheduling, preventive maintenance, and behavioral modification are equally critical to energy efficiency as technological upgrades, a conclusion also reached by [7] and [22].

III.5 ENERGY CONSERVATION MEASURES (ECMs) AND EXPECTED IMPACT

Based on the audit results, several Energy Conservation Measures (ECMs) were proposed for implementation. These include replacing fluorescent and incandescent lamps with LED lighting, optimizing HVAC temperature settings, instituting preventive maintenance programs, installing occupancy sensors, and exploring on-site solar photovoltaic (PV) generation. LED retrofitting alone could yield 30–50% reductions in lighting energy use, while HVAC optimization could achieve an additional 15–20% reduction, consistent with results from previous university audits [5], [14], [15]. The integration of PV systems, particularly for high-load facilities like the Cocofed and CBA buildings, could further offset 10–15% of grid-supplied electricity, as demonstrated by [5] and [17]. A study [15] documented a 33% reduction in overall energy consumption following a comprehensive university retrofit in Morocco, while [17] achieved a 40% reduction through building-envelope improvements and smart control systems at Nanjing Audit University. These benchmarks suggest that UEP's targeted 15% reduction is realistic and achievable under existing operational and financial constraints. The successful implementation of ECMs would translate to annual savings of approximately ₱692,000, which could be reallocated to support campus development and research. Moreover, the institutionalization of an Energy Management Committee would facilitate long-term monitoring, verification, and sustainability, as recommended by [13].

III.6 COMPARATIVE ANALYSIS WITH OTHER INSTITUTIONS

When compared with other international energy audit studies, UEP's consumption profile and potential savings fall within a common range for tropical universities. [22] reported that Indonesian universities achieved 18–22% energy reductions after adopting targeted ECMs. In Malaysia, [16] and [21] documented up to 20% savings following the implementation of behavioral awareness programs and smart control technologies. Similarly, [17] in China achieved significant efficiency gains through green envelope retrofits and integrated energy management systems. These findings collectively indicate that universities operating in tropical and humid climates—like those in Southeast Asia—share common challenges related to air-conditioning dependence, inefficient equipment, and behavioral patterns. The consistency of UEP's results with these studies confirms that systematic energy audits are effective diagnostic tools for identifying both technical inefficiencies and policy gaps, ultimately leading to sustainable institutional energy governance.

III.7 SUMMARY OF FINDINGS

The comprehensive audit established that UEP's rising electricity consumption is driven by a combination of structural, operational, and behavioral factors. Buildings housing laboratories, administrative offices, and specialized facilities exhibited the highest energy intensities. Seasonal and academic-cycle variations further exacerbated load demands, particularly during the dry and hot months. By implementing cost-effective ECMs and adopting behavioral and policy-level strategies, the university could feasibly achieve a 15% reduction in energy use and align with international best practices in campus energy management. The study reinforces prior evidence that data-driven energy audits serve as essential foundations for developing institutional energy policies, improving operational efficiency, and advancing sustainability goals in public universities [6], [7], [15], [17], [22].

IV. CONCLUSIONS

This study conducted a comprehensive energy audit of the University of Eastern Philippines (UEP) to evaluate its electricity consumption patterns, identify inefficiencies, and propose data-driven conservation strategies. The analysis of three years of electricity records (2016–2018) revealed a 51.4% increase in energy expenditure, rising from ₱4.77 million to ₱7.22 million. This significant escalation highlights the growing energy demand associated with the expansion of academic infrastructure, increased equipment usage, and the intensified adoption of air-conditioning systems across campus. Building-level analysis showed that a small number of facilities—the Cocofed Building, College of Business Administration (CBA) Building, Bio-Physical Laboratory, and RCCC & Criminology Building—accounted for the majority of total energy consumption. These buildings exhibited high load densities due to continuous operations, specialized equipment, and extensive cooling requirements.

Monthly data indicated strong seasonal variation, with peak consumption occurring between May and October, corresponding to warmer weather conditions and heightened academic activity. The audit also uncovered several operational inefficiencies, including the use of outdated lighting systems, lack of zoning and control in HVAC units, and absence of automated energy management systems. By implementing targeted Energy Conservation Measures (ECMs) such as lighting retrofits, HVAC optimization, and behavioral reforms, UEP could feasibly reduce its electricity consumption by at least 15%, equivalent to an annual savings of approximately ₱692,000. Overall, the study demonstrates that systematic energy audits are essential tools for identifying both technical and behavioral inefficiencies in university environments. The findings provide a solid foundation for establishing a campus-wide energy management framework that promotes sustainability, reduces operational costs, and enhances institutional resilience against rising energy prices.

V. RECOMMENDATIONS

1. *Implement High-Impact Energy Conservation Measures (ECMs).* Immediate actions should prioritize cost-effective measures such as LED lighting retrofits, HVAC system maintenance, thermostat optimization, and installation of occupancy sensors. These interventions can yield substantial energy savings with minimal capital investment.
2. *Establish an Energy Management Committee (EMC).* A university-level EMC should be formed to coordinate and oversee all energy-related initiatives. This committee should develop policies, monitor energy performance, and ensure that efficiency measures are implemented and sustained over time.
3. *Adopt Smart Metering and Real-Time Monitoring Systems.* Installing sub-meters and digital energy monitoring tools will allow precise tracking of electricity usage per building, enabling early detection of anomalies, accurate benchmarking, and data-driven decision-making.

4. *Integrate Renewable Energy Technologies.* The university should explore the installation of solar photovoltaic (PV) systems on suitable rooftops, particularly high-load facilities such as the Cocofed and CBA buildings. Even partial adoption could offset a portion of grid-supplied electricity and demonstrate the university's commitment to sustainability.
5. *Strengthen Institutional Policies and Awareness Programs.* Energy efficiency should be embedded into university policies, procurement guidelines, and maintenance practices. Conducting awareness campaigns, student-led initiatives, and staff training can encourage responsible energy behavior and ensure long-term cultural change.
6. *Conduct Regular Energy Audits and Benchmarking.* The energy audit should be repeated every three to five years to evaluate progress and identify new opportunities for improvement. Establishing performance indicators such as energy consumption intensity (kWh/m²/year) will allow comparison with national and international benchmarks.
7. *Explore Long-Term Structural and Thermal Improvements.* Future infrastructure upgrades should consider energy-efficient building designs, thermal insulation, reflective roofing, and natural ventilation strategies to reduce dependency on mechanical cooling systems.

VII. ACKNOWLEDGMENTS

The researchers sincerely thank the University of Eastern Philippines (UEP) led by Dr. Cherry I. Ultra, for the financial support that made this study possible, and the University Administration, particularly the Office of the President and the Office of the Vice President for Research, Development and Extension, headed by Dr. Karina Cui-Lim, for their approval and support. Appreciation is also extended to the College of Engineering, the Facilities Management and Campus Development Office, the Accounting Office, the Electrical Services Division, and other university personnel for their cooperation and provision of essential data. The researchers likewise acknowledge the assistance of the Energy Audit Task Force, academic representatives, and administrative staff. Finally, heartfelt thanks are extended to the researchers' families, friends, and colleagues for their continued encouragement and support.

ABSTRACT

Green hydrogen is sustainable energy and clean source that has the potential to significantly alter important industries like manufacturing, the production of electricity, and transportation. Green hydrogen has the potential to ease the transition to low-carbon energy sources because of its leading role in global decarbonization initiatives. Increasing manufacturing productivity, ensuring the stability of storage, and coordinating usage strategies with commercial scalability remain significant challenges This review examines the application of artificial intelligence (AI) to these pressing issues throughout the green hydrogen value chain. In particular, it examines how optimization, deep learning, and machine learning (ML) can boost electrolyzer efficiency in fuel cell applications, improve energy conversion processes, forecast system performance, and optimize storage options. In addition, it is shown how AI-driven real-time monitoring systems and digital twins can be integrated into hydrogen infrastructures, showing how these tools make adaptive operational control and predictive maintenance easier. This article uses current technology advancements and a few selected case studies to critically examine how AI accelerates innovation in green hydrogen technologies in order to facilitate the development of affordable, scalable, and sustainable energy systems of the next generation.

I. INTRODUCTION

The greenhouse gases, like methane, nitrous oxide and carbon dioxide, with the increase of emissions, have significantly exacerbated global warming. These gases cause irregularities in climate, threatening to raise sea levels, and subjecting the world to frequent natural disasters [1], [2]. Thus, transitioning to low-carbon, sustainable energy systems has become a strategic imperative in the world's search for immediate intervention to counter the challenging effects of climate change. Of these choices, green hydrogen is receiving attention as a promising vector of decarbonization for generating power, movement, and course industries [3]. Green hydrogen is the environmentally most sustainable type of hydrogen produced by electrolysis using renewable energy and emitting no greenhouse gases. Unlike grey, blue, or brown hydrogen produced using fossil fuels, they neither cause oxygen depletion nor increase water vapour. Yellow and white hydrogen share almost the same benefits, but are less scalable or occur naturally or in the rarest forms. Pink and turquoise hydrogen offer a moderate environmental impact, depending on whether one goes for the nuclear route or carbon-handling [4]. Figure. 1 display the production of green hydrogen types.

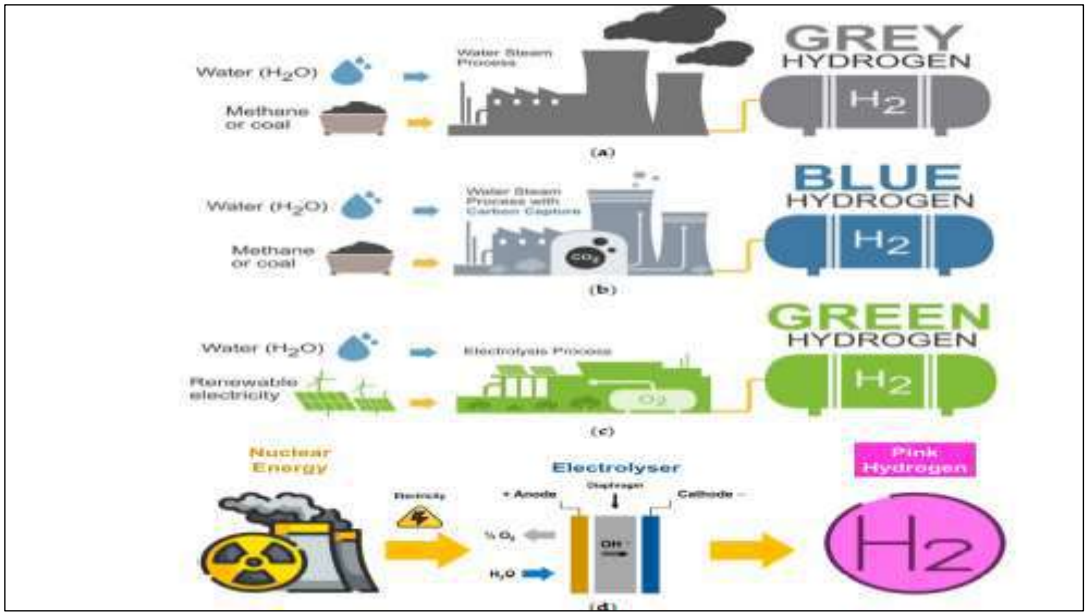

Figure 1: Production methods of hydrogen types.
Source: [5].

Green hydrogen is primarily an energy carrier that needs to remain clean and flexible, produced by splitting water molecules using electrolysis powered by wind, solar, or other renewable energy sources.at least slightly, or somewhat, zero emissions at the point of use [6], [7]. Electrolytic hydrogen production methods from renewable sources are compatible with modular and scalable infrastructures for energy generation, enabling constant flux to meet supply patterns and demand a capability that traditional fossil fuels cannot match [8]. While grey hydrogen uses steam methane reforming to produce (9–12) of CO_2 per ton of H_2, green hydrogen is carbon-free [9]. This flexibility is advantageous for ammonia production and other energy-intensive applications [10]. However, problems persist throughout the green hydrogen value chain despite these advantages. The two types (Metal hydrides and liquid organic hydrogen) carriers are storage technologies that are far behind conventional storage systems like underground caverns or compressed gas in terms of development, which results in inefficiencies and safety risks [11]. Moreover, the lack of an established distribution infrastructure and also technical challenges, such as hydrogen embrittlement and leakage caused by small molecular size, do not allow consideration of these highways to be integrated into existing natural gas grids [12].The term Artificial Intelligence (AI) is currently popular as a method to power solutions for these varying issues. Algorithms of optimization, machine learning, deep learning, and other methods of artificial intelligence can effectively model complex, nonlinear systems and draw valuable information from voluminous data [13].Figure. 2, illustrate how artificial intelligence and machine learning are infused into the hydrogen cycle, including production, storage, safety, and distribution, to produce a worthwhile energy system that is sustainable, safe, and efficient.

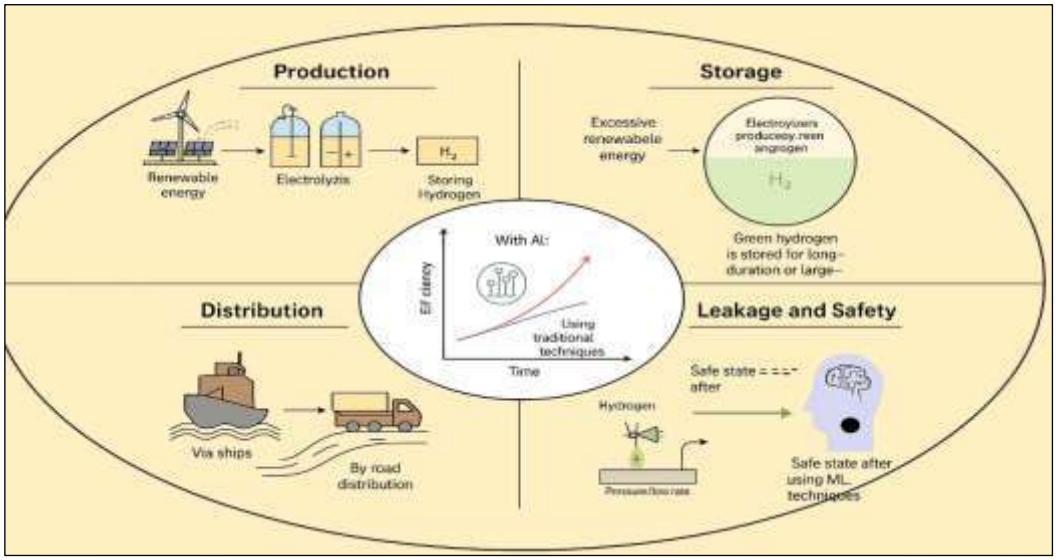

Figure 2: ProAI and ML integration across the hydrogen cycle from production to safety and distribution.
Source: [14].

Process control and reduce energy consumption in green hydrogen production, potentially increasing efficiency by up to 20%. Similarly, AI enables demand forecasting, predictive maintenance, and system-level integration with renewable energy grids for storage and utilization [15]. AI offers the disruptive path to accelerate the commercialization of green hydrogen technologies in response to the growing impetus for a global energy economy based on hydrogen.

II. GREEN HYDROGEN PRODUCTION USING RENEWABLE ENERGY SOURCES II.1 SUBTITLE

Green hydrogen production significantly reduces carbon emissions compared to conventional methods of hydrogen production by utilizing renewable energy from resources like solar ,wind power and other resources to drive water electrolysis. This sustainable strategy is necessary to advance clean energy and lessen the effects of greenhouse gases [16].Figure 3 demonstrates the integration of water electrolysis and energy storage with renewable energy sources like solar and wind energy in a grid-connected green hydrogen production facility.

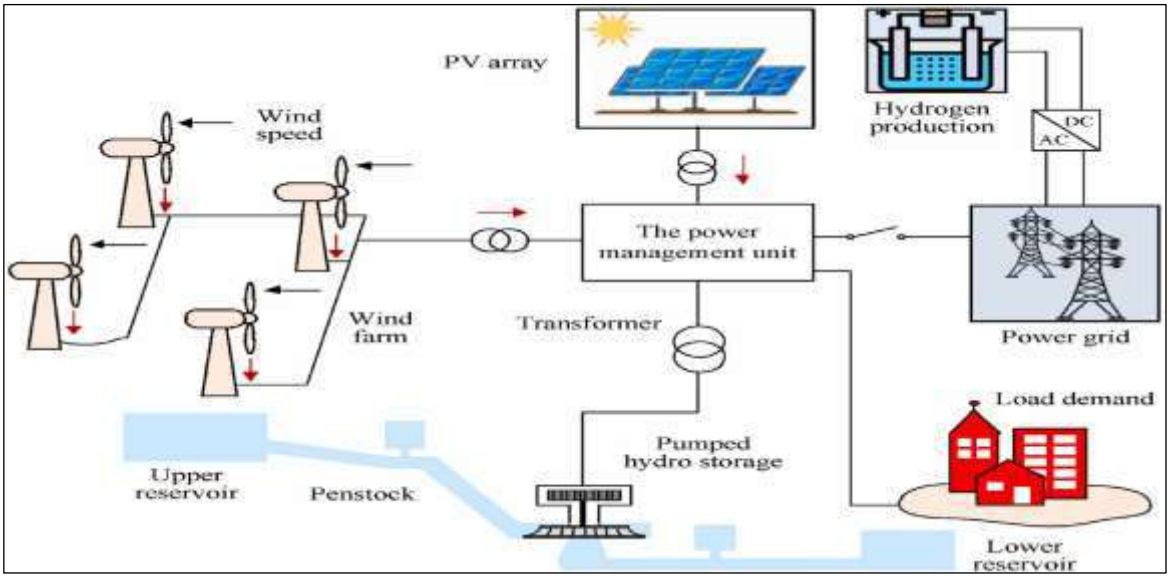

Figure 3: A diagram of a green hydrogen production system integrated into the grid using renewable resources, water electrolysis, and energy storage.
Source: [17].

The system can regulate fluctuations in the supply of renewable energy and maintain constant hydrogen production thanks to this integration. The testbed demonstrates, through its advanced power management and conversion technologies, how electrolysis and renewables can be balanced to create a more secure and environmentally friendly energy network. Examples of these developments include novel methods like the production of hydrogen through photo-electrochemistry and biological processes, as well as technological advancements in the production of green hydrogen such as enhanced electrolyzer performance thanks to cutting-edge catalysts and materials. These strategies also increase sustainability and efficiency by utilizing wind and solar power [18].In spite of the fact that technological advancements have proved the capability of photovoltaic (PV)-driven electrolysis systems to convert solar to hydrogen (STH) with high efficiency, there are still concerns regarding the stability of operations, safety, and storage under changing weather conditions [19]. By Combining different sources like(solar, wind, and geothermal energy) not only makes the system easier to scale up but also minimizes environmental impacts in a greater extent if backed by appropriate legal and economic frameworks [20].The national technoeconomic study has pointed that through using solar energy and various electrolysis technologies, Canada could theoretically produce more than 200 million tons of green hydrogen per year which would largely depend on regional optimization [21]. The 7 kW electrolysis system in Namibia has been successfully integrated with off-grid community wind energy and has shown that surplus wind energy can be utilized without affecting the system's load requirements to produce up to 235 kg of green hydrogen annually. This is a clean fuel substitute for the local needs that are not met like backup power and cooking [22]. In the same way, a regional study done in the Piura region estimated that yearly over 947,000 tons of green hydrogen produced through electrolysis which was majorly powered by solar PV (94.8%), with the rest wind and biomass. The study also put out that only 47.4% of hydrogen would be enough for the whole energy demand of the region and in this way there would be a significant reduction of greenhouse gas emissions [23].

III. GREEN HYDROGEN APPLICATIONS

Green hydrogen plays the role of hydrogen source in several applications such as clean fuel for transport, energy systems and industries that do not impact the environment. The most important areas in hydrogen utilization are mainly fuel cells, ammonia production, power-to-metal technology to produce aluminum and steel anodes from water electrolysis, and synthetic fuels. They all have a pivotal role in the development of global sustainability by consuming nearly half of the global production of hydrogen [24].Fuel cells are high-efficiency energy converters fueled by hydrogen, emitting no emissions. Adding membranes can produce additional pure water. Fuel cells make up 28% of final energy demand and are recommended by Peter Thiele of Siemens for managing electricity waste. Siemens fuel cells have an AC output of over 90%, making them an efficient option for powering various sectors globally [25].Energy systems, conversely, would stand to benefit greatly from green hydrogen, particularly when combined with intermittent renewables such as wind and solar. The storage of excess electricity as hydrogen and conversion back into electricity during times of demand dramatically improves grid stability and flexibility, and thereby serves, as a buffer against the variable nature of renewable generation [26] .The interest in green hydrogen for industrial applications that are hard to convert to renewable electricity is high. The amount of hydrogen needed is typically rather low, but is needed for specific purposes, including hydrogen as feedstock, and hydrogen as reducing agent for metal oxides, or synthesis of more complex molecules.

The high energy consumption, the specific application and the tradition of steam methane reforming lead to much of the industrial application being found at coal sites, steel locations or refineries, as well as in ammonia production for the fertilizer market [27] , [28].The iron and steel sector is the largest industrial consumer of hydrogen used in the reduction of iron ore pellets . In this process, hydrogen reacts with the oxidized concentrate and, in combination with the carbon oxide, generates a steel result. Still used in large quantities, carbon oxide is emitted to the atmosphere and will be limited to meet climate goals. One of the ways to decarbonise the steel process is to use green hydrogen generated with zero emissions [29],[30]. The production of chemicals, such as methanol or ammonia, is another hydrogen industrial application. In the ammonia production, steam methane reforming is the traditional process and the main world source, driven by its low capital cost, high efficiency and development in the first half of the 20th century. However, the use of steam methane reforming leads to a large hydrogen carbon footprint, in one of the sectors that most contributes to the global CO2 emissions [31]. Figure. 4 depicts current and future industrial applications of green hydrogen, emphasizing its importance in industries that include oil refining, ammonia, and methanol production, metalworking, and chemical processing.

IV. ARTIFICIAL INTELLIGENCE ROLE IN GREEN HYDROGEN PRODUCTION TECHNOLOGIES

Artificial Intelligence plays a key role in driving green hydrogen production by making it more efficient and cost-effective. The use of machine learning on large datasets makes it possible to modify the operational settings of electrocatalysts making them perform better, produce more hydrogen, and consume less energy [33]. These artificial intelligence-based tools quickly match material compositions with desirable properties, powering the discovery of low-cost, high-performance electrode materials for water electrolysis. Load balancing, by storing the excess of possible solar and wind energy, is made easier through AI technologies because AI allows for dynamic adjustment of operations so that electrolyzers operate during peak generation only [34]. Refining demand-supply forecasting is a significant avenue of AI, which improves forecasts for renewable energy outturns and energy demand estimations, leading to better operation and innovation in green hydrogen systems [35]. Supported by data-driven screening and optimization, AI accelerates the design process of catalysts, which can be time-consuming and costly through traditional experiments, and enables pinpointing highly potent ones. With the help of a data-driven screening and optimization process, AI speeds up the design of catalysts, reduces experimental times and costs, and ensures the accurate discovery of high-performing materials [36]. Together, these advances highlight the importance of AI as a key enabler in the (sustainable, cheaper) development of green hydrogen technology .AI and automation are widely used in renewable energy, including solar and wind energy AI is the mainstay in the green hydrogen production process as it regulates the electrolyzer performance with the aid of cybernetic control[37].

The system has the ability to utilize weather forecasting to predict the renewable energy delivery and thus, to maintain the operation at the required level [38].AI has, in fact, become the key factor in the production of hydrogen and the co-generation of solar and wind power, both of which are working together to provide a more sustainable and energy-efficient system for the future. Energy was wisely handled and hence a significant reduction in carbon emissions was achieved which, in turn, is going to power a grid of the future that is going to be not only more reliable but also more sustainable [39]. Besides these, the AI application to predictive maintenance and the hydrogen production equipment life cycle extension was an advantage. AI will be deployed to analyze the data from sensors mounted on the trucks and simultaneously, an artificial intelligence system will be used to monitor, predict, and control the maintenance in a modern, efficient, and effective way. ITM Power has released a case study on its stage 2 and claimed an availability percentage that is up to 12% greater. This also worked out well for the equipment's lifespan as it increased by twice and operating costs got cut. These results indicate that AI can greatly improve hydrogen production industry wide in terms of both productivity and stability [40]. A new hybrid system for energy dangers and hydrogen generation has been named Zink-Zwischenschritt-Elektrolyseur (ZZE) in German. The model utilized several machine-learning models to predict the state of charge (SOC). The LSTM neural network achieved the lowest error in its forecasting (MAE = 3.21%). The precise SOC estimation is vital for the optimization of future ZZE management software.

The findings highlighted the support of data-driven AI methods in next-generation hydrogen storage technologies development [41]. Table 1 explain the summary of the key AI-centered works intended to enhance the range of green hydrogen production processes via electrolysis. It highlights that the new method can beat the traditional ones not only in terms of efficiency but also in accuracy of prediction and performance of systems in applications of Green Hydrogen Technologies.

Table 1: The AI-Driven Enhancement of Electrolysis-Based Green Hydrogen Production.

Study	Key focus	Model used	Key finding
[42]	AI in Electrolysis – Optimal Operational Prediction	Support Vector Machine (SVM), XGBoost, and Random Forest (RF) trained on electrolysis variables (electricity input, temperature, pressure, water quality). Dataset: experimental data from electrolysis processes	AI models predicted optimal electrolysis conditions, enhancing electrocatalyst performance and reducing energy loss. Outperformed manual tuning by ensuring consistent hydrogen output under varying inputs
[43]	Parametric Modeling of Alkaline Electrolyzers	MATLAB/Simulink parametric model using inputs like temperature, KOH concentration, and pressure. Not AI-based, serves as a traditional comparison baseline.	Higher temperatures and a 30 wt% KOH solution reduced cell voltage, thereby boosting system efficiency. Provides a baseline to compare improvements from AI-enhanced models
[44]	PEM(Proton Exchange Membrane) Electrolyzer Design Optimization via ML (Machine Learning)	Polynomial and Logistic Regression trained on 148 experimental samples to predict 11 PEM design parameters (e.g., electrode area, hydrogen production rate.	Achieved MAE of 0.615 and 83.6% classification accuracy. Enabled faster and more precise PEM cell design than conventional iterative approaches
[45]	Hybrid Modeling of Electrocatalysts	Adaptive Neuro-Fuzzy Inference System (ANFIS) + Pelican Optimization Algorithm (POA) using catalyst property datasets	A hybrid AI model improved hydrogen output by 1.7% vs traditional methods by optimizing catalyst behavior under electrolysis conditions.
[46]	DRL (Deep Reinforcement Learning) for Predictive Maintenance of Electrolysers	Deep Reinforcement Learning (DRL) with Long Short-Term Memory (LSTM) and feature selection. Dataset: sensor time-series data from electrolyser systems	DRL model identified sensor faults with 0.99 correlation and RMSE of 0.1351, enhancing maintenance efficiency and reducing downtime compared to manual diagnostics

V.ARTIFICIAL INTELLIGENCE TECHNIQUES FOR GREEN HYDROGEN STORAGE OPTIMIZATION

AI is a great help for green hydrogen storage. It helps to identify and control the production easily, monitor the status of storage, and predict the demand. It uses the same data analytics and optimization algorithms for efficiency and reliability thus solving the hydrogen storage and power supply cycle problem in a sustainable manner [47]. A smart system using neural networks can measure the non-linear dynamics of PEM (Proton Exchange Membrane) with a small average absolute prediction error of 0.05179. This makes the TITAN (Technology Intelligent Testbed for Advanced Networks) system more efficient and reliable for hydrogen generation and storage control compared to conventional methods of data collection. It is a revolution that not only accelerates the clean energy technology developments but also allows energy sustainability by supporting hydrogen energy developments through such innovations [48]. A MATLAB/Simulink model of the hydrogen subsystem was developed, employing a regression model to estimate hydrogen flow rates in response to input electrolyzer currents. A dynamic simulation of hydrogen storage is also developed, providing a reference for the high-pressure and compression pressures required and their effect on performance, as well as the evaluation of hydrogen storage, low energy density, and high pressure. This increases momentum for policy and regulatory support, as well as investment facilitation, for sustainable energy technologies. For this purpose, this work aims to integrate renewable-based energy storage solutions, enhance system reliability, and implement regulatory policies for sustainable energy solutions [49]. An AIoT-HES is developed based on a knowledge engineering model. With real-time analytics and predictive maintenance, hydrogen production, storage, and distribution costs are minimized while output is optimized. As a result, the AIoT ensures the operational security of the system by promptly identifying risks and determining intelligent storage conditions, which will be connected to other types of renewable energy. Maintenance or risk management of machine learning models can further enhance predictive capacity. The articles are also promoting sustainable energy alternatives, regulations, and a durable H2 infrastructure no information loss is incurred [50].

VI.APPLICATIONS OF AI IN GREEN HYDROGEN DEVELOPMENT ACROSS KEY COUNTRIES

Artificial Intelligence plays a crucial role in fronting the development of green hydrogen technologies, including production, storage, distribution, and utilization. Recent comprehensive reviews showing that AI techniques—such as Artificial Neural Networks (ANNs)—are largely employed in making electrolyzer technologies more efficient, forecasting inputs of renewable energy, optimizing storage procedures, and facilitating integration with a smart grid and GIS-based site selection [36].In India, a deep learning-based forecasting model for solar-powered green hydrogen production was introduced. The model works through four phases, including solar irradiance forecasting, electrolyzer scheduling, and cost-effective production of hydrogen through photovoltaic sources [51]. In Turkey, hybrid artificial intelligence modeling combining CEEMDAN and GRU neural networks for hourly hydrogen production prediction was developed for optimal scheduling and integration of hydrogen production within renewable energy mechanisms [52]. For both Saudi Arabia and Germany, AI modeling frameworks were developed for the estimation of green hydrogen generation by PtX systems. Those models consider data-driven forecasting and optimise the techno-economical feasibility of hydrogen generation from renewable sources. In Saudi Arabia, the high solar irradiance is used with AI to maximize electrolyzer performance and cost efficiency. In Germany, AI tools are used to manage intermittent wind and solar inputs while optimizing grid integration. The comparative analysis helps define strategies for the installation of green hydrogen infrastructure based on ambient and economic real-time parameters [53].

In the U.S., more than 500$ million in funding has been approved by the Department of Energy toward AI-assisted decarbonization and infrastructure development for hydrogen. According to the U.S. Energy Information Administration (EIA), AI applications optimizing electrolyzer performance and predictive maintenance would likely bring green hydrogen costs down by 20% or more in the next 10 years, further enhanced by heuristic algorithms optimizing operational parameters, yielding 15%-30% efficiency improvements in pilot projects by startups such as H2Pro. The mentioned optimization tools, besides various other AI applications such as predictive analytics, computer vision for leak detection, and AI-assisted planning, get federal tax credits and demonstration funds, which make hydrogen technologies near to commercialization [54].

VII. CONCLUSION

AI has an influential position to play in the full green hydrogen value chain transformation which means enhancing its efficiency, reliability, and scalability. All the way through production, storage, and use, AI is gradually taking over the solutions especially those which rely on machine learning, by modeling complex systems, optimizing performance, and interpreting high-dimensional data in a manner more superior than traditional physical modeling techniques. At the very start of the hydrogen production, the AI has shown its ability by synchronizing renewable electricity disruption with the hydrogen demand variations; thus the operation became more flexible and stable. The world's energy market is still moving to a point where hydrogen can be produced and used as a primary renewable source and, therefore, the traditional models will be unable to portray the complex and dynamic workflows of the new hydrogen economy. All these considered, the future of AI in this sector looks bright but at the same time, issues such as cybersecurity and system integrity are the major obstacles to widespread acceptance. In securing the digital infrastructure that is both safe and resilient, one should not forget that this has to happen in parallel with the technical advancements in the integration of AI in hydrogen systems. In spite of the extensive progress achieved in green hydrogen technologies, the world still has to deal with some economic and technical obstacles that are upholding the large-scale use of hydrogen all over the world. The main issues are the installation of pipelines and other necessary infrastructures that are very costly, the hard task of managing energy supply and demand because of the fluctuating nature of renewable sources, and the long-standing dependence on few and expensive catalyst materials. On top of that, a lack of technically skilled labor and the absence of detailed government laws and policies are making it even harder for the green hydrogen industry to expand gradually. Therefore, it can take to a long time for that to happen unless a well-coordinated approach is adopted consisting of combining technology development, policy intervention, and very long lasting investment plans to finally secure the transition to a low-carbon energy system that is equitable and mainly supported by green hydrogen.

Hybrid fuzzy super-twisting sliding mode control.

ABSTRACT

In the pursuit of advancing renewable energy technologies, optimizing wind turbine performance through sophisticated control systems is pivotal for addressing energy variability and enhancing system efficiency. This paper presents a novel hybrid fuzzy super-twisting sliding mode control (HFSTSMC) strategy for Doubly Fed Induction Generators (DFIGs) used in modern wind turbine configurations. DFIGs are favored for their adaptability and efficiency in managing variable wind speeds, making them integral to sustainable energy solutions. The proposed HFSTSMC integrates the robustness of super-twisting sliding mode control (STSMC) with the adaptive capabilities of fuzzy logic control (FLC), aiming to mitigate the chattering effect inherent in traditional sliding mode controls while maintaining high tracking accuracy and robustness. The hybrid controller utilizes fuzzy logic to dynamically adjust control gains based on system states, enhancing the dynamic performance and stability of DFIG-based wind turbines. Extensive modeling and simulation using MATLAB/SIMULINK validate the effectiveness of HFSTSMC in improving power quality, reducing mechanical stresses, and optimizing energy capture. The results demonstrate significant improvements in system response to rapid wind condition changes and overall operational efficiency under transient and uncertain conditions. This research underscores the substantial benefits of implementing HFSTSMC, highlighting its potential to revolutionize wind turbine control systems and contribute significantly to the global transition towards reliable and efficient renewable energy sources.

I. INTRODUCTION

As the global demand for renewable energy sources intensifies, wind energy has emerged as a vital component of sustainable energy portfolios [1]. The efficiency and reliability of wind turbines are paramount for harnessing this resource effectively. Doubly Fed Induction Generators (DFIGs) are widely employed in modern wind turbine systems due to their superior ability to handle variable wind speeds and contribute to the stability of electrical grids [2]. Traditional control strategies for DFIG-based wind turbines often face challenges such as chattering phenomena and sensitivity to system uncertainties, which can compromise performance and reliability. Sliding Mode Control (SMC) has been recognized for its robustness and effectiveness in dealing with non-linearities and uncertainties. However, conventional SMC techniques are prone to chattering, which can lead to excessive mechanical stress and energy losses [3]. [4]. To address these challenges, this paper proposes a novel Hybrid Fuzzy Super-Twisting Sliding Mode Control (HFSTSMC) approach.

This advanced control strategy combines the robustness of Super-Twisting Sliding Mode Control (STSMC) with the adaptability of Fuzzy Logic Control (FLC). The integration of fuzzy logic allows for dynamic adjustment of control parameters, thereby enhancing system performance and mitigating chattering effects[4-7]. The proposed HFSTSMC strategy aims to improve the dynamic performance, power quality, and operational stability of DFIG-based wind turbines. Extensive modeling and simulation studies are conducted using MATLAB/SIMULINK to evaluate the effectiveness of the proposed control approach. The results demonstrate significant improvements in system responsiveness to rapid changes in wind conditions, reduction in mechanical stresses, and overall optimization of energy capture. This research highlights the potential of HFSTSMC to revolutionize wind turbine control systems, offering a robust and efficient solution for maximizing wind energy utilization. The findings underscore the importance of advanced control strategies in the global transition towards renewable energy sources and the sustainable development of wind energy technology.

II. SYSTEM MODELING

II.1 AERODYNAMIC MODELING

The rotation of the blades due to wind speed generates mechanical power in the shaft. This mechanical power is then converted into electrical power by the Doubly Fed Induction Generator (DFIG)[8-10].

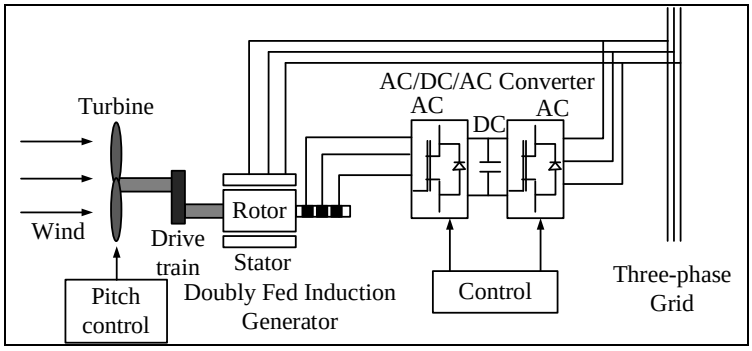

Figure 1: Wind power system.
Source: Authors, (2026).

The power output of the turbine can be described by Eq.(1):

$$P_T = \frac{1}{2} C_p(\lambda, \beta) \rho \pi R^2 {V_w}^3 \tag{1}$$

The power coefficient $C_p(\lambda, \beta)$ is determined using the equations provided in [1]:

$$C_p(\lambda, \beta) = \mathrm{C}_1 \left(\frac{C_2}{\lambda_i} - C_3 \beta - C_4 \right) e^{\frac{\mathrm{C}_5}{\lambda_\mathrm{i}}} + C_6 \lambda \tag{2}$$

With $\frac{1}{\lambda_\mathrm{i}} = \frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1}$, $C_1 = 0.52$, $C_2 = 116$, $C_3 = 0.4$, $C_4 = 5$, $C_5 = 21$, $C_6 = 0.0068$ and $\lambda = \frac{R\omega_{mech}}{v_w}$

By maintaining the tip speed ratio λ at its optimal value (λ_{opt}) the coefficient is at its maximum then as shown in figure (2),the optimal power can calculate using the following equation :

$$P_s^* = \frac{1}{2} C_{pmax}(\lambda_{opt}) \rho \pi R^2 V_w^3 \tag{3}$$

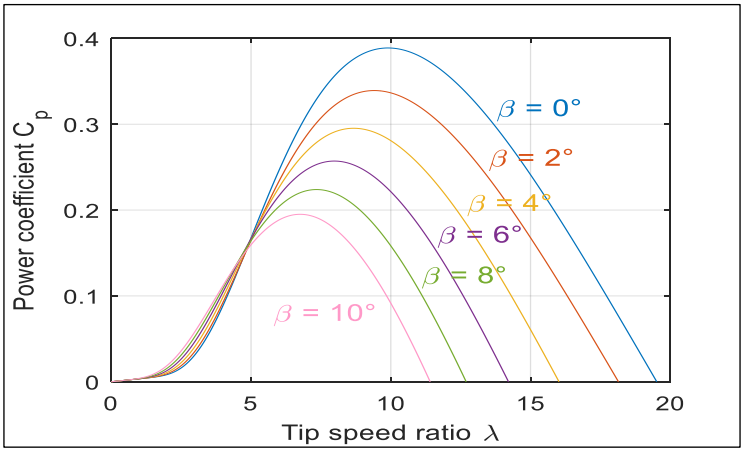

Figure 2: tip speed ratio (λ) vs. Power coefficient (Cp) curve.
Source: Authors, (2026).

II.2 DFIG SYSTEM MODELING

The Doubly Fed Induction Generator (DFIG) is a variable-speed wind turbine generator that efficiently converts wind energy into electrical power. DFIG employs both rotor and grid-side converters, allowing for better control of generator speed and enhanced power quality in the generated output [6-7].

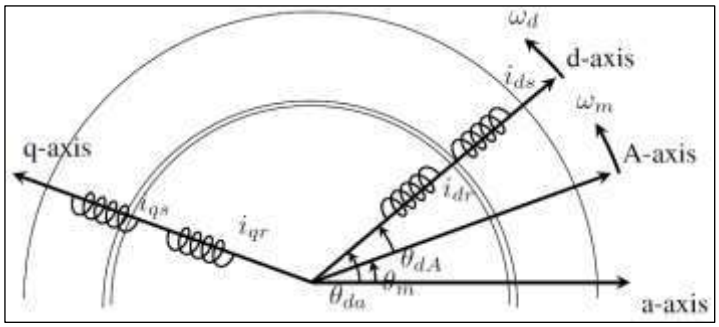

Figure 3: Illustration of stator and rotor with equivalent dq winding.
Source: [6].

After applying the Park transformation and subsequent mathematical derivation as referenced in [8], it was determined:

– The stator, rotor voltages

$$\begin{cases} v_{ds} = R_s i_{ds} + \frac{d}{dt}\phi_{ds} - \omega_d \phi_{qs} \\ v_{qs} = R_s i_{qs} + \frac{d}{dt}\phi_{qs} + \omega_d \phi_{ds} \\ v_{dr} = R_r i_{dr} + \frac{d}{dt}\phi_{dr} - \omega_{dA} \phi_{qr} \\ v_{qr} = R_r i_{qr} + \frac{d}{dt}\phi_{qr} + \omega_{dA} \phi_{dr} \end{cases} \quad (4)$$

– The fluxes can be found in Eq.(5)

$$\begin{cases} \phi_{ds} = L_s i_{ds} + L_m i_{dr} \\ \phi_{qs} = L_s i_{qs} + L_m i_{qr} \\ \phi_{dr} = L_r i_{dr} + L_m i_{ds} \\ \phi_{qr} = L_r i_{qr} + L_m i_{qs} \end{cases} \quad (5)$$

– The stator powers are presented in Eq.(6)

$$\begin{cases} P_s = v_{ds} i_{ds} + v_{qs} i_{qs} \\ Q_s = v_{qs} i_{ds} - v_{ds} i_{qs} \end{cases} \quad (6)$$

– The electromagnetic torque equation

$$T_{em} = \frac{P}{2} L_m \left(\phi_{qr} i_{dr} - \phi_{dr} i_{qr}\right) \quad (7)$$

From Eq.(4), by replacing the fluxes with rotor currents and after Laplace transformation, we obtain:

$$\begin{cases} i_{dr} = \frac{1}{R_r + S\sigma L_r} v'_{dr} \\ i_{qr} = \frac{1}{R_r + S\sigma L_r} v'_{qr} \end{cases} \quad (8)$$

Table 1: Parameters of wind turbine & DFIG.

Parameter	Definition	Value	Unit
J_{Turb}	Wind Turbine Moment of Inertia	2.4x10^6	Kg.m^2
ρ	Air Density	1.2	Kg.m^3

III. CONTROLLER

III.1 SUPER TWISTING SLIDING MODE CONTROL

Super-Twisting Sliding Mode Control (STSMC) is a robust control technique that enhances the traditional SMC by reducing the chattering effect without compromising the system's robustness. The STSMC is a second-order sliding mode control method that does not require the derivative of the sliding variable, making it suitable for practical applications [9-13].

The STSMC law can be described by the following equations:

$$u = u_{eq} + u_n \tag{9}$$

Designing the sliding mode surface as [9] was the initial stage in creating the Super-Twisting Sliding Mode Controller (STSMC):

$$S = \left(\lambda + \frac{d}{dt}\right)^{r-1} e \tag{10}$$

The tracking error is represented by e, the system order is indicated by r, and the variable λ needs to meet the Hurwitz condition. According to Eq. (8), since r=1, our surface become:

$$S = e = I_{dqrDesired} - I_{dr} \tag{11}$$

The Lyapunov function is defined as:

$$V = \frac{1}{2}S^2 \tag{12}$$

The Lyapunov function derivative in Eq. (12) must meet $\dot{V} < 0$ as $S\dot{S} < 0$ in order to guarantee the stability criterion.
The sliding mode function's derivative is:

$$\dot{S} = \dot{e} = \dot{I}_{dqrDesired} - \dot{I_{dr}} \tag{13}$$

$$\dot{S} = \dot{e} = \dot{I}_{dqrDesired} + \frac{(R_r I_{dqr} - V_{dqr})}{\sigma L_r} \tag{14}$$

Therefore, the Lyapunov function may be derived as follows:

$$S\dot{S} = S\left(\dot{I}_{dqrDesired} + \frac{(R_r I_{dqr} - V_{dqr})}{\sigma L_r}\right) \tag{15}$$

To satisfy the condition $S\dot{S} < 0$, the sliding mode controller is designed as:

$$u_{dqr}^{eq} = \sigma L_r\left(\dot{I}_{dqrDesired} + R_r I_{dqr}\right) \tag{16}$$

Ultimately, a discontinuous control term has been introduced to determine the sliding mode control law, as illustrated in Eq.(17) :

$$u_n = -k_1\sqrt{|S|}sign(S) + \int(-k_2 sign(S))\, dt \tag{17}$$

Where k_1, k_2 are strictly positive gains.
Consequently, the resulting control signal is formulated as follow:

$$u = u_{eq} + u_n = \sigma L_r\left(\dot{I}_{dqrDesired} + R_r I_{dqr}\right) - k_1\sqrt{|S|}sign(S) + \int(-k_2 sign(S))\, dt \tag{18}$$

III.2 FUZZY LOGIC ENHANCEMENT

To enhance the performance of the STSMC, a fuzzy logic controller (FLC) can be incorporated to dynamically adjust the gains k_1 and k_2. The FLC uses system state information to modify these gains in real-time, improving the controller's adaptability and reducing residual chattering [14-16]. Input fuzzy membership functions, Our Fuzzy Logic Controller (FLC) uses input membership functions to establish a connection between the control decisions and the error signal. In Figure 4 [1], these membership functions are shown.

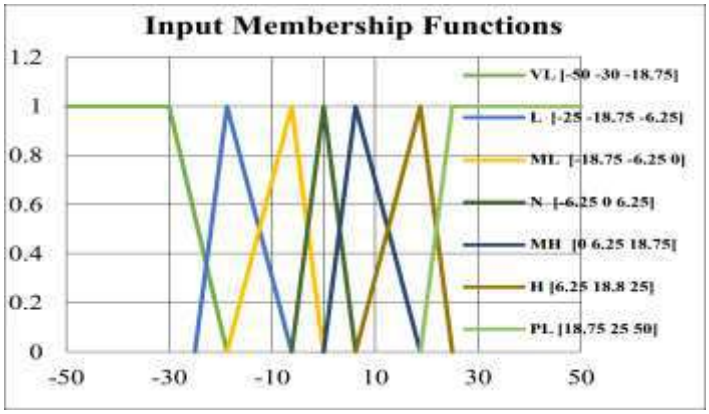

Figure 4: Input variables.
Source: Authors, (2026).

The linguistic variables are: "Very Low" ,"Low", "Moderately Low","Neutral","Moderately High","High" and "Very High" error magnitudes.

– Output fuzzy membership functions

The FLC can precisely modify the gains k_1 and k_2 of the Super-Twisting Sliding Mode Controller (STSMC) due to these output membership functions. This improves the overall performance and stability of the DFIG-based wind turbine by allowing it to function at its best in a variety of wind situations.

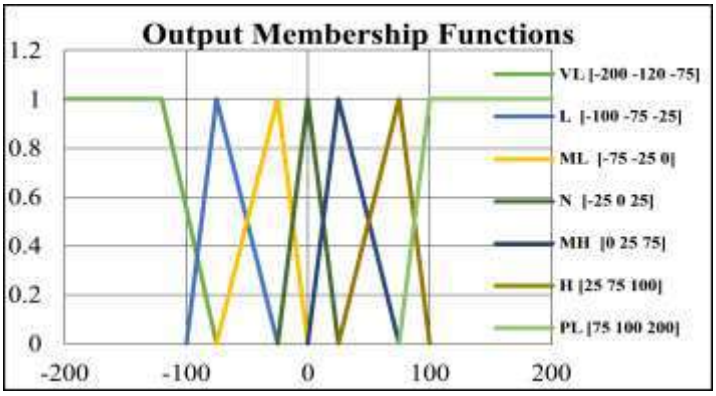

Figure 5: Output variables.
Source: Authors, (2026).

– Rules

These rules define how the FLC interprets input conditions and determines appropriate control actions, enabling it to mimic human-like reasoning and adapt to complex control scenarios.

Table 2: Fuzzy rules.

Output Input	VL	L	ML	N	MH	H	VH
VL	✔	.	.	.	.	.	.
L	.	✔	.	.	.	.	.

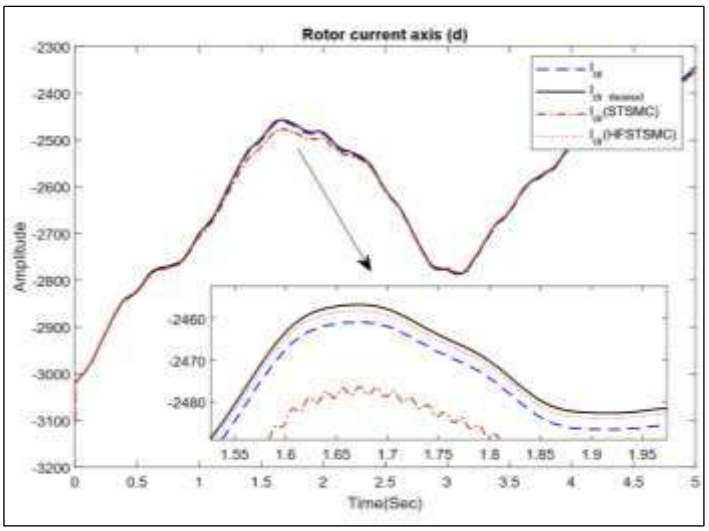
MH	.	.	.	.	✔	.	.
H	.	.	.	.	.	✔	.
VH	.	.	.	.	.	.	✔

Source: Authors, (2026).

To create HFSTSMC, we replace the discontinuous sign function Sign(S) with a continuous fuzzy logic function Fuzzy(S). This modification helps to smooth out the control action and reduce chattering. The fuzzy logic controller dynamically adjusts the control signal based on the system's state.

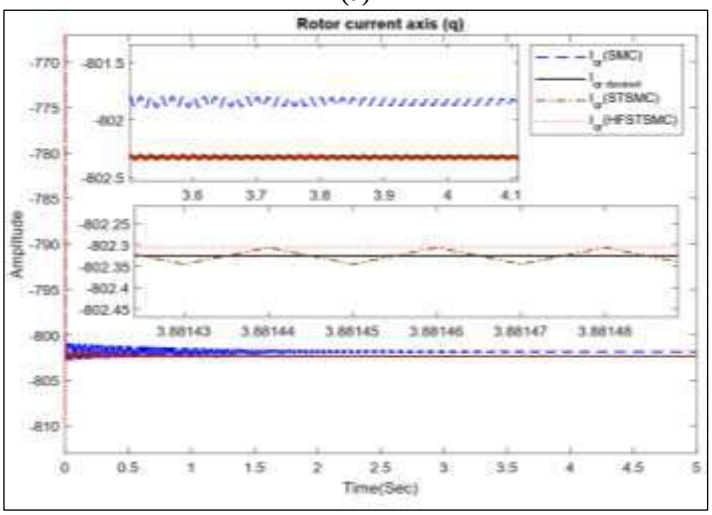
The modified control law becomes:

$$u = \sigma L_r\left(\dot{I}_{dqrDesired} + R_r I_{dqr}\right) - k_1\sqrt{|S|}Fuzzy(S) + \int\left(-k_2 Fuzzy(S)\right)dt \quad (19)$$



IV. RESULTS AND DISCUSSIONS

A Matlab simulation environment was used to assess the efficiency of the examined control techniques [17-19]. The main topics of the simulation were parameter fluctuation and reference tracking. The research made use of a Doubly Fed Induction Generator (DFIG) running at a nominal system voltage of Vs = 398/690V, with parameters shown in Table 1.



IV.1 TRACKING THE REFERENCE SIGNAL

The reaction of the Hybrid Fuzzy Super Twisting Sliding Mode Controller (HFSTSMC) to changing conditions in the environment was tested using a realistic wind speed profile. In order to maintain a unit power factor, the reference for reactive power (Qsref = 0) was set to zero and the reference for active power (Psref) was added using the MPPT technique. The performance of the Hybrid Fuzzy Super-Twisting Sliding Mode Control (HFSTSMC) was compared against the conventional Sliding Mode Control (SMC) and the Super-Twisting Sliding Mode Control (STSMC) to evaluate its effectiveness in controlling a DFIG-based wind turbine. Figure 6 clearly demonstrates that the HFSTSMC exhibited significantly less error compared to both SMC and STSMC. This indicates that the hybrid approach, incorporating fuzzy logic, effectively enhances the accuracy of the control system by dynamically adjusting the control gains in response to varying system states. The reduced error translates to more precise tracking of the desired rotor current, which is crucial for maintaining optimal performance in fluctuating wind conditions.

Figure 7 highlights a critical advantage of the HFSTSMC over the STSMC. The HFSTSMC successfully mitigated the chattering effect, which is a common issue with conventional sliding mode controllers. Chattering can lead to excessive mechanical wear and reduced efficiency. By integrating fuzzy logic to smooth the control actions, the HFSTSMC provides a more stable and efficient operation, minimizing the adverse effects of chattering observed in STSMC. The speed response of the control systems, depicted in Figure 8, showcases the superior performance of the HFSTSMC. The HFSTSMC achieved an extremely fast response with a settling time of $0.05\ ms$, which is ten times faster than the other control strategies. This rapid response is essential for the DFIG-based wind turbine to quickly adapt to changes in wind speed and maintain optimal power output. The significant reduction in settling time underscores the effectiveness of the fuzzy logic-enhanced super-twisting algorithm in improving the dynamic response of the system.

IV.2 ROBUSTNESS

In this section, we evaluate the robustness of the proposed control strategies by altering the reference value of reactive power. This assessment aims to determine how well each control method can adapt to changes in reactive power demands. Additionally, a stepped wind profile is employed to simulate realistic and challenging wind conditions, further testing the resilience and stability of the control systems. This robustness analysis is crucial for ensuring the reliability of DFIG-based wind turbines under varying operational scenarios. Figures 9 and 10 illustrate that the Super-Twisting Sliding Mode Control loses precision when subjected to parameter variations. The control system's ability to accurately track the desired reactive power reference diminishes, highlighting its sensitivity to changes in system parameters.

In contrast, the Hybrid Fuzzy Super-Twisting Sliding Mode Control demonstrates superior robustness. Both figures show that the HFSTSMC maintains its precision and performance even when the system parameters are varied. This indicates that the fuzzy logic component effectively adapts to changes, ensuring consistent control accuracy. Another critical aspect of robustness is the response time of the control system. The HFSTSMC not only preserves its fast response time but also shows no signs of chattering despite the parameter variations and stepped wind profile. This is a significant improvement over the STSMC, which exhibits degraded performance and increased chattering under the same conditions.

V. CONCLUSIONS

This study presents a comprehensive analysis of advanced control strategies for Doubly Fed Induction Generator (DFIG)-based wind turbines, focusing on the development and implementation of a Hybrid Fuzzy Super-Twisting Sliding Mode Control (HFSTSMC) system. The primary goal was to enhance the robustness, accuracy, and efficiency of wind turbine operations under varying and challenging conditions. The HFSTSMC outperformed traditional Sliding Mode Control (SMC) and Super-Twisting Sliding Mode Control (STSMC) in several key aspects. The integration of fuzzy logic with super-twisting sliding mode control effectively reduced the chattering effect, improved control accuracy, and maintained rapid response times even under parameter variations and fluctuating wind conditions. Simulation results confirmed that the HFSTSMC provided superior performance in tracking the desired reactive power reference and exhibited remarkable resilience to changes in system parameters. These findings underscore the potential of HFSTSMC as a highly effective and reliable control strategy for DFIG-based wind turbines. By enhancing the precision and robustness of wind turbine control, this approach significantly contributes to the optimization of wind energy capture and the stability of renewable energy systems. The successful implementation of HFSTSMC highlights its importance in advancing the efficiency and reliability of sustainable energy solutions.

ABSTRACT

The high adoption of cloud computing has thoroughly increased the need to have good security controls in order to ensure the flexibility and uniformity of the services. One of the most disruptive categories of emerging cyber threats is the DDoS attacks that are capable of flooding system resources with very large volumes of traffic and advanced obfuscation methods. Traditional machine learning algorithms like K-Nearest Neighbors, Support Vector Machines, Decision Trees, and Logistic Regression will not perform well when exposed to high-dimensional, noisy, as well as imbalanced network data. To overcome these deficiencies, a novel ensemble deep learning structure along with a superior Quadratic Discriminant Analysis (QDA) is introduced in this paper to apply in the decision-level fusion. Deep neural networks are used to extract the hierarchical and discriminative aspects of traffic, and the classification under the overlapping feature distribution is optimized with QDA. Moreover, an adaptive ensemble stacking algorithm combines the results of several base learners, which optimizes predictions that are based on confidence-based weighting. The results indicate that traditional models achieved accuracies between 92% and 97%, while deep neural networks improved to 99.18% accuracy with 0.87% FPR. In contrast, the proposed Adaptive Stacking + QDA framework performed very well when compared with all baselines, reaching 99.43% accuracy, 99.36% precision, 99.25% recall, 99.30% F1-score, and the lowest false positive rate of 0.62%. These findings confirm that the proposed framework has the robustness and reliability for real-time cloud security. Experimental assessments of benchmark cloud-based DDoS datasets show that there are some effective enhancements in detection accuracy, precision, and false-positive reduction, which thoroughly highlight the framework's efficiency in real-time cloud security applications.

I. INTRODUCTION

Cloud computing marks a major shift toward delivering computing services in a centralized manner, where numerous services are hosted remotely on shared infrastructure. This model involves relocating data and applications from local systems to the "cloud," offering highly scalable, flexible, and cost-efficient resources under a "pay-as-you-go" model. It has gained widespread adoption across industries due to its ability to minimize infrastructure costs, reduce deployment time, and offer on-demand services. The core service models—Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS)—enable users to leverage cloud functionalities without direct hardware management.However, with the rise in cloud adoption, there has been a concurrent increase in sophisticated cyberattacks targeting cloud-based infrastructure. Among these, Sharma, [1] Distributed Denial-of-Service (DDoS) attacks are particularly damaging, affecting the Internet of Things (IoT), Vishwakarma, [2] smart cities, healthcare systems, and enterprise platforms.

DDoS attacks exploit the very nature of shared and scalable cloud services by flooding target servers or applications with massive traffic, this leads to exhaustion of computational resources, which makes services inaccessible for genuine users. DDoS attacks are classified into two main categories: (i) Reflection-based attacks, where attackers send large volumes of request traffic using spoofed IP addresses through intermediary servers, which unknowingly redirect the traffic to the victim; and (ii) Direct flood attacks, where massive traffic is sent directly from compromised devices under the attacker's control Sallam, [3]. Common techniques include TCP SYN flooding and spoofing, which result in the victim server exhausting its capacity to respond to legitimate requests. As the scale and frequency of DDoS attacks increase, so does their complexity. Modern DDoS threats are dynamic and capable of adapting to countermeasures, making real-time detection and mitigation increasingly difficult. Based on these issues, machine learning (ML) approaches have been considered to detect DDoS at very high-speed cloud traffic with a minimum of false positives Tahsien, [4]. K-Nearest Neighbors, Support Vector machines, Decision Trees, and Logistic Regression algorithms have proved to be very useful in studying traffic trends. Nonetheless, high-dimensional data, imbalanced classes, and dynamic attack patterns that are common in cloud settings, which tend to be a challenge to these models, deep learning (DL) methods have become more resilient to these challenges.

Deep learning involves the use of several nonlinear layers to automatically extract hierarchical features in some of the very important input data, like traffic logs, system signals, or metadata. Architectures such as Convolutional Neural Networks (CNNs) have been shown to be very useful in more complex pattern recognition problems, such as image classification and anomaly detection. The proposed work presents a new and refined DDoS detection model that thoroughly integrates ensembled deep learning with Quadratic Discriminant Analysis (QDA) to perform a strong classification. Deep networks are used to extract highly complex features, but QDA increases class separability, particularly with overlapping traffic patterns. Moreover, an adaptive ensemble stacking mechanism is introduced in this study, in which multiple base learners are dynamically added to the final decision, according to real-time performance measures. Such a combination guarantees down-weighting of poorly-performing classifiers, and dominance of strong learners in the final output, which thoroughly enhances overall accuracy and responsiveness to novel threats. Since cloud-based services are dynamic and at large scale, the combination of deep learning, QDA, and adaptive ensemble methods is a promising way to achieve scalable as well as intelligent DDoS detection systems.

I.1 CLOUD CHARACTERISTICS

Infrastructure as a Service (IaaS) allows users to fully access and control virtualized computing resources via the internet. IaaS allows the user to dynamically provision resources and to configure software environments without investing in physical infrastructure as well. This pay-as-you-use model allows organizations to scale services in an effective manner, which pays only based on the virtual machine space or time used. Notably, Platform as a Service (PaaS) is enhanced by providing a complete software development environment, such as operating systems, development tools, and database management systems as well. Although cloud services are very beneficial, users develop and deploy applications through secure channels such as VPNs and private networks. Cloud services expose users to certain vulnerabilities. An example of direct DDoS attacks is when compromised devices transmit traffic directly to a target server and flood the server with packets. The traffic can be of numerous different sources with virus carriers, but the point of attack is centralized disruption, commonly through flaws in protocols like the TCP SYN flood. In such an approach, the attacker will use TCP handshake to ping the server with a lot of SYN packets, which thoroughly triggers the server to wait until the connection is acknowledged, which never happens, and thereby fills its connection queue. Spoofing techniques are also employed to redirect responses, leading to further confusion and traffic buildup.

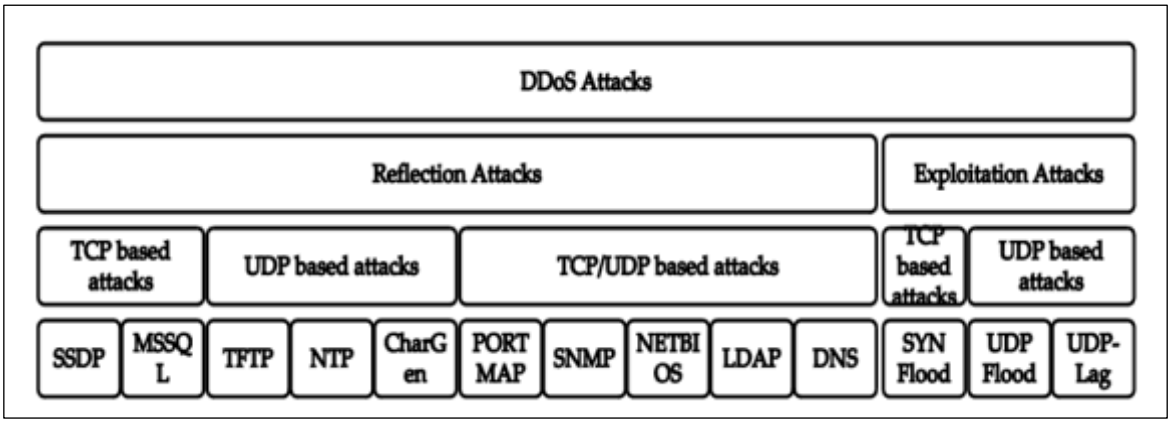

Figure 1: Taxonomy of DDoS Attack.
Source: [5].

As cloud applications continue to scale, the importance of intelligent detection systems becomes paramount. Traditional rule-based security mechanisms fall short in distinguishing between legitimate spikes in traffic and malicious floods. Deep learning, through its layered architecture of input, hidden, and output layers, has proven effective for automated feature extraction and classification from large-scale data, including network traffic. CNNs and other deep models can process packet-level details and derive abstract representations for anomaly detection. In the proposed system, we integrate de nep learning with QDA as a fusion classifier, combining the strength of deep models in feature learning with QDA's capability to model class variance. Moreover, an adaptive ensemble stacking framework is incorporated, allowing the system to adaptively weigh and combine predictions from multiple models based on their real-time performance. This thoroughly helps to improve the system's resilience against evolving DDoS strategies and reduces false alarms, which makes it very effective for cloud-based DDoS detection.

II. RELATED WORKS

Within the past ten years, the usage of deep learning (DL) methods within networking and cybersecurity has experienced significant velocity. DDoS attacks are a very significant issue in this space, mainly because of the challenge of distinguishing between bad traffic and normal traffic in a dynamic cloud traffic environment. Deep learning-based classifiers have demonstrated the capability to automatically discover the appropriate features in raw network traffic, as well as differentiate between benign and malicious traffic. A number of studies have used classical machine learning (ML) algorithms like Naive Bayes and Random Forest to identify and characterize DDoS traffic patterns [6]. Although these techniques are very effective with structured data, they are ineffective in data dimensionality and non-linear relationships settings. DDoS detection is also a common area of research by Artificial Neural Networks (ANNs). As an example, a model created by [7] was able to identify various categories of DDoS attacks, but with lower accuracy, especially when it was applied to the classification of UDP-based floods because it did not allow capturing complicated time-related traits of the data. [8] suggested a traffic analysis method based on the features of Time to Live (TTL), protocols, source ports, and IP addresses.

Their model, trained on an outdated dataset, provided initial insights into static feature-based detection but lacked adaptability to newer attack vectors. In further work, [8] also introduced an edge-centric detection model involving Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) architectures. These models achieved high accuracy—98.9% for LSTM and 99.9% for CNN—by learning temporal and spatial features in traffic, and were optimized for deployment on resource-constrained edge devices to reduce operational latency. Entropy-based detectors integrated with Software Defined Networking (SDN) have also been explored to identify anomalies in IoT-driven cloud ecosystems. The system proposed by Galeano-Brajones [8] achieved a detection confidence ranging from 68% to 99.7% based on network state monitoring. This reflects the growing trend of combining intelligent classifiers with programmable networks for adaptive DDoS mitigation. Despite the progress, most existing approaches rely on single-model classifiers or traditional stacking techniques that do not adjust dynamically to varying data distributions.

As attacks evolve, fixed models are prone to concept drift, leading to degraded detection performance. [9] noted that the increasing scale and complexity of modern DDoS attacks outpace static detection frameworks, particularly in IoT and smart environments where devices have limited processing power. The large-scale DDoS attack in 2016, which disrupted major ISPs and impacted services like Netflix, CNN, and Twitter, is a strong reminder of the financial and reputational risks posed by these threats [10]. Several works have achieved strong results using deep learning. In a comparative analysis, [11] demonstrated that SVM outperformed traditional models in accuracy. Similarly, [12] evaluated five different classifiers in IoT-based networks and achieved near-perfect accuracy (>99.9%). However, the study acknowledged that models trained on offline datasets still struggled with unseen traffic features in real-time deployment. [13] developed an AI-based DDoS detection model that employed feature extraction and machine learning to detect malicious traffic. It was providing a high degree of accuracy although it was based on offline training and fixed features.

This restricts its flexibility to changing attacks resulting in the possible inefficiency and increased false positives in changing networks. [14] employed an ANN-based model that was trained on a limited feature set (about five features), resulting in inconsistent classification across different DDoS variants. Neural Network (NN) and Naive Bayes (NB) methods to DDoS classification proposed by Yudhana, I. [15] were used to analyze network forensics, and their performance was superior to other classification methods. The method is however constrained by high computation cost and low flexibility to changing patterns of attack in real-time networks. A comprehensive survey by [16] revealed that while multiple ML techniques could detect DDoS attacks with good accuracy, no single model consistently outperformed the others across all datasets. Additionally, their study lacked detail on the specific TCP/IP and ICMP-level features used for training. Thapngam [17] also found over 98% accuracy in their ML models but noted the limitation of relying on outdated and overly feature-rich datasets. Similarly, [5] demonstrated in an SDN environment that classifier accuracy often drops significantly when tested on live traffic compared to offline datasets.

[18] introduced the use of machine learning to detect DDoS attacks in cloud computing configuration whereby a greater accuracy of detection was attained, however; it experienced difficulties in the ability to deal with changing attack patterns dynamically.The research by Mouli, [19] on the systematic literature review of web services attacks and security discusses typical vulnerabilities and vectors of attacks, but this study has not been effective in the practical implementation and assessment of the defense mechanisms. The security of web service frameworks against Denial-of-Service attacks were evaluated by Oliveira, [20], which is a vast evaluation of the weaknesses of frameworks; the study did not however offer automated detection propositions. [21] studied the effect of the announcement of DDoS attacks on stock values of the victims, which provided information about the economic effects, but did not consider technical methods of detection and prevention. Subbulakshmi, [22] was able to come up with Enhanced Support Vector Machines (SVM) and a real-time generated data to be used in detecting DDoS attacks, which had a better classification but consumed many computational resources and could not handle large-scale traffic.

[23] discussed the problems and issues in countering DDoS attacks and found that there were major gaps in the current security practices, but it had no specific implementation plans. Samtani, [24] investigated how Artificial Intelligence (AI) could be used in cybersecurity, which formed a basis to be able to detect attacks intelligently, but the methods proved to be theoretical and could not adapt to the real-time environment. Zarpelão, [25] surveyed intrusion detection in Internet of things (IoT) noting various methods of detection, but could not be scaled and limited resources. [26] suggested an intrusion detection technology based on immunity of IoT, which provided the adaptive detection performance but had the drawback of high complexity and implementation in non-homogeneous devices. In 6LoWPAN-based IoT networks, Denial-of-Service detection was proposed by [27]. Kasinathan, P et al., and was able to detect efficiently in a constrained setting, however, it could not cope with changing attack patterns and network dynamics. Given these limitations, the proposed work extends existing research by introducing an adaptive ensemble-based approach that not only employs deep learning for rich feature extraction but also integrates Quadratic Discriminant Analysis (QDA) to improve classification boundaries for overlapping traffic patterns.

The novelty is in the application of adaptive ensemble stacking, which dynamically assesses and weights base models upon real-time detection confidence as well as accuracy. This provides a great enhancement over previous fixed-model techniques and also provides very high resilience in changing cloud-based DDoS threat environments.

III. METHODOLOGY

In this section, the different machine learning and deep learning models have been discussed, which are employed in the proposed model for identifying Distributed Denial-of-Service (DDoS) attacks within a cloud setup. It starts by describing the individual traditional classifiers as base learners. Next, the suggested hybrid model combining a Deep Neural Network (DNN) and Quadratic Discriminant Analysis (QDA) with the adaptive stacking mechanism was presented. This hybrid architecture thoroughly ensures the successful learning of complex and overlapping traffic patterns and adaptively responds to changing attack behavior as well.

III.1 TRADITIONAL CLASSIFIERS

In order to cover a wide range of traffic patterns and provide model diversity, we include multiple classical machine learning classifiers in the bottom layer of the ensemble. These models offer different decision boundaries and generalization facilities, which are very essential when dealing with dynamic and imbalanced network traffic information. The Naive Bayes classifier is a probabilistic learning algorithm that uses the Bayes theorem, subject to the assumption that the features are individually conditionally independent. It approximates the posterior probability of classes using previous probabilities and probability based on the training data. Naive Bayes is computationally inexpensive and has a good performance in those cases where the distribution of the features fits its assumption of independence. But its power to isolate subtle traffic variations is not so much, particularly in situations where correlated network traits are at stake. A Decision Tree classifier is a supervised learning algorithm that recursively splits the data set depending on the values of features to create a tree-like model.

Internal nodes indicate decisions that are made on feature attributes, and the leaf nodes are the class label. Decision Trees are also very useful in finding interpretable rules based on traffic data. Nevertheless, they tend to overfit, particularly when trained on noisy or highly skewed datasets, which is very common in the real-world cloud setup. The K-Nearest Neighbors (KNN) algorithm is a non-parametric classifier that thoroughly helps to classify a given input in the feature space by the majority of the closest K neighbors. KNN is effective in capturing local data variations and works well in distinguishing between different stages of DDoS attacks, such as flooding and probing. Nevertheless, its performance degrades significantly in high-dimensional settings, and it is computationally inefficient for real-time classification tasks. The Support Vector Machine (SVM) is a powerful binary classification technique that constructs an optimal hyperplane to separate classes with the maximum margin.

It utilizes kernel functions to transform non-linearly separable data into higher dimensions where linear separation becomes possible. SVM is very accurate on balanced data sets with well-defined boundaries, but has been found to be difficult to scale and adapt to changing or noisy attacks. Random Forest classifier is an ensemble algorithm that consists of many decision trees, where each decision tree is trained on a bootstrap sample, and features are selected randomly. Majority voting on all trees makes predictions. This model is better at generalization and overfitting and works very well on high-dimensional network traffic. Random Forests are able to identify a wide variety of attack patterns, though they can lose interpretability with more trees. The Stochastic Gradient Descent (SGD) classifier is a linear model whose optimization is based on gradient descent. It is specifically adapted to large-scale problems and to online education as well.

SGD modifies model weights on a per-training instance or mini-batch basis, and therefore can be used to learn streaming data effectively. But it is also sensitive to feature scaling, and it needs to be hyperparameter-tuned for convergence and stability. The Deep Neural Network (DNN) is the deep learning part of our base learners. It comprises multiple hidden layers with non-linear activation functions, enabling hierarchical feature extraction from raw input data. The DNN model learns complex, non-obvious relationships in network traffic, allowing it to generalize across a wide variety of known and unknown DDoS attack types. Backpropagation and optimization techniques such as Adam or RMSProp are used to train the model effectively. However, without proper regularization, DNNs may overfit the training data, particularly in scenarios with class imbalance.

III.2 ADAPTIVE DEEP ENSEMBLE FRAMEWORK (DNN–QDA INTEGRATION) FOR CLOUD DDOS DETECTION

A novel hybrid framework is introduced in this study that integrates Deep Neural Networks (DNN) with Quadratic Discriminant Analysis (QDA) in an adaptive ensemble stacking mechanism. The DNN extracts very complex hierarchical traffic characteristics, whereas QDA guarantees the fine-grained decision fusion by extracting the class-specific variances. The adaptive stacking layer is dynamic with regard to changing model weights based on unlabeled traffic and thus completely self-learns and resists the changing format of attacks as well. Combining deep learning with adaptive statistical decision fusion, the proposed system demonstrates very high accuracy, real-time scalability, and false alarms when detecting cloud-based DDoS.

Algorithm 1: Adaptive Deep Ensemble Framework (DNN–QDA Integration) for Cloud DDoS Detection.

Input:

- Training dataset $D = (x1, y1), (x2, y2), \ldots, (xn, yn)$
- Base learners $B1, B2, \ldots, Bm$ (Naïve Bayes, SVM, RF, etc.)
- Deep Neural Network (DNN)
- Unlabeled traffic data U
- Small labeled dataset L

Output:

- Final predicted class label $\hat{y}$
- Updated labeled dataset L

Steps:

1. **Initialization:**

Partition dataset: $L\leftarrow$ small labeled subset, $U\leftarrow$ unlabeled data.
Pre-train DNN on L to extract hierarchical traffic features.

2. **Base Learner Training:**

Train each base learner B_i on feature space from DNN + raw features.

3. **Prediction on Unlabeled Data:**

For each instance $x \in U$:
a. Obtain predictions $p_i(x)$and confidence scores $c_i(x)$ from each B_i.
b. Normalize scores to compute adaptive weights $w_i(x$.

4. **Adaptive Ensemble Aggregation:**

Compute weighted prediction:

$$y_{agg}(x) = \sum_i w_i(x) \cdot p_i(x)$$

5. **Meta-Classification with QDA:**

Apply Quadratic Discriminant Analysis (QDA) on $y_{agg}(x))$ to estimate posterior probabilities.
Assign final label:

$$\hat{y} = argmax_k [\, P(y = k|x)]$$

6. **Self-Training Update:**

If $\hat{y}(x)$is predicted with high confidence, move xxx from U to L with label $\hat{y}(x)$
Retrain base learners and update DNN feature space using expanded L.

7. **Iteration:**

Repeat Steps 3–6 until stopping criteria (no more confident predictions or convergence).

Return: Final prediction $\hat{y}$ and updated labeled dataset L.

Source: Authors, (2026).

This algorithm unifies deep feature extraction (DNN), statistical decision fusion (QDA), as well as adaptive ensemble stacking with self-training, which thoroughly enables robust as well as dynamic DDoS detection in cloud environments.

III.3 QUADRATIC DISCRIMINANT ANALYSIS (QDA)

Quadratic Discriminant Analysis (QDA) is a supervised learning algorithm used in our framework as a meta-classifier to perform decision-level fusion. Unlike Linear Discriminant Analysis (LDA), which assumes equal covariance among classes, QDA permits each class to have its own covariance structure. This flexibility makes it especially effective in handling non-linear and overlapping feature distributions—an essential property for classifying cloud network traffic where benign and malicious behavior often intersect.QDA operates under the assumption that the data from each class follows a Gaussian distribution, characterized by its own mean vector and covariance matrix. It calculates the posterior probability of each class for a given input and assigns the label with the highest probability. In our architecture, QDA plays a critical role in combining the outputs from multiple base classifiers, leveraging its capacity to distinguish subtle variations in feature distributions caused by evolving attack patterns.

III.3.1 QDA Mathematical Formulation

The QDA classifier relies on three core equations:
Class-conditional likelihood (Gaussian distribution)

$$P(^{x}/_{y}=k)=\frac{1}{(2\pi)^{d/2}|\Sigma k|^{1/2}}exp\left(-\frac{1}{2}(x-\mu_k)^T\sum_{\mathrm{k}}^{-1}(x-\mu_k)\right) \quad (1)$$

Posterior probability (Bayes' theorem)

$$P(y=k/x)=\frac{P(x|y=k)*P(y=k)}{\sum_{=1}^{\mathrm{k}}P(x|y=j)*P(y=j)} \quad (2)$$

Decision rule (QDA classifier)

$$\hat{y}=\ argmax_k[\ P(y=k|x)] \quad (3)$$

Equations (1), (2), and (3) ensure that QDA captures the unique variance of each class, improving classification accuracy when working with overlapping or imbalanced cloud traffic features.

III.3.2 QDA Algorithm

The algorithm below outlines the QDA implementation used for decision fusion in our model.

Algorithm 2: Quadratic Discriminant Analysis (QDA) for Decision Fusion.

Input:
- *Training dataset* $D\ =\ \{(x1,y1),(x2,y2),\dots,(xn,yn)\}$
- *Prediction outputs from base classifiers*
- *New input instance* x

Output:
- *Final predicted class label* $\hat{y}$

Steps:

1. *For each class* k *in* $\{1,2,\dots,K\}$:
   a. *Compute class mean vector* μk *from training data*
   b. *Compute class covariance matrix* Σ_k
   c. *Estimate prior probability* $P(y=k)$
2. *For the new input instance* x:
   a. *For each class* k:
      i. *Compute class − conditional likelihood*:
      $P(x|y=k)=\ Gaussian_PDF(x;\ \mu_k,\Sigma_k)$
      ii. *Compute posterior probability*:

$$P(y=k|x)=\frac{[P(x|y=k)*\ P(y=k)]}{\sum_{=1}^{\mathrm{k}}[P(x|y=j)*\ P(y=j)]}$$

3. *Assign final label*:

$$\hat{y}=\ argmax_k[\ P(y=k|x)]$$

4. *Return* $\hat{y}$ *as the fused decision.*

Source: Authors, (2026).

This algorithm ensures that QDA captures the unique variance of each class and yields high discrimination accuracy when combined with diverse base classifiers.

III.4 ADAPTIVE ENSEMBLE STACKING

To overcome the limitations of static ensemble methods and improve robustness, we introduce an adaptive ensemble stacking mechanism. In traditional stacking, base learners are trained independently, and a meta-learner is used to combine their outputs using fixed weights. However, this approach does not account for variations in model performance across different traffic scenarios. Our adaptive stacking framework addresses this issue by dynamically adjusting the contribution of each base classifier based on real-time confidence metrics such as accuracy, false positive rate, and output certainty. The adaptive ensemble stacking module continuously monitors the performance of base learners on recent data and assigns them confidence scores accordingly. These scores are normalized and used as dynamic weights for combining predictions. This strategy allows the ensemble to prioritize base models that are currently more reliable, thus improving overall decision accuracy, especially when facing previously unseen or evolving attack vectors. The final fusion is handled by the QDA meta-classifier, which takes these weighted predictions as input and learns to make the final classification based on the underlying data distribution. The interaction between adaptive weighting and QDA fusion ensures that the model remains flexible, accurate, and robust under changing network conditions. The algorithm below describes the adaptive stacking mechanism integrated into our DDoS detection framework.

Algorithm 3: Adaptive Ensemble Stacking for DDoS Detection.

Input:

- P: Predictions from base learners
- U: Unlabeled traffic data
- L: Small labeled dataset

Output:

- Final class prediction
- Updated labeled dataset L

Steps:

1. **Initialization:**
Set $L \leftarrow$ small labeled set
Set $U \leftarrow$ remaining unlabeled instances
2. **Base Learner Training:**
Train each base learner B_i on L.
3. **Prediction on Unlabeled Data:**
For each instance $x \in U$:
Obtain prediction $pi(x)$ and confidence score $ci(x)$ from each base learner B_i
4. **Adaptive Weight Computation:**
Normalize confidence scores $ci(x)$ to obtain adaptive weights $wi(x)$
5. **Ensemble Aggregation:**
Compute weighted prediction:

$$y_{agg}(x) = \sum_i w_i(x) \cdot p_i(x)$$

6. **Meta-Classification:**
Use QDA (Quadratic Discriminant Analysis) meta-classifier on $y_{agg}(x)$ to predict final class label $y(_x)$
7. **Self-Training Update:**
If $y(_x)$is predicted with high confidence:
Move x from U to L with assigned label $y(x)$
8. **Iteration:**
Update base learner confidence profiles.
Retrain base learners on expanded L.
Repeat steps **3–8** until stopping criteria are met (e.g., no more confident predictions or convergence).

Source: Authors, (2026).

By repeating these steps iteratively, the model continuously improves as more data is labeled and fed into the system. This adaptive process ensures real-time responsiveness to traffic distribution changes while maintaining high detection accuracy and minimizing false positives.

IV. IMPLEMENTATION RESULTS

To evaluate the effectiveness of the proposed adaptive ensemble framework for DDoS detection, we conducted extensive experimentation using a Software Defined Networking (SDN)-based dataset developed through the Mininet emulator. The dataset was specifically tailored to replicate realistic network conditions and enable robust machine learning and deep learning-based classification of traffic flows. A total of ten distinct network topologies were configured in the Mininet environment, each managed by a centralized Ryu controller interfacing with OpenFlow switches. Both benign and malicious traffic types were generated within these topologies. Legitimate traffic included UDP, ICMP, and TCP protocols, while malicious traffic comprised TCP SYN flood, ICMP flood, and UDP flood attacks. The inclusion of diverse attack types ensured the dataset's relevance for detecting complex DDoS behavior patterns. Each traffic instance in the dataset includes 23 carefully selected features. These features were either directly collected from the SDN controller or derived through computed metrics to provide a granular view of network activity. Core features such as packet_count, byte_count, switch_id, duration_sec, source_ip, destination_ip, tx_bytes, and rx_bytes were combined with higher-level indicators like byte_per_flow, packet_rate, flow_table_entries, tx_kbps, port_bandwidth, and others. These features capture both volumetric and behavioral aspects of the network flows. The dataset is labeled such that a class value of '0' represents benign traffic and '1' indicates malicious activity, establishing a binary classification problem. Over a 250-minute simulation period, the environment generated a comprehensive dataset comprising 104,345 traffic samples.

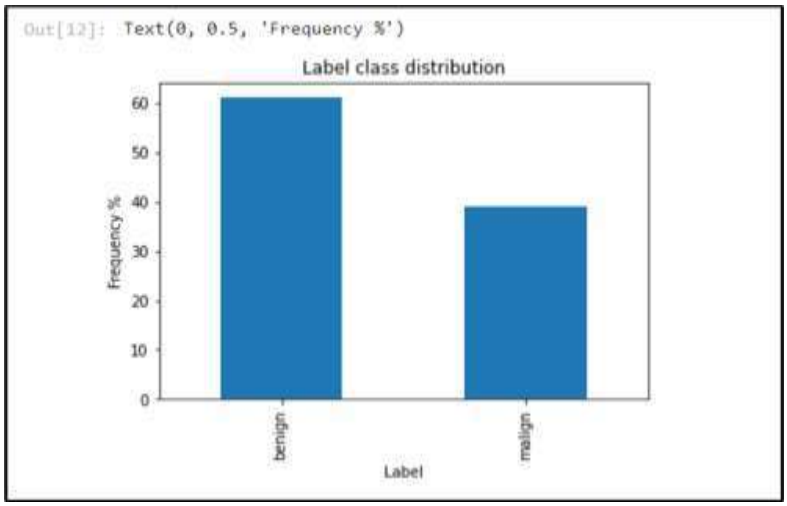

Figure 4: Class distribution of DDos Attacks.
Source: Authors, (2026).

Prior to training, the dataset underwent preprocessing that included data normalization, feature scaling, and timestamp alignment. Several base classifiers, including Random Forest, Support Vector Machine (SVM), Decision Tree, K-Nearest Neighbors (KNN), Stochastic Gradient Descent (SGD), and Deep Neural Network (DNN), were independently trained as a very first step to give initial predictions after preprocessing. These classifiers generated prediction scores and confidence values, which in turn were passed on to the adaptive ensemble stacking module. The adaptive stacking layer dynamically evaluated the reliability of every base learner using real-time confidence measurements (extracted accuracy, false positivity, and output confidence). Classifiers with very high and consistent performance were given more weight in the process of aggregation. This confidence-weighted system thoroughly enabled the ensemble to be sensitive to network behavioral changes and also provided resistance to distribution drift and novel attack patterns. At the last prediction stage, a Quadratic Discriminant Analysis (QDA) meta-classifier was used to fuse the prediction outputs of the adaptively weighted base learners. The use of QDA enabled the model to deal with overlapping feature distribution in a very effective manner through modeling each class with its own covariance structure. This had been especially useful in cloud traffic, where both malicious and benign flows can frequently exhibit similar properties. The nonlinear decision boundaries that QDA was able to build also increased the accuracy of the ensemble in the classification.

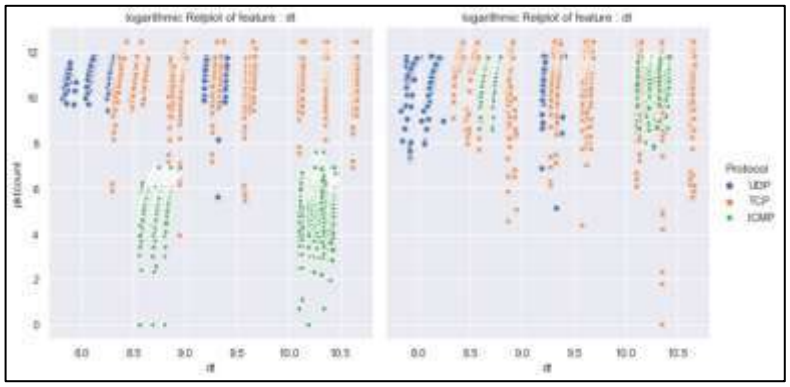

Figure 5: The distribution of continuous features with respect to packet count, protocol, and type of attack.
Source: Authors, (2026).

The Deep Neural Network (DNN) baseline was fine-tuned by hyperparameter optimization and architecture tuning. Activation functions, learning rates, batch sizes, and layer depths were iteratively tested to identify the optimal configuration. The DNN achieved a precision of 99.18%, making it the most performant standalone classifier in our experiments and establishing a strong lower bound for the ensembles expected performance.

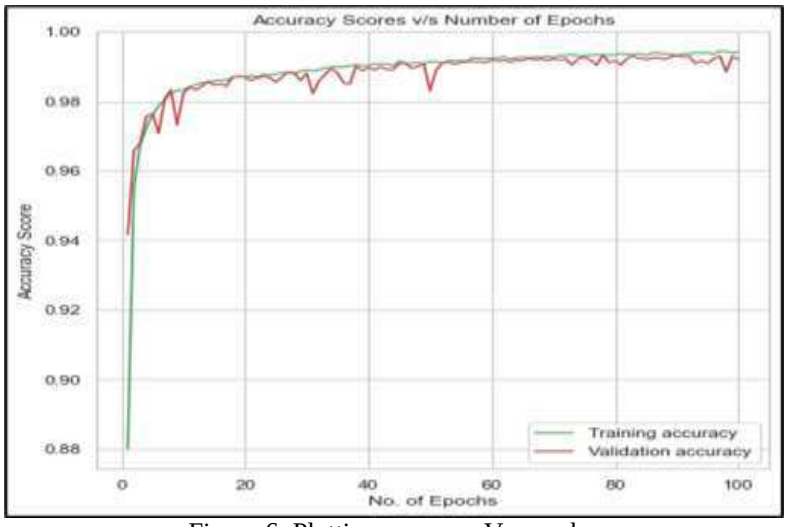

Figure 6: Plotting accuracy Vs epochs.
Source: Authors, (2026).

To clearly demonstrate the advantage of our adaptive ensemble stacking with QDA, we compare its performance against each individual base learner and traditional ensemble methods in Table I. The proposed framework consistently outperforms the baselines in all key metrics, especially in reducing the false positive rate and improving the F1-score, two of the most critical aspects in DDoS detection.

Table 1: Performance Comparison of Classifiers and Proposed Model.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	False Positive Rate (%)
Naïve Bayes	92.67	90.21	89.75	89.98	6.40
Decision Tree	94.38	93.10	91.85	92.47	4.88
K-Nearest Neighbors (KNN)	95.12	93.56	92.33	92.94	3.89
SVM	96.45	95.20	94.81	95.00	2.95
Random Forest	97.82	96.70	96.12	96.41	1.98
SGD Classifier	95.87	94.01	93.48	93.74	3.12
Deep Neural Network (DNN)	99.18	99.18	98.75	98.96	0.87
Proposed Model (Adaptive Stacking + QDA)	**99.43**	**99.36**	**99.25**	**99.30**	**0.62**

Source: Authors, (2026).

As shown in Table I, the proposed adaptive stacking model with QDA yields the highest overall accuracy and the lowest false positive rate among all models evaluated. While the standalone DNN achieved impressive performance, it still exhibited slightly higher false positives in borderline cases. The ensemble, by contrast, leverages the strengths of multiple learners while mitigating individual weaknesses through adaptive confidence weighting and discriminative fusion via QDA.

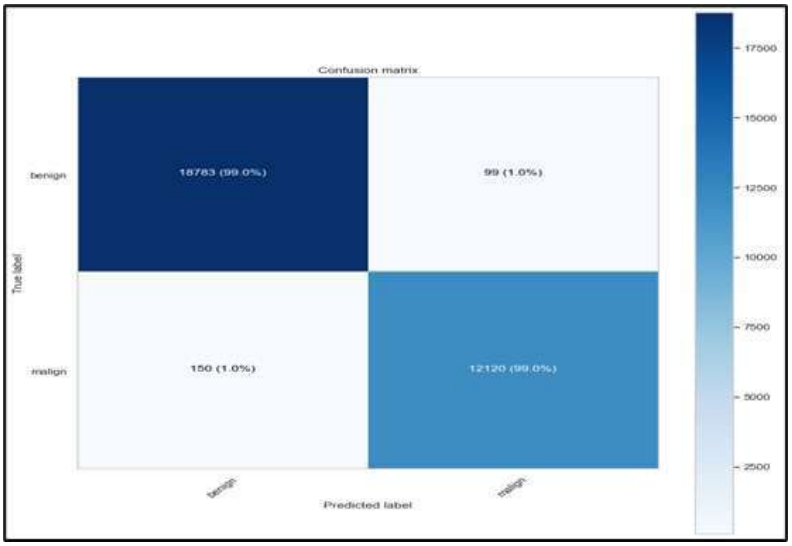

Figure 7: Visualize Accuracies of the Models.
Source: Authors, (2026).

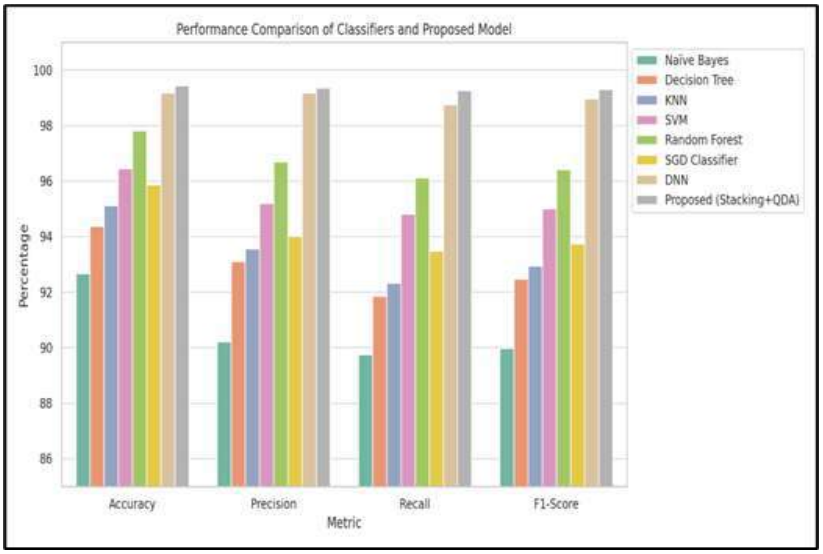

Figure 8: Confusion matrix.
Source: Authors, (2026).

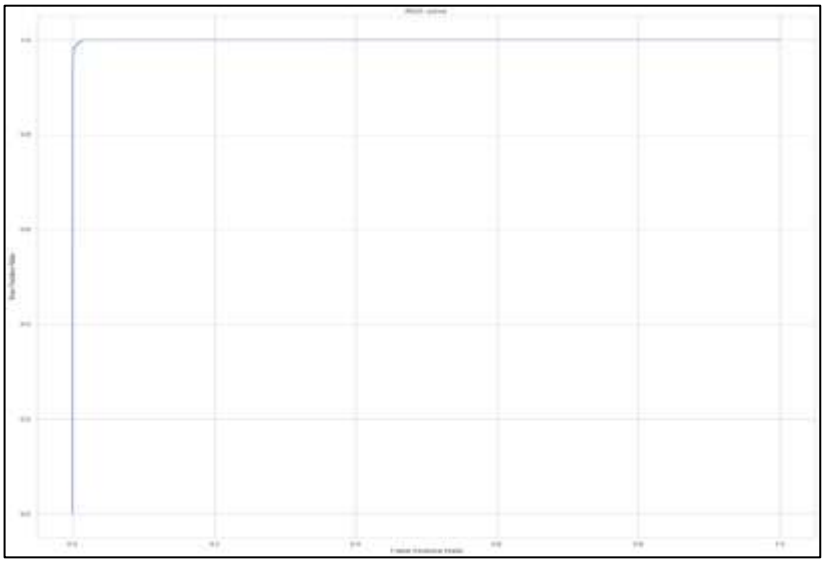

Figure 9: ROC-AUC curve of proposed model.
Source: Authors, (2026).

The confusion matrix confirmed the ensemble model's ability to minimize misclassifications of both benign and malicious traffic. Additionally, the ROC-AUC curve represented an almost perfect distinction of the two classes, which once again confirmed the applicability of the model in detecting real-time DDoS attacks in cloud-integrated SDN systems. The dimensionality of the feature space (high-dimensional), combined with the adaptability of the ensemble and the discriminative ability of QDA, thoroughly helped to explain the higher performance of the suggested model in all evaluation measures as well. In summary, the experimental findings confirmed the strength as well as efficacy of the suggested hybrid framework. The model was shown to be a very effective and reliable real-time detector with low false positive rates, thus making it a very viable solution to current cloud infrastructures where security and availability are a priority.

V. CONCLUSION

In this paper, a powerful deep learning-based architecture to identify the Distributed Denial-of-Service (DDoS) attacks in Software-Defined Networking (SDN)-enabled cloud infrastructure was presented. The Mininet emulator, along with Ryu controller, was used to create a realistic dataset including benign and malicious traffic over a variety of topologies. The criterion set was 23 important features and more than 104,000 cases, which were relevant and diverse to train. The initial evaluation was done with the baseline machine learning models: Naive Bayes, decision tree, KNN, SVM, random forest, and SGD. The highest standalone accuracy of a Deep Neural Network (DNN) was 99.18%. To further enhance the performance, it was suggested to use an adaptive ensemble stacking strategy. This dynamically varied the influence of each base classifier according to its performance and prediction confidence, responding to the overlapping features and to changing attacks. QDA was used in the decision layer as a meta-classifier, which gives nonlinear boundaries and better separation of classes. This enhanced the capability of the framework to differentiate between malicious and benign traffic across high-dimensional spaces. The last ensemble using QDA had an accuracy of 99.43 and a low false positive rate of 0.62, and was better than all single models. To conclude, deep learning with adaptive stacking and discriminant-based fusion is quite effective in detecting DDoS in SDN-enabled cloud environments on a large scale and with high accuracy.

ABSTRACT

This paper addresses the limitations of traditional Maximum Power Point Tracking (MPPT) algorithms in photovoltaic (PV) systems under fluctuating irradiance. Fixed step-size methods such as Perturb and Observe (P&O) often suffer from tracking drift and instability due to their inability to distinguish between actual power changes and environmental disturbances. To overcome these challenges, a Hybrid Fuzzy-Gradient Perturb and Observe (HFG-P&O) algorithm is proposed. The method integrates Fuzzy Logic to provide rapid response to large power deviations and Adaptive Gradient Descent (AGD) to fine-tune the step size during steady-state conditions. A dual-mode control mechanism dynamically selects between the two modes based on the magnitude of power variation. The proposed HFG-P&O was validated through MATLAB/Simulink simulations using real PV panel data under dynamic irradiance scenarios. Results show 98.5% tracking efficiency, a 63% reduction in power oscillations, and 47% faster convergence compared to conventional and enhanced P&O methods. These improvements are achieved without sacrificing system stability. The algorithm offers intelligent step-size adaptation, enhanced robustness to changing environmental conditions, and effective drift elimination, making it a promising solution for real-world PV applications.

I. INTRODUCTION

Photovoltaic (PV) systems have become central to clean energy production due to their ability to convert solar energy into electricity, addressing environmental concerns and supporting sustainable development [1],[2]. However, their efficiency is greatly influenced by environmental variables such as irradiance and temperature, which cause significant fluctuations in output power [3]. To cope with this variability, Maximum Power Point Tracking (MPPT) techniques are employed to continuously adjust operating points for optimal power extraction [4]. Among these, the Perturb and Observe (P&O) method remains widely adopted thanks to its simplicity and low implementation cost [5],[6]. Despite its popularity, P&O shows limitations under rapidly changing irradiance conditions. Various studies have proposed improvements to enhance its tracking performance, including adaptive variants designed for partial shading scenarios, which showed better efficiency and faster response [7]. Early implementations using boost converters validated its practicality in PV systems [8]. Recent reviews highlight two major concerns with classical P&O: fixed step sizes and susceptibility to power drift in dynamic environments [9]. Several works examined variable step-size approaches, confirming that step-size tuning is crucial for balancing convergence speed and accuracy [10]. Hybrid methods incorporating voltage and current sensing were also introduced to distinguish environmental changes from algorithmic effects, aiming to suppress drift [11]. Still, most existing techniques rely on fixed or semi-fixed steps, creating a trade-off: larger steps improve speed but induce oscillations, while smaller steps enhance precision at the cost of slower response [12].

This has motivated the development of adaptive MPPT algorithms capable of dynamically adjusting step size to achieve robust and efficient tracking under varying conditions. Intelligent control strategies have become increasingly relevant in enhancing MPPT performance under dynamic environmental conditions. AI-based techniques and fuzzy logic have shown great promise in improving tracking accuracy and reducing power oscillations [13]. Adaptive fuzzy-P&O algorithms, for instance, have demonstrated fast response and minimal oscillations under variable irradiance [14], while fuzzy logic controllers improved tracking stability in PV applications [15]. Hybrid fuzzy methods, including their integration with classical MPPT algorithms like P&O and INC, have been reported to enhance overall system performance [16],[17]. Advanced intelligent controllers such as ANFIS and ANN have also proven effective in maintaining accurate MPPT under partial shading and unstable conditions [18],[19]. Hybrid techniques combining ANN with conventional methods showed notable capability in extracting global MPPs [20], and further enhancements were observed when ANN was combined with metaheuristics like the Grey Wolf Optimizer (GWO) [21]. Reviews on optimization techniques highlighted the importance of variable step-size methods for improved tracking efficiency and stability [22].

Hybrid AI-based MPPT methods have also proven effective in addressing drift and enhancing overall adaptability [23]. Other contributions include a two-stage adaptive controller integrating reference-model adaptation with gradient descent for accurate tracking in both standalone and grid-tied PV systems [24], and a Lyapunov-based controller achieving 99.07% efficiency under rapid variations [25]. A triple-hybrid controller combining P&O, PSO, and fuzzy logic achieved 99.5% efficiency [26], while GWO alone proved robust under partial shading [27]. Additionally, fuzzy logic integrated with Deep Deterministic Policy Gradient (DDPG) has shown resilience against fluctuating conditions [28]. Although many advances have been made in MPPT algorithm design, both conventional and modified Perturb and Observe (P&O) methods continue to face notable limitations. A key challenge is the phenomenon of tracking drift, especially under rapidly changing irradiance, which causes the system to lose alignment with the actual maximum power point (MPP). Moreover, the use of fixed step sizes introduces a fundamental trade-off: large steps accelerate convergence but increase oscillations, while small steps improve precision but slow down the dynamic response.

These drawbacks highlight the need for a more adaptive MPPT strategy that can intelligently balance tracking speed and stability across varying conditions. To address these challenges, this paper introduces a Hybrid Fuzzy-Gradient Perturb and Observe (HFG-P&O) algorithm, combining fuzzy logic with Adaptive Gradient Descent (AGD) to achieve dynamic step-size adjustment. The fuzzy logic component is designed to react rapidly to significant power deviations, enhancing responsiveness and suppressing drift. In contrast, AGD operates during steady-state or low-variation periods to refine the step size, minimizing oscillations and improving long-term accuracy. This coordinated, dual-mode mechanism allows the controller to respond flexibly to a wide range of environmental scenarios while maintaining efficient power tracking. The proposed HFG-P&O algorithm was validated through detailed simulations in MATLAB/Simulink. The results demonstrate its ability to maintain a balanced performance across different metrics, achieving fast convergence, low steady-state error, and strong robustness under variable irradiance. As shown in Table 1, the algorithm outperforms several recent MPPT techniques in terms of adaptability and dynamic efficiency, confirming its suitability for real-time PV system applications.

Table 1: Comparative Analysis of MPPT Algorithms Based on Key Performance Metrics and Adaptability to Irradiance Variations.

MPPT Algorithm	**[29]**	**[30]**	**[31]**	**[32]**	**Proposed HFG-P&O**
Tracking	Fast	Fast	Very Fast	Moderate	Very High
Stability	Moderate	High	High	Improved	Optimal
Oscillations	Moderate	Reduced	Low	Moderate	Minimal
Step Size	Adaptive	Adaptive	Adaptive	Fixe	Dynamic
Intelligence Level	Low	Moderate	Moderate-High	Low	High

Source: Authors, (2026).

This research focuses on improving Maximum Power Point Tracking (MPPT) in photovoltaic (PV) systems, especially under dynamic irradiance. Traditional and modified Perturb and Observe (P&O) algorithms often suffer from drift and limited adaptability due to fixed or semi-fixed step sizes, affecting performance during rapid environmental changes. To address these issues, a Hybrid Fuzzy-Gradient P&O (HFG-P&O) method is proposed. It combines fuzzy logic, for quick response to sudden power changes, with Adaptive Gradient Descent (AGD) for fine step-size adjustment during stable periods. This combination aims to enhance both tracking speed and stability.

The study follows three main steps:

- To analyze the weaknesses of conventional and modified P&O algorithms (drift-free P&O). Although these improved versions reduce drift or introduce partial adaptability, they still rely on limited or semi-fixed step-size adjustment, resulting in inefficiency under highly fluctuating conditions.
- To design a Hybrid Fuzzy-Gradient Perturb and Observe (HFG-P&O) algorithm that integrates fuzzy logic for rapid adaptation during sudden power variations and Adaptive Gradient Descent (AGD) for fine-tuning the step size in steady-state conditions.
- To validate the proposed HFG-P&O algorithm using MATLAB/Simulink simulations with PV parameters and irradiance scenarios, and to compare its performance with conventional and modified P&O algorithms.
  Results show improved adaptability, reduced drift, and better performance across varying irradiance profiles.

II. METHOD

II.1 ELECTRICAL MODELING OF THE PV SYSTEM

Photovoltaic (PV) cells are the core units that convert sunlight into electricity. To optimize MPPT performance, precise electrical modeling is crucial. The widely used single-diode equivalent model Figures 1 offers a reliable representation of PV cell behavior under different environmental conditions [33].

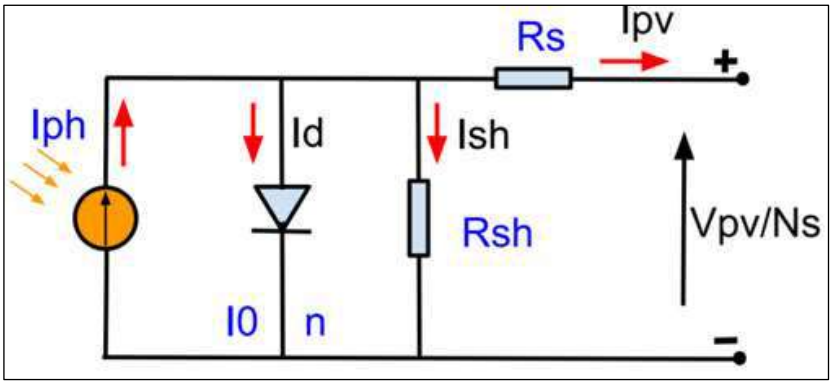

Figure 1: Single-diode equivalent circuit model commonly used to represent the electrical behaviour of a photovoltaic (PV) cell. Source: Authors, (2026).

The mathematical representation of the components in Figures 1 captures the detailed electrical behavior of a PV cell. Each element contributes uniquely to the overall current-voltage (I–V) relationship:

$$I_{ph} = \left[I_{sc} + K_1(T_c - T_{ref})\right]\frac{G}{G_{ref}} \quad (1)$$

$$I_{ph} = \left[I_{sc} + K_1(T_c - T_{ref})\right]\frac{G}{G_{ref}} \quad (2)$$

$$I_{sh} = \frac{(V+R_s.I)}{R_{sh}} \quad (3)$$

Combining these equations, the total current-voltage relationship of the PV cell is given by:

$$I = \left[I_{sc} + K_t(T_c - T_{ref})\right].\frac{G}{G_{ref}} - .\left[\exp\left(\frac{q.(V+R_S.I)}{N.K.T}\right)\right] - \frac{(V+R_S.I)}{R_{sh}} \quad (4)$$

where:

I_{ph}**:** Photocurrent generated by solar radiation.

I_d**:** Diode current representing the p-n junction of the PV cell.

R_s **:** Series resistance accounting for internal losses.

R_{sh} **:** Parallel resistance modeling leakage currents.

II.2 ANALYSIS OF THE DRIFT PROBLEM AND MODIFIED ALGORITHM

The Perturb and Observe (P&O) algorithm adjusts the operating voltage or current of a PV system and monitors the resulting power change. If power increases, the adjustment continues in the same direction; otherwise, it reverses. While this logic makes P&O a popular MPPT method due to its simplicity [34],[35], it faces a major limitation: drift. Drift occurs under rapidly changing irradiance, where the algorithm misinterprets environmental power changes as responses to its own perturbations, leading to incorrect tracking decisions and deviation from the true Maximum Power Point (MPP), resulting in energy loss [36]. This effect is illustrated in Figures 2, adapted from [37],[38], where a sudden irradiance increase causes the operating point to shift away from the actual MPP (Vmpp2) toward an erroneous point (4), highlighting the algorithm's inability to differentiate between internal control actions and external irradiance effects.

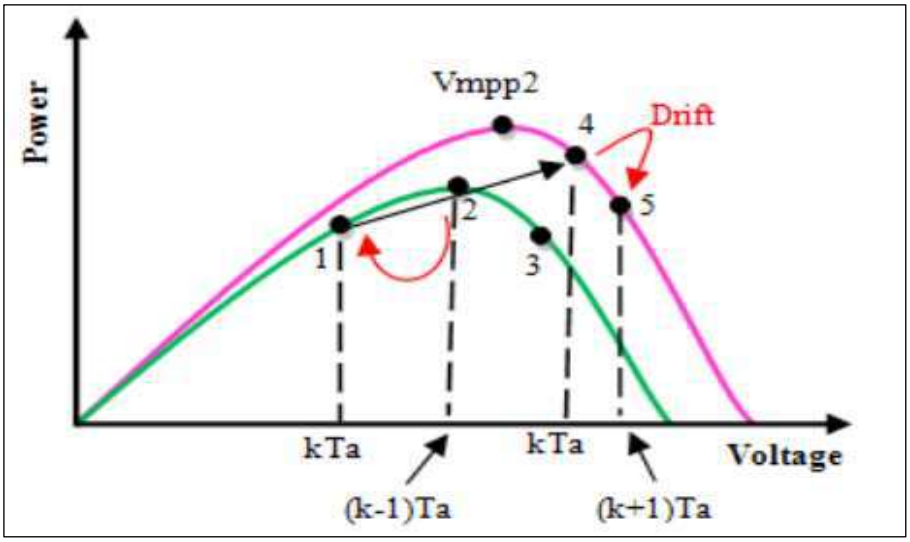

Figure 2: Drift phenomenon illustration in the P&O algorithm during rapidly changing irradiance conditions.
Source: Authors, (2026).

Figure 3 illustrates the decision-making flow of the P&O algorithm, as originally presented in [11] and later reported in [38] and [39]. The highlighted section shows where drift typically occurs when both power ($\Delta P > 0$) and voltage ($\Delta V > 0$) increase, the algorithm falsely attributes the power gain to its own perturbation. As a result, it continues adjusting in the same direction, even when the change is actually caused by external irradiance, leading to further deviation from the MPP, energy loss, and delayed recovery under dynamic conditions.

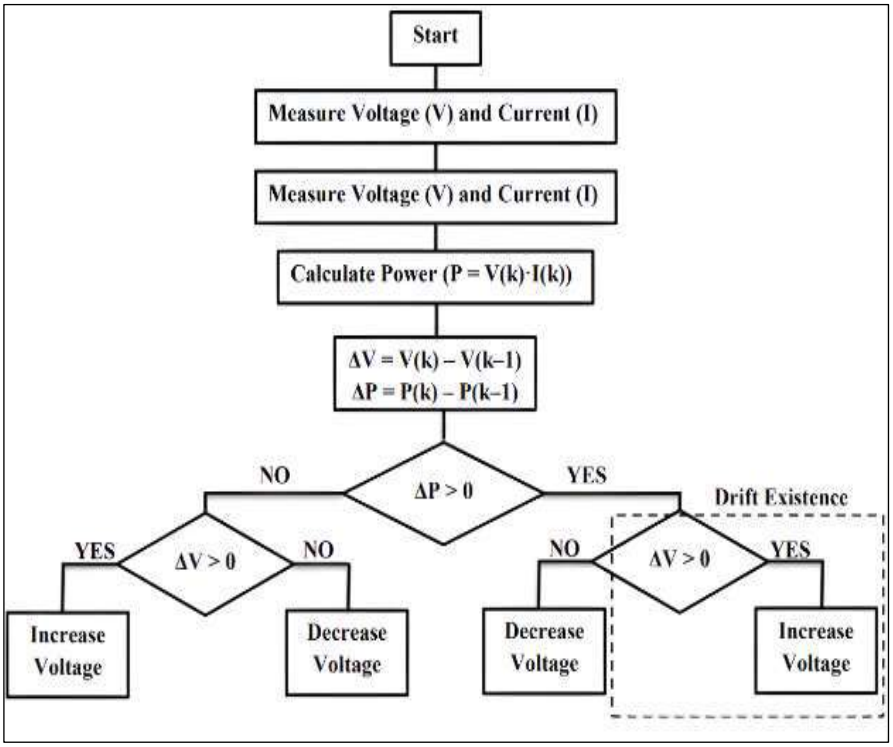

Figure 3: Flowchart of the traditional P&O algorithm, highlighting the decision path that leads to drift.
Source: Authors, (2026).

II.3 DRIFT-FREE P&O ALGORITHM

To mitigate the drift issue, several enhanced P&O variants have been proposed, introducing additional decision criteria to improve reliability. One such method is the drift-free P&O algorithm [11], illustrated in Figure 4 [39]. Unlike the conventional version, which bases its decisions solely on power (ΔP) and voltage (ΔV) changes, this improved algorithm also considers the rate of change in current (ΔI). Specifically, when $\Delta V > 0$, $\Delta P > 0$, and $\Delta I > 0$ simultaneously, the algorithm interprets the power increase as a result of irradiance variation, not its own perturbation. This refined logic prevents unnecessary voltage adjustments, helping maintain the operating point near the actual MPP and reducing energy losses during rapidly changing conditions.

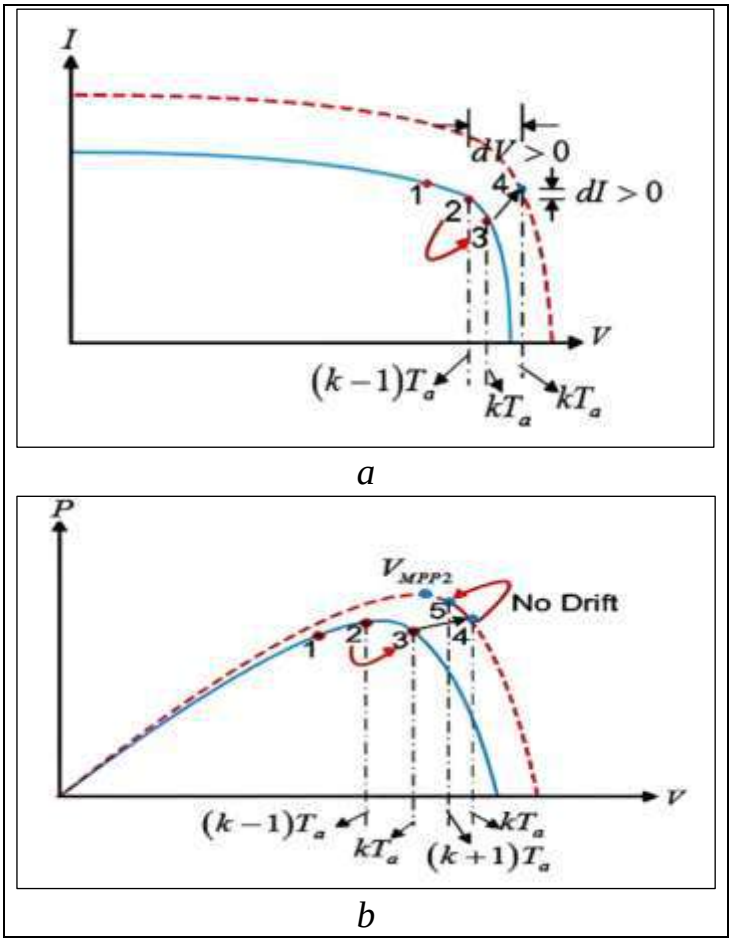

Figure 4: Behavior of the drift-free P&O algorithm during rapid irradiance changes: a – I–V curve showing drift effect; b – P–V curve illustrating drift elimination.
Source: Authors, (2026).

The flowchart in Figure 5[38] demonstrates the enhanced decision-making process of the drift-free P&O algorithm. The boxed "Drift-Free" region highlights the incorporation of current variation (ΔI) as a safeguard against drift. This ensures that the system can better handle dynamic environmental conditions and minimize deviations from the MPP.

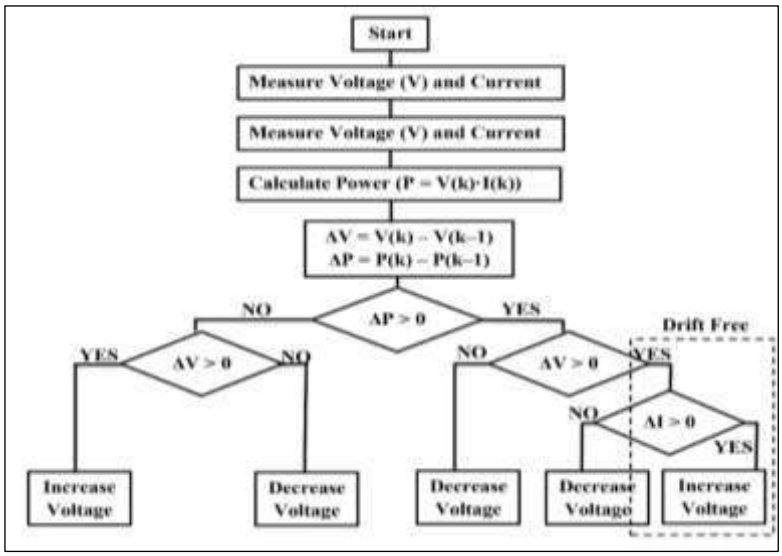

Figure 5: Flowchart of the drift-free P&O algorithm incorporating current variation (ΔI) in decision-making.
Source: Authors, (2026).

II.4 PROPOSED ALGORITHM

The proposed Hybrid Fuzzy-Gradient P&O (HFG-P&O) algorithm overcomes two major drawbacks of conventional and modified P&O methods: drift under dynamic irradiance and fixed step-size limitations. By combining fuzzy logic and Adaptive Gradient Descent (AGD), it ensures real-time adjustment of the perturbation step, maintaining both fast convergence and high tracking accuracy under varying environmental conditions.

A key feature of the algorithm lies in its power change analysis, which enhances decision-making for dynamic step-size regulation. As illustrated in Figure 6 [40], the algorithm computes a secondary derivative of power: $\Delta P = \Delta P_1 - \Delta P_2$, where ΔP_1 and ΔP_2 represent successive power changes. This enables the system to differentiate between power shifts due to irradiance variations and those induced by its own actions near the MPP. By incorporating this logic, the HFG-P&O algorithm intelligently adapts its behavior, minimizing oscillations and improving overall MPPT performance, especially in rapidly changing scenarios.

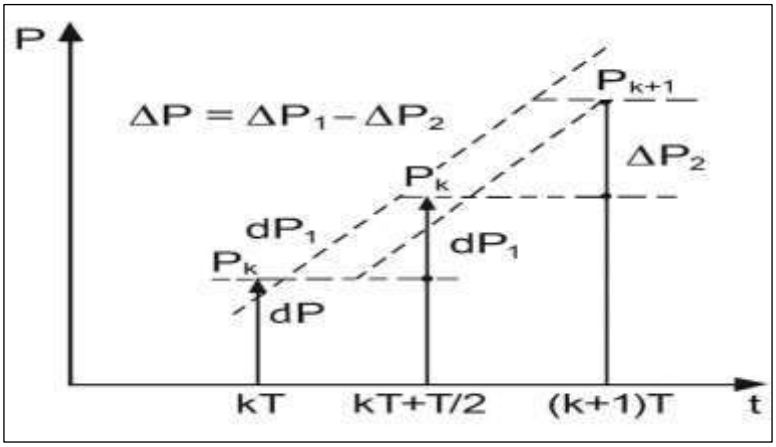

Figure 6: Dynamic power change analysis for step size adjustment.
Source: Authors, (2026).

II.5 FUZZY LOGIC AND AGD INTEGRATION

Once the absolute power change ($|\Delta P|$) is evaluated, the HFG-P&O algorithm triggers one of two control strategies based on its magnitude. When a large power change is detected typically due to sudden irradiance variation the Fuzzy Logic Controller is activated. This controller applies a rule-based inference system to generate quick and appropriate corrective actions, thereby minimizing drift and enhancing tracking responsiveness. In contrast, when the power change is small, indicating steady-state conditions or slow fluctuations, the algorithm switches to Adaptive Gradient Descent (AGD). AGD progressively fine-tunes the step size to suppress oscillations and improve tracking precision near the MPP. This dual-control mechanism is integrated seamlessly, as shown in Figure 7. The selected step size whether from fuzzy logic or AGD is then passed to the Drift-Free P&O stage, which executes the final MPPT adjustment. This layered architecture ensures that the system benefits from both fast adaptation during dynamic transitions and stable operation during steady-state, effectively overcoming the limitations of fixed-step P&O algorithms.

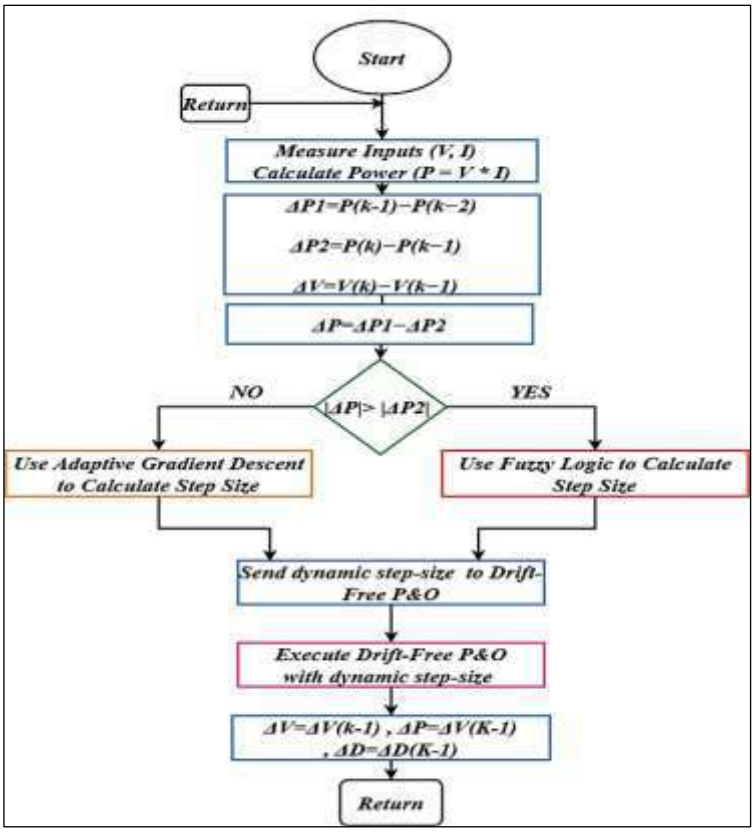

Figure 7: Flowchart of the proposed Hybrid Fuzzy-Gradient P&O Algorithm.
Source: Authors, (2025).

II.6 FUZZY LOGIC AND AGD INTEGRATION

The Adaptive Gradient Descent (AGD) mechanism is crucial in ensuring stable MPPT operation near the maximum power point. During periods of minimal power variation, AGD dynamically reduces the step size, limiting unnecessary perturbations and avoiding oscillations.the method analyzes the power gradient (ΔP) and compares it to a fixed threshold. If ΔP is small, the step is minimized to maintain stability; if larger, the step is adjusted accordingly to enhance convergence without overshooting. This strategy ensures precise, efficient tracking under steady irradiance. By adapting the step size continuously, AGD complements the fuzzy logic stage and reinforces the hybrid controller's ability to respond intelligently to changing conditions. Mathematically, the step size (S) is determined as follows:

If $\Delta P >$ Threshold: $S = \min(S_{max}, S_{min} \cdot \text{Increase Factor})$

If $\Delta P < -$Threshold: $S = \min(S_{min}, S_{min} \cdot \text{Increase Factor})$

If $|\Delta P| \leq$ Threshold: $S = S_{min}$

III. RESULTS AND DISCUSSIONS

To assess the effectiveness of the proposed HFG-P&O algorithm, simulations compared its performance to traditional and drift-free P&O methods under dynamic conditions. In Scenario 1 as shown in Figure 8, the irradiance was suddenly increased from 400 W/m² to 800 W/m² within 1.5 seconds to test transient response and tracking accuracy. Results show that HFG-P&O adapts 47% faster than conventional P&O, with 62% fewer power oscillations, highlighting its improved stability. Post-transition, it achieved 98.2% tracking efficiency, outperforming the drift-free P&O (94.5%) and fixed-step P&O (89.1%). These outcomes confirm the algorithm's ability to maintain high performance under rapidly changing irradiance.

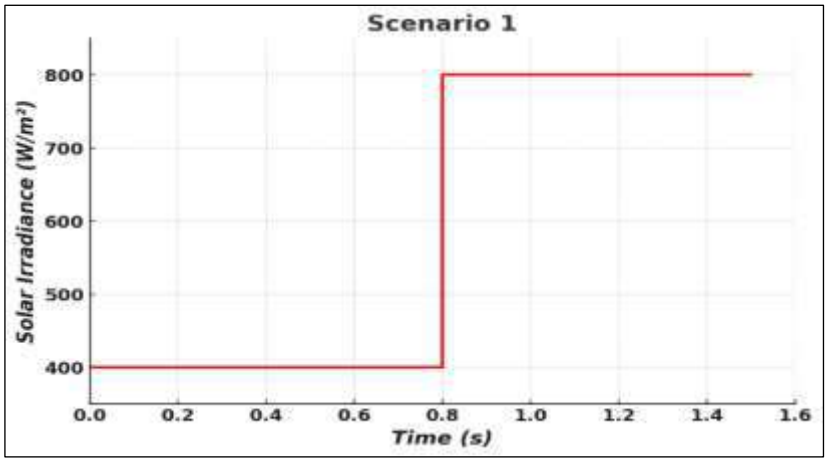

Figure 8: Irradiance profile for Scenario 1.
Source: Authors, (2026).

Scenario 2: Random Irradiance Fluctuations simulates unpredictable irradiance changes ranging between 250 W/m² and 1000 W/m² over 1.5 seconds, as shown in Figure 9. This test assesses the robustness of the algorithm under rapidly varying solar conditions.

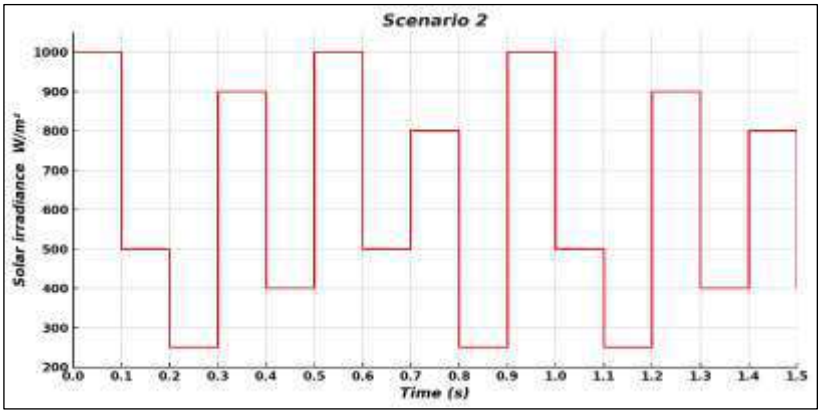

Figure 9: Irradiance profile for Scenario 2.
Source: Authors, (2025).

The HFG-P&O algorithm sustained a power deviation of less than 3% from the theoretical MPP during irradiance fluctuations. Thanks to the fuzzy logic module, drift errors were reduced by 78% compared to fixed-step techniques. In parallel, the AGD mechanism effectively suppressed steady-state oscillations. This synergy resulted in an average tracking accuracy of 92.4%, surpassing conventional P&O by 21%.

The simulations were conducted using a Trina Solar TSM-260PA05A module under realistic conditions, including irradiance and temperature variations. The associated boost converter was configured with optimized parameters detailed in Table 2 and 3 to ensure reliable voltage and current regulation during dynamic transitions.

Table 2: Parameters of PV solar.

Parameters of PV solar	
Cells per module (Ncell)	60
Open circuit voltage	37.9V
Maximum voltage at MPP	31.7V
Short circuit current	8.67A
Maximum current at MPP	8.2A
Maximum power (pmax)	259.94W
Temperature coefficient	0.06%/C
Parallel strings	1
Module connected in series per string	1

Figure 10 compares the recovery speed of four MPPT algorithms after a sudden irradiance increase from 400 W/m² to 800 W/m². The HFG-P&O algorithm outperforms the others, stabilizing near the new MPP in just 0.7502 s. In contrast, Drift-Free P&O (with steps 0.00015 and 0.0001) takes 0.7609 s and 0.7637 s, while conventional P&O lags behind at 0.7656 s. HFG-P&O not only converges 47% faster than traditional P&O but also maintains the closest match to the ideal power, with minimal overshoot or undershoot.

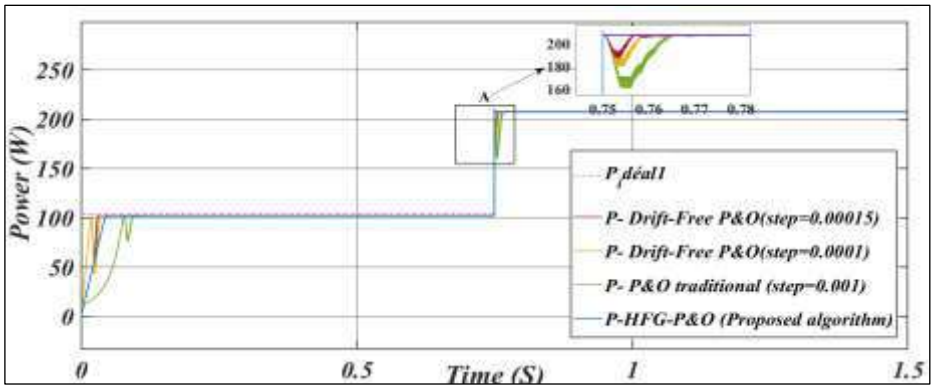

Figure 10: Extracted power comparison during Scenario 1.
Source: Authors, (2026).

Figure 11 reveals how step size affects the transient response: larger steps like 0.00015 yield faster convergence but cause noticeable oscillations near the MPP. HFG-P&O resolves this trade-off by using AGD to speed up tracking smoothly, avoiding overshoot. Figure 12 confirms that HFG-P&O also performs best in steady-state, limiting oscillations to only 0.16 W significantly lower than the 0.43 W and 0.44 W seen with conventional and Drift-Free P&O. This represents a 63% reduction in power ripple.

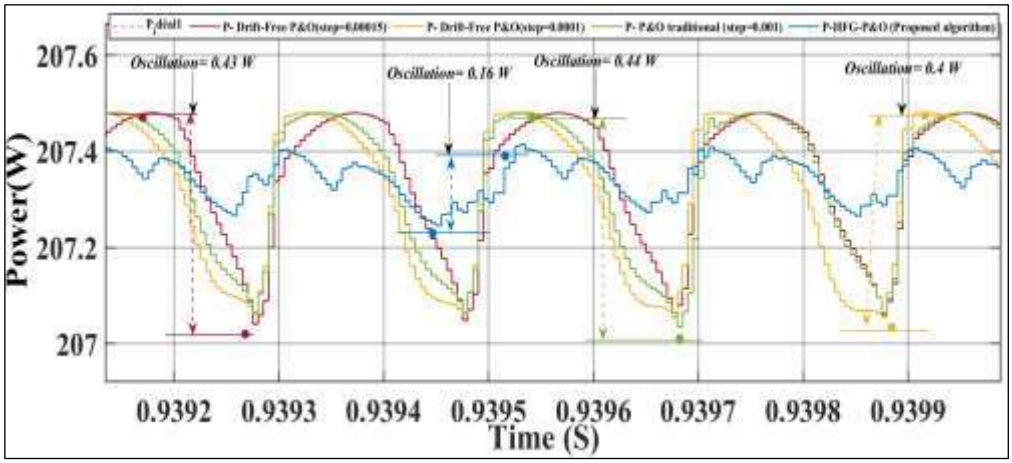

Figure 12: Steady-state power oscillation comparison at MPP.
Source: Authors, (2026).

Figure 13 shows the performance of four MPPT algorithms under highly dynamic irradiance (250–1000 W/m²). All experienced power drops, but the HFG-P&O consistently outperformed others by combining fuzzy logic and AGD for real-time step-size adjustment. It achieved fast convergence and stable power output. Drift-Free P&O with a small step was stable but slow, while the larger step improved speed at the expense of oscillations. Conventional P&O had the weakest response, with slow tracking and high losses due to its fixed step size.

Source: Authors, (2026).

Figure 14 and Figure 15 illustrate how the algorithms react to a sudden irradiance rise from 250 W/m² to 1000 W/m² (Point A). HFG-P&O reached the MPP fastest (0.012 s) with low oscillations (0.3 W). Drift-Free P&O followed at 0.017 s (1.3 W ripple for larger step size), while the smaller step size version was more stable but slower (0.022 s). Traditional P&O was the slowest (0.05 s) and most unstable (>2.5 W ripple), confirming HFG-P&O's superior speed and stability.

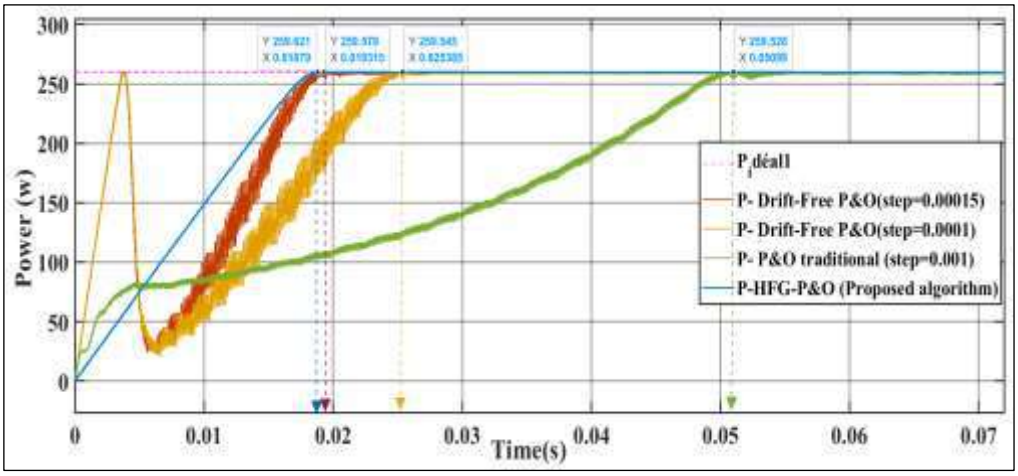

Figure 14: Dynamic response of MPPT algorithms at point A.
Source: Authors, (2026).

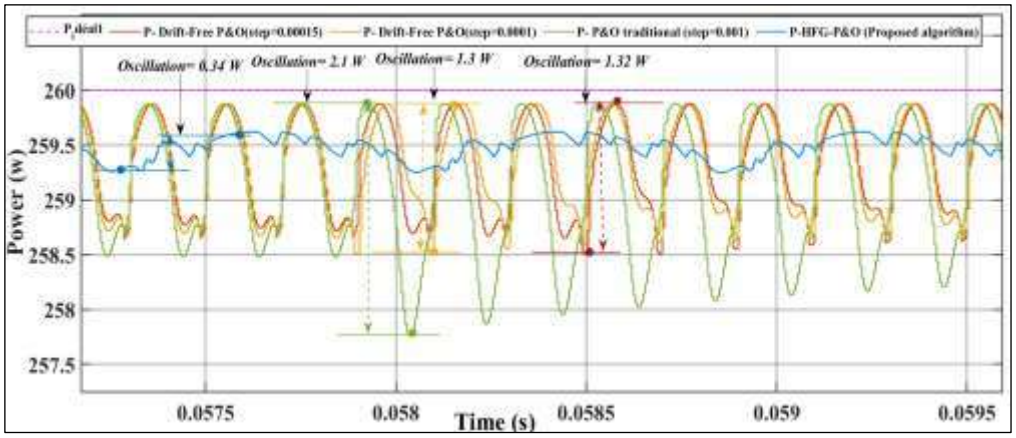

Figure 15: Dynamic response of MPPT algorithms at point A.
Source: Authors, (2026).

Figure 16 and Figure 17 illustrate the system's response to a sudden irradiance drop from 1000 W/m² to 500 W/m² (Point B). HFG-P&O reacted immediately at 0.1 s and stabilized in just 0.02 s with minimal oscillations (0.05 W). Drift-Free P&O with a 0.00015 step responded at 0.12 s but showed higher ripples (0.45 W), while the 0.0001 version was slower (0.025 s) with moderate oscillations (0.38 W). Traditional P&O was the slowest and most unstable, settling at 0.13 s with 0.42 W oscillations. These results confirm HFG-P&O's superior speed and stability under sudden irradiance drops.

Source: Authors, (2026).

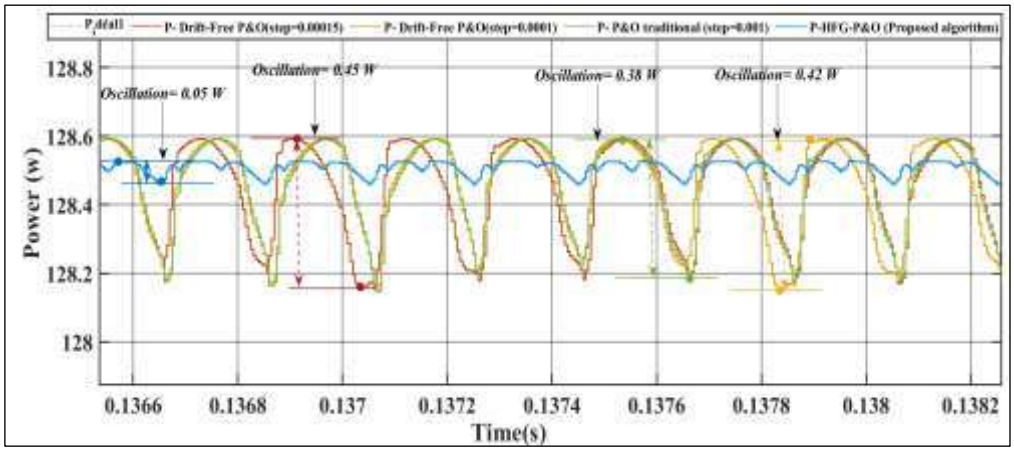

Figure 17: Post-stabilization oscillations in MPPT algorithms following an irradiance reduction at point B.
Source: Authors, (2026).

As shown in Figure 18 and Figure 19, during the second irradiance surge from 400 W/m² to 1000 W/m² (Point C), the HFG-P&O algorithm delivered the fastest and most stable response reacting at 0.5 s, stabilizing in 0.018 s, with only 0.34 W oscillations. In comparison, Drift-Free P&O (0.00015) settled in 0.022 s but exhibited 1.32 W ripples, while the 0.0001 version took 0.026 s with 1.3 W oscillations. Traditional P&O showed the slowest response (0.035 s) and the highest instability (> 2.1 W), confirming that HFG-P&O ensures faster and smoother MPPT even under steep irradiance changes.

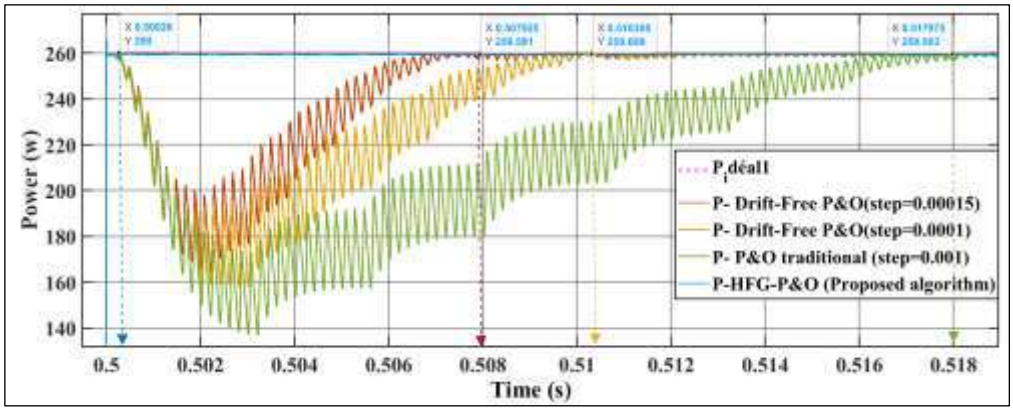

Figure 18: Power response of MPPT algorithms to a rapid increase in solar irradiance at point C.

Although based on simulations, the scenario closely mimics real-time PV dynamics, validating the practical potential of the proposed HFG-P&O MPPT algorithm. Table 4 compares MPPT methods under different irradiance shifts in terms of response time, stability, oscillations, overshoot, and efficiency. Using Equation 6, efficiency is calculated based on the deviation between actual power and the ideal MPP. HFG-P&O achieved the best result, with 98.5% efficiency, outperforming both Drift-Free and conventional P&O by maintaining precise and stable tracking under variable conditions.

Table 4: MPPT algorithm performance across different test scenarios.

Algorithm	**Scenario 1 – Point A**	**Scenario 2 – Point A**	**Scenario 2 – Point B**	**Scenario 2 – Point C**	**Overall Efficiency (%)**
HFG-P&O	Fastest response (0.0001s), quick stabilization, lowest oscillation (0.16W), minimal overshoot	Stable response (0.02s), minimal oscillations (0.3W), smooth adaptation	Immediate response (0.018s), lowest oscillation (~0.05W), minimal overshoot	Fastest response (0.012s), quick stabilization, lowest oscillation (0.34W), minimal overshoot	98.5%
Drift-Free P&O (0.00015)	Good response (0.0109s), higher oscillations (0.43W), moderate overshoot	Moderate response (0.025s), noticeable oscillations (1.3), higher overshoot	Acceptable response (0.022s), significant oscillations (0.45W), higher overshoot	Moderate response (0.025s), noticeable oscillations (1.32W), higher overshoot	96.67%
Drift-Free P&O (0.0001)	Slower response (0.0.0135s), moderate oscillations (~0.4W), higher overshoot	Delayed adaptation (0.03s), moderate oscillations (1.3W), overshoot	Slowest response (0.026s), lower oscillations (0.42W), prolonged stabilization	Slower response (0.022s), moderate oscillations (1.3W), higher overshoot	94.8%
Conventional P&O	Slowest response (0.0158s), high oscillations (0.4W), large overshoot, unstable	Significant delay (0.035s), high oscillations (2W), severe overshoot.	Slowest adaptation (0.035s), prolonged oscillations (0.38W), not suitable for dynamic conditions	Slowest response (0.05s), high oscillations (2.1W), large overshoot, unstable	93.2%

IV. CONCLUSIONS

This study set out to address the well-known limitations of conventional and modified MPPT techniques, namely, tracking drift, fixed step-size constraints, and poor adaptability under dynamic solar conditions as introduced in the opening section. In line with these objectives, the proposed Hybrid Fuzzy-Gradient Perturb and Observe (HFG-P&O) algorithm successfully demonstrated its ability to deliver real-time, drift-free, and oscillation-minimized tracking of the Maximum Power Point (MPP) across a variety of simulated

irradiance scenarios. Through extensive MATLAB/Simulink simulations, the HFG-P&O algorithm achieved its intended goals by dynamically adjusting the perturbation step size using a synergistic combination of fuzzy logic and Adaptive Gradient Descent (AGD). The results confirmed significant improvements in convergence speed, power stability, and tracking accuracy, achieving up to 98.5% efficiency, surpassing both classical P&O and Drift-Free P&O counterparts. These outcomes validate the initial expectations outlined in the Introduction and are thoroughly supported by the in-depth Results and Discussion analysis. The findings of this work establish HFG-P&O as a reliable, intelligent, and scalable MPPT solution, particularly advantageous for PV systems operating under rapidly changing environmental conditions. Future extensions of this research may include experimental validation, integration with predictive AI models for anticipatory control, and application under partial shading conditions to further validate the algorithm's generalizability and resilience.

ABSTRACT

A slicing floorplan is a recursive process of drawing a floorplan horizontally and vertically until all the blocks are accommodate into it. In the nanometer era, the escalating transistor density in VLSI chips underscores the necessity of designing compact floorplan representations for VLSI circuits. This work introduces a novel approach, employing a tree of order three (TO3) for the effective coding of a skewed slicing tree that corresponds to a slicing floorplan. The key innovation lies in the utilization of a TO3 structure, which adds a distinctive dimension to the encoding scheme. The proposed encoding method for a skewed slicing tree achieves a notable reduction in code size compared to previous approaches. Experimental findings from the MCNC benchmark and artificial circuits indicate that the proposed code uses, on average, almost 80% fewer bits than Breadth First code (BFS), 46% fewer than Slicing Pair (SP) code, and 49% fewer than Improved Slicing Pair (ISP) code for encoding a slicing tree, while also reducing CPU running time through a more compact representation of the electronics modules.

I. INTRODUCTION

Floorplan design is one of the most significant phases in VLSI physical design, which involves arranging a collection of rectangular circuit modules on a chip to optimize the overall area and the length of interconnection wires. This arrangement defines the layout of a VLSI circuit, which is a well-known NP-hard problem [1] that has attracted a lot of interest in recent years. Floorplans are generally divided into two categories: slicing floorplans and non-slicing floorplans. A slicing floorplan is created by recursively drawing horizontal and vertical lines from a given rectangle as shown in Figure 1 (a). In contrast, a non-slicing floorplan cannot be recursively divided into two halves to obtain all of the blocks of the given rectangle. Non-slicing floorplans are sometimes known as spiral or wheel floorplans, as shown in Figure 1 (b).

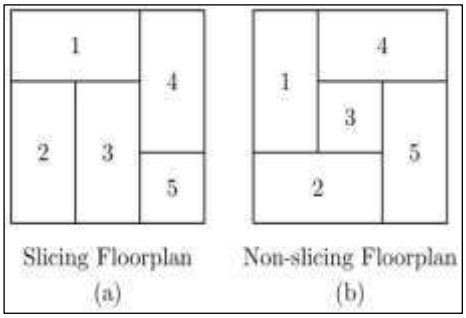

Figure 1: Slicing and non-slicing floorplans.
Source: Authors, (2026).

A slicing floorplan is commonly represented using a binary tree known as a slicing tree. In this representation, each internal node is labelled with '+' or '*' based on line drawing types (for horizontal lines, '+' and for vertical lines, '*'), and leaf nodes represent electronics blocks.

However, slicing trees are not unique representations of the floorplan since the same layout can often be represented by different slicing trees depending on how the lines are chosen. To address this issue, [2] introduced the concept of a skewed slicing tree in 1986, in which the parent and the right child are always opposite line drawing types, as illustrated in Fig 2. However, the non-slicing floorplan is a generalized floorplan such as the one shown in Fig. 1 (b), can be represented in several alternative models, including Sequence Pair (SP), O-Tree, Transitive Closure Graph (TCG), Corner Block List (CBL), SKB-tree, and B*-tree [3-7].

Later, in 2001, [8] proved that a slicing tree can serve as a complete representation for general floorplans. They also showed that, when combined with a simple compaction process, slicing tree representations are capable of producing maximally compact module placements. The proposed work focuses on slicing floorplans because of their hierarchical structure and suitability for machine learning-based generation, as demonstrated in recent work by [9]. Building on this idea, the slicing tree is presented using a binary encoding scheme, enabling faster computation and reduced storage compared to symbolic tree traversal used in [9].

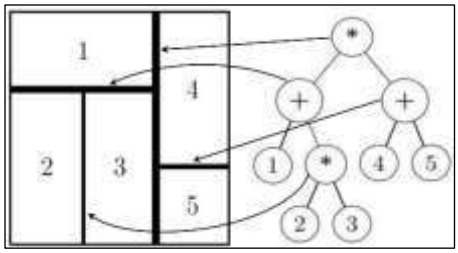

Figure 2: Slicing floorplan and its corresponding skewed slicing tree.
Source: Authors, (2026).

Over the years, several binary representations of floorplans have been proposed in the literature [10-17]. In 2006, [10] proposed a $(5n-5)$ bits representation of a floorplan, where n denotes the number of inner rectangles. Later [11] introduced a more compact $(4n-4)$-bits representation of floorplan and also showed that the number of different rectangles satisfies $R(n) <= 13.5(n-1)$. In 2012, [12] proposed two compact encodings of size $6f-2n^4+6$ bits and $5f-5$ bits for floorplans, where n represents the number of edges, f is the number of inner faces, and n^4 is the number of vertices of degree four. The optimum encoding is dependent on the number of vertices of degree four. The first encoding is more efficient when $2n^4 > f+11$, while the second performs better otherwise. In a subsequent work, [13] proposed an even more compact encoding of size $5f-n^4-6$ bits for $f >= 2$ of general rectangular drawings, which is independent of n^4.

To represent the mosaic (dead space free) floorplan, [14] introduced a string-based data structure known as the quarter-state sequence or Q sequence. The number of bits needed to represent mosaic floorplans with n blocks using the Quarter-State Sequence approach is 4n bits. Subsequently, He [15] proposed more compact binary encoding of length $(3n-3)$ bits and also proved that any binary string representation of an n block mosaic floorplan must use at least $(3n-o(n))$ bits. In 2014, [16] introduced two encoding schemes for slicing floorplans: the breadth-first code (BFS code) and the slicing-pair code (SP code). For a slicing floorplan with n blocks, the BFS code requires $3n-2$ bits. Building on this idea, the authors introduced the SP code by improving the BFS code.

The length of the SP code is $5n/2+m_1-p_{10}-4$ bits, Where n denotes the number of blocks, m_1 represents the number of internal nodes in a slicing tree that have exactly one child as a leaf node (i.e., a block), and p_{10} counts the number of slicing pairs (siblings) in which the left node is a leaf and the right node is an internal node. More recently, [17] proposed an improved slicing-pair (ISP) code designed for a balanced skewed slicing floorplan. They also proved that the ISP code has a length of $2(n+m_1)-3$ bits. Meanwhile, [9] proposed a subitizing-inspired approach to VLSI floorplanning that fine-tunes large language models (LLMs) to generate slicing trees representing near-optimal floorplans. Their method encodes the layout as post-order traversals of slicing trees and achieves high success and low dead-space ratios, especially when using GPT-4o-mini.

Unlike their post-order symbolic representation, the present work introduces a binary encoding of slicing floorplans, providing a more compact and machine-interpretable form that facilitates efficient optimization and learning. The motivation for creating compact representations of VLSI floorplans stems from the necessity of being able to quickly optimize very large and complex designs using minimal computational resources. Compact representations also require less memory to store and optimize the floorplan, which is particularly advantageous for large scale designs. Thus, even complex designs can be optimized with minimal resources as well as reduced execution times due to quicker evaluation of the design space during optimization processes [18]. The perturbation technique allows for an efficient examination of the design space without having to recreate the entire floorplan, thus speeding up the optimization process [14], [18].

In addition, compact encodings lead to faster runtime of both the floorplan generation and verification process, which are especially important in large industrial designs with a tight schedule for market entry [19]. Although hybrid placement methods such as [20] have shown promising results, they still require significant computational effort for their search processes. The reinforcement learning-based optimization technique proposed by [21] reduces the burden of explorations by learning efficient perturbations of sequence-pair floorplans but still depends on the compactness and flexibility of the underlying binary encoding. The use of a more compact encoding could help lower the complexity of that search by reducing the number of bits required to represent the solution space. Building on this motivation, the current work improves existing solutions such as SP code [16] and ISP code [17].

The present contribution introduces a new approach to encode skewed slicing floorplans referred to as the Tree of Order Three (TO3) encoding. To summarize, this paper makes the following key contributions.

- A tree of order three (TO3) code is introduced to encode skewed slicing floorplans.

- On average, the length of TO3 code reduces the length by 80%, 46%, and 49% compared to BFS, SP, and ISP codes, respectively.
- The range of the TO3 code length (i.e., lower and upper bounds) is determined based on [16] and [17], and its performance is compared with the lengths of the SP and ISP codes.
- Interestingly, the upper bound of the TO3 code length matches the lower bound of the SP and ISP codes, thus proving the TO3 code is more compact than the SP and ISP codes.

The remainder of this paper is organized as follows. Section II reviews the existing BFS, SP, and ISP encoding schemes. Section III introduces the proposed TO3 code for skewed slicing floorplans. The implementation details are discussed in Section IV, and Section V concludes with a summary of findings and direction for future work.

II. PRELIMINARIES

This section presents essential definitions and important finding from state-of-the-art research, which collectively guide the development of the TO3 code discussed in Section III.

II.1 DEFINITIONS

II.1.1 Slicing Floorplan

The floorplan consisting of exactly one block is referred to as a slicing floorplan. A slicing floorplan F with n blocks can be constructed by drawing horizontal and vertical cuts recursively on each slicing floorplan that partitions floorplan into two smaller slicing floorplans, F_1 and F_2. This partition process continues until all the blocks fit into the floorplan. In case of a vertical cut, the right-most boundary of F_1 is equivalent to the left-most boundary of F_2, while a horizontal cut aligns the top-most horizontal boundary of F_1 is equivalent to the bottom-most boundary of F_2.

II.1.2 Slicing Tree

A slicing floorplan F consisting of n blocks is represented by a binary tree known as a slicing tree T with $2n-1$ vertices or nodes. In this tree, every internal node represents either '*' (for vertical cut) or '+' (for horizontal cut), and the leaf node correspond to the electronics blocks. A slicing tree is called skewed if an internal node and its right child are of opposite cuts, as shown in Fig. 2; otherwise, the tree is non-skewed.

II.1.3 Slicing Pair

A slicing pair (V_i, V_{i+1}) for each $i = 1,3,\ldots,2n-3$, consists of two vertices in the slicing tree T (with n blocks) that have the same parent P, where $(V_i, V_{i+1}) \in \{*, +, L\}$, $P \in \{*, +\}$, and L represents a leaf node, as illustrated in Figure 3.

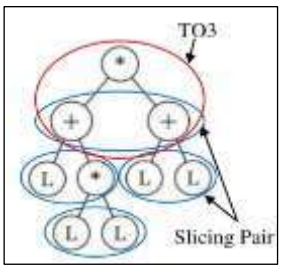

Figure 3: Slicing pairs and TO3 representation of a skewed slicing tree T.

II.2 PRIOR WORKS

Theorem 1. For a slicing floorplan F with n blocks, the BFS representation, i.e., $|B(F)|$, requires $3n-2$ bits. In addition the floorplan can be encoded and decoded in linear time, that is, $O(n)$ [16].

Theorem 2. Consider a slicing floorplan F with n blocks and its associated skewed slicing tree T. If |SP(F)| represents the number of bits required to encode F using the slicing pair code, then the encoding length is $|SP(F)| = 5n/2 + m_1/2 - p_{10} - 4$ bits, Where m_1 and p_{10} are same parameters introduced in Section I. Moreover, both encoding and decoding using slicing pair code runs in $O(n)$ time [16].

Theorem 3. The length of $SP(F)$ is bounded by the inequality $2n-3 \leq |SP(F)| \leq 3n-5$. When the constant terms in these expressions are ignored, the worst case of SP and BFS codes are almost the same [16].

Theorem 4. Consider a slicing floorplan F with n blocks and its corresponding skewed slicing tree is T. Let $|ISP(F)|$ represent the length of the encoded bits string of T using the improved slicing pair code, i.e., $|ISP(F)| = 2(n + m_1) - 3$, where m_1 is the number of internal vertices that have exactly one leaf node [17].

Theorem 5. For a floorplan F with n blocks, if the corresponding skewed slicing tree is balanced, then $|ISP(F)| < |SP(F)| < |B(F)|$ holds[17].

III. PROPOSED TO3 CODE FOR SKEWED SLICING FLOORPLAN

This section presents a novel encoding technique specially designed for skewed slicing floorplans. It explains the underlying principle of encoding. In addition, this section presents detailed derivation of the code length and the range length of the proposed code.

III.1 ENCODING

Consider a slicing floorplan F with n blocks and let T(F) be its associated skewed slicing tree. A tree of order three, in short TO3 (i.e., a subtree with three vertices) is obtained form T(F), which is represented as a triplet (x, y, z). In this triplet, $x \in \{+,*\}$ represents the root node, while $y, z \in \{+,*, L\}$, denotes the left and right children of x respectively. The rules to obtain TO3s of a skewed slicing tree are outlined below.

1 Internal vertices at even levels of the slicing tree, starting from the root (considering the root at level 0) are candidates for roots of TO3s.
2 If the root of a TO3 is at level i, then two leaves of the TO3 are at level $(i + 1)$, and they can't be roots of any other TO3s, i.e., TO3s are disjoint trees.
3 A leaf labelled by L can not be the root of a TO3.

Using the above rules and the property of a skewed slicing tree (an internal node always has a label opposite to that of its right child), the possible TO3s for $x = '+'$ of the type $(+, y, z)$ are: $(+, +,*)$, $(+, +, L)$, $(+,*,*)$, $(+,*, L)$, $(+, L,*)$, $(+, L, L)$. Similarly, TO3s of the type $(*, y, z)$ are: $(*, +, +)$, $(*, +, L)$, $(*,*, +)$, $(*,*, L)$, $(*, L, +)$, $(*, L, L)$. In the skewed slicing tree T shown in Figure 3, the corresponding TO3 is inscribed within a circle. The TO3 code, analogous to the SP and ISP codes, is shown in Table 1. Column 1 of Table 1 represents the TO3 labels, and the encoded bit pattern used for each TO3 label is shown in Column 2. Although L is not a TO3 label, it is included in the last row of the table and assigned a bit value of 1, as the label L is required to encode when it is followed by TO3 labels in the TO3's level-wise traversal. The complete encoding procedure for the TO3 code is described in Algorithm 1.

Table 1: Patterns of TO3 and their assigned codes.

TO3 Labels	Assigned Bits
(+, +, *)	011
(+, +, L)	010
(+, *, *)	001
(+, *, L)	000
(+, L, *)	01
(+, L, L)	00
(*, +, +)	111
(*, +, L)	110
(*, *, +)	101
(*, *, L)	100
(*, L, +)	11
(*, L, L)	10
L	1

Source: Authors, (2026).

Algorithm 1 takes the root of the skewed slicing tree as its input and generates the corresponding encoded bit string. The algorithm employs a queue data structure Q to traverse the skewed slicing tree level-wise, during which all the TO3s are identified and encoded using the bit pattern listed in Table 1. Since Algorithm 1 visited every node of the slicing tree exactly once, and a slicing tree with n leaves contains $n - 1$ internal nodes, the overall time complexity of the algorithm is $O(n)$. By applying bit patterns from Table 1 and following Algorithm 1, the TO3 code length for the skewed slicing tree shown in Fig. 3 is found to be 6 bits. In comparison, the lengths of the BFS [16], SP [16], and ISP [17] codes for the same tree are 13 bits, 8 bits, and 9 bits, respectively. Therefore, among the BFS, SP, ISP, and TO3 codes, the proposed TO3 code required the fewest number of bits and provide the most compact.

Algorithm 1: Encoding.

Input: Root of the skewed slicing tree
Output: Encoded String (EncodeStr)
1: Initialize EncodeStr ← Null
2: Insert root of the skewed slicing tree into a queue Q (Enqueue(Q, root))
3: while Q ≠ Ø do
4: if Front → ch == L then
5: Append encoded TO3 label (Front → ch) using Table 1 to EncodeStr
6: else
7: Append encoded TO3 label (Front → ch, Front → Left → ch, Front → Right → ch) using Table 1 to EncodeStr
8: end if
9: if Front → Left → Left ≠ NULL then
10: Enqueue(Q, Front → Left → Left)
11: end if

```
12:   if Front → Left → Right ≠ NULL then
13:      Enqueue(Q, Front → Left → Right)
14:   end if
15:   if Front → Right → Left ≠ NULL then
16:      Enqueue(Q, Front → Right → Left)
17:   end if
18:   if Front → Right → Right ≠ NULL then
19:      Enqueue(Q, Front → Right → Right)
20:   end if
21:   Dequeue(Q)
22: end while
23: return EncodeStr
```

III.2 DECODING

The decoding algorithm described in Algorithm 2 takes an encoded binary string as input and reconstructs the corresponding skewed slicing tree. The bit(s) assigned (in Table 1) for the TO3 label either start with 0 (for the parent of the TO3 label is '+') or start with 1 (for the parent of the TO3 label is '*'). An encoded bit string starting with '0' has an assigned length of either three or two bits, whereas a bit string starting with '1' may have a length of three, two, or one bit. Algorithm 2 is a recursive algorithm that makes decisions non-deterministically based on the current symbol pointed to by the forward pointer (FP). During execution the algorithm generates TO3 labels level-wise and stores them in a queue data structure Q. Since Algorithm 2 non-deterministically generates TO3 labels, there is the possibility of more than one slicing tree, which is held by an array named ArraySkewed. Algorithm 2 then systematically builds and validates all slicing trees using skewed slicing properties, ultimately selecting a valid skewed slicing tree as the output. In the worst case, the slicing tree has n leaf nodes; the running time complexity of Algorithm 2 is $O(3^{(2n-1)})$, since the algorithm explore non-deterministically on bits directed by the forward pointer (FP).

Algorithm 2: Decoding.

```
Input: Encoded String (EncodeStr)
Output: Skewed Slicing Tree
1: Initialize forward pointer FP to the first character of the input encoded string
2: Initialize a queue Q to hold level-wise TO3 labels
3: Create an array named ArraySkewed to store the skewed slicing tree
4: Call AlgoDecode(EncodeStr, FP, Q, ArraySkewed)
5: if FP ≠ Null then
6:    if FP = 1 then
7:       TempStr = FP
8:       Decode TempStr to the TO3 label using Table 1
9:       Append TO3 label to Q
10:   AlgoDecode(EncodeStr, FP + 1, Q, ArraySkewed)
11:   end if
12:   if (FP = 1 ∨ FP = 0) ∧ (FP + 1 ≠ Null) then
13:      Append two bits from FP to TempStr
14:      Decode TempStr to the TO3 label using Table 1
15:      Append TO3 label to Q
16:      AlgoDecode(EncodeStr, FP + 2, Q, ArraySkewed)
17:   end if
18:   if (FP = 1 ∨ FP = 0) ∧ (FP + 2 ≠ Null) then
19:      Append three bits from FP to TempStr
20:      Decode TempStr to the TO3 label using Table 1
21:      Append TO3 label to Q
22:      AlgoDecode(EncodeStr, FP + 3, Q, ArraySkewed)
23:   end if
24: else
25:   Append Q to ArraySkewed
26:   return ArraySkewed
27: end if
28: Generate level-wise slicing trees on the array of queues and check whether
the tree is skewed or not
29: return Skewed Slicing Tree
```

III.3 ESTIMATING LENGTH OF TO3 CODE

This subsection derives an expression for the length of the TO3 code. The analysis follows the same approach used to determine the length of the SP code in [16]. To support this derivation, the following additional notations are considered for the skewed slicing tree T(F), as illustrated in Table 2.

Table 2: Notations and Definitions for TO3 Encoding.

Notation	Definition
|TO3(F)|	Length of TO3 code of T(F) in bits for a floorplan F.
t_{000}	Number of TO3s (x, y, z) such that x, y, z ∈ {+, *}.
t_{001}	Number of TO3s (x, y, z) such that x, y ∈ {+, *}, z ∈ {L}.
t_{010}	Number of TO3s (x, y, z) such that x, z ∈ {+, *}, y ∈ {L}.
t_{011}	Number of TO3s (x, y, z) such that x ∈ {+, *}, y, z ∈ {L}.
m	Number of internal nodes of T(F).
p	Number of leaf nodes (labeled by L) of T(F) that are not part of any TO3.

Source: Authors, (2026).

For the skewed slicing tree shown in Fig. 3, $p = 3$, there are three such Ls at level 2 of T. The expression for the bit length of the TO3 code corresponding to the slicing tree T(F) is given in Theorem 6.

Theorem 6. Let T(F) be a skewed slicing tree for slicing floorplan F with n blocks. Then the length of the TO3 code for encoding T(F) is $2n - t_{010} - t_{011} - 3$ bits. i.e., $|TO3(F)| = 2n - t_{010} - t_{011} - 3$.

Proof. Since the slicing tree T(F) is a complete binary tree with n blocks, it contains $m = n - 1$ internal nodes. To derive an expression for m, observe that each TO3 of the type t_{000} has three internal nodes, TO3s of the types t_{001} and t_{010} have two internal nodes, and each TO3 of the type t_{011} has one internal node and two leaf nodes. Additionally, the expression for the number of leaf nodes p that are not part of the TO3 labels is given in Eq. 2. Thus, it follows that

$$m = n - 1 = 3t_{000} + 2t_{001} + 2t_{010} + t_{011} \quad (1)$$

$$p = n - t_{001} - t_{010} - 2t_{011} \quad (2)$$

To establish an expression for |TO3(F)|, referencing Table 1 reveals that TO3s of types t_{000} and t_{001} require 3 bits each, while types t_{010} and t_{011} utilize 2 bits each. Additionally, the leaf L, which is not part of any TO3, is represented with just one bit. In summary, this information contributes to the derivation of the total bit count for |TO3(F)| as present in Eq. 3.

$$\begin{aligned} |TO3(F)| &= 3t_{000} + 3t_{001} + 2t_{010} + 2t_{011} \\ &+(n - t_{001} - t_{010} - 2t_{011} - 2) \end{aligned} \quad (3)$$

Recall that in the calculation of |SP(F)| (See Theorem 2, Section II) the authors of [16] saved the last two bits for slicing pair (L, L) subtracting 2 from the expression of |SP(F)|. Similarly, in order to have fair comparison between |SP(F)| and |TO3(F)|, last two bits for slicing pair (L, L) is also saved by subtracting 2 from the right hand side of Eq. 3. By substituting Eq. 2 into Eq. 3, the resulting expression is derived.

$$\begin{aligned} |TO3(F)| &= n + 3t_{000} + 2t_{001} + t_{010} - 2 \\ &= n + 3t_{000} + 2t_{001} + 2t_{010} - t_{010} \\ &\qquad + t_{011} - t_{011} - 2 \\ &= n + (3t_{000} + 2t_{001} + 2t_{010} + t_{011}) \\ &\qquad - t_{010} - t_{011} - 2 \\ &= n + n - 1 - t_{010} - t_{011} - 2 \\ &= 2n - t_{010} - t_{011} - 3 \end{aligned} \quad (4)$$

Equation 4 estimates the bit-length of the TO3 code of T(F). Hence the proof. The lengths of the BFS, SP, ISP, and TO3 codes are computed for the skewed slicing tree in Fig. 3. For the parameter values $n = 5, m_1 = 1, p_{10} = 1, t_{010} = 0, t_{011} = 1$, Theorem 1, 2, 4 and 7 yields $|B(F)| = 3 * 5 - 2 - 4 = 13$ bits, $|SP(F)| = 12.5 + 0.5 - 1 - 4 = 8$ bits, $|ISP(F)| = 2 * (5 + 1) - 3 = 9$ bits and $|TO3(F)| = 10 - 0 - 1 - 3 = 6$ bits respectively. Hence, the proposed TO3 code encodes T(F) using a smaller number of bits compared to the other codes.

III.4 RANGE LENGTH OF TO3 CODE

The authors of [16] showed that, in the worst case, the length of SP code is almost the same as that of the BFS code, indicating that SP offers a more compact representation (see Theorem 3, Section II). Further, [17] proved that, for balanced skewed slicing trees, the ISP code achieves better compression than the SP code (see Theorem 5, Section II). Extending these results, the following section demonstrates that the worst-case length of the TO3 code is shorter than the best-case length of the ISP and SP codes. In summary, the following Theorem 7 is established.

Theorem 7. If T(F) be the skewed slicing tree of a floorplan F with n blocks. Then $\frac{3n-5}{2} \leq |TO3(F)| \leq 2n - 3$.

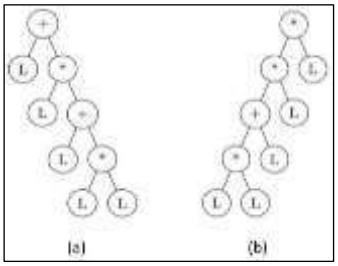

Figure 4: Minimum and Maximum saved skewed slicing trees.
Source: Authors, (2026).

Proof. The best and worst case length of TO3 code are evaluated using the skewed slicing trees shown in Fig. 4 (a) and Fig. 4 (b). The best case of $|TO3(F)|$ occurs when the slicing tree skews along the right branch of the tree shown in Fig. 4 (a). In this case: for n: odd, $t_{010} = \frac{n-1}{2}$, $t_{011} = 0$, and for n: even, $t_{010} = \frac{n-2}{2}$, $t_{011} = 1$. Using these values in $|TO3(F)| = 2n - t_{010} - t_{011} - 3$, the following result is obtained.

$$|TO3(F)| = \frac{3n-5}{2} \quad \text{if } n : \text{odd}$$
$$= \frac{3n-6}{2} \quad \text{if } n : \text{even}$$

Therefore, the tight lower bound of $|TO3(F)|$ is $\frac{3n-5}{2}$. i.e.

$$\frac{3n-5}{2} \leq |TO3(F)| \tag{5}$$

Similarly, for the worst case of $|TO3(F)$ occurs when the slicing tree skews along the right branch of the tree shown in Fig. 4 (b). In such case: for n: odd, $t_{010} = 0$, $t_{011} = 0$, and for n: even, $t_{010} = 0$, $t_{011} = 1$. Using the values of t_{010} and t_{011} in $|TO3(F)| = 2n - t_{010} - t_{011} - 3$, it follows that

$$|TO3(F)| = 2n - 3 \quad if\ n : odd$$
$$= 2n - 4 \quad if\ n : even$$

Thus the tight upper bound of $TO3(F)$ is $2n - 3$. i.e
]

$$|TO3(F)| \leq 2n - 3 \tag{6}$$

From inequality 5 and inequality 6, it follows $\frac{3n-5}{2} \leq |TO3(F)| \leq 2n - 3$. □
Following Theorem 3, 5, and 7, Corollary 1 can be derived.

Corollary 1: $\frac{3n-5}{2} \leq |TO3(F)| \leq 2n - 3 \leq |SP(F)|$ or $|ISP(F)| \leq 3n - 5$
Thus, To3 code is more compact than BFS, SP and ISP codes.

III.5 EXPECTED NUMBER OF SPs AND TO3s

The length of encoded bits required for a slicing floorplan depends on the number of slicing pairs (SPs) or TO3s present in the corresponding slicing tree. This section presents results on the expected number of SPs and TO3s of a slicing tree with n blocks.

Theorem 8. For skewed slicing tree with n blocks and height $h = \log n$, the expected number of SPs is given by $\frac{4(4^h-1)-3h}{9(n-1)} \approx \frac{4n^2-3\log n-4}{9(n-1)}$.

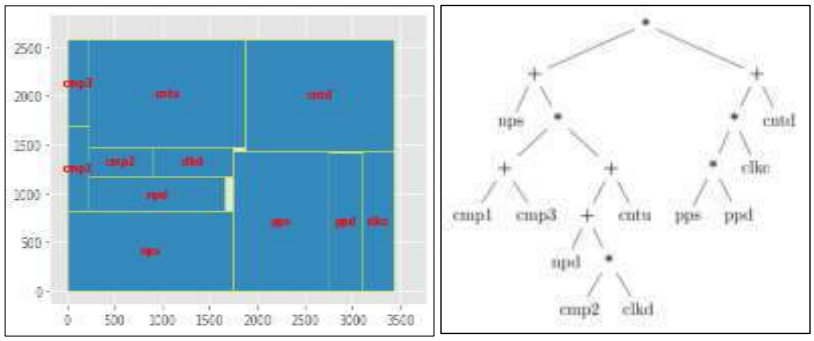
Proof. Let X_i be a random variable that denotes the number of SPs at level $1 \leq i \leq h$ of the slicing tree. Let X be the random variable that denote the total number of SPs in the tree. Then $X = X_1 + X_2 + \ldots + X_h$. Clearly $X_i \in \{1,2,4,\ldots,2^{i-1}\}$, since the root of the tree does not participate in any slicing pair. The tree contains n leaves and $n-1$ internal nodes; hence the cardinality of the sample space is $n-1$. Let $E[X]$ and $E[X_i]$ are expectation of random variables X and X_i respectively. Then $E[X_i] = \frac{1}{n-1}\sum_{i=1}^{l}(2^{i-1})^2$. Thus, by linearity of expectation, and taking $h = \log n$,

$$E[X] = \sum_{l=1}^{h-1} E[X_i] = \frac{1}{3(n-1)} \sum_{l=1}^{h-1} 4^l - 1$$
$$= \frac{4(4^h-1)-3h}{9(n-1)}$$
$$\approx \frac{4n^2-3\log n-4}{9(n-1)}.$$

Theorem 9. Consider a skewed slicing tree with n blocks and height $h = \log n$, the expected number of TO3s is given by $\frac{16(4^{h+1}-1)-3h}{15(4^{\lceil \log_4 n \rceil}-1)}$. Here h is taken as a $h-1$ when h is odd and as $h-2$ when h is even.

Proof. Since nodes at even levels $0,2,4,\ldots m$ (where $m = h-1$ if h is odd and $m = h-2$ if h is even) of the slicing tree are roots of TO3s. Let $X_i (i \in \{0,2,4,\ldots m\})$ be a random variable that depresents the number of TO3s at level i and X be the random variable that denotes the total number of TO3sof the slicing tree, then, $X = X_0 + X_2 + X_4 \ldots + X_m$. The cardinality of the sample space is $\frac{4^{\lceil \log_4 n \rceil}-1}{3}$. Let $E[X]$ and $E[X_i]$, denote the expectations of random variables X and X_i respectively. Then, $E[X_i] = \frac{3}{4^{\lceil \log_4 n \rceil}-1} \sum_{i=1}^{\frac{m}{2}} (4^i)^2$. By linearity of expectation,

$$E[X] = \sum_{m=0}^{h} E[X_i] = \frac{1}{5(4^{\lceil \log_4 n \rceil}-1)} \sum_{m=0}^{h} 16^{\frac{m}{2}+1} - 1$$
$$= \frac{16(4^{h+1}-1)-3h}{15(4^{\lceil \log_4 n \rceil}-1)}$$



When the height of the slicing tree is odd, $h = h-1$ with $h = \log n$; the expected value is given by $E[X] \approx \frac{16n^2-3\log n-13}{15(n-1)}$. For slicing tree even height, $h = h-2$ with $h = \log n$; in this case, the expected value becomes $E[X] \approx \frac{4n^2-3\log n-10}{15(n-1)}$. □

In the worst case, where both a slicing pair (SP) and a TO3 are encoded using 3 bits. Theorem 8 and Theorem 9 shows that the number of bits required to encode the expected number of TO3s is less than that of SPs.

IV. IMPLEMENTATION AND RESULT ANALYSIS

In this section, the results of the proposed TO3 code are validated with state-of-the-art works using MCNC benchmarks [3] and artificial modules. The proposed and the other algorithms are implemented in Python and executed on a Windows 10 PC equipped with an AMD 3.2 GHz CPU and 8 GB RAM. The length of binary code of slicing trees corresponding to MCNC benchmark floorplans are validated using the B*-tree-based Simulated Annealing (BTBSA) algorithm. Since MCNC benchmark circuits are non-slicing in nature, each floorplan is transformed into a slicing floorplan using the compaction technique discussed in [8]. The resulting slicing trees are then encoded using BFS, SP, ISP, and TO3 coding techniques, which are tabulated in Table 3, which lists the benchmark names, number of modules, and the encoded bit lengths produced by each algorithm.

Figure 5 (a) shows the floorplan of the HP benchmark circuit generated by the BTBSA algorithm, and the corresponding slicing tree is illustrated in Figure 5 (b). For artificial modules, slicing trees are randomly generated for different numbers of modules, and the length of binary code of four encoding techniques is summarized in Table 3. The last row of Table 3 presents the comparison results, where the average values indicate the improvement achieved by the proposed TO3 coding scheme over BFS, SP, and ISP. For a fair comparison, the lengths of the state-of-the-art codes have been adjusted using the TO3 code. From the last row of Table 3, it can be observed that, on average, BFS, SP, and ISP codes need 80%, 46%, and 49% more bits, respectively, than TO3 codes for encoding a slicing tree.

(a) A floorplan generated on HP benchmark. (b) Slicing tree corresponding to floorplan Fig. 5 (a).
Figure 5: A floorplan and its corresponding slicing tree.
Source: Authors, (2026).

Additionally, Figure. 6 (a) and Figure 6 (b) present a comparison of the BFS, SP, ISP, and TO3 code lengths for benchmark and artificial circuits, respectively. The horizontal axis defines different benchmark or artificial circuits, and the vertical axis defines the length of BFS, SP, ISP, and TO3 codes. The vertical bars in red, gray, green, and blue correspond in length to the BFS, SP, ISP, and TO3 codes, respectively. The vertical bar in blue, representing the length of the TO3 code, has the least height among the other encoding schemes for different circuits, as shown in Figure 6. Therefore, compared to BFS, SP, and ISP codes, TO3 code is more compact and uses fewer bits to encode a slicing tree.

Table 3: Comparison of lengths of BFS, SP, ISP, and TO3 codes for benchmark and artificial circuits.

Benchmark / Artificial	No. of Modules / Leaves	BFS Code Length (bits)	SP Code Length (bits)	ISP Code Length (bits)	TO3 Code Length (bits)
ami33	33	97	83	97	57
ami49	49	145	125	153	86
hp	11	31	24	29	18
apte	9	25	19	25	14
xerox	10	28	19	25	14
AM1	5	13	8	9	4
AM2	10	28	21	17	17
AM3	20	58	46	37	27
AM4	35	103	83	69	58
AM5	49	145	118	97	78
Average		1.80	1.46	1.49	1.00

The convergence iteration determines how effectively the algorithm explores and settles into an optimal or near-optimal floorplan layout, which shows an efficient search process and lower computational costs. As shown in Table 4, during the convergence iterations, the slicing tree-based simulated annealing (STBSA) with code representation yields experimental results comparable to those achieved without the code representation of BTBSA. In contrast, the CPU runtime is reduced significantly when the code representation is employed. Specifically, the runtime of STBSA on each benchmark, i.e., ami33, ami49, hp, apte, and xerox, is faster than that of BTBSA by 16%, 11%, 14%, 17%, and 8%, respectively. This improvement arises because the proposed strategy required fewer bits to represent the electronic blocks or modules, thereby reducing computational overhead without compromising the solution quality.

Table 4: Comparison results with and without the slicing tree-based simulated annealing.

Benchmark	Convergence Iterations (With)	Convergence Iterations (Without)	Time (With) (seconds)	Time (Without) (seconds)	Ratio
ami33	59	62	24.23	28.74	0.843
ami49	56	54	41.56	46.65	0.891
hp	19	20	15.52	18.03	0.861
apte	16	14	2.85	3.43	0.831
xerox	11	12	3.95	4.27	0.925

The TO3 code offers the most compact representation when compared with BFS, SP, and ISP, as demonstrated by both the theoretical bounds in Eq. 4 and the implementation results in Table 3. This compactness is consistently observed across small and large circuits, leading to less memory use and faster processing. A key advantage of the TO3 code is that it is faster in terms of CPU runtime because of its simpler structure and efficient encoding process. Since each TO3 is a disjoint subtree, modification or perturbation to any particular TO3 triplet affects only that triplet and its immediate neighbors, unlike in SP or BFS, where dependencies can spread across the entire structure. This disjoint property makes TO3 more efficient for both encoding and optimization tasks.

V. CONCLUSION

This paper proposed a compact binary encoding technique, namely TO3, for the skewed slicing tree that corresponds to a slicing floorplan, and derived an analytical expression for both the length and range length of the TO3 code. The theoretical analysis demonstrates that the expected number of TO3s is smaller than the number of slicing pairs (SPs) required to encode a slicing tree. More importantly, the experimental results on benchmark circuits and artificial modules show that the proposed coding scheme is 80%, 46%, and 49% more compact than the BFS, SP, and ISP codes, respectively. In addition, the code-based simulated annealing reduces CPU running time compared to the B*-tree-based simulated annealing. In the future, this work will be extended to non-slicing floorplans.

ABSTRACT

In an era of social media and online learning platforms, there are several opportunities for learning different technologies and topics that students do not easily understand. However, it also presents challenges by diverting students' attention, such as notifications, multitasking activities, advertisements, etc. Assessing students' level of focus during cognitive tasks is crucial and complex. This study evaluates students' cognitive engagement through various activities, including arithmetic calculations, reading technical articles, listening to technical podcasts, reading transcripts, browsing the internet, and engaging in relaxation exercises, utilizing EEG signals. Concentration levels are classified using deep learning algorithms, specifically Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), and Artificial Neural Networks (ANN). The performance of these algorithms is also evaluated based on metrics such as accuracy, F1 Score, precision, and loss.

I. INTRODUCTION

With the advent of technology, the utilization of mobile phones has witnessed a surge across all age groups. Research has revealed that social networking applications offer users shorter material and can significantly increase their dopamine levels [1]. The floods of dopamine induced by these spikes lead individuals to develop an addiction to rapidly consuming stuff, so negatively impacting their capacity to sustain and concentrate on specific jobs for prolonged durations and acquire new knowledge. It is vital to evaluate the cognitive involvement of an individual when performing various jobs. This will help us determine their degrees of attentiveness to different cognitive focus requirements.

Within the realm of education, the ability to discern pupils' degrees of concentration during the acquisition of new knowledge might potentially enable us to intervene to sustain their attention [2]. The concentration level of students can be inspected by examining their eye contact, body language, and response to a question or communication feedback [3]. The concentration examination techniques are subjective and can be influenced by the student's mood or the external environment. Additionally, different students may have different concentration indicators, so applying one metric to all students will be accountable for inconsistency. It isn't easy to manually assess the concentration level of a student while performing any cognitive task.

To address these issues, a data-driven, objective process is needed to assess concentration levels. EEG is a promising solution for quantifying cognitive focus and engagement [4]. EEG captures electrical signals caused by neuronal communication in the brain, representing the fine-granular, real-time cognitive states. Initially, the EEG device is used for medical diagnosis, for example, for diagnosing epilepsy [5], Parkinson's disease [6], Alzheimer's disease [7], sleep disorders [8], and emotion detection [9], [10]. EEG is now being seriously examined in non-medical fields, such as in education [11–13], human-computer interfaces [10], and cognitive workload estimation [14], [15].

The success of previous studies in classifying cognitive states [14], human emotions [9], and comprehension levels [11], [16] in learning exercises using EEG signals is a proven track record. Cognitive engagement is directly linked to brain activity; EEG can provide a more timely and accurate reading of levels of focus than a test of behaviour [17]. When humans perform different cognitive

efforts, corresponding EEG patterns have different properties [16]. The complexity of EEG signals makes them challenging to analyze, as they are highly non-linear, multi-dimensional, and susceptible to noise. Although traditional machine learning algorithms have been proven capable of doing well in cognitive state classification based on EEG, it is hampered by their hand-engineered feature dependency [18]. The feature engineering process in analyzing EEG is traditionally complex and domain-specific, making scaling difficult.

The traditional algorithms also struggle to capture deep hierarchical representations in EEG signals [19], leading to a non-optimal outcome in concentration prediction. Deep learning is a revolutionizing tool for processing EEG signals, overtaking traditional machine learning algorithms [19]. The combined usage of ANNs and LSTMs in a joint model is highly accurate in cognitive state decoding, making it highly suitable for predictive levels of concentrations [16]. The intersection of deep learning and the processing of EEG signals is opening new paths for real-time monitoring of concentrations in learning, workplaces, and clinics [20]. In online learning contexts, EEG-based prediction of concentration can support adaptive learning systems reacting in a timely manner to learners' cognitive states [11–13], [21].

By identifying periods of lower levels of attention, one can adopt a smart tutoring system for teaching and improve the motivation and retention of the students. In occupational contexts, EEG-based concentration monitoring can enhance productivity by making tailored suggestions for inter-burst periods, task reconfigurations, and workloads [22], [23]. Additionally, in clinical contexts, prediction of levels of concentration can assist in diagnosing, in an early stage, attention-related diseases such as Attention-Deficit/Hyperactivity Disorder (ADHD), allowing for directed treatments for enhanced cognitive well-being [24], [25]. While it is potentially valuable, several challenges exist for EEG-based concentration prediction. The signals in an EEG can vary significantly between different individuals, necessitating robust feature extraction algorithms and adaptation in a specific domain [26], [27]. Computative efficiency is critical for real-time usage, especially for a wearable EEG device [28].

Transfer learning, data augmentation, and attention mechanisms have been tried to enhance a model's adaptability and generality in different populations [12], [21]. This study examines the EEG data collected during five different tasks. Each of these activities necessitates different degrees of cognitive involvement from an individual, necessitating differing amounts of concentration [12]. We employ deep learning algorithms to categorize these signals according to their concentration categories. The rest of the article is organized in the following sections: The related work in detailed and background about the several terminologies used in the experiment is described in section 2, followed by a detailed description of the methodology in section 3. The performance measures used for the described methods are in section 4. The results of the proposed methodologies are discussed in section 5, and finally, the article concludes in section 6.

II. RELATED WORK AND BACKGROUND

This section reviews previous research work using EEG signals to predict concentration, attention level, and cognitive load using deep learning algorithms. The authors [19] presented a comprehensive review of recent advancements in deep learning methodologies for classifying EEG signals. The paper also elucidated the efficacy of various deep learning architectures, including ANN, CNN, LSTM, and MLP, in the processing and analysis of EEG data and compares deep learning approaches with the traditional machine learning techniques, highlighting the superior accuracy and efficiency achieved through deep learning in EEG classification tasks. The authors [16] preferred EEG recordings to classify students' cognitive states during learning activities automatically. The data preprocessing techniques included noise reduction and artefact removal from raw EEG signals, followed by feature extraction using summary statistics from various frequency bands.

Several classification algorithms were used in the study, with logistic regression serving as the primary technique for model training. These algorithms include local models, global models, and multi-task learning approaches. According to the data, global models—which take into account more contextual information—predict recall levels more accurately than local models, which predict concentration levels with an accuracy of 91.88%. To address the impact of distractions on cognitive performance, the authors used EEG signals to classify human concentration levels [21], [29]. The dataset comprises brain signals collected using an EEG device from individuals in both relaxation and concentration states. This data was preprocessed using high-pass filtering to eliminate low-frequency noise and segmentation of signals into the delta, theta, alpha, and beta frequency bands.

Statistical features were calculated using the PyEEG library to extract features. The classification of concentration levels is executed using the Support Vector Machine (SVM) algorithm with a radial basis function (RBF) kernel, achieving an overall accuracy of 84% to classify EEG signals into low and high concentration levels. The research findings of [30] suggested that effective brain-machine interfaces can be developed for distinguishing mental states, even with inexpensive EEG devices. The authors used a low-cost, toy-grade EEG device to collect EEG signals to classify relaxed and concentrated mental states. Data was preprocessed by converting raw EEG signals into time-frequency representations and aggregating spectral components into EEG bands such as alpha, beta, and gamma.

The SVM and multilayer feedforward neural networks (BPNN) classification algorithms were preferred in the study. Experimental results demonstrated that using features from the combined alpha, beta, and gamma bands with a bandwidth of 4Hz yields an average accuracy exceeding 80% across subjects, with some individuals achieving accuracies above 90% using the SVM classifier. The authors put forward a strong correlation between students' concentration levels and learning outcomes by analysing brain signals captured by an EEG device [31], [32]. The brain wave data was collected from junior high school students performing cognitive tasks, specifically the Culture Fair Intelligence Test (CFIT) and the Indonesian Competency Test (CT). EEG signals were extracted using Fast Fourier Transform (FFT) followed by normalization to standardize the data range.

The study used the K-Nearest Neighbor (KNN) algorithm, with a K-value of 5 for identifying patterns in the extracted data and reports an impressive classification accuracy of 94.59% to classify concentration levels. The classification accuracy was evaluated using K-Fold Cross Validation with a K-value of 11. The study by [22] investigated young adults' (ages 18-30) cognitive activity and concentration levels using EEG data. At the same time, participants performed IQ tests based on the Standard Progressive Matrices

(SPM). The data preprocessing involved signal reduction and filtering beta waves in the frequency range of 13-30Hz to enhance the data quality. The classification of concentration levels was performed using the k-nearest Neighbor (KNN) algorithm into three categories: high, medium, and low. The model achieved an accuracy of 70%, providing insights into the correlation between brain activity and cognitive performance. The paper presented by [33] gave a method for classifying EEG signals into three mental states: relaxation, moderate, and high concentration.

The brain signals were captured using an EEG device with four electrodes and preprocessed by applying a large Laplacian filter, a notch passive filter, and a wavelet filter. Mental states in the time domain were examined by segmenting the measured signal into windows, from which various features are extracted. These extracted signals were utilized in machine learning algorithms to classify the different mental states. The two-fold cross-validation method was used to evaluate the classification. A novel model tailored for embedded systems to classify attention levels while performing specific tasks. This system used a single-channel EEG device to capture brain signals that were subsequently increased through spectrum analysis to increase the dimensionality of the features. The authors used simulated annealing and geometric particle swarm optimization algorithms to optimize feature selection. Classification of mental states (concentrated or relaxed) was achieved using an SVM. Furthermore, Echo State Networks, a class of neural networks well-suited for embedded systems, demonstrated satisfactory accuracy in meeting the model's requirements [34].

The research paper [13] tackled the critical issue of assessing student attention in online learning, a challenge intensified by the COVID-19 epidemic. The authors proposed a brain-computer interface (BCI) system that uses EEG data to evaluate student involvement and attention levels. A publicly available EEG dataset was preferred, and the quick Fourier transform extracted power spectral density (PSD) features and various attention metrics were calculated. The study encompassed three classification algorithms: KNN, SVM, and random forest (RF), with the RF model achieving the highest accuracy of 96% in holdout validation. The method encompassed data collection, preprocessing, feature extraction, and model training, culminating in classification performance assessment. The results indicated that the suggested RF model successfully differentiates attention states, presenting a viable alternative for improving online learning experiences.

The classification of normal and pathological EEG patterns using deep learning models enhanced with attention mechanisms is investigated in the paper [26]. A systematic approach was used to preprocess EEG data to filter and normalize signals, extract time-domain and frequency-domain features, and segment the data into frames for study. The authors tested InstaGATs, LSTM with Attention, and CNNs with Attention against baseline models without attention mechanisms. The CNNs with Attention model has the highest accuracy of 96.98% on the TUH EEG Seizure dataset. The research faced intrinsic noise in EEG recordings, the difficulty of distinguishing anomalies, and the need for efficient feature extraction from varied datasets. Attention processes can improve classification performance by stressing relevant data items and enhancing clinical EEG analysis interpretability and efficacy. Attention-enhanced deep learning models can significantly improve EEG classification tasks, enabling more robust implementations in real applications.

II.1 BACKGROUND

II.1.1 EEG Device

The neuron is the smallest unit of the human brain. Electric signals are generated when neurons communicate with each other. An electroencephalogram is a device used to capture the electrical signals generated by neurons in the brain. These electrical signals are recorded with the electrodes of an EEG device. With the help of electric signals captured by EEG devices, abnormal changes in the brain can be detected, which is why EEG devices are widely used in the medical sector to diagnose brain-related diseases such as epilepsy, sleep disorders, and so on. In recent years, EEG devices have also been utilized in the education sector to solve various research problems, such as determining attention levels, mental engagement, and cognitive load. This study uses a MUSE EEG device to record brain wave data while performing various cognitive tasks. This device has four electrodes named FP1 and FP2, located in the frontal lobe of the brain, and TP9 and TP10, located in the parietal lobe of the brain, as shown in Figure 1.

Table 1: Types of Brain Waves.

Types of Wave	Frequency (Hz)	Task
Delta	0.5 – 4	Deep sleep
Theta	4 – 8	Relaxing or meditating
Alpha	8 – 12	Just after woke up and before going to sleep
Beta	12 – 35	Routine work
Gamma	> 35	Deep concentration on some task or doing cognitive activity

Source: Authors, (2026).

II.1.2 EEG Signals

Five different types of brain waves are emitted by the brain and recorded using an EEG device, as shown in Table 1. Delta and theta waves are small amplitude waves emitted, implying an individual's deep sleep or relaxation. Their frequency ranges from 0.5Hz to 8Hz. These waves are produced in large quantities as compared to other types of waves while doing tasks such as relaxing with closed or open eyes, browsing the internet, and so on. When humans are in partial sleep, waking up, or transitioning into a deep sleep state, the brain emits alpha waves with a frequency range of 8Hz to 12Hz. The beta and gamma waves indicate high cognitive activity. Their frequency range is 12Hz to 35Hz and >35Hz, respectively. Among all the waves, gamma and beta waves are produced in large quantities with more intensity while doing high-concentration tasks such as doing arithmetic calculations or reading technical articles.

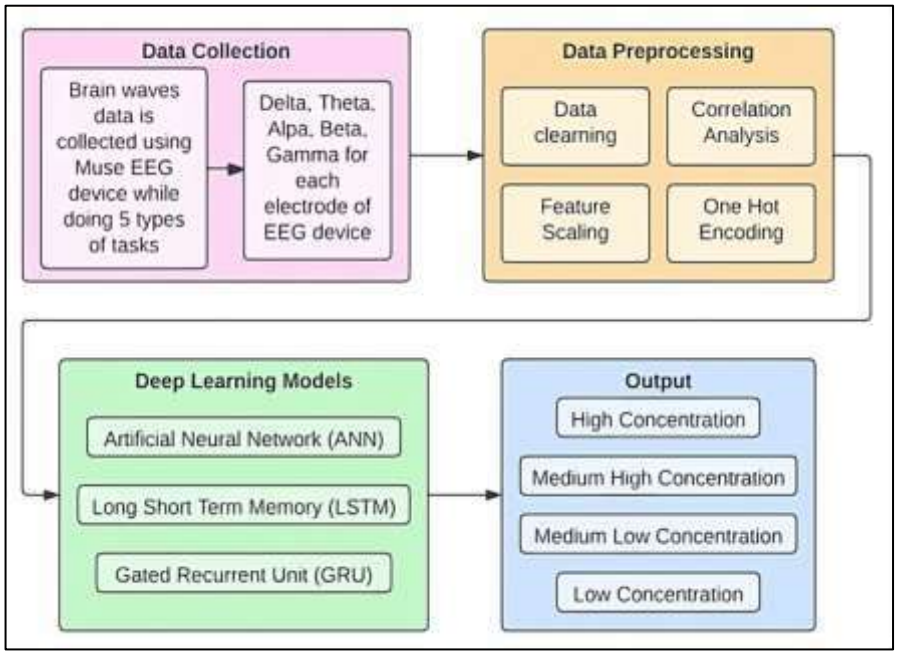

Figure 2: Flowchart Diagram of the Proposed System.

III. METHODOLOGY

The proposed methodology for predicting concentration levels utilizing EEG signal inputs and deep learning algorithms is presented in Figure 2. The procedure has four major phases: Data Collection, Data Preprocessing, Deep Learning Models, and Output Classification. Data collection refers to the methodology employed in acquiring the necessary brain wave data for forecasting concentration levels using an EEG device, the parameters included in the dataset, the number of features present, and the associated concentration levels for each recorded instance. The subsequent phase is data preprocessing, which involves preparing the data as input for deep learning algorithms. The process entails cleaning the data to eliminate redundant data, correlation analysis to identify pertinent features for predicting their target variable, feature scaling to prevent bias in weight assignment during deep learning model training, and one-hot encoding for the transformation of the target variable. The subsequent phase involves training various deep learning models—ANN, LSTM, and GRU—and evaluating their accuracies on test data to assess their performance on unknown data. The data input for these algorithms is categorised into four distinct classes: high concentration, medium-high concentration, medium-low concentration, and low concentration.

Table 2: Concentration Level for Corresponding Tasks.

Task	Concentration Level
Performing Arithmetic Calculations	High
Reading Technical Articles, listening to technical podcasts	Medium-High
Reading the transcripts	Medium-High
Browsing the Internet	Medium-Low
Just sitting there, eyes open or closed	Low

III.1 DATA COLLECTION

The dataset used for predicting an individual's concentration level during activities of varying levels of attention is shown in Figure 3. An individual wears the Muse EEG device on their scalp while participating in five activities. Table 2 gives the activities' details and associated concentration levels. The EEG device has four electrodes, to which we assign the numbers 0, 1, 2, and 3. Five different types of brain waves—delta, theta, alpha, beta, and gamma—are captured from each electrode while performing each task.

The captured brain waves are labelled with their names and subscripted with the electrode number to neatly identify the features in the dataset. For instance, if electrode 0 captures waves in the frequency range of 0.5 to 4Hz (delta wave frequency), we will refer to that frequency as "delta0". In this way, all 20 features (five types of brain waves from each of the four electrodes) in the dataset are captured by an EEG device and labelled according to the given method. For each record, the concentration level (low, medium low, medium high, and high) has been assigned as shown in Table 2. This dataset serves as the basis for identifying an individual's cognitive engagement.

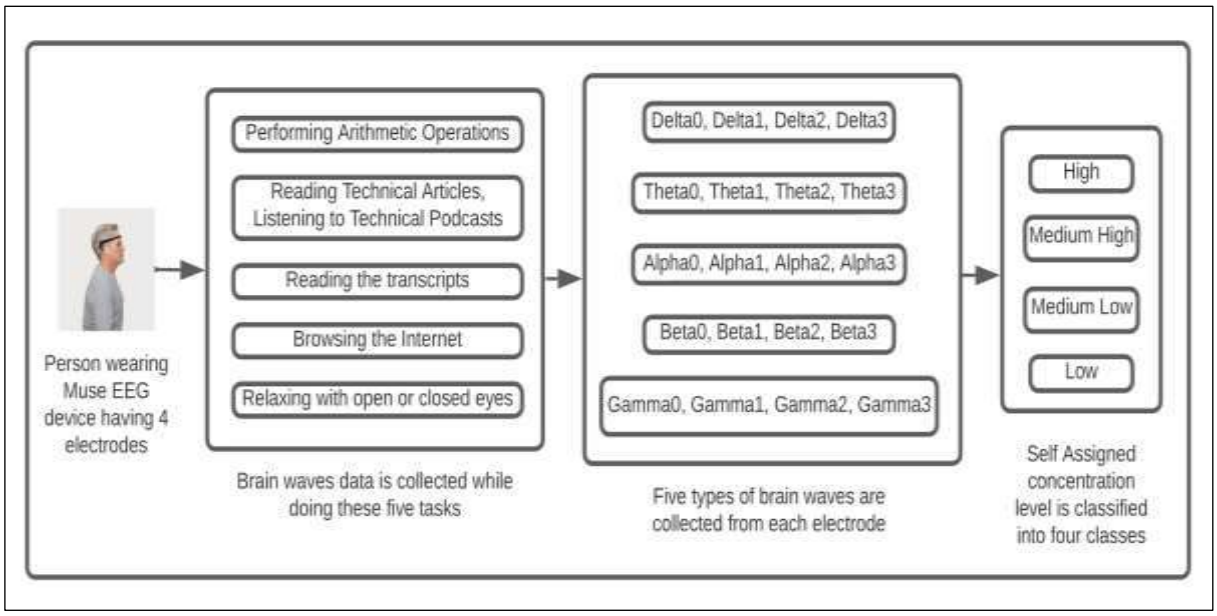

Figure 3: Data Collection Process.

III.2 DATA PREPROCESSING

Data preprocessing is the most crucial step after data collection and before applying any deep learning algorithm. The following four steps are performed to prepare the collected brain wave data in the required format to provide as input to the algorithms.

a) **Data Cleaning:** When an EEG device's electrodes capture brain wave data, there is a strong possibility that eye movements or even slight head movements could introduce noise into the data. Eliminating that noise is important before going ahead to ensure the correct predictions. The integrated software on the device has already removed noise from the collected dataset.

b) **Correlation Analysis:** Correlation analysis involves finding the direct relationship between the target variable and the input features of the dataset. There are two types of correlation: positive correlation, which means if input features are increasing, then the value of the target variable will also increase, and vice-versa. Another type is negative correlation, which means if input features are increasing, then the value of the target variable will decrease, and vice versa. In the current study, the target variable is an individual's concentration level, while the input features are five types of brain waves captured from four electrodes. Correlation analysis proves no positive or negative correlation between the input features and target variables.

c) **Feature Scaling:** Due to the varied frequency ranges in brain wave data, deep learning models might give greater importance to higher-magnitude values during training and less importance to lower-magnitude ones. To address this possible bias, a scaling approach is used to normalize the data by adjusting each feature's minimum and maximum values to 0 and 1, respectively. The following formula will calculate the new scaled value:

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (1)$$

This formula normalizes the values of all features. This process ensures that all features are treated equally, preventing magnitude-based bias in the training process.

d) **One Hot Encoding:** The concentration level feature is converted using one-hot encoding, a technique that transforms categorical data into numerical arrays with a length equal to the number of unique categories as stated by [12]. For this case, we have four distinct categories of concentration levels, i.e., High concentration, Medium high concentration, Medium low concentration, and Low concentration, resulting in an array length of four.

This procedure produces binary vectors, in which the element matching the appropriate class is assigned a value of one while all other elements are set to zero. For example, if we had a brain wave record that indicates high concentration during a task, the corresponding one-hot encoded array would be [1 0 0 0], where 1 will denote the current record is for the High concentration level task, and other classes will be set to 0. In this way, brain wave records are encoded using one-hot encoded arrays and then used as input for future processing and analysis.

III.3 DEEP LEARNING ALGORITHMS

Preprocessed data is provided as input to three deep learning algorithms: Artificial Neural Network (ANN), Long Short-Term Memory (LSTM), and Gated Recurrent Unit (GRU). All the models use one input layer, three hidden layers, and one output layer. The output layer contains four neurons and uses the softmax activation function, which is best for multiclass classification problems. All three models are trained with 70% and tested on 30% of the data. A categorical cross-entropy loss function is used since predicting the concentration level is a multi-class classification problem. To update the weights while training these models, the Adam optimizer is used as an optimization algorithm instead of the classical stochastic gradient descent procedure.

a) **Artificial Neural Network (ANN):** The neuron is the fundamental component of an Artificial Neural Network (ANN). ANN consists of several linked neurons that process information by applying weights and activation functions. Each time the neuron receives an input, a random weight is assigned to that value, which shows the significance of that value in the prediction process. Subsequently, all the data is combined and given to an activation function. This activation function introduces non-linearity in the data. Lastly, the output is computed. The error is backpropagated, and the weights are modified based on the difference between the calculated and actual output to minimize the difference. The accuracy of an ANN increases as the difference decreases. The preprocessed data of the brain waves is given as input to the ANN to predict the concentration level while doing different cognitive tasks. The architecture of the ANN model is illustrated in Figure 4. The input layer of the ANN consists of 12 neurons and employs the ReLU activation function. It features three hidden layers with 128, 256, and 128 neurons, each utilizing the ReLU activation function. The output layer comprises four neurons, which classify the data into four different concentration classes and use the softmax activation function, which is optimal for multiclass classification tasks.

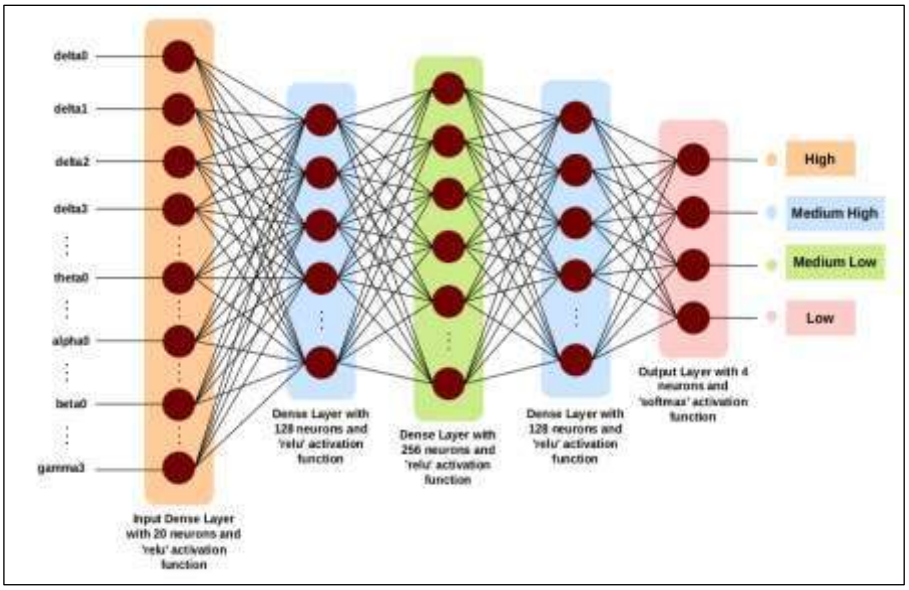

Figure 4: Architecture of Proposed Artificial Neural Network.
Source: Authors, (2026).

b) **Long Short Term Memory (LSTM):** Brain wave data refers to the frequency of electrical activity recorded over time, similar to time series data. Recurrent neural networks do well in processing time series data, but cannot learn long-term dependencies. LSTM networks are a specific form of recurrent neural networks that successfully overcome this drawback. The fundamental structure of LSTM includes the cell state, the input gate, the output gate, and the forget gate. The cell state is the central part of the LSTM network, which stores long-term dependencies and decides which information to let go of and which information to send for further analysis. The other three gates regulate the flow of information: the input gate admits new data, the output gate outputs the information, and the forget gate erases redundant data. The LSTM network uses the truncated backpropagation of error to enhance its accuracy and train it to understand long-term data dependencies. The architecture of the LSTM has been illustrated in Figure 5.
It consists of three LSTM layers, each containing 128, 256, and 128 neurons. The activation function used in these layers is the Rectified Linear Unit (ReLU). The input comprises preprocessed and reshaped data that is suitable for LSTM cells. After undergoing additional processing through three LSTM layers, the data ultimately reaches the output layer, which consists of four neurons for each concentration level class. The softmax activation function is employed as it is the most suitable choice for multiclass classification tasks.

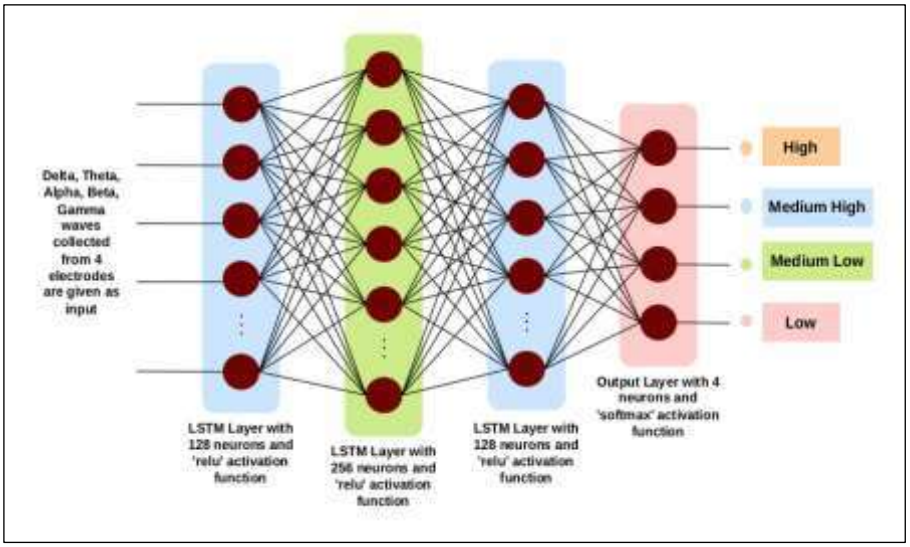

Figure 5: Architecture of Proposed Long Short-Term Memory.
Source: Authors, (2026).

c) **Gated Recurrent Unit (GRU):** GRUs is a kind of RNN that addresses the limitations of LSTM networks and traditional RNNs. Unlike LSTM, which is a cell state, the basic unit of GRU is the hidden state. Compared to LSTM, the GRU has fewer gates. The gates include the reset gate, which forgets redundant information, and the update gate, which balances past information and new important data for longer. Due to its reduced number of gates and parameters, the GRU model can be trained more quickly than the LSTM. The architecture of the GRU model has been illustrated in Figure 6. It consists of one input layer, three dense GRU layers, each containing 128, 256, and 128 neurons, and the output layer, which consists of four neurons for each concentration level class. The ReLU is the activation function in these layers. The input comprises preprocessed and reshaped data that is suitable for GRU cells. After undergoing additional processing through three GRU layers, the data ultimately reaches the output layer, where the softmax activation function is employed because it is the most suitable choice for multiclass classification tasks.

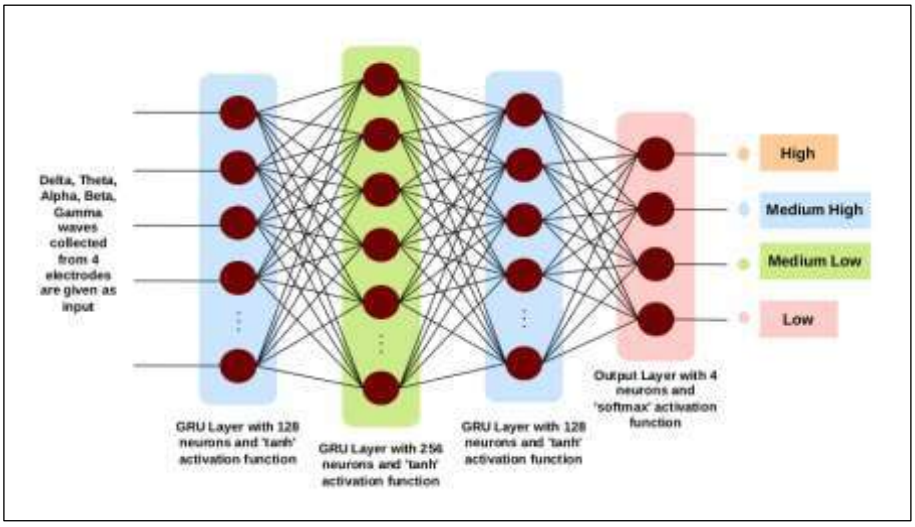

Figure 6: Architecture of Proposed Gated Recurrent Unit.

IV. PERFORMANCE MEASURES

Performance evaluation ensures the proposed methodology's efficiency, validity, and applicability. The proposed models are evaluated using the following metrics.

a) **Confusion Matrix:** A confusion matrix is a crucial performance evaluation tool that encapsulates the accuracy of a classification model. It helps to determine where our model underperforms when differentiating between classes. The matrix enumerates the counts of true positives (TP), which reveals how frequently a model accurately identifies a positive sample as positive; true negatives (TN), which means the frequency with which a model labels a positive sample as negative; false positives (FP), which indicate how frequently a model wrongly labels a negative sample as positive; and false negatives (FN), which reflects how often a model accurately labels a positive sample as Negative. According to data analysis, these four categories can be specified for the high concentration class as follows: TP refers to the number of instances in which the recorded brain waves indicative of high concentration were accurately classified by proposed algorithms.

TN relates to cases where the proposed algorithms accurately predict brain wave recordings classified as non-high concentrations belonging to other categories, such as medium-high, medium-low, or low concentrations. FP denotes false positives, indicating the frequency of brain wave records that belong to different classes but are incorrectly classified by the proposed system as belonging to the high-concentration class. FN denotes false negatives, indicating the frequency of brain wave recordings associated with high-concentration tasks misclassified as belonging to concentration classes other than high-concentration activities when processed by the proposed system. Specifically, a confusion matrix is an N × N matrix employed to assess the performance of a classification model, where N denotes the total number of target classes. It compares the actual values of the target class in the dataset with the predicted target class by the proposed model; if both match, then the prediction is correct; otherwise, it is not. It helps to identify how well our classification model performs and what kinds of errors it makes.

b) **Accuracy**: Accuracy metrics provide insight into how well the proposed model classifies a specific data set into the appropriate class. Accuracy is calculated as the percentage of accurate predictions over all other predictions.

$$Accuracy = \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{TN} + \mathrm{FP} + \mathrm{FN}} \tag{2}$$

Equation 2 provides the formula for calculating accuracy and finds the per centage of correctly classified brain wave records to each class among all the predictions.

c) **Precision:** Precision measures the percentage of true predictions within all positive predictions. The proportion of accurately categorized positive samples (TP) to the total number of positively classified samples (either correctly or incorrectly) is known as precision, as given in Equation 3.

$$Precision = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FP}} \tag{3}$$

Regarding the classification problem, precision is the rate at which the proposed model accurately classifies a given brain wave record to the actual concentration class. The precision value increases as the number of FP decreases. FP refers to the number of records that do not belong to a specific class but are falsely classified as belonging to that class. FP increases when the model has not accurately learned the parameters to detect records that do not belong to the current class. That is why the model erroneously classifies the brain record as positive. Increased precision indicates that the model has effectively learned the parameters that allow it to classify records accurately, distinguishing which belong to a specific class.

d) **Recall:** The recall is determined as the proportion of correctly identified positive samples, i.e., TP to the total number of actual positive samples, which encompasses both TP and those that are positive but incorrectly identified as negative (FN), as given in Equation 4 as shown below:

$$Recall = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}} \tag{4}$$

The recall value increases as the FN decreases. FN represents the count of records that belong to a specific class but are misclassified as belonging to another class. FN will increase when the model has not accurately learned the parameters necessary to identify data belonging to the current class. That is why the model erroneously categorises the brain record as negative. A higher recall indicates the model has not effectively learned the parameters to classify this data into the right class.

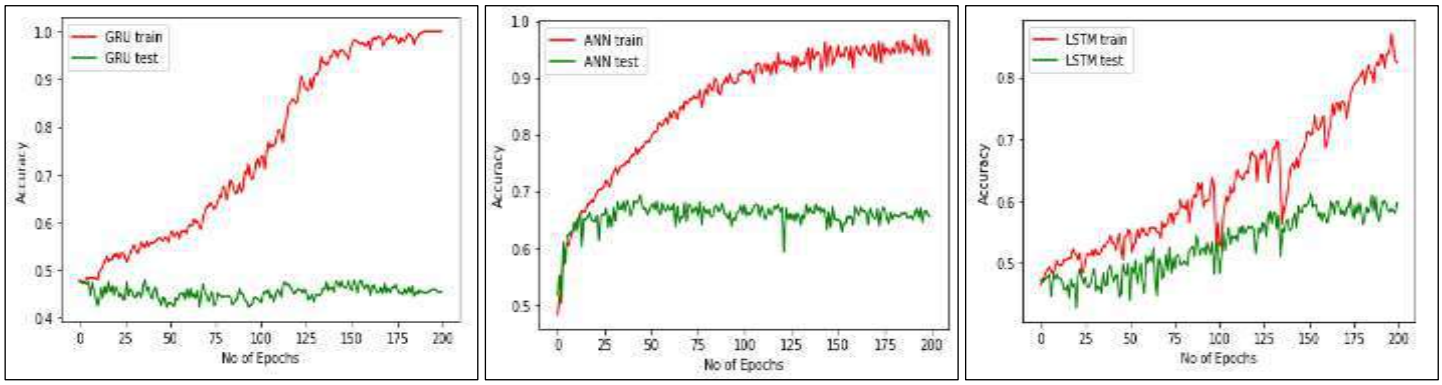
e) **F1 Score:** The F1 Score, defined as the harmonic mean of precision and recall, offers a consolidated metric that integrates precision and recall, thus equilibrating the trade-off between these two measures. The formula to calculate the F1 Score using precision and recall is given in Equation 5.

$$F1\ Score = 2 * \frac{\mathrm{Precision} * \mathrm{Recall}}{\mathrm{Precision} + \mathrm{Recall}} \tag{5}$$

Since FP influences precision, and FN influences recall. Evaluating both precision and recall when computing the F1 Score enables one to assess the model's capacity to identify FP and FN. As the number of data points for each class differs in an unbalanced dataset, the proposed model must discern the parameters that accurately classify each record as belonging or not belonging to a specific class. If precision is the sole performance indicator, the model's capacity to accurately identify positive records may be overlooked. On the other hand, focusing solely on recall could hinder the model's capacity to identify bad records. Both features are essential for an effective model. The F1 Score is an excellent indicator for assessing model performance, as it mitigates the substantial bias inherent in precision and recall.

V. RESULT ANALYSIS AND DISCUSSION

This section presents the results of implementing deep learning methods for predicting concentration levels, demonstrating how an individual engages cognitively in different attention activities. The dataset has 20 features, including five unique brain wave frequencies, each recorded from four electrodes. The data set undergoes data preprocessing, which includes cleaning, correlation analysis, feature scaling, and one-hot encoding of the target variable. After this, the dataset is fed into three deep-learning algorithms to predict concentration levels in four categories. The preprocessed dataset is partitioned into two subsets, with 70% of the data utilized for training the model and the remaining 30% used for evaluating its performance.



The models, including ANN, LSTM, and GRU, are trained for 200 epochs using different batch sizes. The ANN model uses a batch size of 5, the LSTM model uses a batch size of 64, and the GRU model uses a batch size of 32. The additional parameters for training these models are specified in Table 3. The performance of models is evaluated using various measures, including accuracy, precision, recall, and F1 Score.

Table 3: Parameter values used to train deep learning models.

Parameter	Values
Optimizer	Adam
Loss Function	Categorical Cross-entropy
Metric	Accuracy
Epoch	200

Source: Authors (2026).

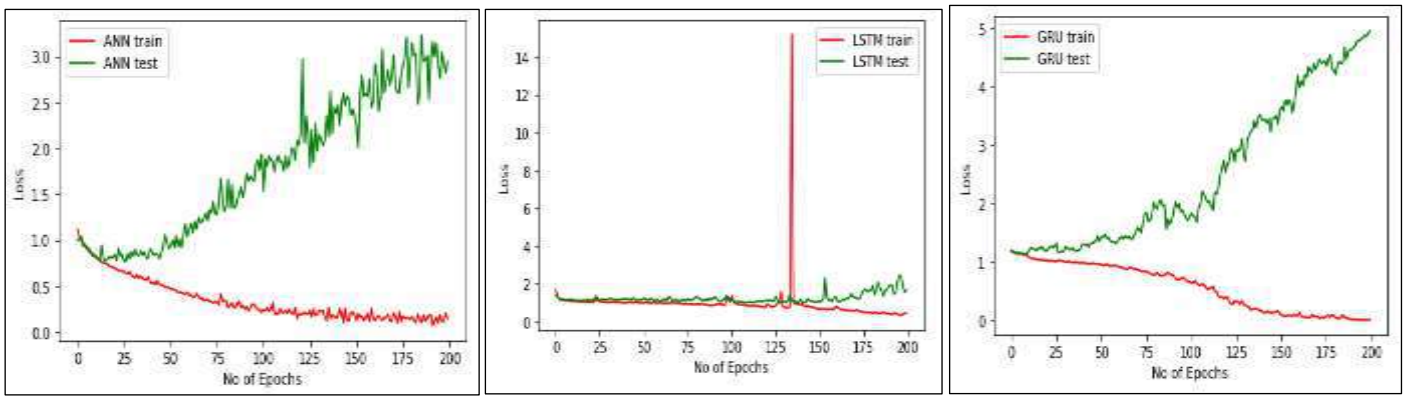


Figure 7 shows that ANN's training and testing accuracies steadily increase up to 50 epochs. After that, although there is an increase in training accuracy, the testing accuracy shows only a slight improvement. In the case of LSTM, both the training and testing accuracies show fluctuations until the 125th epoch. However, after this point, the testing accuracy remains constant, regardless of the continued increase in training accuracy. The GRU model consistently improves training accuracy up to 100 epochs, whereas testing accuracy remains relatively stable. The ANN, LSTM, and GRU models demonstrate overfitting of the data at epochs 50, 125, and 50, respectively.

(a) GRU (b) ANN (c) LSTM

Figure 7: Training and Testing Accuracy of Deep Learning Algorithms.
Source: Authors (2026).

The same phenomena are observed from the loss graphs in Figure 8. The training and testing loss for ANN reduces up to 50 epochs, LSTM up to 125 epochs, and GRU up to 100 epochs. However, after that point, only the training loss decreases while the testing loss increases, suggesting that the models are overfitting the data. Figure 9 compares the classification accuracy of algorithms ANN, LSTM, and GRU. The ANN achieves maximum accuracy, which is 65.63%, followed by LSTM, which is 59.67%, and GRU networks, which is 45.39%.

(a) ANN (b) LSTM (c) GRU

Figure 8: Training and Testing Loss of Deep Learning Algorithms.
Source: Authors (2026).

The imbalance of the data set, as indicated in Table 4, compromises the reliability of accuracy as a sole metric for assessing the performance of deep learning models. There is a need to determine the model's ability to correctly classify the major class (containing a more significant number of records) and the minor class (containing a smaller number of records). The accuracy of the models for each class is provided in the confusion matrix for each deep learning technique mentioned in Table 5. The confusion matrix indicates that the ANN model exhibits a higher count of TP and TN than the LSTM and GRU models. Precision verifies the model's quality, determining the accurate classification of positive samples from the total number of positive samples.

As depicted in Figure 10a, the ANN model exhibits marginally superior precision to the LSTM network for the low and medium high concentration classes. Conversely, the LSTM network demonstrates higher precision than the ANN for the high and medium low concentration classes. Recall is a measure of quantity that identifies the number of correctly classified positive samples from the total number of positive samples. A model with a high recall value will yield more relevant results. Based on the data presented in Figure 10b, it is evident that ANN exhibits superior performance in tasks involving high and medium-high concentrations. On the other hand, LSTM networks demonstrate better performance in tasks involving low concentrations. ANN and LSTM networks exhibit similar recall values for tasks involving medium-low concentrations.

Table 4: Number of records for each concentration level class.

Class	No. of Records
High Concentration	3410
Medium_High Concentration	501
Medium_Low Concentration	909
Low Concentration	2423

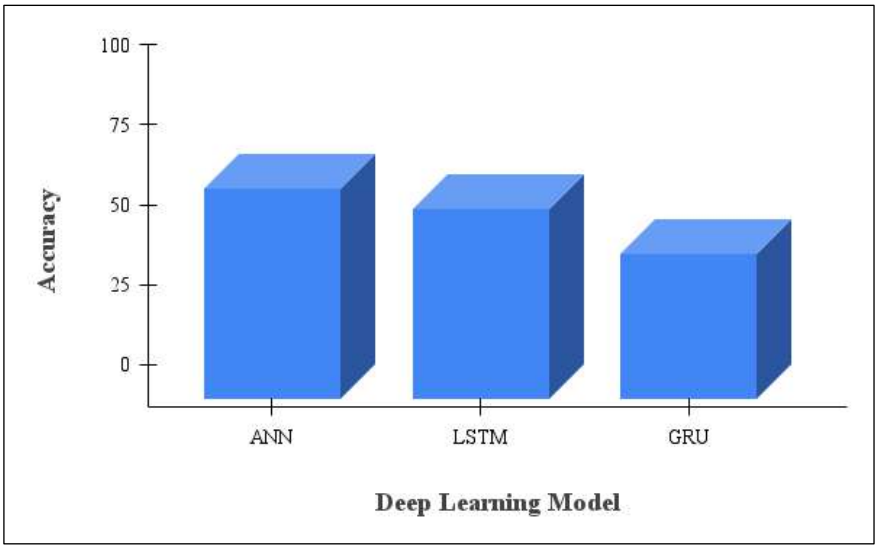

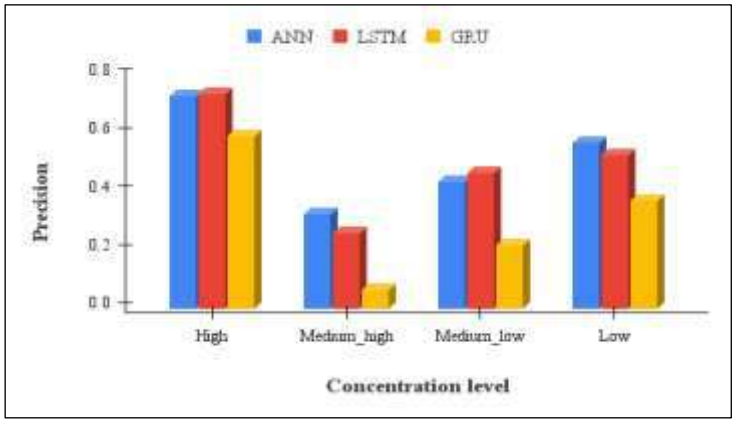

Figure 9: Comparison of Accuracies of Deep Learning Algorithms.
Source: Authors, (2026).

Support is a measure of the class frequency that appears in the dataset. Due to the imbalance in the dataset, which can be seen in Figure 10d, the precision and recall values are likely to be biased. To address this issue, the F1 Score metric, the harmonic mean of precision and recall, is computed to measure the model's overall performance. Figure 10c shows that the ANN model has a higher F1 Score for high and medium high concentrations classes than other models. For low and medium low concentration classes, LSTM networks have a slightly higher F1 Score than ANN.

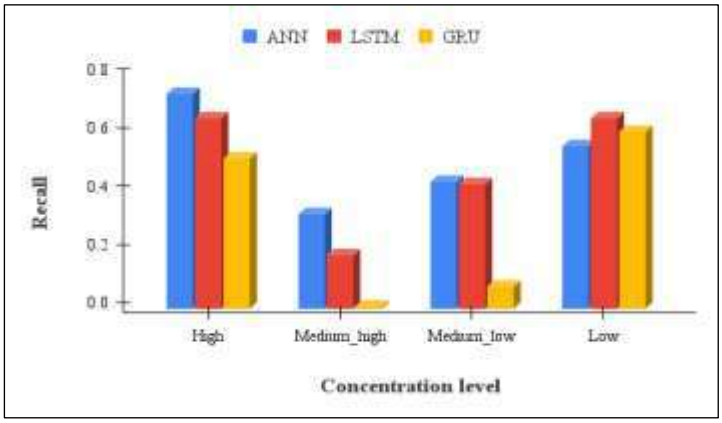

Table 5: Confusion Matrix of Deep Learning Algorithms.

Algorithm	True Value	Predicted Value			
		High	Medium_High	Medium_Low	Low
ANN	High	575	38	27	74
	Medium_High	36	32	8	19
	Medium_Low	32	13	56	77
	Low	117	11	46	288
LSTM	High	547	34	44	209
	Medium_High	53	22	10	34
	Medium_Low	27	10	100	96
	Low	114	18	60	380
GRU	High	430	6	45	353
	Medium_High	44	1	9	65
	Medium_Low	42	2	18	171
	Low	207	6	10	349

VI. CONCLUSION

This study used recorded brain signals from the Muse EEG device to compare the effectiveness of three deep learning algorithms in predicting concentration levels while performing various cognitive tasks such as arithmetic calculations, reading technical articles, listening to technical podcasts, reading transcripts, browsing the Internet, and simply relaxing with closed or open eyes. Deep learning algorithms, such as ANN, LSTM, and GRU, are used to analyse the brain signals; of these, ANN provides the best accuracy (65.63%), followed by LSTM (59.67%) and GRU (45.39%). ANN outperformed LSTM and GRU networks in accurately predicting concentration levels by analysing EEG data.

When evaluating the F1 Score, ANN demonstrated superior performance in classes with high and medium-high concentrations. Still, LSTM networks perform better for classes with low and medium-low concentrations than the other two networks. This study utilizes the brainwave data obtained from the Muse EEG equipment, equipped with four electrodes, to predict the degree of concentration. To further enhance this research in the future, one can augment the data collection process by collecting brainwave data from several people using an EEG device equipped with many channels. Subsequently, the data collected can be examined to identify the underlying trends in the brainwave data and to build a reliable deep-learning model to evaluate the students' cognitive involvement.

ABSTRACT

Breast cancer stands as one of the most formidable challenges in contemporary global healthcare, with approximately 18.1 million new cancer cases reported worldwide and an urgent need for revolutionary advances in early detection methodologies. Current breast cancer diagnostic methodologies present significant limitations through unimodal approaches, where mammography suffers from masking effects and false positives/negatives, thermography demonstrates low specificity of 57.8%, and clinical tabular data alone proves insufficient for definitive diagnosis. This research presents a comparative study of four late fusion strategies for breast cancer diagnosis, integrating predictions from deep learning models trained on mammography images, thermography images, and clinical tabular data. The fusion methods evaluated include probability multiplication (product rule), weighted averaging, stacking metaclassifier, and log-opinion pool fusion. The log-opinion pool fusion method achieved superior performance with 97.5% overall accuracy, surpassing the other fusion approaches and all individual. The method has also achieved precision of 0.91–0.95 for benign cases 1.00 for malignant cases, with fusion approaches maintaining zero false positive rate and recall for malignant cases up to 95%.

I. INTRODUCTION

Breast cancer stands as one of the most formidable challenges in contemporary global healthcare. It has consistently maintained its position as the most frequently diagnosed cancer among women globally, while simultaneously serving as a leading cause of cancer-related mortality. The World Health Organization's data reveal approximately 18.1 million new cancer cases reported worldwide in 2020, where breast cancer contributed significantly to this staggering figure, ultimately resulting in 9.6 million cancer-related deaths [1], hence the urgent and critical need for revolutionary advances in early detection methodologies, as the window of opportunity for successful treatment narrows dramatically with delayed diagnosis.

Medical evidence consistently demonstrates that patients diagnosed during the early stages of breast cancer experience dramatically improved treatment outcomes, enhanced therapeutic efficacy, and substantially higher survival rates compared to those diagnosed at advanced stages [2]. However, the current landscape of breast cancer diagnostic methodologies presents significant limitations that compromise the reliability and accuracy of early detection efforts. This diagnostic inadequacy represents a critical gap in healthcare delivery that demands immediate attention and innovative solutions.

In parallel to diagnostic innovation, there is growing interest in novel, non-thermal therapeutic modalities for breast cancer. For instance, plasma-activated water has demonstrated selective cytotoxic effects against breast cancer cells, representing a promising direction for integrated therapeutic strategies alongside advances in diagnostic imaging [3].Contemporary breast cancer detection predominantly relies on unimodal diagnostic approaches, each carrying inherent limitations that collectively contribute to suboptimal diagnostic accuracy [4].

Mammography faces substantial challenges that compromise its diagnostic reliability such as dense fibroglandular tissue that can effectively mask tumors, creating a phenomenon known as masking effect, which substantially reduces the visibility of malignant lesions [5]. Furthermore, mammography demonstrates concerning vulnerability to both false negative results, where existing cancers remain undetected, and false positive results, which incorrectly indicate the presence of cancer. Advanced segmentation methods such as the Expectation-Maximization Gaussian Mixture Model (EM-GMM) have shown promise for improving the identification of suspicious areas in mammograms, supporting subsequent analysis and diagnosis [6]. False negatives delay crucial treatment interventions, while false positives generate unnecessary patient anxiety and often trigger invasive follow-up procedures that could have been avoided with more accurate initial screening.

Thermography, while offering promising advantages as a non-invasive and radiation-free diagnostic modality that detects metabolic activity-related temperature changes associated with tumor presence, presents its own set of critical limitations. Historical analysis reveals that thermography suffers from significantly lower specificity compared to mammography, with documented specificity rates of only 57.8% compared to mammography's 73.3% [7]. This reduced specificity stems primarily from thermography's inability to detect minute calcium deposits, known as microcalcifications, which are often successfully identified through mammographic examination. The poor specificity rate of 55.7% attributed to high False Positive Rates (FPR) further undermines thermography's reliability as a standalone diagnostic tool.

Clinical tabular data, exemplified by datasets such as the Breast Cancer Wisconsin (Diagnostic) dataset, provides valuable numerical insights derived from fine needle aspiration (FNA) analysis, including cellular characteristics such as size, shape, and texture. However, when utilized in isolation, this data modality proves insufficient for definitive diagnosis. While these numerical features originate from image analysis and offer detailed cellular-level information, they fundamentally lack the comprehensive visual representation of tissues and cells that imaging modalities provide. The emergence of multimodal diagnostic approaches represents a paradigm shift in breast cancer detection methodology, offering unprecedented potential to overcome the limitations inherent in unimodal systems.

This performance is comparable to other healthcare applications where binary classification methods have achieved high accuracy with fast computational performance [8]. By strategically combining information from multiple data sources, multimodal approaches can leverage complementary information streams to achieve more accurate and comprehensive diagnostic outcomes. However, despite the considerable research efforts invested in this domain, significant opportunities remain for advancement, particularly in the development of optimal fusion strategies that can maximize the diagnostic potential of multimodal data integration. This research presents a novel late fusion approach for breast cancer diagnosis that uses probability multiplication to combine predictions from independent deep learning models trained on mammography images, thermography images, and clinical tabular data.

Unlike traditional fusion methods that rely on simple averaging, this sophisticated probability multiplication strategy strengthens diagnostic confidence when models agree while maintaining robustness during disagreement, preserving each modality's independent feature extraction while enabling advanced decision-level integration. The methodology addresses critical gaps in current multimodal medical diagnostics by developing specialized architectures for each data type, with the final classification determined by the highest probability after mathematical multiplication of individual model outputs. This timely research leverages the growing availability of diverse medical data and advancing deep learning technologies to potentially improve diagnostic accuracy, reduce healthcare costs associated with false positives and negatives, minimize patient anxiety, and ultimately save lives through earlier and more reliable breast cancer detection.

II. MATERIALS AND METHODS

This research implements an end-to-end multimodal late-fusion framework for breast cancer detection that independently processes mammography, thermography, and structured clinical data through modality-specialized networks (ResNet50 for imaging an a DNN for tabular data), producing class-posterior probabilities per branch for decision-level integration, as illustrated in . Four alternative late-fusion strategies are comparatively assessed at inference, that is product rule, weighted averaging, log-opinion pool, and stacking meta-classifier while preserving modular feature extraction and auditability for each modality. The solution is evaluated based on accuracy, precision, recall, F1-score, macro/weighted averages, and confusion matrices metrics with a balanced 40-sample test set across all branches and fusion rules. The final model is selected by optimizing a predefined validation objective (e.g., macro-F1 or accuracy) under clinically motivated sensitivity–specificity considerations, and the chosen operating point is documented with per-class metrics and confusion matrices for interpretability and clinical relevance.

II.1 DATASET DESCRIPTION AND MODALITY CHARACTERISTICS

The research utilizes three carefully selected datasets representing different aspects of breast cancer diagnosis. The Breast Cancer Wisconsin (Diagnostic) dataset [9] provides clinical tabular data containing 30 numerical features derived from fine needle aspiration (FNA) analysis, including radius, texture, perimeter, area, smoothness, compactness, concavity, concave points, symmetry, and fractal dimension measurements. This dataset comprises 569 samples with a distribution of 357 benign and 212 malignant cases, offering comprehensive cellular-level information for diagnostic analysis. The thermography modality incorporates the Breast Thermography dataset [10], captured using FLIR A300 cameras under controlled medical conditions with room temperature maintained between 22-24°C and relative humidity of 45-50%. Following the American Academy of Thermology (AAT) protocol, three images are acquired from each patient: anterior, left oblique, and right oblique positions (see **Erro! Fonte de referência não encontrada.**). This modality provides non-invasive, radiation-free metabolic activity detection through thermal signature analysis. Data samples of this dataset are show in Figure 2.

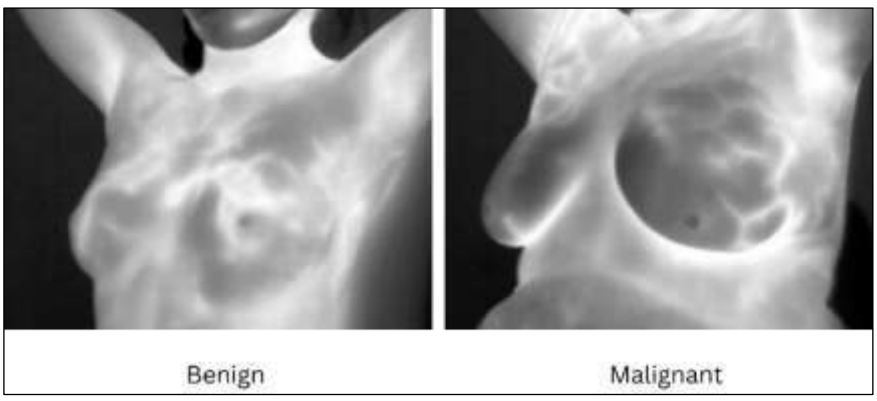

Figure 2: Data Sample of Breast Thermography Dataset.
Source: Authors, (2026).

The mammography component utilizes the CBIS-DDSM dataset [11], a curated subset of the origi-nal DDSM database containing 10,239 images from 6,671 subjects. This dataset has been professionally de-compressed, converted to DICOM format, and enhanced with updated ROI segmentations and bounding boxes by trained mammographers. The dataset encom-passes both calcification and mass cases, providing comprehensive mammographic representation for di-agnostic analysis. Data samples of this dataset are show in Figure 3.

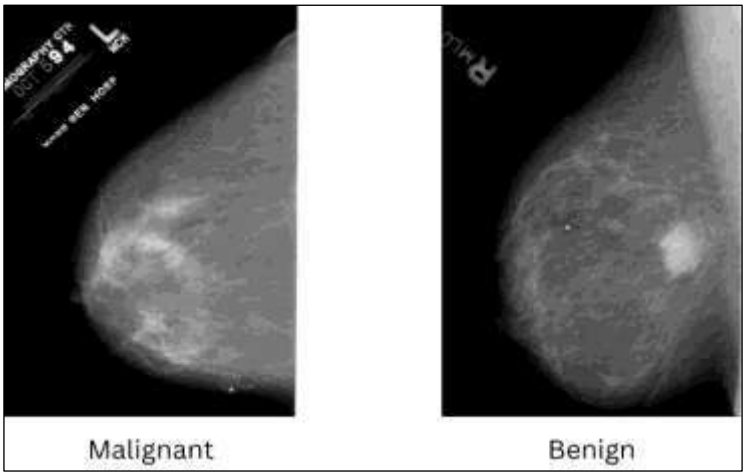

Figure 3: Mammography Sample of CBIS-DDSM Dataset.

II.2 MULTIMODAL DATA PROCESSING AND MODEL IMPLEMENTATION

The multimodal approach encompasses three distinct data processing pipelines tailored to each modality's characteristics. For tabular data, comprehensive exploratory data analysis utilizing violin plots, box plots, and swarm plots guides feature selection through correlation analysis, eliminating highly correlated features (correlation coefficient = 1). Gaussian Noise Augmentation enhances the dataset by adding calculated noise based on class-specific standard deviations. The Deep Neural Network architecture features three fully connected layers (input: 30 features, hidden: 15 neurons, output: 1) with dropout regularization, utilizing 3,065 total parameters and 1,021 trainable parameters. Thermography image preprocessing incorporates extensive augmentation strategies including horizontal flipping, rotational transformations (±10°), translations (5% of dimensions), shearing (±0.05), and specialized thermal enhancements through unsharp masking and Laplacian edge enhancement, while mammography preprocessing addresses class imbalance through majority class downsampling while maintaining pixel intensity analysis for benign-malignant differentiation [12]. Both imaging modalities utilize ResNet50 architectures with identical configurations (25,687,940 total parameters, 2,100,226 trainable parameters) and all images are normalized and resized to 224×224 pixels for model compatibility.

ResNet50 implementation in medical imaging has demonstrated promising results across various disease detection tasks, as shown in gastrointestinal disease classification by [13] achieving superior accuracy, precision, recall and computational efficiency compared to VGG16 and MobileNetV2 on endoscopic image datasets, and in brain tumor detection by [14] where ResNet50 achieved 92.34% accuracy for multi-class classification of glioma, meningioma, and pituitary tumors from MRI scans with 70% training and 30% testing data split. Additionally, tuberculosis detection studies by [15] demonstrated that ResNet50 performed exceptionally well in binary classification tasks for TB detection from chest X-rays, outperforming VGG16, U-Net, and DenseNet169 models, providing a scalable solution for regions with limited access to qualified radiologists and reducing human error in diagnostic processes. Moreover, CNN architectures have proven effective across diverse domains, including speech recognition where 89% accuracy was achieved for contactless applications in healthcare settings [16], demonstrating the versatility of CNN-based approaches in medical technology applications.

II.3 LATE FUSION STRATEGIES

This study adopts a family of decision-level fusion schemes that integrate per-modality posterior probabilities into a single diagnostic decision while preserving the independence of modality-specific feature extraction and training pipelines, thereby maintaining modularity and clinical traceability of each component model. Let $p_k(c)$ denote the posterior probability estimated by modality $k \in$ {tabular,thermography,mammography} for class $c \in$ {benign,malignant}, and let $p_{\text{fuse}}(c)$ be the fused posterior used for final decision-making via $\arg\max_c p_{\text{fuse}}(c)$, with optional renormalization across classes to ensure probabilistic interpretability.

II.3.1 Product Rule

The product rule aggregates evidence by multiplying per-class probabilities across modalities and selecting the class that maximizes the resulting product, with an optional normalization across classes to restore a proper probability simplex when desired for reporting and threshold calibration. This methodology adapts the theoretical framework established by Depeursinge et al. [17], originally demonstrated for lung tissue classification in high-resolution computed tomography, where late fusion achieved 84% maximum accuracy with 10% improvement over single-modality approaches. The core decision function is expressed in Equation (1),

$$p_{\text{fuse}}(c) = \prod_k p_k(c),\ \tilde{p}_{\text{fuse}}(c) = \frac{\prod_k p_k(c)}{\sum_{c'} \prod_k p_k(c')} \quad (1)$$

Where c indexes the diagnostic class, k indexes the modality, and $\tilde{p}_{\text{fuse}}(c)$ denotes the normalized fused probability used when calibrated posteriors are required for downstream analysis such as clinical thresholding or risk communication. This rule amplifies consensus across modalities and aligns with an independence assumption at decision level; in practice, it tends to preserve high specificity when models agree, which is advantageous in screening contexts where minimizing false positives can reduce unnecessary follow-up procedures. The multiplicative combination is sensitive to miscalibration and overconfident errors because a single low probability can down-weight the fused score substantially, potentially suppressing true positives in the presence of one uncertain modality, especially when per-modality calibration has not been performed.

II.3.2 Weighted Averaging

The weighted average rule forms a convex mixture at the probability level by learning nonnegative modality weights that sum to one, typically optimized on a validation split to maximize macro-F1 or minimize log-loss for balanced clinical performance. This methodology ap-plies a weighted late fusion framework for human activity recognition using accelerometer and gyroscope signals on the HAR dataset, where late fusion achieved a maximum accuracy of 92.94% an improvement of ap-proximately 4.61% over the best single-modality approach (88.33% using only the accelerometer) [18]. The decision function is expressed in Equation (2),

$$p_{\text{fuse}}(c) = \sum_k \alpha_k \, p_k(c), \; \sum_k \alpha_k = 1, \; \alpha_k \geq 0 \tag{2}$$

Where α_k denotes the learned reliability weight of modality k that reflects its relative contribution to the final decision under the target operating point and dataset shift constraints. This approach is robust when modalities exhibit unequal reliability, remains simple and interpretable, and is compatible with per-modality temperature scaling to stabilize probability calibration before mixing, thereby limiting the influence of overconfident but poorly calibrated sources. Because it is a linear mixture, it may underfit complex inter-modal interactions and can blur decisive signals when weights are not well tuned or when class-conditional reliability varies across the clinical spectrum, which motivates complementary non-linear meta-modeling baselines.

II.3.3 Log-Opinion Pool

The log-opinion pool generalizes the product rule by introducing modality-specific exponents that multiplicatively reweight each source's influence, followed by normalization across classes to obtain a valid posterior distribution for interpretability and thresholding. This methodology adopts knowledge-inspired fusion strategies for PM2.5 inference from AOD, where a UNet employing decision fusion of AOD, wind, humidity, pressure and temperature inputs achieved a MAE of 4.33 µg/m³ on CAMS data a 27.9% reduction compared to a single-modality AOD-only Random Forest baseline (MAE = 6.01 µg/m³) [19]. The fusion function expressed in Equation (3),

$$p_{\text{fuse}}(c) \propto \prod_k (p_k(c))^{\beta_k}, \; \tilde{p}_{\text{fuse}}(c) = \frac{\prod_k p_k(c)^{\beta_k}}{\sum_{c'} \prod_k p_k(c')^{\beta_k}} \tag{3}$$

Where $\beta_k \geq 0$ controls the relative strength of modality k such that larger β_k emphasizes its contribution, and $\tilde{p}_{\text{fuse}}(c)$ denotes the normalized fused probability used for decision and calibration reporting. By tuning β_k, the method mitigates domination by a single modality and flexibly adapts to heterogeneous modality quality, often improving robustness to one weak or noisy source without abandoning the consensus-amplifying nature of multiplicative fusion. Performance depends on selecting appropriate β_k values, and the approach remains sensitive to probability calibration; in practice, grid search or Bayesian optimization on validation data is typically required to set β_k reliably for the intended operating point.

II.3.4 Stacking Meta-Classifier

Stacking treats per-modality outputs as features and learns a meta-classifier that maps these decision-level signals to the final posterior, with logits preferred to encode confidence on a linear scale and to reduce saturation effects observed with near-0 or near-1 probabilities. This methodology adopts the stacking late fusion framework described by [20], concatenating per-modality logits (multi lead ECG and accelerometer) into a logistic regression metalearner, yielding 99.57% accuracy on activity recognition a 11.24% improvement over the best single modality accelerometer only model (88.33%). A logistic meta-model can be expressed as shown in Equation (4),

$$\hat{p}(\mathrm{c}) = \sigma\left(\beta_0 + \sum_k \beta_k \, \mathrm{logit}\big(p_k(\mathrm{c})\big)\right) \tag{4}$$

Where $\sigma(\cdot)$ is the sigmoid function, $\mathrm{logit}(p) = \log\left(\frac{p}{1-p}\right)$, β_0 is an intercept, and β_k are meta-level coefficients that quantify each modality's learned contribution after accounting for the others, enabling transparent attribution and ablation at decision level. Stacking captures linear and weakly non-linear interactions among modalities, learns data-driven weights aligned to the target metric, and preserves decision-level interpretability via coefficients or feature importance while keeping modality encoders unchanged and auditable. Reliable training requires careful out-of-fold procedures to avoid information leakage from the same samples used to fit base models, and performance benefits from pre-fusion calibration to prevent logit saturation and improve stability under dataset shift. Each modality undergoes independent training with appropriate optimization strategies: tabular DNN utilizes binary cross-entropy loss with Adam optimization, while both ResNet50 implementations employ transfer learning with pre-trained ImageNet weights, fine-tuned for medical imaging applications. To ensure fair comparison across modalities, the evaluation process employs a standardized test dataset comprising 40 carefully selected samples: 20 benign cases and 20 malignant cases.

This balanced evaluation approach enables direct performance comparison between individual modalities and the proposed late fusion method. Each modality-specific model generates probability predictions for the identical test samples, ensuring consistent and comparable results across all approaches.

II.3.5 Evaluation Maethodology And Performance Assessment

The evaluation framework assesses both individual modality performance and fusion effectiveness through comprehensive metrics. Performance evaluation utilizes standard classification metrics with the following mathematical formulation:

Accuracy measures the overall correctness of predictions as shown in Equation (5).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{5}$$

Precision quantifies the proportion of positive predictions that are actually correct, as defined in Equation (6).

$$Precision = \frac{TP}{TP+FP} \tag{6}$$

Recall (Sensitivity) measures the proportion of actual positives correctly identified, as expressed in Equation (7).

$$Recall = \frac{TP}{TP+FN} \tag{7}$$

F1-Score provides the harmonic mean of precision and recall, as calculated using Equation (8)

$$F1 - Score = \frac{2\times Precision\times Recall}{Precision+Recall} \tag{8}$$

Where TP represents True Positives, TN represents True Negatives, FP represents False Positives, and FN represents False Negatives. Confusion matrices provide de-tailed classification performance analysis across all classes, while comparative studies demonstrate the supe-riority of the multimodal fusion approach over individual modality predictions. Statistical significance testing validates the improvement achieved through late fusion compared to single-modality approaches. The evaluation process ensures robust assessment of the proposed methodology's clinical applicability and diagnostic reliability, providing comprehensive evidence for the effectiveness of the probability multiplication fusion strategy in breast cancer detection applications.

III. RESULTS

III.1 EVALUATION MAETHODOLOGY AND PERFORMANCE ASSESSMENT

The comprehensive evaluation of each modality-specific model reveals distinct performance characteristics across the three data types utilized in this multimodal breast cancer detection framework. Performance assessment was conducted using accuracy, precision, recall, and F1-score metrics to provide thorough analysis of each modality's diagnostic capabilities, as summarized in Table 1.

Table 1: Training Performance Comparison Across Different Modalities.

Modality	Accuracy (%)	Precision	Recall	F1-score
Thermography	65	0.66	0.65	0.65
Mammography (Downsampled)	54	0.55	0.55	0.54
Tabular Data (Feature Selected)	98	0.95	0.95	0.95

Source: Authors, (2026).

The confusion matrices for each individual modality provide detailed insight into classification performance, as illustrated in Figure 4.

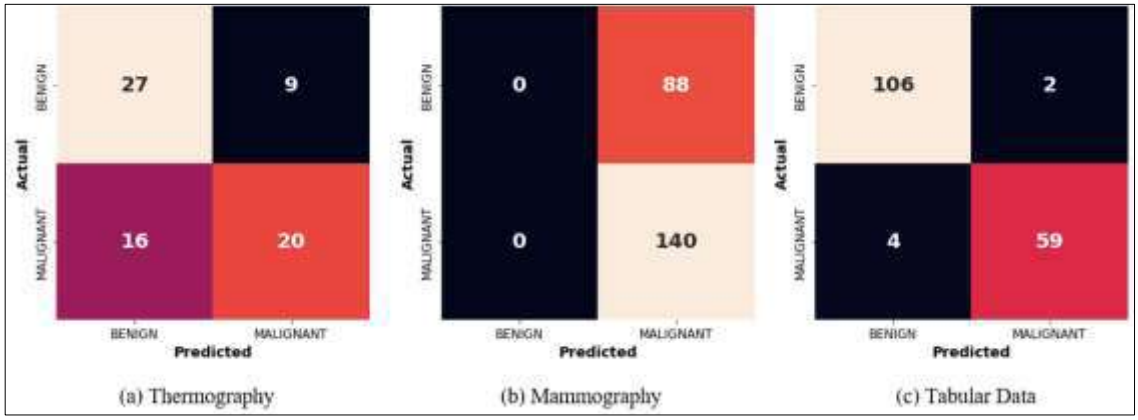

Figure 4: Confusion Matrices for Individual Modality Performance.
Source: Authors, (2026).

Thermography Performance: During the training process, the ResNet50 model achieved moderate performance with 65% accuracy on 72 test samples. Training for benign case classification showed precision of 0.63 and recall of 0.75, while malignant detection achieved precision of 0.69 but lower recall of 0.56. This recall limitation observed during training is concerning from a clinical perspective, as missing malignant cases can have severe consequences for patient outcomes.

Mammography Performance: Initial training evaluation using original dataset distribution revealed significant class imbalance issues with the model unable to detect benign cases effectively. After implementing down sampling of the majority class during the training phase, performance improved to 54% accuracy with more balanced metrics across both classes. However, overall training performance remained suboptimal, highlighting ongoing challenges in automated mammography analysis.

Tabular Data Performance: Throughout the training process, the DNN model demonstrated exceptional performance, significantly outperforming imaging modalities with 98% accuracy using feature selection. Training for benign classification achieved precision of 0.99 and recall of 0.93, while malignant detection showed precision of 0.90 and recall of 0.98. The superior training performance can be attributed to carefully engineered features derived from fine needle aspiration analysis that capture essential cellular characteristics highly predictive of malignancy.

The performance disparities between modalities observed during training underscore the complementary nature of different data types, with tabular data providing quantitative cellular information, thermography offering metabolic activity insights, and mammography revealing structural abnormalities. These distinct strengths demonstrated in training results justify the multimodal fusion approach to leverage comprehensive diagnostic information for enhanced breast cancer detection accuracy.

III.2 LATE FUSION MULTIMODAL PERFORMANCE

III.2.1 Product Rule Fusion

Erro! Fonte de referência não encontrada. presents the confusion matrix and performance summary for the late fusion model utilizing the product rule. This approach multiplies per-class probabilities predicted by individual modality-specific models thermography, mammography, and clinical tabular data to generate a unified diagnostic outcome. As illustrated in **Erro! Fonte de referência não encontrada.**, the product rule fusion achieves an overall accuracy of 95%. Notably, it demonstrates excellent precision (0.91) and recall (1.00) for benign cases, as well as perfect precision (1.00) and strong recall (0.90) for malignant cases. The model's robustness in minimizing false positives is advantageous in clinical screening, as confirmed by its high specificity reflected in the confusion matrix. This result substantiates the clinical value of product rule fusion in enhancing the reliability of breast cancer diagnosis across heterogeneous data modalities.

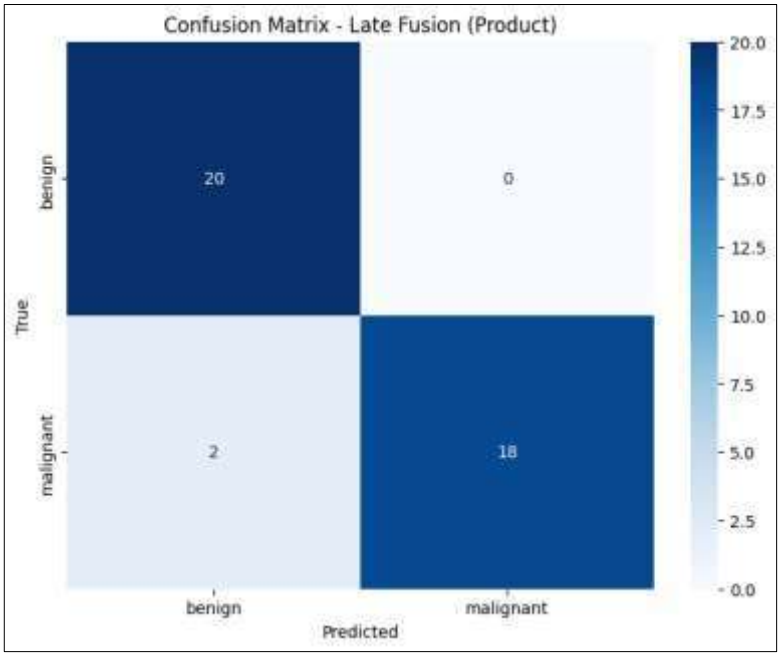

Figure 5: Confusion Matrix of Product Rule Fusion.
Source: Authors, (2026).

III.2.2 Weighted Averaging Fusion

Erro! Fonte de referência não encontrada. summarizes the weighted averaging fusion results. In this scheme, per-class probabilities from each modality are linearly combined using modality-specific weights that sum to one, optimized for macro-F1 or validation accuracy. As displayed in **Erro! Fonte de referência não encontrada.**, the approach attains an overall accuracy of 95%, with consistently high precision and recall across benign and malignant classes. This method remains interpretable and simple to implement, and its adaptability to the relative quality of each source makes it broadly applicable within clinical workflows. The confusion matrix in **Erro! Fonte de referência não encontrada.** confirms that the weighted averaging fusion is effective at integrating complementary information and limiting the influence of unreliable or noisy modalities.

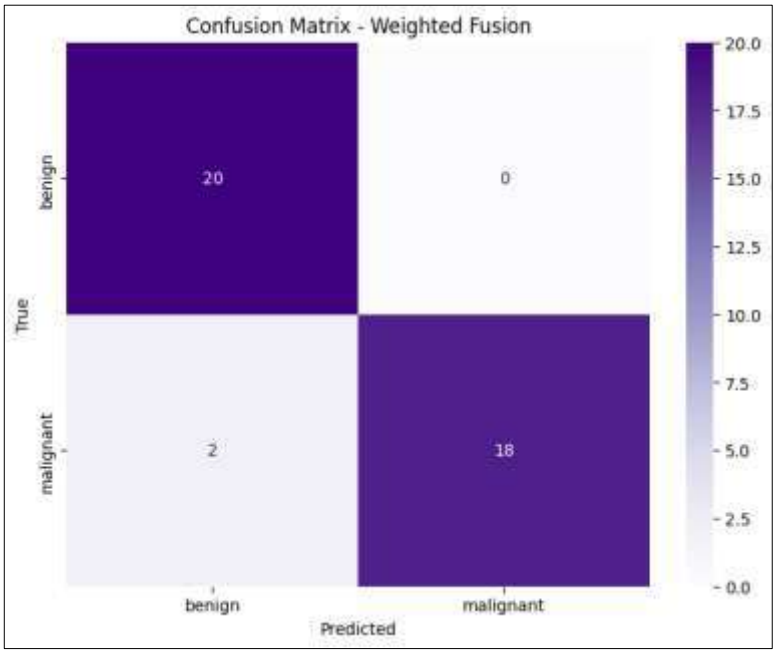

Figure 6: Confusion Matrix of Weighted Averaging Fusion.
Source: Authors, (2026).

III.2.3 Log-Opinion Pool Fusion

Erro! Fonte de referência não encontrada. details the output of the log-opinion pool fusion method. This approach introduces learnable exponents to reweight the contribution of each modality in multiplicative fusion before normalization. As presented, the log-opinion pool fusion yields the highest accuracy among all fusion schemes at 97.5%. It achieves near-perfect precision and recall for both benign and malignant classes, as shown in both the metric summary and confusion matrix in **Erro! Fonte de referência não encontrada.**. This enhancement highlights the advantage of exponent-based weighting in mitigating overconfidence from a single modality and improving overall diagnostic reliability, especially in heterogeneous clinical settings.

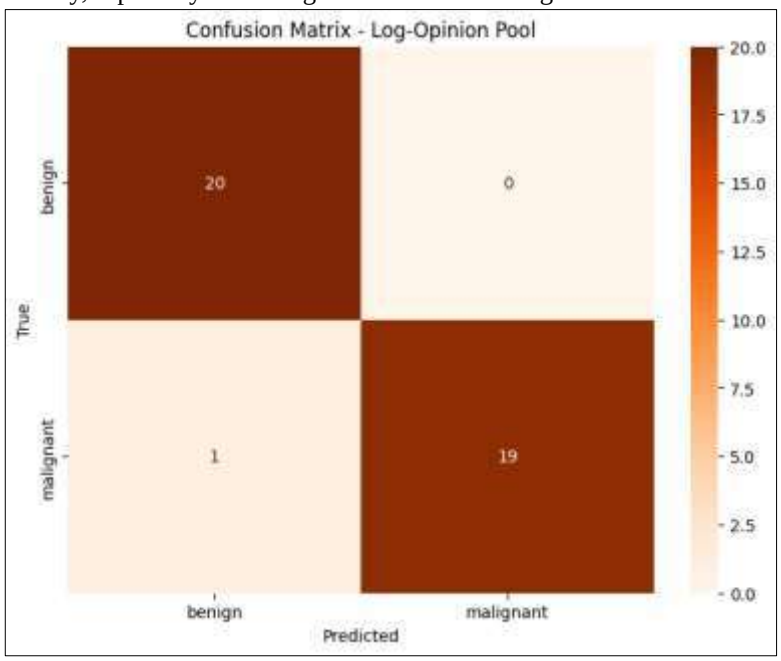

Figure 7: Confusion Matrix of Log-Opinion Pool Fusion.
Source: Authors, (2026).

III.2.4 Stacking Meta-Classifier Fusion

Erro! Fonte de referência não encontrada. presents the confusion matrix and classification report for the stacking meta-classifier fusion method. Here, modality outputs are treated as features for a meta-classifier typically a logistic regression model trained on out-of-fold predictions. According to **Erro! Fonte de referência não encontrada.**, stacking attains an overall accuracy of 95%, with balanced precision and recall values (0.95) for both benign and malignant categories. The method captures both linear and moderate non-linear interdependencies between modalities, thereby providing optimal diagnostic integration and interpretability through feature attribution.

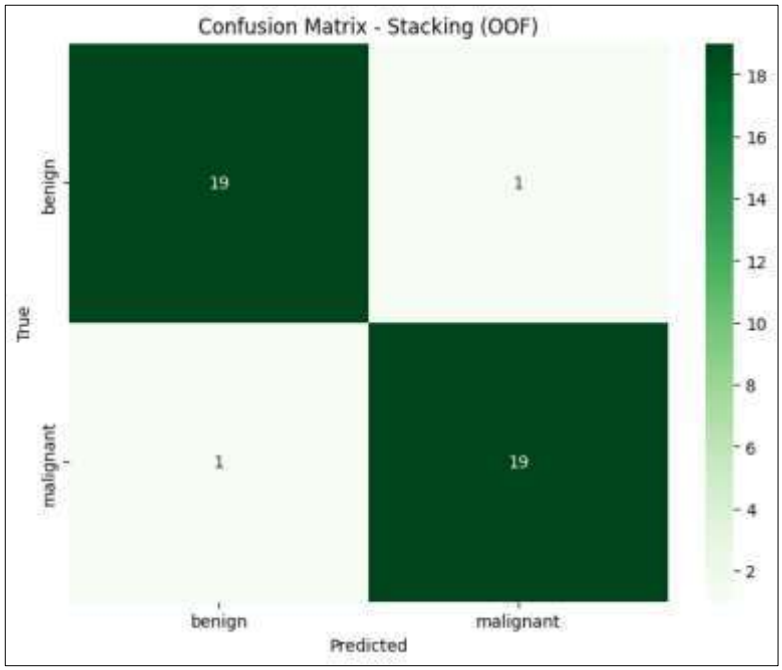

Figure 8: Confusion Matrix of Stacking Meta-Classifier Fusion.
Source: Authors, (2026).

Table 2 provides a comprehensive comparison of all fusion methods on the external test set, reporting accuracy, precision, recall, and F1-score for both benign and malignant cases. The log-opinion pool fusion outperformed all others, achieving an accuracy of 97.5% and a macro F1-score of 0.97. Both product rule and weighted averaging fusion scored 95% accuracy and 0.95 macro F1-score, with stacking meta-classifier matching this performance but demonstrating slightly higher precision consistency across classes. This comparative analysis in Table 2 evidences that log-opinion pool fusion delivers superior robustness in multimodal breast cancer diagnosis, while the other strategies also achieve clinically relevant reliability.

Table 2: Performance Comparison of Late Fusion Methods on Multimodal Test Set.

Late Fusion Models	Accuracy (%)	Precision Benign	Precision Malignant	Recall Benign	Recall Malignant	Macro F1-score
Product Rule	95	0.91	1	1	0.9	0.95
Weighted Averaging	95	0.91	1	1	0.9	0.95
Log-Opinion Pool	97.5	0.95	1	1	0.95	0.97
Stacking (Meta-Classifier)	95	0.95	0.95	0.95	0.95	0.95

Source: Authors, (2026).

III.2.5 Fusion Enhancement During Inference

Figure 9 depicts the fusion enhancement observed during inference, benchmarking the diagnostic accuracy of single-modal models (thermography, tabular, and mammography) against all four fusion strategies on an identical external test set. The performance curve in Figure 9 demonstrates a substantial increase in accuracy from single-modal baselines to multimodal fusion, with the log-opinion pool fusion clearly leading. These findings reinforce the necessity of integrating complementary data sources through optimized fusion mechanisms to achieve reliable breast cancer diagnostics in clinical practice.

A thorough analysis of inference metrics highlights the marked performance disparities between individual modalities and multimodal fusion strategies. As demonstrated in Table 2 and Figure 9, single-modality models exhibit limited performance: thermography achieves 57.5% accuracy, mammography 50.0%, and tabular data 92.5%. These unimodal models present considerable challenges in distinguishing between benign and malignant cases, reflected by suboptimal recall and precision values, particularly in thermography and mammography.

Fusion methods substantially elevate diagnostic reliability on the standardized external test set of forty cases. Product Rule Fusion, Weighted Averaging Fusion, and Stacking Meta-Classifier Fusion each yield 95.0% accuracy, with precision and recall metrics balanced between benign (precision: 0.91–0.95; recall: 1.00–0.95) and malignant classes (precision 0.95–1.00; recall: 0.90–0.95). Most notably, Log-Opinion Pool Fusion achieves the strongest result, with 97.5% accuracy, 0.95 precision and recall for the benign class, and perfect precision (1.00) and elevated recall (0.95) for malignant cases. Macro F1-scores reinforce this superiority, with Log-Opinion Pool reaching 0.97 outperforming other fusion techniques (0.95 each).

Erro! Fonte de referência não encontrada. visually captures the dramatic enhancement yielded by fusion mechanisms during inference, where multimodal integration surpasses the accuracy of any single model. The transition from unimodal to fusion-based decision-making produces an accuracy jump of over 40 percentage points for mammography and thermography, and a 5–6 percentage point improvement over the tabular model, culminating in a peak accuracy of 97.5% via Log-Opinion Pool Fusion. This validates the effectiveness of decision-level fusion in real-world clinical scenarios and illustrates the consistent diagnostic gain achievable through advanced aggregation of complementary data sources.

The implications of these findings are highly significant in a clinical context. The sharp reduction in false positives and false negatives with fusion methods substantially lowers patient risk, minimizes the likelihood of unnecessary follow-up procedures, and reinforces the confidence of clinical decision-support systems. The zero false positive rate (as shown in Table 2 for certain fusion strategies) eliminates unwarranted patient anxiety, while the high recall for malignant cases ensures that nearly all positively-identified cancers are correctly detected. These outcomes directly translate to improved patient pathways, earlier interventions, and potentially enhanced survival rates cornerstones of effective breast cancer screening programs.

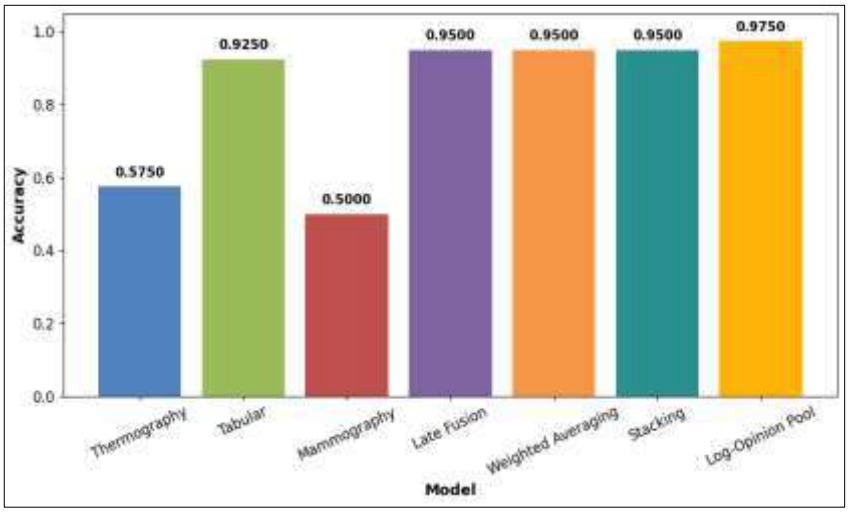

Figure 9: Accuracy Comparison Across Modalities Using Standardized 40-Sample Test Dataset.
Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

The results demonstrate that the expanded late fusion framework, incorporating four distinct strategies probability multiplication (product rule), weighted averaging, stacking meta-classifier, and log-opinion pool fusion consistently outperforms individual modality predictions. Notably, the log-opinion pool fusion achieves the highest overall accuracy at 97.5%, surpassing product rule and weighted averaging fusion (both at 95%), and stacking meta-classifier (95%). These values substantially exceed unimodal classifiers, such as thermography (65%), mammography (54–61%), and tabular data (95–98%). This multifaceted approach validates recent findings in multimodal breast cancer detection literature [21-23], where advanced fusion strategies are shown to consistently outperform unimodal models. Among these, exponent-based weighting (log-opinion pool) offers distinct diagnostic advantages, further improving accuracy and recall while maintaining robustness during modality disagreement.

Unlike early fusion approaches, the late fusion methodology preserves each modality's independent feature extraction capabilities [24], [25], addressing key limitations identified in contemporary literature: mammography's vulnerability to dense tissue masking [5], [7], thermography's specificity challenges, and the incomplete diagnostic picture provided by individual modalities when used independently. Several limitations should be acknowledged when comparing with recent international studies. The standardized evaluation on a relatively small test dataset of 40 samples contrasts with larger studies utilizing thousands of samples [26],[27], while the mammography modality's suboptimal performance suggests potential issues that warrant investigation.

From a clinical perspective, the 10% false negative rate represents an acceptable threshold for screening applications, while the zero false positive rate eliminates unnecessary patient anxiety and invasive follow-up procedures [28], [29]. Future research should focus on expanding evaluation to larger, more diverse datasets, investigating alternative fusion strategies including attention-based mechanisms, and developing real-time clinical decision support systems based on multimodal methodologies [30]. The integration of complementary information sources creates a more robust diagnostic framework that could support clinical decision-making, as evidenced by recent research showing improved patient outcomes through multimodal diagnostic systems, particularly in survival risk stratification and personalized treatment planning applications.

V. CONCLUSIONS

This research successfully introduces a comprehensive late fusion framework for breast cancer detection, integrating mammography images, thermography images, and clinical tabular data through four decision-level fusion strategies: probability multiplication (product rule), weighted averaging, stacking meta-classifier, and log-opinion pool fusion. The log-opinion pool fusion, in particular, achieved superior diagnostic performance with an overall accuracy of 97.5%, surpassing product rule, weighted averaging, and stacking meta-classifier methods (all at 95%), as well as individual modalities thermography (57.5%), mammography (50%), and tabular data (92.5%).

The proposed fusion approaches demonstrated strong clinical applicability by achieving perfect (1.00) precision for malignant cases, 0.91–0.95 precision for benign cases, and maintaining a zero false positive rate while achieving up to 95% recall for malignant cases. These improvements represent meaningful advances over the best-performing individual modality and prior unimodal benchmarks, confirming the added value of sophisticated multimodal integration. The fusion strategies successfully preserved independent feature extraction in each modality while providing advanced decision-level aggregation, effectively addressing critical limitations in current multimodal medical diagnostic approaches.

While these findings validate the effectiveness and clinical relevance of late fusion in breast cancer detection, several avenues for future research remain critical. These include scaling evaluation to larger and more diverse cohorts for enhanced generalizability; exploring novel fusion strategies such as attention-based mechanisms and transformer models; developing real-time, clinically deployable decision support systems based on multimodal deep learning; and integrating additional data types such as genetic information and longitudinal patient history to construct even more robust diagnostic frameworks. Further work should also prioritize optimizing computational efficiency for clinical adoption, incorporating explainable AI to foster clinical interpretability, and pursuing prospective clinical trials to validate real-world effectiveness, ultimately advancing the field toward more accurate, reliable, and widely applicable systems for breast cancer diagnosis.

ABSTRACT

Roads represent one of the main concerns in infrastructure development, and a significant part of the overall budget is dedicated to their construction, improvement, and maintenance. The realization of flexible pavements requires large quantities of high-quality materials such as aggregates and crushed sand. However, these materials are becoming increasingly difficult to obtain in the quantities needed, especially near construction sites. In order to create road layers that meet technical, mechanical, and durability requirements, it is often necessary to improve existing soils through the use of hydraulic binders, including lime and cement. This context led us to initiate our research, which provides an important opportunity to enhance and promote the use of a locally available material, namely dune sand, through appropriate treatment techniques based on hydraulic binders. At the same time, this approach helps address the growing shortage of noble materials traditionally used in pavement construction. By exploring alternative solutions and encouraging the use of local resources, our study aims to contribute to more sustainable, economical, and efficient practices in road engineering while responding to current and future challenges faced by the sector.

I. INTRODUCTION

The knowledge of ground stabilization in geotechnics has been well documented recently. Articles and manuals on stabilization techniques are available to students, practicing engineers and consultants in the field of geotechnics. During soil stabilization, the formation of dust due to aggressive binders is not a requirement. For this, soil studies have been carried out to find the solution to this problem. Companies have invested in research and development for several years already and are notably turning towards soil stabilization techniques using hydraulic binders. This method of soil modification uses lime and/or hydraulic binders to optimize soil properties [1] has undergone significant development recently. The use of materials such as lime, hydraulic binders and/or cements [2] in soil treatment facilitates the formation of fill and foundation layers. This type of treatment requires a good knowledge of the material to be treated. Road construction requires a large quantity of materials to create not only the road layers but also especially the embankments and the subgrade layers, to create the longitudinal profile. Two methods are used, either by adding aggregates, or by treating the soil in place. The aggregate supply technique requires the use of large quantities of trucks to, on the one hand, dump excess soil and on the other hand, transport aggregates to the site in large quantities.

The scarcity of aggregate resources and the nuisance generated by transport have encouraged decision-makers to valorize existing soils through treatment with hydraulic binders. Recently, in Algeria, a very consistent program was launched in terms of road construction. However, these types of initiatives require the use of large volume of high-quality materials [3],[4], which are not systematically available in the vicinity of the projects to create pavement layers with using hydraulic binders to treat the soil in place. This is the reason why it is interesting to promote local materials [5],[6] by a treatment technique. This permits to compensate for the deficit in noble materials, and to respond to economic and environmental concerns [7], [8]. The treatment of soils with hydraulic binders and lime is a process which improves the workability of materials. This treatment technique makes it possible to improve the physical and mechanical characteristics of soils after compaction. The advantages of this technique are well known in earthworks and are exploited for the construction of road, motorway, railway embankments, industrial platforms, etc. Soil treatment with hydraulic binders has become common practice in the field of road construction. This technique presents technical, economic and environmental advantages [7],[8].

Soil treatment makes it possible to save natural aggregate resources, limit the transport of materials and re-use existing soils, which are often too wet and not very supportive. Algeria is known for its sand dunes, which adorn postcards, are tourist destinations, but also which swallow up land and palm groves, and invade certain oases. However, this sand, which occupies almost the entire surfaceof the Algerian Sahara, is currently not valued for exploitation. Many researchers, in various scientific themes, seek to exploit this clean and abundant material. It couldbe used due to its high silica concentration. In the field of civil engineering, this sand also has significant economic and environmental importance for Algeria. Indeed, the growth in demand for sand for construction in Algeria, the inability of Algerian quarries to supply fine sand along with the planned cessation of using sea sand, which leads to a major ecological and tourist problem for Algeria, are all reasons for the valorization of this product. We are therefore interested in the valorization of this type of very abundant sand, which can exploit massively. The range of use of sands in the world is very wide, electronics [9-12], abrasive materials (sandpaper, files, discs, sandblasting, etc. for example.) [13-16]. Taking into account its particle size (medium to fine, naturally less than 1mm) [17-19], its morphology, its cleanliness and its hardness, we focused on its valorization in the layers of the roadways. Several studies have been carried out on the use of dune sand in road techniques [4], [17-25].

II. MATERIALS AND METHODS

II.1 MATERIALS

II.1.1 Dune Sand

The sand used comes from the dunes of Djelfa, a region located 300 km south of Algeria. It is an extremely fine sand, free of particles smaller than 80 µm. More than 90% of its components have dimensions ranging from 0 to 0.4 mm [17-19], this abundant material is characterized as a permeable, incoherent soil, low resistance, low bearing capacity [26],[27] and poorly graded grain size. Our studied dune sand is located approximately 60 km northwest of Djelfa at a place named Zaafrane. The mineralogical analysis carried out on the dune sand samples and the particle size analysis are presented in Figures 1a and 1b and the chemical composition is given in Table 1. According to the chemical examination presented in Table 1, the dune sand is composed mainly of silica; it consists of a large proportion of SiO_2 (silica), while there are some traces of calcium and magnesium species. The X-ray examinations reveal a significant concentration of quartz, as well as traces of Illite and calcite. Table 2 summarizes the physical characteristics of the dune sand.

II.1.2 Lime

The lime used in our study comes from Saida, which is characterized by a low concentration of oxide elements such as silicates SiO_2 and aluminates $A1_2O_3$ and a high concentration of basic elements such as free lime CaO. Its absolute density is between 2.2 and 2.4 g/cm3 and an apparent density (g/cm^3) as well as a specific surface area between 8000 and 12000 cm^2/g. Table 3 presents a summary of the chemical composition of the lime.

Table 3: Chemical composition of lime (%).

CaO	MgO	Fe_2O_3	AL_2O_3	SiO_2	SO_3	CO_2	$CaCO_3$
>73.3	<0.5	<2.0	<1.5	<2.5	<0.5	<5.0	<10.0

Source: Authors, (2026).

II.1.3 Cement

Chemical analysis of cement using a Scanning Electron Microscope (SEM) was carried out in the M'sila cement factory laboratory, the results are presented in Table 4.

Table 4: Chemical analysis of cement (%).

SiO_2	Al_2O_3	Fe_2O_2	CaO	MgO	SO_3	K_2O	Na_2O	Cl	CaO

II.2 METHODS

The research focuses on the impact of the incorporation of heavy substitutes, such as lime and cement, on the mechanical properties of the sand examined. The mixtures, which have been developed in this direction contains lime percentages of 4%, 6% and 8% and cement percentages of 5%, 7% and 9%. It is important to emphasize that these percentages were set in accordance with the guidelines of the standards concerning road networks [28] (GTR, 2000). The purpose of compaction is to densify the soil in place, to minimize its deformation and to optimize its bearing strength. Proctor standard compaction tests were carried out in accordance with the standard NF P94-093 [29] to determine the maximum dry density (MDD) and the optimum water content. Before being placed in the shear box, all mixtures underwent static compaction until an optimum Proctor was reached. The test is carried out at a rapid speed of 1 mm/min, which corresponds to an unconsolidated and undrained (UU) test in accordance with standard NF P 94-071-1[30]. It should be noted that the results regarding the optimum moisture content were also used to prepare the CBR and strength tests on the soil samples examined. Then, the CBR tests, shear strength, compressive strength and tensile strength were carried out in accordance with the standards NF P 94-078 [31], NF P 94-071-1 [30], standard EN 13286-53 [32] and standard EN 13286-42 [33], respectively, on the soil samples studied.

III. RESULTS AND DISCUSSIONS

III.1 EFFECT OF STABILIZERS ON THE PARAMETERS OF THE STANDARD PROCTOR COMPACTION TESTS

The obtained results are represented in Figures 2a and 2b. It is observable that the various additions seem to shift the coordinates of the Proctor modified (optimum moisture content and maximum dry density) to the right, by increasing the maximum dry density (MDD) and optimal water content (OMC) (Figures 4a and 4b). This trend of increasing the optimal water content becomes clearer for the case of cement mixtures. The densification of this material allowed us to note a dry density systematically higher than that of formulations based on cement. Lime mixtures result in an increase in dry density from 1.72 g/cm^3 to 1.81 g/cm^3. The optimum water content varies in the range of 5% to 7.8%. For cement-based formulations, the optimal water content varies in the range of 5% to 9.9% for a dry density between 1.72 g/cm^3 and 1.82 g/cm^3. The increase in density is attributed to the increase in the concentration of fine particles and their substitution by particles, which is the origin of the behavior observed in the various mixtures.

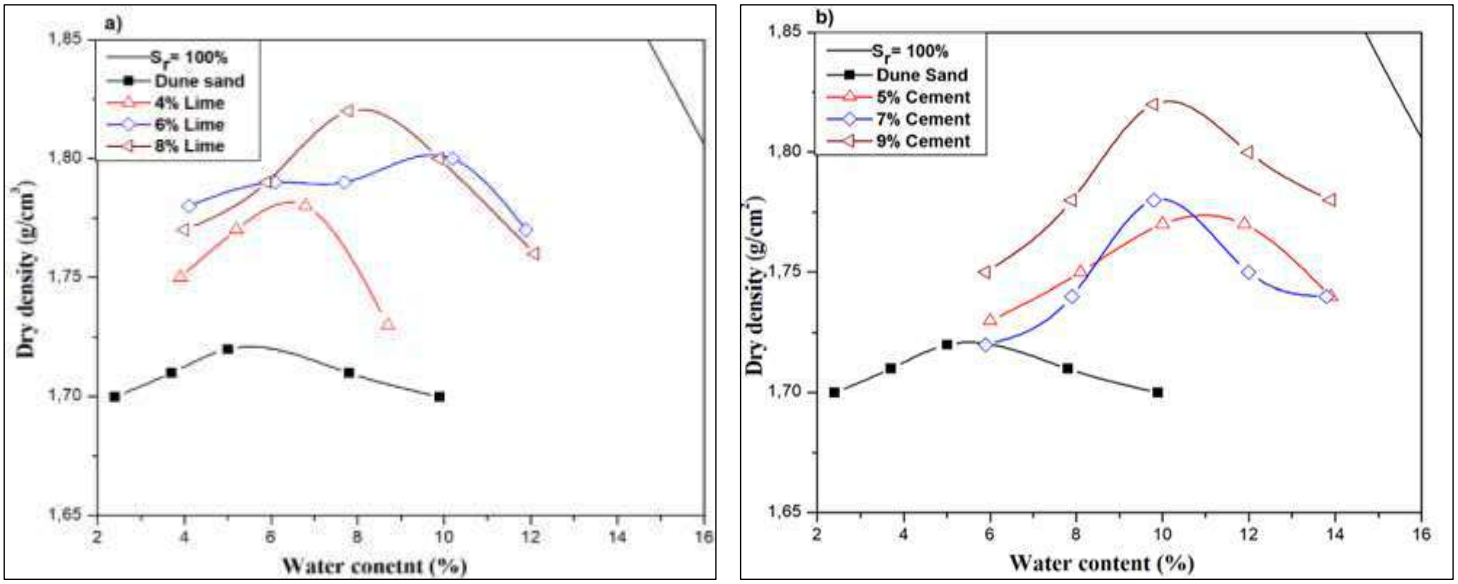

Figure 2: a) Modified Proctor of lime mixtures, b) Modified Proctor of cement mixtures.
Source: Authors, (2026).

III.2 EFFECT OF STABILIZERS ON THE CBR TESTS

To determine the CBR values at 95% of the optimum consists of punching into the CBR mold samples were made using various compaction energies (10 blows per layer, 25 c/c, 55 c/c), and at water content which corresponds to the optimal of the modified Proctor test. The aim being to obtain 3 castings with clearly different compactness (this compactness is respectively of the order of 90%, 95% and 100% of the maximum dry density of the modified Proctor). The material is then introduced according to the process of the modified Proctor test in 5 successive layers of equal thickness which will each be compacted with the same modified Proctor lady according to different compaction energies which are generally 10, 25 and 55 strokes per layer. According to the curves which represent the pressure of the piston as a function of its depression (Figure 3a and 3b), we determine the CBR index for each compaction energy.

This makes it possible to illustrate the change in dry density as a function of CBR index [γd = f(ICBR)] (Figure 4a and 4b). The final CBR index, determined graphically, is that which equals 95% of the maximum dry density of the modified Proctor test. Figure 5 a and b illustrates the variation of CBR at 95% for lime mixtures and cement mixtures. Figure5a show that lime improves the immediate bearing capacity from 8.28% to 13.45%for 4% lime. Beyond this value, we note a slight decrease to 12.32% for 8% lime. At the same time, in immersion, the lift improves from 6.45% to 12.10% for 6% lime then it drops to 9.5% for 8% lime. Just like lime, cement (Figure 5.b) showed a very significant increase in immersion lift of up to 162% in the case of 9% cement. This is obviously due to the cement setting. Unlike the lift in immersion, the immediate lift of cement shows values close to the values of lime where we note 26.5% for 5% cement then it drops to 21% for 9% cement.

III.3 EFFECT OF STABILIZERS ON THE SHEAR STRESS TESTS

The test is intended to evaluate the mechanical characteristics of a soil, that is to say the cohesion C, the friction angle Φ and the shear resistance τ_{max} at the moment of rupture. The cohesion of a soil is the property that makes it possible to oppose the sliding of the grains which compose it and to resist a shear force, that is to say to oppose the sliding of a layer, this allowing exposure to the danger of landslides to be limited. The used test to determine the parameters is the unconsolidated undrained direct shear test (U.U) in accordance with standard NF P 94-071-1. The samples of the dune sand-lime, dune sand-cement mixtures were placed between two half-boxes, which have the ability to move relative to each other. In addition, a piston makes it possible to exert a stress normal to the shear plane. The samples of the sand-binder mixtures are sheared at their compaction water contents. The standard constraints applied during these tests are as follows:

σ1 = 100 kPa; σ2 = 200 kPa; σ3 = 300 kPa. The shear speed used is 1mm/min.

The mechanical parameters of the mixtures are determined by graphically representing the Coulomb lines (intrinsic curves) in an orthonormal coordinate system, where the abscissa axis indicates the vertical stresses (σi) and the ordinate axis the maximum shear stresses (τimax). The slopes of these lines represent the tangents of the internal friction angles Φ of the sand-binder mixtures, on the one hand. On the other hand, the cohesions C are obtained by the intersection of these lines with the ordinate axis. The values of the angle of friction and cohesion are obtained analytically according to Coulomb's law:

$$\tau = C + \sigma\, tg(\Phi) \quad (1)$$

Figure 6a and 6b show the intrinsic curves of the dune sand-lime and dune sand-cement mixtures. Figure 7 and 8 present the variations of the cohesion of the mixtures and the variation of the friction angle depending on the binders added. The dune sand-lime and dune sand-cement mixtures show an increase in cohesion ranging from 2 kPa to 81 kPa for 6% lime and 46 kPa for 5% cement. Beyond these contents, we observe a slight decrease in cohesion, which becomes around 24 kPa for 8% lime and 15 kPa for 9% cement. However, the function of cement is to strengthen the structure of the sand by binding the particles together, thanks to the setting of the binder; on the other hand, the dune sand-cement mixture becomes less flexible and risks cracking quickly under traffic. However, it is necessary to choose a proportion of cement which improves the bearing capacity without making the mixture too stiff once it has hardened. Unlike cohesion, the friction angle shows a decrease to 32° for 5% cement and to 21° for 6% lime followed by an increase to 40° for 9% cement and to 27° for 8% lime. It is evident that all the dosages of hydraulic binders analysed demonstrate an increase in cohesion which is inversely proportional to the friction angle.

III.4 EFFECT OF STABILIZERS ON THE COMPRESSIVE AND TENSILE STRENGTH TEST

In accordance with standard 13286-53, the series of cylinders with dimensions φ = 100 mm and H = 100 mm was set up for the various mixtures. The mixture was arranged in a uniform layer in a double piston mold and then statically compressed until the optimum dry density and moisture content were reached, established according to the modified Proctor method in accordance with EN 13286-41. Following their preparation in accordance with standard EN 13286-53[32], the samples were kept in bags at 20 ± 2 °C until testing. The different mixtures were tested on days 7, 14, 28, 60, and 90. The tensile tests were performed on cylindrical samples for the different mixtures. The tensile tests were carried out on cylindrical specimens of the same dimensions in accordance with standard EN 13286-42 [33] by measuring the indirect tensile strength, but the specimens were compacted and preserved in the same way until the date of the test (at 90 days). Figures. 9a and 9b show the progression of compressive strength over various curing times and binder ratios. The compressive strength capacity following curing time demonstrates a moderate growth up to 265.59 kPa for a curing duration of 90 days (Figure 9a) for 8% lime mixture.

It is clear from the results that lime does not act as a good stabilizer on sandy material since only the role of grain size corrector is predominant. For the case of cement (Figure 9b), the results are greater than those obtained with lime and go up to 2734.25 kPa and 2973.41 kPa respectively for mixtures with 7% and 9% cement for a curing duration of 28 days and at 3425.26 kPa and 3845.68 kPa for a cure duration of 90 days. This lets us notice that the increase in compressive strength is less significant from 28 days to 90 days, which explains the rapid hydration of the cement for the first period (28 days). Figures 10a and 10b illustrate the variation of the tensile strength depending on the binders incorporated. The tensile strength generally increases with the percentage of binder added. According to Figure 10a, lime has low values before 8% lime, value for which the resistance becomes more significant. For the case of cement, we notice an increase in the tensile strength up to the respective values of 398.23 kPa and 538.75 kPa corresponding to the percentages of 7% and 9% respectively for a curing duration of 28 days. It is clear that cement mixtures give better tensile strength compared to those obtained with lime mixtures.

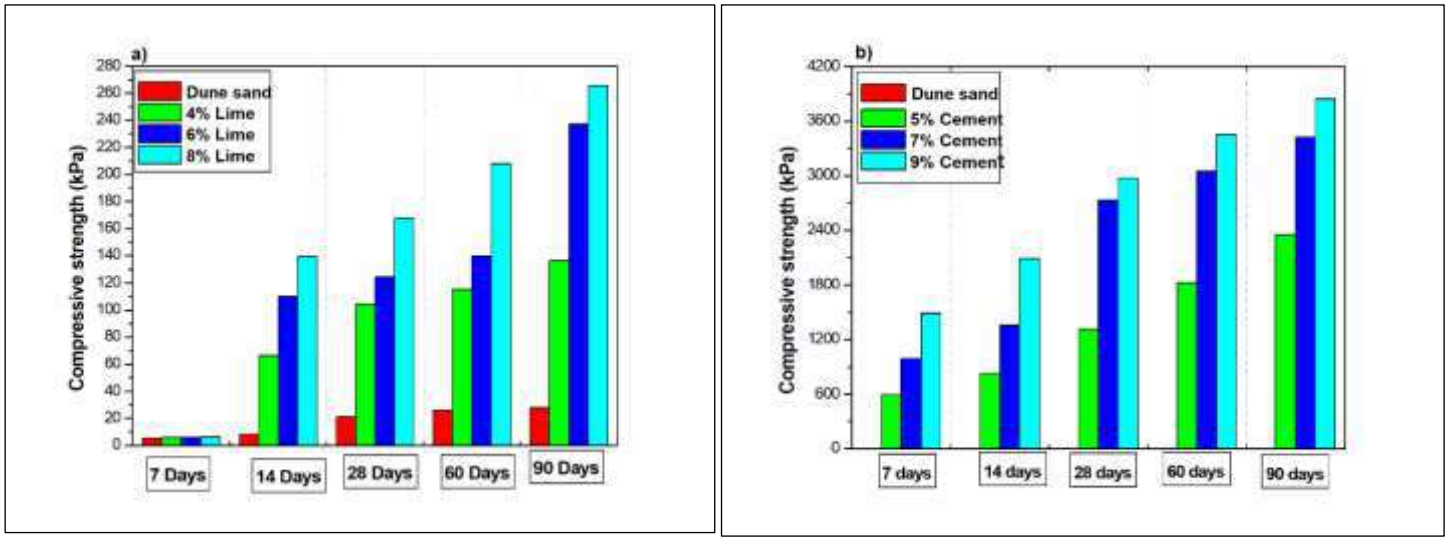

Figure 9: a) Evolution of the compressive strength according to the percentage of lime, b) Evolution of the compressive strength according to the percentage of cement.
Source: Authors, (2026).

In order to valorize dune sand, taking into account the environmental and economic aspects, the work focused on materials formulation techniques by adding hydraulic binders: lime and cement. The aims set were to examine the impact of the incorporation of percentages of fines (hydraulic binders) on the improvement of the mechanical characteristics of the dune sand treated. The results obtained from the present study show that the use of hydraulic binders and lime acts, in a very significant way, on improving the mechanical properties of this treated material. The following main conclusions can be drawn:

- Hydraulic binders such as lime and cement have a very positive effect on the mechanical performance of dune sand-based mixtures for use as pavement bases.
- Lime is less effective in improving mechanical characteristics than cement.
- Lime as a stabilizer is more suitable for fine soils (silt and clay) than for grainy soils (sand). It acts as a grain size corrector rather than a stabilizer.
- The addition of increasing quantities of hydraulic binder demonstrated a trend towards a permanent increase in the optimal water content.
- The use of hydraulic binders improves the tested mechanical performance (tensile and compressive strength).

ABSTRACT

Electric vehicles have become increasingly popular for their high efficiency and zero emissions, making them vital for sustainable transportation. The Permanent Magnet Synchronous Motors (PMSM) are widely used in Electric Vehicles, because of the Active discharge mechanism play a critical role in maintaining the safety and reliability of Electric Vehicle (EV) system. The proposed control strategy ensures that, the DC bus capacitor voltage is safely discharged to an acceptable level during emergency fault conditions. This paper proposed a robust winding-based capacitor discharge strategy that effectively utilizes the inherent machine windings of the PMSM as an alternative discharge path when the active circuit is unavailable. The control strategy discharge mechanism operates in two distinct stages to ensure rapid and controlled voltage reduction. In the first stage, a large flux-enfeebling in d-axis current which is injected to quickly suppress the back electromotive force (EMF), thereby achieving an immediate reduction in the DC bus voltage. In the second stage, a voltage regulation process compensates for residual energy caused by switching losses and inductive effects, maintaining the voltage at a safe level until the system stabilizes. This approach eliminates the dependence on external resistors for improving the system safety and cost-effectiveness. During normal operation to enhance the dynamic performance of the electric vehicle system, a PMSM drive systems with an integrated ANFIS controller is used for speed regulation. The proposed control strategy synergizes the adaptive learning capability of neural networks with the rule-based reasoning of fuzzy logic, to resulting in improved nonlinear control characteristics compared with PI, FUZZY and ANN Controllers. This paper presents the design and simulation of an PMSM drive system with ANFIS based speed control for EV system. To validate the effectiveness of the proposed system, the MATLAB Simulink model is implemented on a three-phase Surface-mounted PMSM (SPMSM) drive platform. The PMSM drive with ANFIS-controller, exhibits precise and stable speed control, even under rapid transients and varying load conditions and enhanced performance during standard operation offering a reliable, intelligent and cost-efficient solution for modern electric vehicle drive systems.

I. INTRODUCTION

The permanent magnet synchronous motor (PMSM) is commonly used as the power train in electric vehicles [1-4] due to on hand benefits, such as high efficiency, high torque density, and excellent torque ratios [5-9]. Additionally to enhance the driving efficiency of PMSMs and minimize the driving currents increasingly rely on high-voltage drive systems [10]. However, high-voltage power train pose a risk of electric shock to the driver in the event of an emergency, such as a car crash, to address this concern, the United Nations Vehicle Regulation ECC R94 mandates that the DC bus capacitor voltage is reduced to safe level with a short duration [11], [12].

The winding-based discharge method can not only reduce the volume of the discharge circuit but also be cost- effective [13-15]. The schematic block diagram of the EV powertrain actuation system as shown in Figure 1. The topology of an Electric Vehicle (EV) powertrain employing a Permanent Magnet Synchronous Motor (PMSM). The system includes a battery pack, DC–DC boost converter, inverter, PMSM, and gearbox. The battery supplies DC power, which is boosted and converted into three-phase AC by the inverter to drive the PMSM. The motor output is transmitted to the wheels through the gearbox.

A breaker is incorporated for safety and is tripped during emergencies or crashes to isolate the battery, ensuring system protection and operational safety. A dc-bus voltage regulator based on a proportional integral controller and a modulation index controller are used to generate the reference d-axis current in order to stop the bus voltage. A fixed d-axis current and piecewise q-axis current control is suggested in [16] with the goal of discharging the capacitor voltage of specific EV driven systems with large inertia and minimal safe current. Furthermore, the synchronous reference frame of the three-phase PWM rectifier model is nonlinear, making the ANFIS based approach inapplicable to the system. The purpose of this study is to provide a reliable dc-bus capacitor discharge method for PMSM EV drives in the event of a discharge circuit failure. To achieve the dc-bus voltage constant and prevent voltage spikes, the measured total disturbance is instantly corrected to the dc-bus capacitor energy loop control law.

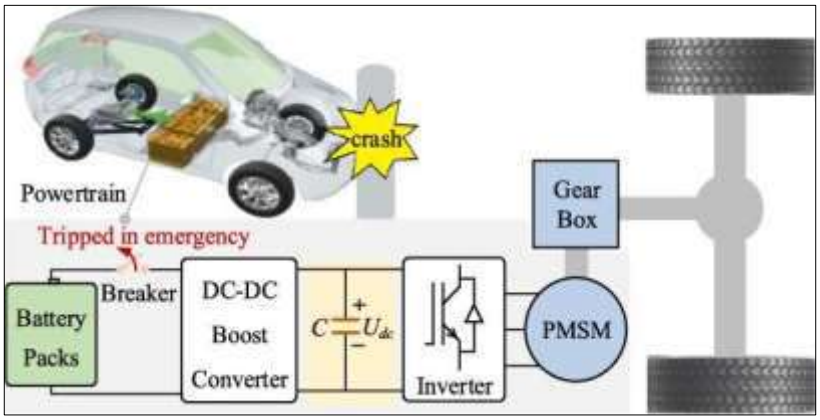

Figure1: Schematic diagram of PMSM-EV powertrain systems.
Source: Authors, (2026).

In the event of an emergency involving electric vehicles, a malfunctioning or failed bleeding resistor can pose serious risks of electric shock to both passengers and rescuers. To enhance EV safety, a practical solution is to implement advanced discharge circuit fault-handling techniques. These techniques ensure that the discharge process adheres to critical safety standards, such as completing discharge within five seconds while preventing voltage surges. By integrating these safeguards, the risk of high-voltage exposure can be significantly minimized, making emergency responses safer and more effective. To stabilize the voltage, ESO is used to monitor the dc-bus capacitor energy until the voltage drops to zero. The active disturbance rejection observer, which includes ESO [17]. The mathematical model of the Permanent Magnet Synchronous Motor (PMSM) in the rotating dq-reference frame is employed because it accurately represents both the electrical and mechanical dynamics of the motor during the capacitor discharge operation. The following equations describe the stator voltage, current variation, and torque production in the PMSM [18-20].

$$\begin{cases} u_d = R_s i_d + L_s \dfrac{di_d}{dt} - \omega_e L_s i_q \\ u_q = R_s i_q + L_s \dfrac{di_q}{dt} + \omega_e L_s i_d + \omega_e \psi_f \\ T_e = \dfrac{3}{2} p \psi_f i_q \end{cases} \tag{1}$$

Where i_d, i_q and u_d, u_q: d axis and q-axis of stator currents and voltages, L_s: stator inductance, R_s: Stator resistance, ω_e: electrical angular velocity, p: pole pair, ψ_f: flux linkage T_e: electromagnetic torque. Under steady state condition the mechanical equation of the permanent magnet synchronous motor can be expressed as,

$$J \frac{d\omega_m}{dt} = T_e - B_m \omega_m \tag{2}$$

Where ω_m : mechanical angular velocity, J and B_m: inertia and mechanical damping coefficient. Under dynamic state condition the dc capacitor voltage u_{dc} can be expressed based on the 3-phase inverter circuit which is shown in Figure 2

$$C \frac{du_{dc}}{dt} = i_{dc} \tag{3}$$

Where i_{dc} and u_{dc} stand for the dc-bus current and voltage, respectively, and C is the capacitor.

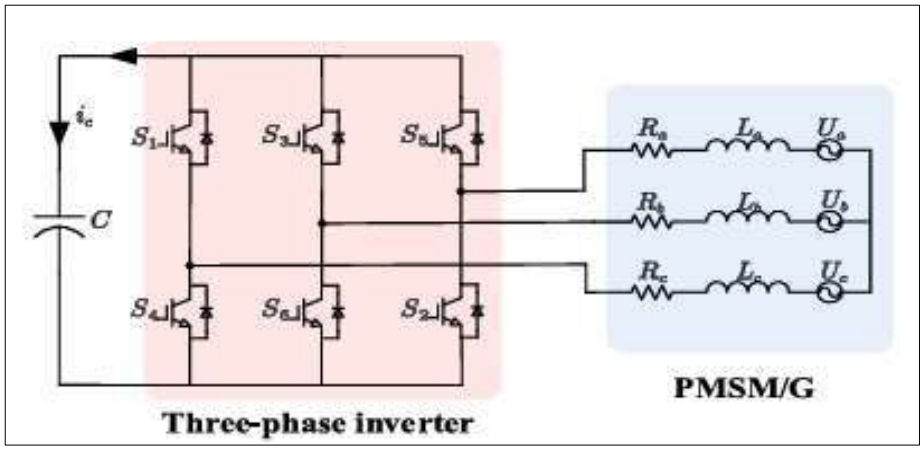

Figure 2: Three phase inverter with PMSM winding based dc-bus capacitor.
Source: Authors, (2026).

The Figure 2 shows that the three phase inverter with PMSM winding based dc bus capacitor discharge, however from the basic fundamentals the converter's power loss, the AC side's power should match the DC side's power, which means

$$u_{dc}i_{dc} + P_{con} = -\frac{3}{2}\left(u_d i_d + u_q i_q\right) \tag{4}$$

Where p_{con}: Power switching loss. To examine the power flow process during discharge, substitute (1) and (3) equations into the instantaneous power balance equation (4).

$$\frac{d}{dt}\left(\frac{1}{2}Cu_{dc}^2\right) = -\frac{3}{2}\omega_e\psi_f i_q - \frac{3}{2}R_s\left(i_d^2 + i_q^2\right) - \frac{3}{2}\left(L_s i_q\frac{di_q}{dt} + L_s i_d\frac{di_d}{dt}\right) - P_{con} \tag{5}$$

From equation. (5) it is observed that, a portion of the permanent magnet synchronous motor's electromagnetic power output is converted to inductance coil energy, copper winding loss, and converter loss. The capacitor's energy storage is then modified using the residual.

II. PROPOSED MODEL OF THE ROBUST WINDING BASED DISCHARGE METHOD

When EVs experience an emergency with an active discharge circuit defect, it's critical to redesign a robust discharge strategy in order to achieve a safe and dependable discharge technique. Thus, this section presents a reliable winding-based dc-bus capacitor discharge method based on ESO.

II.1 RAPID DISCHARGE STATE:

When an active discharge is needed, it is significant and safe for both passengers and rescuers if the dc-bus voltage can drop to safe levels right away. When an emergency occurs in an electric car, the back electromotive force (EMF) is more than the safe voltage because the motor speed is higher. Due to the dc-bus capacitor voltage follow the back EMF, the dc-bus capacitor voltage can drop to safe voltage when the back EMF is reduced to safe voltage. According to the flux-enfeebling principle, a large d-axis current is injected to rapidly reduce the EMF because the dc-bus voltage is proportional to the PMSM's EMF. At the same time, the q-axis current remains at zero to stop the conversion of kinetic energy into electrical energy [21]. From EVs PMSM powertrain system which is shown in fig.1. The dc-bus voltage is expressed as

$$u_{dc} = \sqrt{3}\omega_e\left(\psi_f + L_s i_d\right) - R_s\sqrt{i_d^2 + i_q^2} - 2V_{on} \tag{6}$$

Where V_{on} : diode conducted voltage. The voltage should decrease to a safe level during the rapid discharge stage. Then, the flux-enfeebling current on the d-axis is expresse

$$i_d^* = \frac{U_{safe} - \sqrt{3}\omega_e\psi_f}{\left(\sqrt{3}\omega_e L_s + R_s\right)} \tag{7}$$

Where U_{safe} : safe voltage 60V. Consequently, once the active discharge is needed, the estimated d-axis current can be injected to lower the dc-bus voltage to the safe voltage. A zero q-axis current is applied concurrently to stop any electromagnetic power from turning into electrical energy.

II.2 BUS VOLTAGE CONTROL STAGE ON ESO

The Extended State Observer (ESO) is a powerful control method widely used to manage disturbances and enhance the robustness of dynamic systems, particularly in challenging environments in electric vehicle (EV) powertrains. In the context of Permanent Magnet Synchronous Motor (PMSM) drives, the ESO plays a crucial role in managing uncertainties, compensating for system disturbances, and improving control precision. When the DC-bus voltage reaches 60 V, the ESO-based voltage control stage is activated. To maintain the voltage within a safe range 60 V the controller regulates the discharge process and ensures stable operation, a robust voltage control loop is designed. Since the energy flow during the discharge mode described in Equation (5) exhibits nonlinear characteristics, the PI, FUZZY controller is unable to produce adequate results, particularly when motor parameters will alter during the discharging mode to overcome this ANFIS with ESO-based ultra-local model is introduced to effectively address this issue. For converting Equation (5) into an integral series form, the first-order ultra-local model of a single-input and single-output system is defined as given in [22–25].

$$y^{\cdot} = F + \alpha u \tag{8}$$

Where F Stands for known and unknown components of the system, u : control variables, y : output variables, and α : nonphysical scaling factor. This article's mathematical model of the energy flow-based ESO can be stated using formulas (5) and (8).

$$\frac{dE_c}{dt} = F + \alpha u \tag{9}$$

Where E_c: $0.5Cu^2_{dc}$, u: i_q, α: $-1.5\omega_e\psi_f$ and the other terms on the right side of equation (5) except $-1.5\omega_e\psi_f i_q$ are treated as the total disturbance and notated as F

$$F = -\frac{3}{2}R_s\left(i_d^2 + i_q^2\right) - \frac{3}{2}\left(L_s i_q \frac{di_q}{dt} + L_s i_d \frac{di_d}{dt}\right) - P_{con} \tag{10}$$

Equation (10), shows that the total disturbance corresponds to the overall power loss, which includes switching loss, winding copper loss, and inductive coil energy storage. It is assumed that *F* remains constant during each sampling period. A linear equation of ESO, can be formulated based on the ultra-local model, which is shown in fig.4 proportionately considering E_c and F as a variables given in Equation (8) is expressed as.

$$\begin{cases} e_1 = z_1 - E_c \\ \dot{z}_1 = z_2 - \beta_1 e_1 + \alpha u \\ \dot{z}_2 = -\beta_2 e_2 \end{cases} \tag{11}$$

Where z_1 and z_2: estimated value of E_c and F. β_1 and β_2: feedback gains it can be estimate the real-time value of E_c and F that is, $Z_1 \rightarrow E_C$; $Z_2 \rightarrow F$. From the above mathematical model analysis the winding based DC- bus capacitor discharge is implemented with proposed control strategy mechanism is described with ANFIS and ESO which is described in the subsequent sections.

III. WINDING BASED DC BUS CAPACITOR DISCHARGE STRATEGY WITH ANFIS

The conventional and suggested discharge methods using the dc-bus voltage controller based on ESO. It also presents the suggested resilient dc- bus capacitor discharge strategy. The proposed winding based dc-bus capacitor discharge control system as shown in fig.3 and the corresponding bus voltage control strategy on ESO of internal diagram as shown in fig.4. The proposed strategy consists of two stages. In the rapid discharge stage, a large flux-enfeebling d-axis current is injected into the motor, reducing the back electromotive force (EMF) and consequently lowering the dc-bus voltage to a predefined safe threshold. During this stage, the q-axis current is maintained at zero to prevent additional energy conversion from mechanical to electrical form.

Once the safe voltage is reached, the process transitions into the voltage regulation stage. During normal driving, Port-1 is turned ON the motor uses vector control to run the vehicle, while the ESO helps the current follow the reference smoothly. When the system receives a discharge command, Port-2 is turned ON, and the ESO-based discharge control is used to safely and quickly reduce the dc-bus capacitor voltage through the motor windings [26]. ANFIS are used in the d-axis and q-axis current loops so that the current can respond fast and accurately in both normal operation and discharge mode. Where as ESO is employed to estimate and compensate for system disturbances such as copper losses, switching losses and inductive energy storage

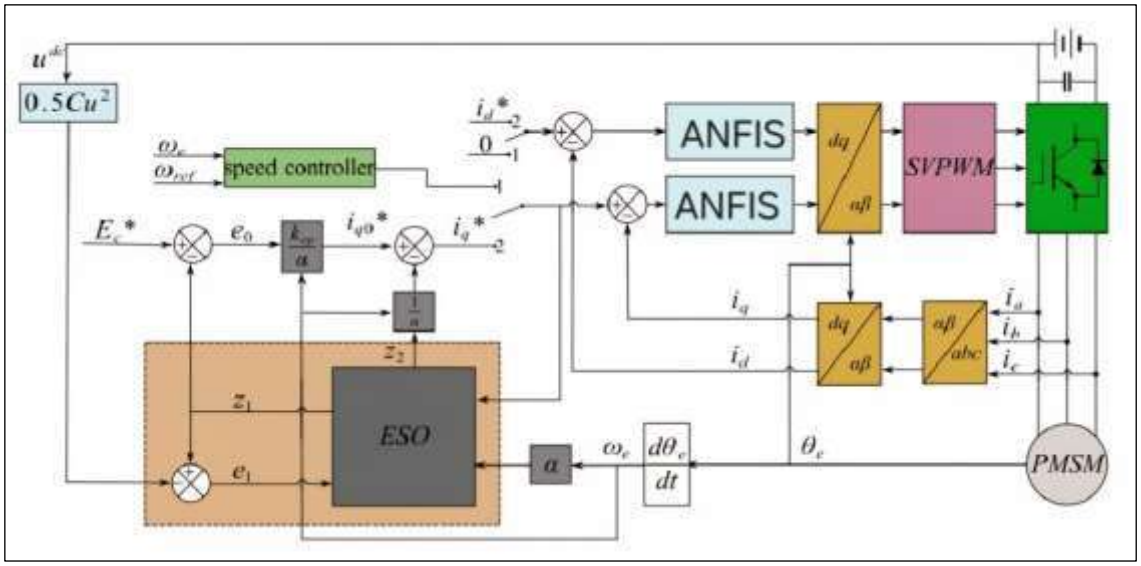

Figure 3: Block diagram of the winding based dc bus capacitor discharge strategy.

The ESO shown in the above block diagram fig.3 is represented as a subsystem in the fig.4 below, showing its internal structure.

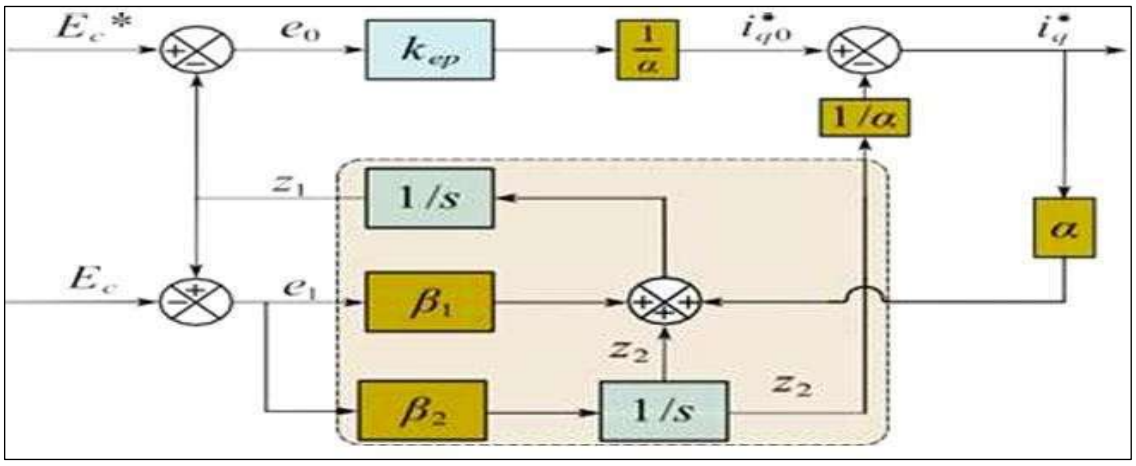

Figure 4: Bus voltage control strategy on Extended State Observer (ESO).
Source: Authors, (2026).

The ESO-based design enhances the robustness of the discharge control by effectively addressing nonlinear dynamics and parameter variations that conventional PI controllers cannot handle. In addition to ensuring safety under emergency conditions, maintaining high performance under normal operating modes is equally important for EV traction systems [27]. This work also incorporates an Adaptive Neuro-Fuzzy Inference System (ANFIS) controller for PMSM speed regulation. The ANFIS controller combines the self-learning capability of neural networks with the reasoning ability of fuzzy logic. This hybrid intelligent control strategy improves dynamic response, robustness, and overall stability of the PMSM drive during normal operation.

IV. PROPOSED ADAPTIVE NEURO FUZZY INFERENCE SYSTEM (ANFIS) CONTROLLER

Fig.5 shows that an Adaptive Neuro-Fuzzy Inference System (ANFIS) consists of a five-layer feed-forward structure that integrates the human-interpretable fuzzy logic framework with the adaptive learning capability of neural networks. Each layer performs a specific computational function in the Sugeno-type fuzzy inference process. The rules are expressed which is shown in table.1

Table:1 Sugeno ANFIS Rule Base.

Rule	Antecedent (IF …)	Consequent (THEN …)
R1	If (x) is (A_1)	($f_1 = p_1x + q_1$)
R2	If (x) is (A_2)	($f_2 = p_2x + q_2$)
R3	If (x) is (A_3)	($f_3 = p_3x + q_3$)

Source: Authors, (2026).

Here, $\boldsymbol{A_1}, \boldsymbol{A_2}$,and $\boldsymbol{A_3}$ denote the three membership functions corresponding to the input variable. The parameters $\boldsymbol{p_i}$ and $\boldsymbol{q_i}$ represent the consequent parameters, which are tuned during the learning process to achieve optimal system performance.

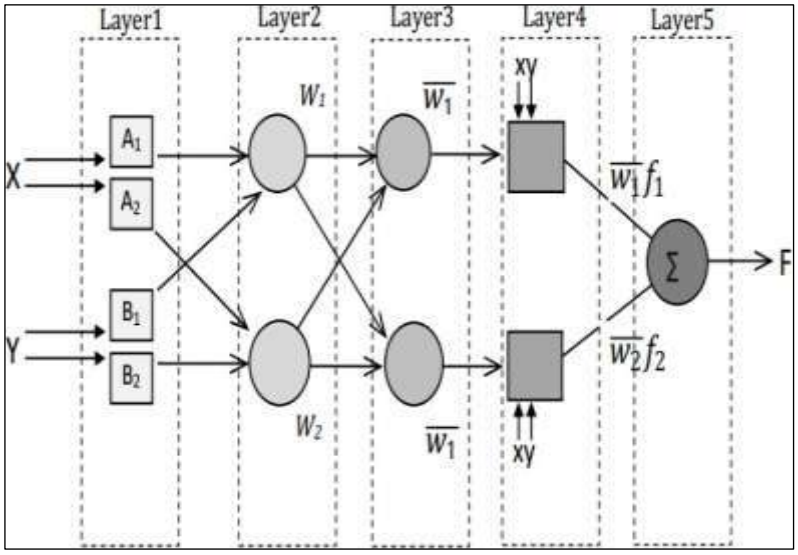

Figure 5: Rule based Adaptive Nuero Fuzzy Inference System.
Source: Authors, (2026).

From the fig.5 it is observe that the five-layer structure of a typical Sugeno-type ANFIS model.

Layer 1: Fuzzification Layer (Input Membership Functions)

This layer transforms the crisp input variables into fuzzy values by evaluating their membership degrees. Each neuron corresponds to a linguistic term such as Negative, Zero, or Positive. The output of this layer is:

$$O_{1,i} = \mu_{A_i}(x) \tag{12}$$

Where $\mu_{A_i}(x)$denotes the membership grade of input $x$to fuzzy set A_i. The parameters of this layer are called premise parameters, which are tuned during training.

Layer 2: Rule Layer (Firing Strength Computation)

Each neuron in this layer represents a fuzzy rule. The nodes multiply the incoming fuzzified signals to compute the firing strength of each rule. For a 2-input system:

$$O_{2,i} = w_i = \mu_{A_i}(x) \cdot \mu_{B_i}(y) \tag{13}$$

Thus, this layer models fuzzy logic's AND operation using the product operator.

Layer 3: Normalization Layer

This layer normalizes the firing strengths of all rules to ensure they sum to one. The normalized weight for rule $i$is calculated as:

$$O_{3,i} = \bar{w}_i = \frac{w_i}{\sum_{k=1}^{n}.w_k} \tag{14}$$

This normalization reflects the contribution level of each rule in the inference process.

Layer 4: Consequent Layer (Sugeno Rule Output)

Each neuron in this layer generates the rule's output based on a first-order Sugeno fuzzy model. The output of this layer is:

$$O_{4,i} = \bar{w}_i f_i = \bar{w}_i(p_i x + q_i y + r_i) \tag{15}$$

Here, p_i, q_i, and r_i are consequent parameters, trained together with premise parameters using a hybrid learning algorithm.

Layer 5: Output Layer (Defuzzification)

This layer aggregates the weighted outputs of all rules to obtain a single crisp system output. The output is computed as:

$$O_5 = \sum_{i=1}^{n}.\bar{w}_i f_i \tag{16}$$

Thus, Layer 5 performs defuzzification through a weighted average, delivering the final ANFIS prediction or control action. From section I to section IV are integrated based on the scope of the proposed control strategy of PMSM with EV system is tested in MATLAB Simulink Environment which described elaborately in the subsequent section in this paper.

V. TESTING OF SIMULINK BLOCK WITH PROPOSED METHOD

The Simulink block implemented by integrating of PMSM dc bus capacitor winding based with ESO and ANFIS which is shown in the fig.6 and it demonstrates the dual benefits of the winding-based capacitor discharge method and the ANFIS speed regulation strategy for PMSM-driven electric vehicles. The parameters of the PMSM Simulink model as shown in table.2. The Simulink block consists of the main functional subsystems required for the proposed robust dc-bus capacitor discharge control. The power supply section includes the fuel cell and battery connected through a bidirectional DC/DC converter. The power inverter drives the Permanent Magnet Synchronous Machine (PMSM) using space-vector pulse-width modulation (SVPWM).

The motor control strategy is implemented using an ANFIS-based speed controller along with d-q axis current controllers for accurate torque and current tracking. An Extended State Observer (ESO) is integrated to estimate disturbances and maintain dc-bus voltage stability during discharge events. Additionally, an electric braking interface and sensor feedback loops are included to ensure safety and smooth operational transitions between normal driving and discharge mode. From stable operation the EV battery fuel systems charging with an SOC condition. Once discharge the system automatically switches back to normal operation, where the fuel cell supplies power to the dc-bus and recharges the battery. This ensures a smooth transition and efficient recovery of the vehicle's energy.

Table:2 Parameters of PMSM.

Parameter	Symbol	Value
DC Bus Capacitor	C	420μ_F
DC Bus Voltage	V_{dc}	320V
Stator Resistance	R_s	0.2 Ω
d-axis Inductance	L_d	1.5 mH
q-axis Inductance	L_q	2.0 mH
Permanent Magnet Flux	ψ_f	0.12 Wb
Pole Pairs	p	4
Rotor Inertia	J	0.01 kgm²
Load Torque	T_{load}	10 - 50 Nm
Motor speed	ω_m	1000rpm

Source: Authors, (2026).

During the emergency scenario, the capacitor discharge process was initiated by injecting a large flux- enfeebling current through the stator windings, where the Extended State Observer (ESO) played a vital role in estimating system uncertainties such as copper losses, switching effects, and residual inductive energy. By compensating for these disturbances, the ESO ensured that the dc-bus voltage was held within a safe operating margin, preventing any rebound or unsafe levels of stored energy. However the Simulink model is tested and the corresponding test results are analyzed based on the speed regulation, torque, stator voltage, stator current as a case study 1. Steady state operation and 2. Dynamic state operation.

Case:I The steady state behavior of the PMSM drive system: ANFIS with EV

In this case, the steady-state performance of the ANFIS-controlled PMSM drive is evaluated at 1000 rpm under constant load that is 25 Nm. The controller accurately maintained the reference speed with negligible error and ensured stable dc-bus voltage (320V), battery voltage (130V), and current (25A,). The dq-axis currents remained steady, providing effective flux and torque control, while the electromagnetic torque showed 25Nm output with minimal ripple. The corresponding test output results speed characteristics 7(a), torque characteristics 7(b), DC bus voltage 7(c) and stator current characteristics 7(d) are shown in fig.7 under steady state operation.

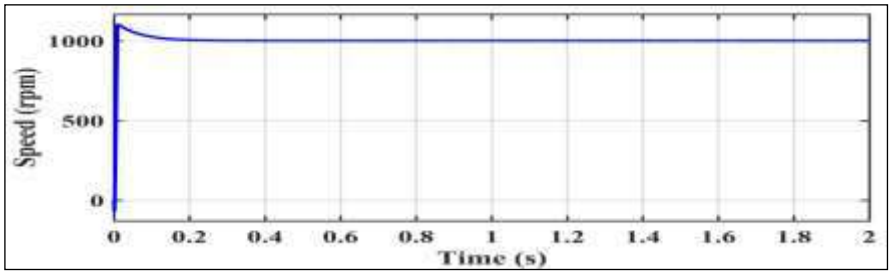

Figure 7(a): Speed(rpm) v/s Time(s).

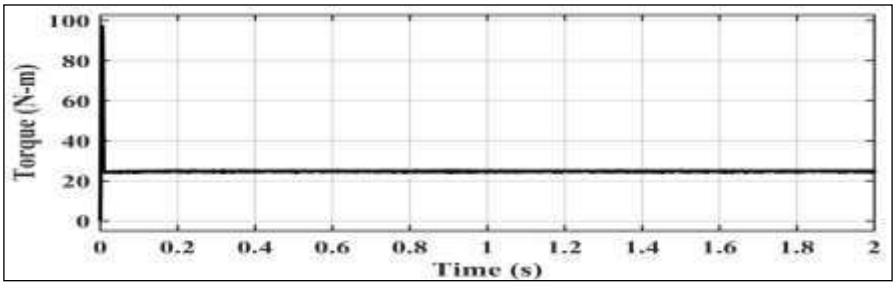

Figure 7(b): Torque(N-m) v/s Time(s).

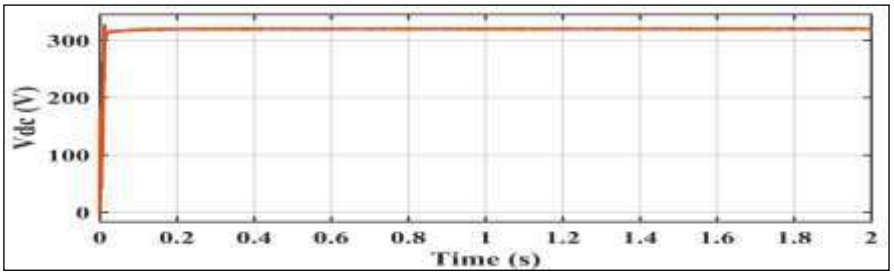

Figure 7(c): V_{dc} (v) v/s Time (s).

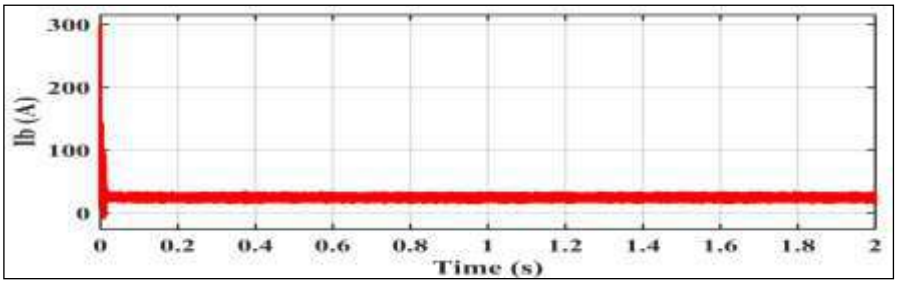

Figure 7(d): Ib (A) v/s Time (s).

Figure 7: Simulation results of the PMSM drive under steady-state operation.
Source: Authors, (2026).

Fig.7 shows that the Simulation test results of the PMSM drive under steady-state operation. Fig7(a), it is observed that PMSM with EV drive system initially the speed raises above the rated speed because of the rapid acceleration of torque and then the 0.2s speed is stabilizes and it reaches the rated speed of 1000 rpm proportionately maintain constant, validating its effectiveness for EV DC-bus capacitor discharge. Fig7(b) shows torque response reached peak value approximately 95Nm without damping oscillations because of the controller applies maximum acceleration torque to reach the reference speed rapidly, After the motor reaches the constant speed, therefore, the electromagnetic torque decreases and confirming stable performance of torque 25Nm during DC-bus discharge in EV. Fig 7(c) shows DC-bus voltage reached 340V because of the DC-bus capacitor draws a large inrush current.

After charging, the control system regulates the bus voltage, causing it to reduce and stabilize at the rated level and then maintained constant 320V, indicating stable regulation during capacitor discharge in EV. Fig 7(d) shows that the stator current initialy reached 300A peak value because of the motor needs a big initial torque to start moving, so the controller sends a large current for a short time and the fraction of seconds will falldown to low steady value and maintaining constant for confirming safe and controlled discharge in the EV PMSM drive. and then decreased 50A with high settling time and maintained constantly without any damping oscillations.

Case:II The dynamic behavior of the PMSM drive system: ANFIS for EV

The PMSM drive system under ANFIS control simulation model is tested with multiple speed transitions under a constant load that is 25Nm. The motor operated at different speeds 1000 rpm, 500 rpm, 300 rpm, 600 rpm, 800 rpm and 1000rpm. Throughout these variations, the ANFIS controller ensured fast speed tracking with negligible steady-state error and minimal overshoot. The dq-axis currents adapted smoothly, maintaining flux and torque control, while the electromagnetic torque showed minimal ripple. The dc-bus voltage (320V), battery voltage (130V), and current (25A,) remained stable, confirming effective power management.

The ANFIS-controlled PMSM drive demonstrated excellent dynamic performance and stability, making it well-suited for electric vehicle. The corresponding test output results speed characteristics 8(a), torque characteristics 8(b), DC bus voltage 8(c) and stator current characteristics 8(d) are shown in fig.8 under dynamic state operation.

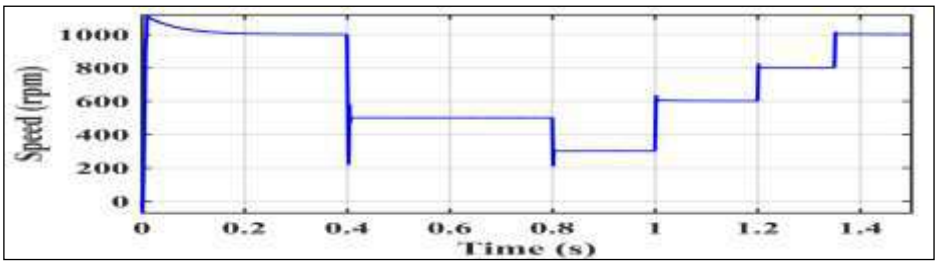

Figure 8(a): Speed(rpm) v/s Time(s).

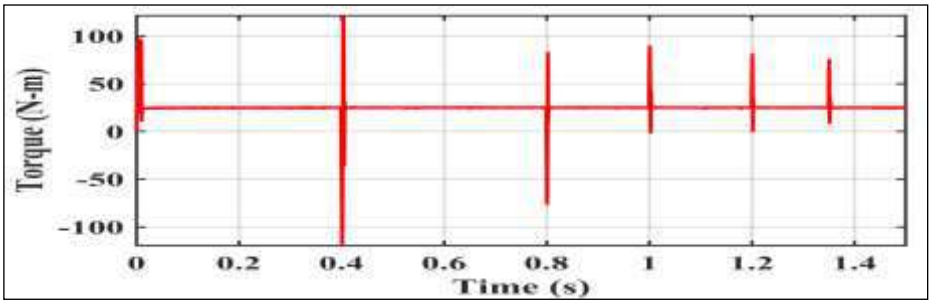

Figure 8(b): Torque (N-m) v/s Time(s).

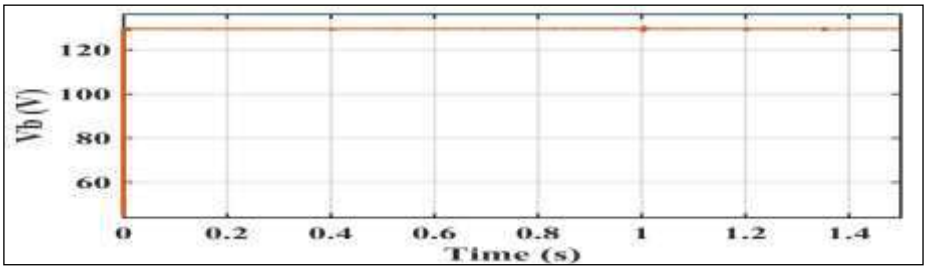

Figure 8(c): Vb (v) v/s Time(s).

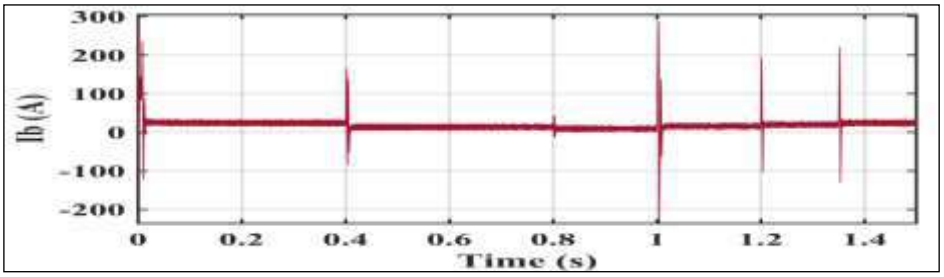

Figure 8(d): Ib(A) v/s Time(s).

Figure.8: Simulation Results under Dynamic Behavior of the PMSM Drive System.
Source: Authors, (2026).

Figure 8 shows that the Simulation test results of the PMSM drive under dynamic state operation. From the fig.8(a) observed that initially the speed shows peak value in a fraction of seconds and slightly settles the rated speed 1000 rpm because of the rapid acceleration of torque and it continuous and slowly step down to 500rpm at 0.4 s, after that it will continues and step down to 300rpm at 0.8s proportionately with 0.2 s time intervals the speed can be reaches to 1000rpm at 1.6s this process is analyzing until to reach the steady state. The motor tracks each reference level accurately, confirming strong dynamic response in EV drive conditions. Multiple speeds are used to evaluate controller performance under varying operating points.Fig. 8(b) shows torque variations in both positive and negative directions at different time intervals like 0.1s the load torque is 95Nm and then decreases to the statutory load limit 25Nm maintained with constant without damping oscillations at 0.4s, 0.8s and 1.4s respectively it indicating smooth transitions between motoring and regenerative modes with fast and controlled response.

Figure 8(c) shows that the DC-bus voltage stays around 125 V, confirming stable regulation during EV capacitor discharge. Fig 8(d) shows the range of current 20 A during normal operation. The speed reference changes, a sharp transient current spike at 0.4 s raised to nearly +180 A and then drops to –150 A as the motor responds to the speed reduction. The transient peaks at 0.8 s, 1.0 s, 1.2 s, and 1.4 s, where the current briefly reached values between 150-200 A, after each transient, the current quickly returns to its steady value around 10-20 A discharge current stays close to zero with different intervals only brief switching transients, demonstrating effective current regulation and stable capacitor discharge in the EV PMSM drive.

VI. ESO CONTROLLER FOR WINDING BASED SAFE DISCHARGE OF DC-BUS CAPACITOR

The simulation model of ESO controller as shown in fig.9. The Extended State Observer (ESO) controller is evaluated for the proposed winding-based safe discharge method in PMSM drives. During emergencies, the stator windings dissipate the dc-bus capacitor's stored energy after an initial flux-enfeebling d-axis current triggers rapid voltage reduction. The ESO accurately estimated and compensated for disturbances such as copper and switching losses, ensuring smooth, stable voltage decay without rebound. The simulation test results of the system as shown in fig 10(a) speed characteristics, fig 10(b) bus voltage characteristics, fig 10(c) torque respectively.

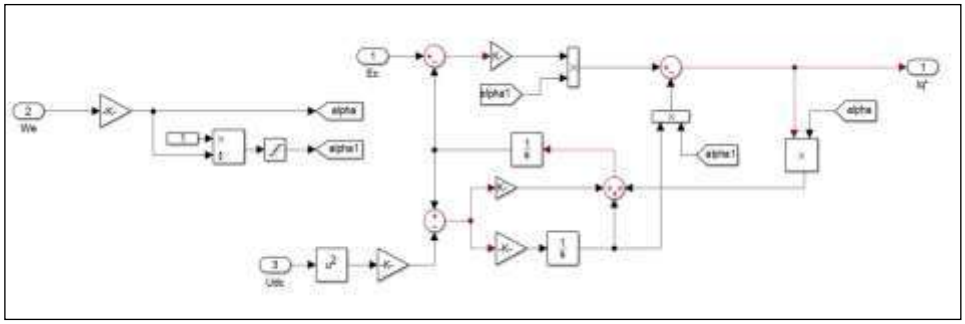

Figure 9: Simulation mode of ESO controller.
Source: Authors, (2026).

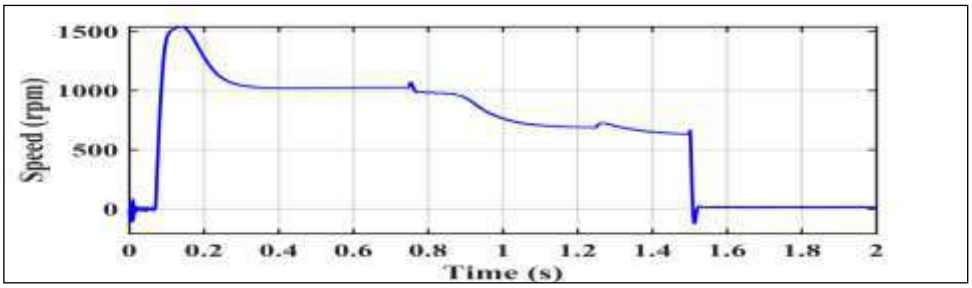

Figure 10(a): Speed(rpm) v/s Time(s).

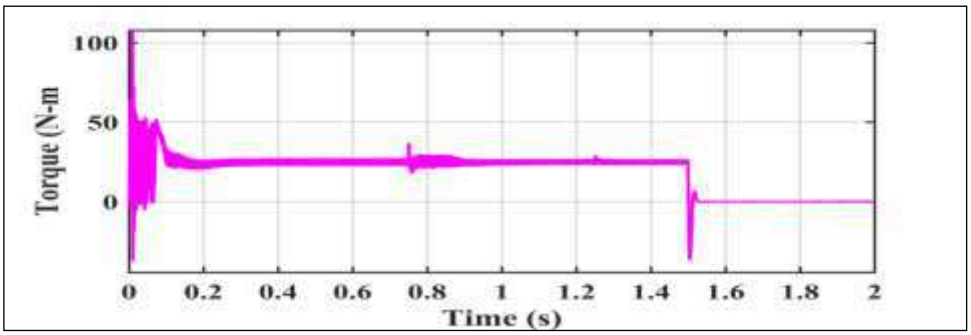

Figure 10(b) : Torque (N-m) v/s Time(s).

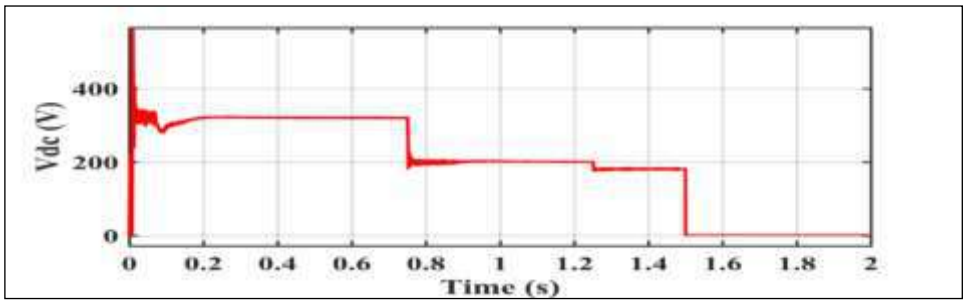

Figure 10(c): Vdc(v) v/s Time(s).

Figure 10: Simulation Results of ESO-Based Winding DC-Bus Capacitor for Safe Discharge.
Source: Authors, (2026).

From the simulation test results it is observed that fast discharge to safe voltage levels within limits compared to conventional methods, the ESO based approach achieved faster response, better disturbances rejection, and higher robustness confirming its effectiveness for safe PMSM operation in EV fault conditions. Fig.10 shows that the Simulation test results of the ESO controller for winding based safe discharge of dc bus capacitor. From the fig10(a) it is observed that PMSM speed during discharge the speed raises high peak around 1500 rpm due to the fast corrective action of the ESO, stabilizes near 1000 rpm, then gradually decreases in steps until it reaches zero, indicating controlled deceleration.

Figure 10(b) it is observed that the torque initially raised 100 Nm due to the startup transient and then settles around 40-45 Nm. A small disturbance appears near 0.8 s, 1.45 s the torque drops sharply to nearly 0 Nm, after it remains constant. Fig10(c) it is observed that the DC-bus voltage raised 390 V due to the initial transient, then stabilizes 300 V. At 0.8 s and 1.2 s it drops in steps to around 200 V and 170 V, and finally falls to 20 V at 1.4 s, indicating full capacitor discharge. Finally from the simulation test results are summarized compared to conventional methods with that of the proposed method which is tabulated in table.3.

Table:3 Comparison of test results.

Performance Criteria	PI Controller	Fuzzy Controller	ANN Controller	ANFIS Controller
Steady-State Speed (1000 rpm)	Acceptable regulation but small steady-state error present	Improved error reduction vs PI; dependent on rule accuracy	Good accuracy with reduced ripple but training-dependent	**Negligible error; precise tracking of 1000 rpm**
Dynamic Speed Transitions(1000 → 500 → 300 → 600 → 800 → 1000 rpm at 25 Nm load)	Slow response with overshoot and long settling	Faster than PI but moderate oscillations	Fast response; oscillations still exist	**Fastest response; minimal overshoot; shortest settling time**
Torque Ripple (25Nm)	High ripple	Moderate reduction depending on rules	Reduced ripple but still noticeable	**Smooth torque; minimal ripple**
dq-Axis Current Stability(25A)	Moderate stability	Good stability	Sensitive to parameter/training mismatch	**Excellent stability**
DC-Bus Voltage Regulation (320 V)	Poor stability during variations	Moderate performance	Good but with small fluctuations	**Stable and well-regulated at 320V**
Battery Operating Stability(130 V, 25 A)	Stable but slower dynamics	Good adaptation	Some fluctuations under disturbances	**Stable with strong disturbance rejection**

Source: Authors, (2026).

From the table.3 it is observed that the overall performance of the proposed control strategy for PMSM with EV system.

PI Controller: Shows acceptable steady-state response but suffers from slow transients and higher torque ripple. Stability reduces when dc-bus voltage drops during discharge.

Fuzzy Controller: Improves speed tracking and reduces ripple compared to PI. However, performance depends strongly on rule tuning and operating conditions.

ANN Controller: Provides faster dynamic response and better current regulation. Stability is affected by parameter variations outside the trained region, causing small fluctuations during discharge events.

ANFIS Controller: Delivers the best overall performance with fast settling, negligible speed error, smooth torque, and stable dq-axis currents maintains strong robustness against dc-bus capacitor discharge disturbances in EV operation.

VII CONCLUSIONS

The proposed control strategy discharge mechanism operates through two distinct stages to ensure rapid and controlled voltage reduction effectively addressed the limitations with active discharge circuits. The Simulation results confirmed that the two-stage discharge process, consisting of rapid flux-enfeebling current injection followed by ESO regulated voltage control, ensured a fast reduction of the dc-bus voltage to safe levels while preventing current and voltage overshoot. However the winding-based safe discharge method for the dc-bus capacitor in PMSM-driven electric vehicles, supported by ESO-based regulation and ANFIS-based speed control of electric vehicle.

The ESO demonstrated strong capability in estimating and compensating disturbances. However the integration of ESO based capacitor discharge with ANFIS based speed regulation provides a comprehensive solution that enhances both safety during emergencies and performance during normal driving operations. The proposed method shows strong potential for practical deployment in electric vehicle drive systems, ensuring passenger safety, reliable operation, and improved energy efficiency. Finally the proposed methodology ensures that safe voltage discharge during fault scenarios and enhanced the performance during standard operation, offering a reliable, intelligent and cost efficient solution for modern electric vehicle drive system.

ABSTRACT

The widespread adoption of Kotlin for server-side development has emphasized the importance of efficient JSON processing. This study aimed to empirically evaluate and compare the performance of three JSON libraries—Jackson, Gson, and KotlinX Serialization—in Kotlin-based server environments. Using structured experiments, the research measured execution time, memory utilization, and CPU consumption during parsing, serialization, and deserialization tasks involving nested JSON data with incremental complexity. Statistical analyses confirmed significant performance differences among libraries. KotlinX Serialization consistently outperformed Jackson and Gson across execution speed, memory efficiency, and CPU utilization, primarily due to its compile-time code generation approach. Jackson showed superior memory management and efficient serialization for smaller datasets, while Gson exhibited lower overall performance. These results offer critical guidance for developers selecting appropriate JSON libraries, highlighting KotlinX Serialization's suitability for high-performance applications. The findings significantly enhance the current understanding of JSON processing efficiency and suggest avenues for further investigation into additional libraries and real-world application contexts.

I. INTRODUCTION

The rapid evolution of software technology has significantly elevated the importance of server-side development, as backend systems have become crucial in ensuring scalability, performance, and robustness of modern applications. Kotlin, a statically-typed programming language introduced by JetBrains, has steadily gained popularity as an efficient alternative to Java, particularly for server-side programming. Kotlin's concise syntax, enhanced type safety, interoperability with Java, and modern programming paradigms such as coroutines have substantially increased its adoption among developers [1]. This growth has been notably supported by frameworks explicitly tailored for Kotlin, such as Ktor, and by mainstream Java frameworks like Spring Boot, which have adopted official support for Kotlin [2]. According to the JetBrains Developer Ecosystem Report (2023), approximately 52% of Kotlin developers use Kotlin for backend development, signifying an upward trend in its acceptance within the industry [2].

Leading global enterprises including Amazon, Atlassian, Adobe, and Mercedes-Benz.io have embraced Kotlin within their backend infrastructure, particularly for microservices and enterprise-level applications, further validating its suitability for high-performance environments [3]. A crucial aspect of server-side development involves effective data communication, where JSON (JavaScript Object Notation) has become the standard format due to its lightweight nature, ease of parsing, human readability, and compatibility across diverse platforms[4],[5]. JSON's semi-structured nature makes it adaptable to various application scenarios but also requires efficient processing mechanisms, including parsing, serialization, and deserialization, to transform JSON data into usable native objects within server applications. These processing tasks significantly impact the overall performance of a server, particularly in contexts involving high volumes of concurrent data exchanges [6]. Efficient JSON processing is thus imperative, highlighting the importance of selecting suitable JSON libraries capable of optimizing performance and resource utilization in Kotlin-based server environments.

Despite the availability of numerous JSON processing libraries, empirical comparisons that specifically focus on Kotlin server environments remain relatively scarce. The core research problem arises from the necessity to evaluate performance discrepancies among available JSON libraries under realistic workloads typical of Kotlin server applications. Different libraries approach JSON processing through varying computational strategies. Prominent among these are Jackson, Gson, and KotlinX Serialization, each employing distinct methodologies that directly influence their runtime efficiency. Jackson and Gson predominantly rely on reflection, dynamically inspecting objects at runtime to facilitate JSON transformations[7],[8]. Conversely, KotlinX Serialization employs a fundamentally different strategy, generating serialization logic at compile-time through compiler plugins, thus reducing runtime overhead [9].

Addressing this central problem requires an approach encompassing empirical evaluation, systematic experimentation, and rigorous statistical analysis. General solutions often involve benchmarking libraries against multiple performance metrics, including execution time, memory consumption, and CPU usage, under various data complexity scenarios. However, such evaluations must also explicitly consider statistical significance to ensure robust, scientifically valid conclusions. Existing literature typically lacks this methodological rigor or generalizes findings from non-Kotlin environments, reducing their relevance to the Kotlin ecosystem. Previous research provides insights into JSON processing performance, although these studies differ substantially in terms of contexts, methodologies, and goals.

Maeda examined the efficiency of various serialization formats, including XML, JSON, and binary formats, within Java-based applications, focusing on comparative metrics such as serialization speed and output size[10]. Vanura and Kriz further evaluated the performance of JSON, MessagePack, and Protocol Buffers across languages like Java, PHP, and JavaScript, emphasizing both speed and data compactness[11]. Similarly, Dhalla conducted performance comparisons among native JSON parsers across multiple languages—Java, Python, .NET Core, JavaScript, and PHP—with emphasis on parsing efficiency, memory usage, and CPU consumption [5]. While valuable, these studies either omit Kotlin-specific implementations or neglect rigorous statistical testing, presenting limitations that hinder direct applicability to Kotlin-based server contexts.

Moreover, in studies specifically addressing Kotlin, KotlinX Serialization emerges as a promising solution explicitly designed to address Kotlin's inherent language features and runtime characteristics. Unlike Jackson and Gson, KotlinX Serialization utilizes compiler-generated code, providing native support for Kotlin's language-specific attributes such as data classes, default parameters, and null-safety guarantees, significantly reducing runtime reflection overhead and improving serialization performance[12]. This inherent compatibility and performance optimization through compile-time code generation positions KotlinX Serialization as an advantageous choice, particularly in scenarios demanding rapid processing and minimal resource usage. However, while KotlinX Serialization theoretically offers these advantages, empirical evidence supporting these claims in realistic server-side conditions remains insufficiently explored.

Previous research has generally tested JSON processing performance within generic or language-neutral environments, often neglecting Kotlin's specific runtime interactions and JVM integration nuances. Furthermore, the absence of comprehensive experimental scenarios involving complex, nested JSON structures, which closely resemble practical server-side data exchanges, limits the existing evidence's real-world applicability. Consequently, a clearly defined research gap emerges, characterized by inadequate empirical benchmarking of JSON libraries within the Kotlin server ecosystem, specifically regarding rigorous statistical testing and practical experimental scenarios involving nested and complex data structures. The existing literature demonstrates significant variations in performance among libraries across different environments and programming contexts, yet lacks specificity and methodological rigor for Kotlin-based implementations.

To address this gap, this study aims to empirically evaluate and compare the performance of three widely-used JSON libraries—Jackson, Gson, and KotlinX Serialization—in realistic server-side scenarios explicitly developed for Kotlin. The primary objective is to systematically assess and quantify each library's efficiency in parsing, serialization, and deserialization tasks involving nested JSON data of varying complexities. The experimental design incorporates multiple performance metrics, namely execution time, memory usage, and CPU consumption, measured under strictly controlled, reproducible conditions. Furthermore, the research methodology integrates comprehensive statistical analysis to validate the significance of observed performance differences, enhancing the robustness and scientific validity of the findings.

The novelty of this study resides in its dedicated Kotlin-specific focus, addressing the need for evidence-based insights applicable directly to Kotlin server-side development. By employing rigorous statistical methodologies and realistic, structured experimental scenarios, the research seeks to provide definitive, actionable insights to support informed decision-making among developers selecting JSON processing libraries. The scope of the study is explicitly confined to server-side JSON processing within Kotlin-based environments, excluding mobile and front-end applications, thereby offering targeted relevance and practical utility for Kotlin backend developers and researchers.

II. THEORETICAL REFERENCE

II.1 SERVER-SIDE DEVELOPMENT AND THE ROLE OF KOTLIN

Server-side development has become fundamental to modern software architecture, providing the backbone for scalability, performance optimization, and system robustness. Kotlin, a statically-typed programming language developed by JetBrains, has emerged as a compelling alternative to Java for backend systems. According to the JetBrains Developer Ecosystem Report (2023), approximately 66% of Kotlin developers utilize the language for Android and server-side applications, demonstrating substantial adoption in enterprise environments [13], [14].

Kotlin's design philosophy emphasizes concise syntax, enhanced type safety, and seamless interoperability with existing Java ecosystems. The language incorporates modern programming paradigms, particularly coroutines for asynchronous programming, which enable developers to write non-blocking code in a sequential style without the complexity of traditional callback mechanisms. Spring Boot, one of the most widely adopted backend frameworks, has provided official Kotlin support since 2017, offering first-class coroutine support, Kotlin-specific DSLs, and enhanced null-safety features.

Similarly, Ktor, a lightweight asynchronous framework built by JetBrains specifically for Kotlin, leverages coroutines for high scalability and provides intuitive Domain-Specific Language (DSL) capabilities for server-side development. Major global enterprises including Amazon, Atlassian, Adobe, and Mercedes-Benz have integrated Kotlin into their backend infrastructure, particularly for microservices and enterprise-level applications, validating its suitability for production environments requiring high performance and reliability. Type safety represents a fundamental property of programming languages that ensures variables access only authorized memory locations in well-defined, permissible ways, thereby preventing invalid operations on objects.

Statically-typed languages like Kotlin perform type checking at compile-time, enabling compilers to optimize code execution and memory usage while catching type errors before runtime. Kotlin's type system incorporates null-safety as a first-class language feature, distinguishing between nullable and non-nullable types at the type-system level. This design choice eliminates entire categories of runtime errors common in Java, particularly NullPointerException occurrences. For JSON serialization libraries, native support for Kotlin's type system features—as provided by KotlinX Serialization—theoretically reduces impedance mismatch between language semantics and serialization logic[15].

II.2 JSON AS THE STANDARD FOR DATA EXCHANGE

JavaScript Object Notation (JSON) has established itself as the de facto standard for data interchange in server-side development due to its lightweight structure, human readability, and cross-platform compatibility. JSON's semi-structured nature provides flexibility for representing complex data hierarchies while maintaining simplicity in parsing and generation. Data serialization, defined as the process of converting data objects into byte streams or character sequences for storage or transmission, forms a critical component of server-side operations. The reverse process, deserialization, reconstructs the original data structure from the serialized format.

In distributed systems and high-performance computing environments, efficient serialization directly impacts system throughput, latency, and resource utilization[16], JSON serialization involves encoding complex data structures while preserving information such as type, order, and relationships between nested elements. The performance characteristics of JSON processing—including parsing speed, memory consumption, and CPU overhead—significantly affect overall server performance, particularly in scenarios involving high-volume concurrent data exchanges typical of modern backend applications.

II.3 PERFORMANCE METRICS IN SOFTWARE SYSTEMS

Performance evaluation of software systems relies on standardized metrics that quantify computational efficiency and resource utilization. The three primary performance dimensions assessed in this study are Execution Time, Memory Usage and CPU Consumption. Execution Time (CPU Time) represents the total duration a CPU spends computing a specific task, excluding time spent on I/O operations or executing other processes. CPU execution time can be calculated as the product of CPU clock cycles and clock cycle time, or equivalently, as the ratio of instruction count and clock rate. This metric directly measures computational efficiency and is inversely proportional to system performance.

Memory Usage quantifies the amount of RAM consumed during program execution, typically measured in bytes, kilobytes, or megabytes. Memory utilization patterns significantly impact system scalability, particularly in server environments handling concurrent requests. Excessive memory consumption can trigger garbage collection overhead in JVM-based systems, indirectly affecting execution time. CPU Consumption is the Measures the percentage of CPU resources utilized during execution, providing insight into processor workload and potential bottlenecks. High CPU utilization may indicate computationally intensive operations, while low utilization might suggest I/O-bound or inefficiently parallelized code.

II.4 STATISTICAL SIGNIFICANCE TESTING IN PERFORMANCE EVALUATION

Statistical significance testing provides the methodological framework for determining whether observed performance differences between systems reflect genuine effects rather than random variation. The Neyman-Pearson hypothesis testing paradigm, widely adopted in empirical software engineering, involves formulating a null hypothesis (typically asserting no difference between conditions) and an alternative hypothesis, then calculating the probability (p-value) of obtaining the observed data assuming the null hypothesis is true [17]. A critical consideration in performance benchmarking is the relationship between sample size and statistical power. As sample size increases, the probability of detecting true effects (statistical power) increases while the risk of Type II errors (false negatives) decreases.

However, with very large samples, even trivial effect sizes may achieve statistical significance, necessitating consideration of practical significance in addition to statistical significance [17].The choice of significance threshold (α level, commonly set at 0.05) represents a balance between Type I errors (false positives) and Type II errors (false negatives). Some researchers argue that exploratory studies with small sample sizes may warrant more liberal thresholds (e.g., $\alpha = 0.20$), while confirmatory studies with large samples should employ more conservative thresholds. Beyond p-values, effect size measures quantify the magnitude of observed differences, providing context for practical importance independent of sample size[17].

II.5 PRIOR RESEARCH ON SERIALIZATION PERFORMANCE

Previous empirical studies have examined serialization format performance across various programming language contexts, though comprehensive Kotlin-specific evaluations remain limited. Maeda (2012) compared object serialization libraries across XML, JSON, and binary formats in Java-based applications, focusing on serialization speed and output size as primary metrics. Vanura and Kriz evaluated JSON, MessagePack, and Protocol Buffers across Java, PHP, and JavaScript, emphasizing speed and data compactness but omitting Kotlin implementations and rigorous statistical validation [18]. Conducted performance analysis of native JSON parsers across five programming languages—Java, Python, PHP, .NET Core, and JavaScript—measuring parsing speed, memory usage, and CPU consumption for JSON documents with varying nesting depth and key-value pair counts. Their findings demonstrated substantial performance variation across language environments, though Kotlin was not included in the comparative analysis [19].

Studies specifically examining MessagePack, Protocol Buffers, and other binary serialization formats have consistently found trade-offs between serialization speed, deserialization speed, and payload size. Protocol Buffers typically achieves faster serialization and smaller payloads compared to JSON, while MessagePack offers balanced performance across multiple dimensions. However, these studies generally employ Java-centric implementations without considering Kotlin-specific libraries or language features. Research addressing Kotlin serialization specifically highlights KotlinX Serialization's compile-time code generation approach as theoretically advantageous for performance. However, empirical validation under realistic server-side workloads with rigorous statistical analysis and comprehensive performance metrics remains underrepresented in the literature. This gap motivates the present study's focus on systematic, statistically validated comparison of Jackson, Gson, and KotlinX Serialization within Kotlin server environments [20].

III. MATERIALS AND METHODS

Write This study adopts a quantitative, empirical research approach to systematically evaluate and compare the performance of JSON libraries—Jackson, Gson, and KotlinX Serialization—within a Kotlin-based server environment. A between-subject experimental design was utilized, wherein each JSON library was tested independently against identical JSON data sets. This experimental approach was chosen to ensure unbiased performance metrics specific to each library, allowing precise analysis of differences in execution time, memory utilization, and CPU consumption under controlled conditions. The research diagram shown on Figure 1.

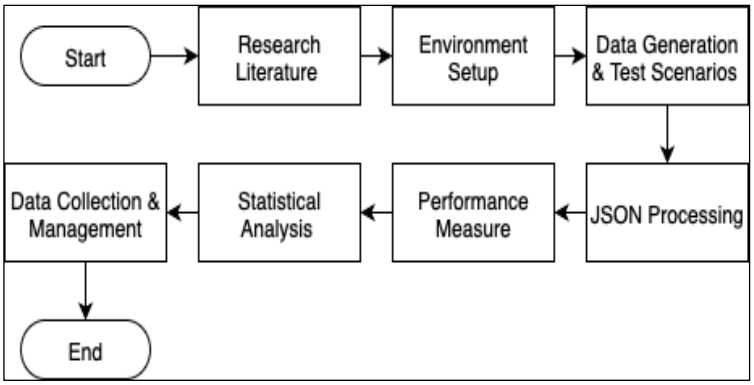

Figure 1: Research Methodology.
Source: Authors, (2026).

III.1 EXPERIMENTAL ENVIRONMENT

The experimental setup consisted of a server developed using the Kotlin programming language, facilitated by the Ktor framework, to ensure relevance to real-world server implementations. Docker containers were employed to guarantee consistency, reproducibility, and isolation of experimental environments across multiple test runs. The hardware specifications used in this research included an HP Pavilion 14 laptop with an AMD Ryzen 5 5500U processor, 16 GB RAM, and Windows 11 64-bit operating system. Precise measurement of execution time was obtained using the System.nanoTime() method. Memory utilization was assessed by comparing heap memory usage before and after each process through the Java MemoryMXBean API, and CPU consumption was monitored using OperatingSystemMXBean.

III.2 DATA GENERATION AND TEST SCENARIOS

Test data were generated using an adapted version of an algorithm developed by [5] to create structured, nested JSON files suitable for benchmarking JSON libraries. The data comprised ten distinct JSON files, each characterized by a fixed nesting depth of 10 levels, with increasing complexity achieved by incrementing the number of key-value pairs at each nesting level from 10 to 100, in steps of 10. Each file thus represented progressively larger and more complex data structures, reflective of realistic server-side processing scenarios. At the deepest nesting level, a structured JSON array containing additional nested objects extended the complexity further to an effective depth of 20 levels, emulating real-world data complexity. The structure data shown on Figure 2. The file size and the number of key shown on Table 1.

III.3 JSON PROCESSING PROCEDURES

The evaluation encompassed three primary JSON data processing tasks: parsing, serialization, and deserialization. Parsing refers explicitly to the transformation of raw JSON strings into intermediary data structures (JsonElement), without type-specific conversions. In contrast, deserialization converts JSON strings directly into typed Kotlin objects, while serialization transforms Kotlin objects back into JSON strings. These definitions align with distinctions drawn by [21] in the KotlinX Serialization documentation, ensuring clarity and consistency across all processing tasks.

Table 1: Key and file Size.

No	*Key Number*	*File Size* (KB)
1	10	58
2	20	117
3	30	176
4	40	236
5	50	295
6	60	355
7	70	414
8	80	474
9	90	533
10	100	592

Source: Authors, (2026).

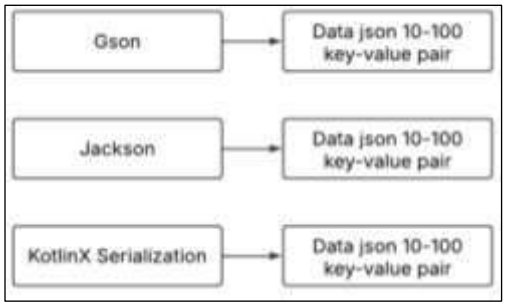

Figure 3: Library and Number Experiments.
Source: Authors, (2026).

Each processing task was performed in two stages to enhance accuracy and reliability: an initial warm-up phase followed by a main measurement phase. The warm-up phase consisted of 500 initial iterations intended to stabilize the JVM environment, mitigating the effects of Just-In-Time (JIT) compilation and runtime optimizations. Subsequently, the main measurement phase involved 5,000 experimental runs, each comprising 50 repetitions of parsing, serialization, or deserialization per test file. Performance metrics were averaged across runs to yield stable and representative results.

III.4 PERFORMANCE METRICS

Three key performance indicators were systematically measured: execution time, memory usage, and CPU consumption. Execution time, recorded in milliseconds (ms), was captured precisely to evaluate processing speed. Memory usage, assessed in megabytes (MB), provided insights into the libraries' efficiency in resource utilization. CPU consumption, expressed as a percentage, indicated computational load under identical processing tasks, offering a comprehensive view of resource efficiency. All metrics were recorded consistently across parsing, serialization, and deserialization processes to enable direct comparative analysis.

III.5 STATISTICAL ANALYSIS

Rigorous statistical analyses were conducted to ensure the reliability and validity of the performance comparisons. Initially, data were tested for normality using the Kolmogorov-Smirnov test to establish appropriate subsequent analytical methods. Due to the non-normal distribution of performance metrics, non-parametric statistical methods were selected for further analysis. Specifically, the Kruskal-Wallis test, a non-parametric alternative to ANOVA, was employed to detect statistically significant differences among library performances across all experimental conditions. A significance level (α) of 0.05 was chosen to determine the statistical significance of observed differences. Following the identification of significant differences via the Kruskal-Wallis test, Dunn's post hoc test was used for pairwise comparisons to pinpoint precisely where significant differences existed between individual library pairs[22].

III.6 DATA COLLECTION AND MANAGEMENT

Performance data obtained from experimental runs were systematically logged and stored in CSV format to facilitate structured data management and subsequent statistical analysis. Each CSV entry contained clearly labelled and timestamped metrics for execution time, memory utilization, and CPU consumption, ensuring traceability and reproducibility of data collection processes. Data integrity and consistency were verified through regular validation checks performed throughout the experimental period.

III.7 LIMITATIONS AND SCOPE

The methodological approach of this study was deliberately limited to evaluating three widely-adopted JSON libraries within a Kotlin-based server context. This decision was guided by the prevalence and relevance of these libraries within Kotlin's developer ecosystem. The scope excluded libraries not explicitly designed or widely used for Kotlin environments and did not extend to front-end or mobile applications. Furthermore, testing was confined to controlled laboratory conditions, and results may vary in different hardware or operating environments.

Future research could explore broader comparisons involving additional libraries, other programming environments, or real-world deployment scenarios. Overall, the structured and systematic approach adopted in this study, encompassing rigorous experimental procedures and comprehensive statistical analysis, was designed to yield valid, reliable, and practically relevant insights into the comparative performance of Jackson, Gson, and KotlinX Serialization libraries within Kotlin-based server environments. This methodology addresses a clear research gap, providing robust empirical evidence to guide informed decision-making among software developers and system architects.

IV. RESULTS AND DISCUSSIONS

IV.1 OVERVIEW OF EXPERIMENTAL RESULTS

This section presents the results obtained from rigorous empirical testing of three JSON libraries—Jackson, Gson, and KotlinX Serialization—within a Kotlin-based server environment. The performance metrics examined include execution time, memory usage, and CPU consumption, measured consistently across parsing, serialization, and deserialization processes. Each process was evaluated using structured nested JSON datasets, progressively increasing in complexity by incrementing key-value pairs from 10 to 100 per nesting level. Detailed statistical analyses were conducted to ensure the reliability and robustness of the findings.

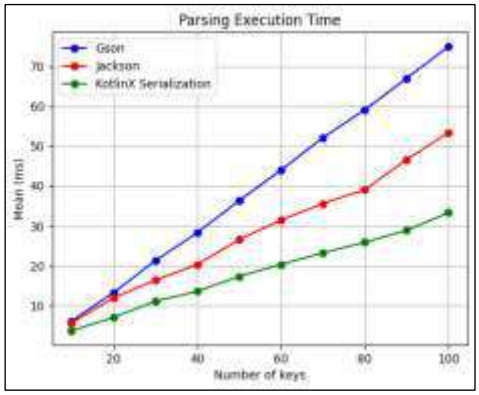

Figure 4: Parsing Performance.
Source: Authors, (2026).

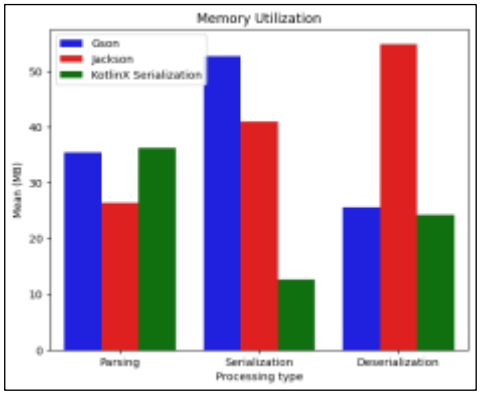

Figure 5: Memory Utilization.
Source: Authors, (2026).

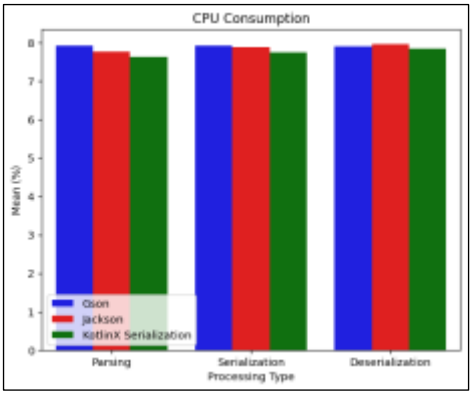

Figure 6: CPU Consumption.
Source: Authors, (2026).

IV.1.1 Parsing Performance

The parsing process involved transforming raw JSON strings into intermediate JSON data structures (JsonElement). The results of performance evaluation shown on Figure 4. Performance evaluation revealed distinct differences among the libraries tested. Specifically, KotlinX Serialization consistently exhibited the fastest execution times across all file complexities. For instance, with the smallest file (10 key-value pairs), KotlinX Serialization achieved an average execution time of 3.63 milliseconds, significantly outperforming Jackson (5.57 milliseconds) and Gson (6.03 milliseconds). As file complexity increased, performance advantages for KotlinX Serialization became increasingly pronounced, with a clear trend observed across all complexity levels. Memory utilization during parsing, serialize and deserialize depicted on Figure 5. Memory utilization during parsing showed a different pattern. Jackson demonstrated superior efficiency, consistently consuming less memory compared to both Gson and KotlinX Serialization.

For example, Jackson's average memory usage was approximately 26.35 megabytes, markedly lower than Gson's 35.46 megabytes and KotlinX Serialization's 36.27 megabytes across all tests. This efficiency advantage for Jackson remained consistent irrespective of file size or complexity. CPU consumption during parsing, serialize and deserialize depicted on Figure 6. CPU consumption data during parsing further emphasized KotlinX Serialization's performance advantage, albeit with narrower margins. KotlinX Serialization recorded the lowest CPU usage at an average of 7.01%, marginally better than Jackson (7.49%) and Gson (7.93%). This lower CPU consumption by KotlinX Serialization suggests better optimization in computational efficiency during parsing processes.

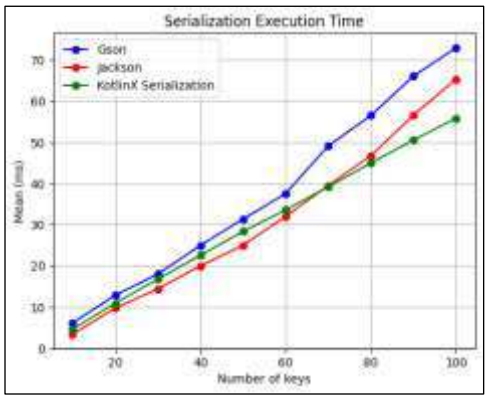

Figure 7: Serialization Performance.
Source: Authors, (2026).

IV.1.2 Serialization Performance

Serialization performance, involving the transformation of native Kotlin objects into JSON strings, presented contrasting results compared to parsing. The results of Serialization performance shown on Figure 7. Jackson emerged as the most efficient library regarding execution time for smaller and medium-sized files (10 to 60 key-value pairs). For instance, at the smallest file size (10 keys), Jackson completed serialization in an average of 3.36 milliseconds, significantly quicker than KotlinX Serialization's 4.56 milliseconds and Gson's 6.08 milliseconds. However, as file complexity grew (70 to 100 key-value pairs), KotlinX Serialization progressively outperformed Jackson and Gson, clearly demonstrating superior scalability for larger data sets.

Memory usage during serialization illustrated pronounced advantages for KotlinX Serialization across all file sizes (Figure 5). KotlinX Serialization consistently used significantly less memory, averaging 12.59 megabytes, compared to Jackson's 40.87 megabytes and Gson's 52.64 megabytes. This substantial efficiency in memory utilization highlights KotlinX Serialization's suitability for resource-constrained server environments. CPU consumption data indicated minimal variations between libraries, with KotlinX Serialization marginally outperforming others (depicted on Figure 6). It exhibited average CPU usage of 7.38%, slightly lower than Jackson (7.43%) and Gson (7.69%), signifying a minor yet consistent advantage in computational efficiency during serialization processes.

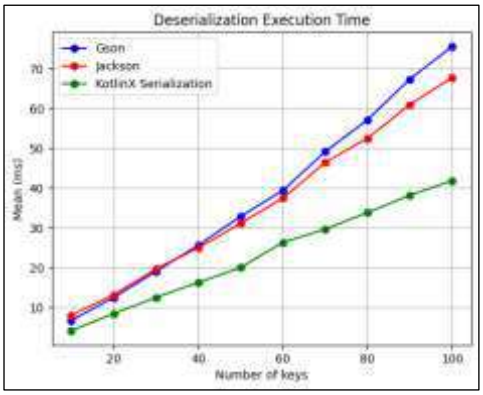

Figure 8: Deserialization Performance.
Source: Authors, (2026).

IV.1.3 Deserialization Performance

The deserialization process, converting JSON strings directly into typed Kotlin objects, underscored KotlinX Serialization's comprehensive performance superiority. The results of deserialization performance shown on Figure 8. Execution time results consistently favoured KotlinX Serialization across all file complexities, from simple to highly complex JSON structures. For instance, at the smallest complexity level (10 keys), KotlinX Serialization deserialized data in an average of 4.11 milliseconds, significantly faster than Gson (6.68 milliseconds) and Jackson (7.99 milliseconds). This advantage was maintained and increased proportionally with growing file complexities. Memory utilization during deserialization (Figure 5) also demonstrated KotlinX Serialization's efficiency, using significantly less memory on average (24.26 megabytes) compared to Gson (25.52 megabytes) and Jackson (54.78 megabytes). These findings reinforce KotlinX Serialization's optimal memory efficiency, making it particularly suited for large-scale server environments dealing with extensive JSON data.

Regarding CPU consumption during deserialization (depicted on Figure 6), KotlinX Serialization again demonstrated superior efficiency. It maintained the lowest CPU usage at an average of 7.44%, slightly outperforming Gson (7.69%) and Jackson (7.84%). These results underscore KotlinX Serialization's balanced approach to resource utilization, delivering consistent performance advantages across all evaluated metrics.

IV.1.4 Statistical Analysis

Wherever To substantiate the empirical findings, statistical analyses were rigorously conducted. Initial normality testing using the Kolmogorov-Smirnov method indicated that the data sets did not follow a normal distribution. Consequently, non-parametric statistical tests were employed to ensure valid and accurate comparative analyses. The Kruskal-Wallis test, a robust non-parametric method, identified statistically significant differences among the three libraries across all performance metrics and JSON processing tasks. All calculated p-values were significantly below the predetermined alpha level of 0.05, thus confirming meaningful performance differences among Jackson, Gson, and KotlinX Serialization. Post-hoc testing using Dunn's test provided detailed pairwise comparisons, clearly delineating significant performance differences between each library pair. These analyses consistently demonstrated that KotlinX Serialization significantly outperformed Jackson and Gson in execution time and CPU efficiency across parsing and deserialization tasks, while Jackson was superior in memory efficiency during parsing tasks.

IV.1.5 Summary Of Findings

The Overall, the comprehensive evaluation of JSON processing tasks—parsing, serialization, and deserialization—revealed clear and statistically significant performance differences among Jackson, Gson, and KotlinX Serialization. KotlinX Serialization consistently demonstrated superior execution speed and CPU efficiency, particularly pronounced during parsing and deserialization tasks, with moderate yet notable advantages during serialization. Jackson showed distinct strengths in memory utilization, particularly during parsing, and competitive execution speeds for smaller datasets during serialization.

Gson generally performed less effectively relative to Jackson and KotlinX Serialization across all tested metrics, highlighting limitations due to its reflection-based approach. These results collectively indicate that KotlinX Serialization's compile-time code generation strategy significantly enhances performance, making it particularly suitable for performance-critical server applications handling large and complex JSON data. Jackson's reflection-based approach, while efficient in certain scenarios such as memory-constrained environments, exhibits scalability limitations under increasingly complex workloads.

Gson's overall performance disadvantages suggest it may be less suitable for scenarios requiring high computational efficiency or large-scale JSON data handling. In conclusion, this study provides clear, statistically validated empirical evidence highlighting the performance characteristics and trade-offs associated with three prominent JSON libraries in Kotlin server environments. These findings equip developers and architects with actionable insights, enabling informed library selection aligned with specific application requirements and performance objectives.

IV.2 DISCUSSION

IV.2.1 Interpretation Of Findings

The primary objective of this study was to systematically evaluate the comparative performance of three prominent JSON libraries—Jackson, Gson, and KotlinX Serialization—in server-side Kotlin environments. The analysis of experimental data consistently indicated significant performance differences among the tested libraries, each exhibiting distinctive advantages and limitations. KotlinX Serialization emerged prominently as the most efficient library overall, particularly excelling in execution time and CPU consumption during parsing and deserialization tasks. Jackson demonstrated notable strengths in memory utilization and serialization speed for smaller data sets. Conversely, Gson consistently underperformed relative to the other libraries in most performance metrics evaluated.

IV.2.2 Impact of Computational Strategies on Performance

The significant performance differences observed among these libraries can primarily be attributed to their underlying computational strategies. KotlinX Serialization's superior performance, especially regarding execution time and CPU efficiency, can be directly associated with its use of compile-time code generation through compiler plugins. This approach minimizes runtime overhead by avoiding reflection mechanisms commonly employed by Jackson and Gson. The elimination of runtime reflection substantially enhances computational efficiency and reduces resource demands, translating into consistently faster and more efficient data processing. Jackson and Gson rely heavily on runtime reflection, dynamically inspecting and processing data structures at runtime.

While reflection provides flexibility, enabling easy integration across various programming scenarios, it inherently introduces computational overhead and increased resource consumption. This reflection overhead is particularly pronounced in Gson, which consistently showed the lowest performance across execution time, memory usage, and CPU consumption metrics. Jackson, although similarly reliant on reflection, demonstrated superior memory efficiency and competitive execution speeds, particularly in serialization tasks involving smaller datasets. Jackson's performance optimization efforts, such as the use of specialized modules for Kotlin support, likely contribute to its improved performance relative to Gson [23].

IV.2.3 Memory Utilization Analysis

Memory usage results revealed another critical performance dimension. Jackson demonstrated superior memory efficiency during parsing tasks, consistently utilizing significantly less memory compared to Gson and KotlinX Serialization. This efficiency advantage suggests Jackson's reflection-based implementation, augmented by Kotlin-specific optimization modules, effectively manages memory resources during intermediate data processing.

Conversely, Gson's higher memory consumption is likely due to less optimized reflection handling, resulting in increased memory overhead during runtime. In serialization and deserialization tasks, KotlinX Serialization achieved substantial memory efficiency, significantly outperforming both Gson and Jackson. This enhanced efficiency likely results from KotlinX Serialization's compile-time code generation strategy, which streamlines object transformation processes and minimizes runtime memory allocations. This inherent advantage is particularly beneficial in resource-constrained or high-throughput server environments where memory optimization significantly influences overall performance and scalability [12].

IV.2.4 Cpu Consumption and Computational Load

As Analysis of CPU consumption further highlighted KotlinX Serialization's balanced and efficient approach. Consistently recording the lowest CPU usage across all tasks, KotlinX Serialization demonstrated effective computational optimization. The observed lower CPU usage is directly attributable to its compile-time generated serialization logic, reducing runtime complexity and computational demands. In contrast, Jackson and Gson's reflection-based methods inherently increase runtime processing complexity and CPU load, reflecting in consistently higher CPU consumption figures. However, the differences in CPU utilization between Jackson and Gson remained marginal, suggesting similar computational load characteristics inherent to reflection-based libraries.

IV.2.5 Practical Implications for Kotlin-Based Server Applications

From a practical perspective, the findings of this study offer actionable insights into library selection for server-side Kotlin applications. KotlinX Serialization's consistent superiority across multiple performance metrics—execution speed, CPU efficiency, and memory utilization in critical scenarios—makes it the preferred choice for high-performance applications, particularly those requiring rapid, large-scale JSON data processing. Its compile-time code generation strategy aligns closely with Kotlin's native features, ensuring optimal compatibility and performance.

Jackson remains an attractive alternative, particularly in scenarios prioritizing memory efficiency or involving moderate-sized datasets. Its reflection-based approach, supplemented by Kotlin-specific modules, provides sufficient performance for many server-side applications, balancing flexibility and resource usage. In contrast, Gson's lower overall performance metrics suggest limited suitability for demanding or resource-intensive server applications, where efficiency and computational load significantly impact application responsiveness and scalability.

IV.2.6 Study Limitations and Recommendations for Future Research

Footnotes Despite its comprehensive methodological approach, this study has certain limitations warranting consideration in interpreting results and guiding future research. Firstly, the scope was deliberately restricted to evaluating three widely adopted JSON libraries within Kotlin server environments. Future research could expand this scope to include additional libraries or different programming environments to offer broader comparative insights.

Secondly, the experiments were conducted under controlled laboratory conditions using specific hardware and software configurations. While this approach ensures methodological rigor and reproducibility, variations in hardware or deployment environments could influence performance outcomes. Therefore, future studies should consider conducting similar evaluations in diverse real-world deployment contexts to validate and extend these findings.

Additionally, the focus on JSON data with structured nesting and incremental complexity provides relevant insights; however, incorporating other data formats or processing scenarios could further enrich understanding of library performance characteristics. Further research could explore alternative serialization formats or real-world data processing tasks typical of industry-specific applications, thereby broadening the practical relevance and applicability of performance evaluations.

V. CONCLUSIONS

In conclusion, this discussion systematically examined the underlying factors influencing performance differences among Jackson, Gson, and KotlinX Serialization libraries, providing comprehensive interpretations of empirical findings. KotlinX Serialization's compile-time strategy consistently emerged as the most effective approach, delivering superior execution speed, memory efficiency, and CPU optimization suitable for high-performance Kotlin server applications. Jackson's memory efficiency and competitive performance in certain contexts provide valuable alternative options, while Gson's general underperformance highlights limitations inherent to reflection-based processing strategies. These insights enable informed decision-making among developers and system architects, ensuring optimal library selection aligned with specific server-side application requirements.

Ethical governance,
Cultural intelligence.

ABSTRACT

Tourism in the digital era is increasingly influenced by user-generated content, where sentiment analysis plays a critical role in understanding traveler perceptions and guiding destination management. This study reviews advancements in sentiment analysis from 2015 to 2024 and forecasts its evolution through 2045, emphasizing the integration of Artificial Intelligence, Natural Language Processing, and ethical-cultural awareness. Employing a narrative literature review, the research synthesizes over 120 academic works to identify technological, ethical, and linguistic challenges shaping the field. The paper proposes the Human-AI Integrative Sentiment Framework (HAISF), a holistic model uniting five dimensions: data diversity, computational intelligence, ethical governance, cultural sensitivity, and sustainable application. This framework supports creating sentiment analysis systems that are easy to understand, protect user privacy, and respect cultural differences, ensuring that the use of artificial intelligence stays consistent with human values. The study concludes that future sentiment analysis in tourism will evolve toward an empathic, multimodal, and ethically grounded paradigm, enabling predictive and socially responsible decision-making across global tourism ecosystems.

I. INTRODUCTION

Tourism is increasingly shaped by digital communication, where travelers continuously express opinions through social media, online reviews, and other user-generated content (UGC) [1]. Understanding these sentiments has become vital for destinations and tourism businesses seeking to improve customer experiences and manage brand reputation effectively [2]. Sentiment analysis, an interdisciplinary approach combining computational linguistics, machine learning, and data analytics, has thus emerged as an indispensable tool for extracting meaningful insights from large volumes of textual and visual data [3]. Early research in tourism sentiment analysis primarily focused on polarity detection (positive, neutral, negative) using lexicon-based and classical machine learning models such as Support Vector Machines and Naïve Bayes [4].

Recent advances in deep learning and transformer architectures, including BERT and RoBERTa, have markedly enhanced the precision of sentiment classification by capturing semantic and contextual nuances [5]. Moreover, multimodal sentiment analysis that integrates text, image, and audio inputs offers a more holistic understanding of tourist experiences [6]. Despite these advances, several challenges persist. Existing models often fail to account for linguistic and cultural diversity, leading to biased interpretations of sentiment [7]. Ethical and privacy concerns also arise as AI systems increasingly rely on personal data. Furthermore, current research remains fragmented, lacking a unified framework that connects technological progress with ethical and socio-cultural considerations in tourism. To address these gaps, this paper aims to forecast the future of sentiment analysis in tourism over the next 20 years, focusing on three objectives:

1. To review and synthesize recent developments in sentiment analysis relevant to tourism;

2. To identify emerging trends and challenges that will shape the field through 2045; and
3. To propose a conceptual framework integrating technology, ethics, and inclusivity for future tourism analytics.

The remainder of this paper is structured as follows: Section 2 describes the research approach; Section 3 reviews the evolution and current state of sentiment analysis in tourism; Section 4 outlines emerging trends and projections; Section 5 discusses ethical and linguistic challenges; Section 6 presents a conceptual framework for future research; and Section 7 concludes with implications for academia and industry.]

II. METHODOLOGY

This study adopts a narrative literature review approach to synthesize academic and applied research on sentiment analysis in tourism from 2015 to 2024. Unlike systematic reviews that focus on quantitative inclusion criteria, a narrative review allows for critical interpretation and theoretical integration across multidisciplinary studies [8]. This approach is particularly appropriate given the rapid evolution of Artificial Intelligence (AI), Natural Language Processing (NLP), and data analytics in tourism research. The literature was retrieved from major academic databases, Scopus, Web of Science, IEEE Xplore, ScienceDirect, and SpringerLink, using a combination of keywords: “sentiment analysis,” “tourism analytics,” “machine learning,” “deep learning,” “natural language processing,” and “AI ethics”. Peer-reviewed journal articles, conference papers, and review studies were included, while opinion pieces, editorials, and non-English publications were excluded. In total, over 120 recent publications were reviewed, with a focus on methodological innovation, application context, and theoretical contribution. The analysis process followed three stages:

1. Conceptual mapping: Identification of key research themes and technological milestones in sentiment analysis within tourism.
2. Thematic synthesis: Grouping studies into categories, methodological development, current applications, ethical/cultural challenges, and future trends.
3. Gap identification and forecasting: Extraction of research gaps and projection of future directions for the next two decades based on technological trajectories and policy reports.

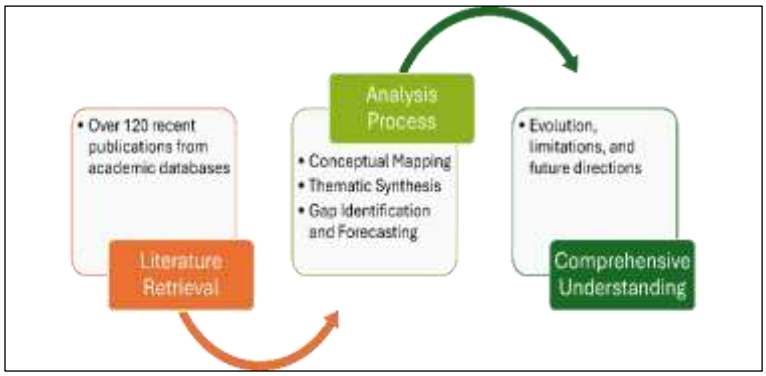

Figure 1: Method.
Source: Authors, (2026).

This process ensured a comprehensive understanding of how sentiment analysis has evolved, the limitations of existing research, and the directions for its future integration into the tourism domain.

III. EVOLUTION AND CURRENT STATE OF SENTIMENT ANALYSIS IN TOURISM

III.1 EARLY DEVELOPMENT AND TECHNOLOGICAL MILESTONES

Sentiment analysis has evolved from simple text classification into a sophisticated, multi-layered analytical process integrating AI and deep learning. Early applications in tourism primarily relied on lexicon-based and machine learning approaches to determine polarity (positive, negative, neutral) in user reviews [4]. Traditional algorithms such as Naïve Bayes [9], Support Vector Machines (SVM), and Decision Trees demonstrated moderate success but struggled with contextual nuances like sarcasm, idioms, and cultural expressions [10]. From 2015 to 2018, Aspect-Based Sentiment Analysis (ABSA) gained attention for its ability to link sentiments to specific service components, such as hotel cleanliness, transportation, or food quality, providing richer managerial insights [11]. The introduction of deep learning architectures, notably Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), marked a methodological leap, allowing models to capture sequential and semantic dependencies within text data [5].

III.2 THE DEEP LEARNING AND TRANSFORMER REVOLUTION

The period after 2019 witnessed a paradigm shift with the introduction of transformer-based language models, including BERT, RoBERTa, and GPT architectures. These models significantly improved accuracy by capturing contextual meaning across entire sentences and multilingual corpora [12]. Such advances enabled researchers to analyze vast and heterogeneous datasets, from TripAdvisor and Yelp reviews to multimodal inputs like photos and videos. Recent studies in tourism have leveraged multimodal sentiment analysis (MSA) to combine textual, visual, and acoustic data, leading to a more comprehensive understanding of traveler emotions [6]. For example, photo-based sentiment analysis in dark tourism sites has revealed that negative emotions often dominate affective responses, offering insights into destination image management [13]. Similarly, transformer-enhanced systems like ChatGPT-based models have demonstrated superior interpretability and accuracy compared with conventional machine learning frameworks [14].

III.3 CURRENT APPLICATIONS IN THE TOURISM INDUSTRY

Sentiment analysis has become a cornerstone of destination management, service quality assessment, and customer relationship management (CRM) in tourism. Organizations increasingly rely on real-time sentiment tracking to evaluate traveler satisfaction, forecast market trends, and tailor marketing strategies [4], [15]. In hospitality, for instance, automated analysis of guest reviews informs operational improvements and service personalization. Airlines have applied sentiment analysis to monitor customer feedback on social media, achieving up to 90% accuracy in classifying sentiment using hybrid BERT–fastText models [16].
Furthermore, Big Data and tourism intelligence systems now incorporate AI-driven sentiment analytics to identify emerging travel patterns, predict seasonal preferences, and manage brand reputation. Platforms such as ReUS [17] and BERTopic-based frameworks [18] demonstrate how unsupervised and topic-modeling methods enhance interpretability for decision-makers. These developments collectively indicate that sentiment analysis is not merely a monitoring tool but a strategic asset driving innovation, competitiveness, and sustainability in the tourism sector.

Table 1: Evolution And Current State Of Sentiment Analysis In Tourism.

Period / Phase	Technological Milestones	Key Methods & Models	Application Contexts in Tourism	Limitations / Challenges	Representative Outcomes or Contributions
Early Development (Pre-2015)	Emergence of sentiment analysis in tourism using basic text classification	Lexicon-based methods; Machine Learning (Naïve Bayes, SVM, Decision Trees)	Analysis of online reviews (TripAdvisor, Booking.com) to determine polarity (positive, neutral, negative)	Inability to handle sarcasm, idioms, and cultural nuances	Provided initial automation of opinion mining and polarity detection in tourism reviews
Aspect-Based Expansion (2015–2018)	Integration of Aspect-Based Sentiment Analysis (ABSA) for fine-grained insights	ABSA frameworks; feature engineering techniques	Evaluation of specific service attributes (e.g., hotel cleanliness, transport, food quality)	Limited scalability; dependence on manual feature extraction	Enabled tourism managers to link sentiments to concrete service dimensions
Deep Learning Era (2018–2019)	Adoption of neural network models for contextual sentiment understanding	CNNs, RNNs, LSTM-based models	Automated analysis of complex textual data from online travel platforms	High computational cost; limited interpretability	Enhanced semantic and sequential text understanding, improving sentiment classification accuracy
Transformer Revolution (2019–2022)	Introduction of transformer-based NLP architectures	BERT, RoBERTa, GPT models	Multilingual and context-aware sentiment analysis; large-scale tourism datasets (TripAdvisor, Yelp)	Requires large labeled data; risk of bias in pretrained models	Achieved state-of-the-art accuracy; improved cross-lingual and contextual sentiment interpretation
Multimodal & Hybrid Systems (2022–2024)	Expansion toward multimodal and hybrid AI-driven sentiment systems	MSA (text + image + audio); hybrid BERT–fastText; topic modeling (BERTopic)	Analysis of traveler emotions via text, photos, and videos; CRM and destination image management	Data integration complexity; privacy and ethical considerations	Enabled real-time tourism intelligence, trend prediction, and customer experience optimization

Source: Authors, (2026).

The evolution of sentiment analysis in tourism has progressed from rule-based polarity detection to sophisticated AI-driven multimodal frameworks. These developments have transformed sentiment analysis from a descriptive tool into a strategic asset for data-driven decision-making, competitiveness, and sustainable tourism management.

IV. EMERGING TRENDS AND FUTURE DIRECTIONS (2025–2045)

The next two decades are expected to mark a transformative era in sentiment analysis, driven by accelerated developments in artificial intelligence, machine learning, and natural language processing [19]. These advancements will not only enhance the precision and interpretability of sentiment classification but will also expand its applicability across the tourism value chain, from destination management and service personalization to predictive marketing and sustainability analytics. The following subsections outline key technological, methodological, and interdisciplinary trends anticipated to define the field through 2045.

IV.1 THE RISE OF LARGE LANGUAGE MODELS AND GENERATIVE AI

The proliferation of Large Language Models (LLMs), such as GPT, LLaMA, and Claude, has already redefined text-based analytics, enabling systems to understand and generate human-like responses with remarkable contextual accuracy. Over the next two decades, sentiment analysis will likely integrate domain-adapted LLMs trained specifically on tourism-related data (e.g., hotel reviews, travel blogs, and destination narratives). These models will outperform general-purpose systems by capturing tourism-specific expressions, idioms, and cultural nuances.

Emerging frameworks will combine neurosymbolic AI, which integrates neural networks with symbolic reasoning [20], to improve explainability and ethical accountability in sentiment decisions. Moreover, fine-tuning techniques and transfer learning will enable models to adapt to new linguistic and cultural contexts with minimal retraining effort, facilitating cross-regional tourism analytics. By 2045, generative AI systems will not only analyze but also simulate tourist sentiments, predicting how policy changes, marketing campaigns, or sustainability initiatives might shape public perceptions before they occur.

IV.2 MULTIMODAL AND REAL-TIME SENTIMENT ANALYSIS

Future sentiment analysis will increasingly move beyond text, leveraging multimodal learning to integrate data from images, videos, voice recordings, and physiological sensors. Advances in multimodal architectures, such as Text-Centric Sharing-Private (TCSP) and Modality Translation-based Multimodal Sentiment Analysis (MTMSA) models, have demonstrated the ability to capture complex emotional cues even when certain modalities are missing [21], [22]. In the context of tourism, multimodal analysis could synthesize visual impressions (e.g., Instagram photos), acoustic tones (e.g., traveler vlogs), and textual reviews to construct a 360-degree emotional map of tourist experiences. Combined with Internet of Things (IoT) sensors embedded in smart destinations, such systems could enable real-time mood analytics, offering immediate feedback to tourism operators about visitor satisfaction, crowd sentiment, and service performance. By 2040, real-time sentiment dashboards powered by edge computing and 6G connectivity could allow destination managers to monitor emotional dynamics across attractions, ensuring responsive service design and crisis management.

IV.3 CROSS-LINGUAL AND CULTURALLY ADAPTIVE SYSTEMS

Language and cultural diversity remain among the greatest challenges in global tourism sentiment analysis. The coming years will see widespread deployment of Cross-Lingual Sentiment Analysis (CLSA) models, which use machine translation, multilingual embeddings, and zero-shot transfer learning to interpret sentiments across languages with limited labeled data [23]. Research has shown that fine-tuned models trained on high-resource languages like English can achieve up to 96% accuracy when adapted to low-resource languages such as Arabic or Tamil [24], [25]. Beyond linguistic translation, future sentiment systems must become culturally adaptive, incorporating local emotional semantics and indigenous knowledge systems. This shift requires interdisciplinary collaboration among linguists, anthropologists, and computer scientists to ensure that AI models reflect diverse worldviews rather than reproducing Western-centric emotion taxonomies. Such inclusivity will be essential for creating equitable, context-aware sentiment analysis tools that resonate with multicultural audiences.

IV.4 INTEGRATION WITH PREDICTIVE ANALYTICS AND DECISION INTELLIGENCE

Between 2030 and 2045, sentiment analysis will evolve from descriptive evaluation toward predictive and prescriptive intelligence. By combining emotional data with behavioral, transactional, and geospatial information, AI systems will forecast tourism demand patterns, destination reputation risks, and visitor satisfaction trends. Techniques such as probabilistic linguistic term sets, multi-granularity decision systems, and emotion variance analysis (EVA) are expected to enhance the interpretive granularity of these predictions [26], [27]. Integrated with Big Data analytics and decision-support systems, these models will enable policymakers and business leaders to conduct scenario planning, for example, anticipating the emotional impacts of climate change, political unrest, or pandemics on tourism sentiment.

IV.5 TOWARD ETHICAL, TRANSPARENT, AND SUSTAINABLE AI

As AI becomes more pervasive, ethical governance will be central to its sustainable deployment. By 2035, sentiment analysis systems are expected to adopt explainable AI (XAI) frameworks that make decision logic transparent to both researchers and end-users. Parallelly, privacy-preserving machine learning techniques, such as federated learning and differential privacy, will become standard to ensure data protection without compromising analytic performance [28]. Regulatory harmonization across jurisdictions, building on frameworks such as the EU General Data Protection Regulation (GDPR) and emerging AI governance acts, will dictate responsible data collection, model training, and sentiment interpretation practices. These ethical innovations will not only mitigate bias and misuse but also strengthen public trust in AI-driven tourism analytics.

IV.6 INTERDISCIPLINARY CONVERGENCE AND THE HUMAN-AI COLLABORATION PARADIGM

The future of sentiment analysis lies in interdisciplinary convergence, where advances in computer science intersect with behavioral psychology, linguistics, and tourism studies [29]. Human-AI collaboration will redefine how emotional intelligence is operationalized in digital tourism environments. AI agents will increasingly act as empathic interfaces, capable of detecting and responding to human emotions in customer service, destination management, and online communication. This will create new roles for human experts, such as AI ethics auditors, data curators, and emotion designers, who oversee fairness, transparency, and inclusivity in AI systems. By integrating human empathy with machine precision, the tourism sector can foster more personalized, ethical, and emotionally resonant experiences.

IV.7 SUMMARY OF FUTURE DIRECTIONS

The emerging trends in sentiment analysis for tourism highlight a shift toward more intelligent, inclusive, and human-centered systems. Large Language Models (LLMs), such as domain-specific GPT variants, enable real-time interpretation of tourist feedback and predictive insight generation. Multimodal analytics, combining text, image, and voice data, provides a holistic view of travelers' emotions and destination experiences. Cross-lingual adaptation through multilingual transfer learning promotes inclusivity and expands global market intelligence.

Predictive and prescriptive AI systems leverage Big Data to forecast emotions and support proactive decision-making, including crisis management. Meanwhile, the rise of ethical and explainable AI ensures transparency, privacy, and compliance in analytical ecosystems. Finally, human–AI collaboration merges automation with empathy, fostering more personalized engagement and enhancing overall visitor satisfaction in the tourism sector.

Table 2: Summary of Emerging Trends and Future Directions.

Trend	Description	Tourism Implication
Large Language Models (LLMs)	Domain-specific, context-aware models (e.g., GPT variants)	Real-time analysis of tourist reviews and predictive insights
Multimodal Analytics	Integration of text, image, and voice sentiment	Comprehensive emotional mapping of destinations
Cross-Lingual Adaptation	Multilingual transfer learning and inclusivity	Broader market intelligence and global reach
Predictive & Prescriptive Systems	Emotion forecasting via AI and Big Data	Proactive decision-making and crisis anticipation
Ethical & Explainable AI	Transparent, privacy-preserving models	Trustworthy and compliant analytics ecosystems
Human–AI Collaboration	Integration of empathy with automation	Enhanced visitor engagement and satisfaction

Source: Authors, (2026).

V. ETHICAL, CULTURAL, AND LINGUISTIC CHALLENGES

As sentiment analysis becomes increasingly integrated into tourism management and policymaking, ethical, cultural, and linguistic considerations will play a defining role in shaping its credibility and societal impact. While advanced algorithms such as deep learning and Large Language Models have greatly improved accuracy and scalability, they also introduce challenges related to data bias, privacy, and cross-cultural misrepresentation. Addressing these concerns is essential to ensure that sentiment analysis remains transparent, inclusive, and responsible in its application within the tourism sector.

V.1 ALGORITHMIC BIAS AND CULTURAL REPRESENTATION

A major ethical issue in sentiment analysis arises from algorithmic bias, which occurs when AI models inherit distortions embedded in their training data. Most sentiment analysis systems are trained predominantly on English-language and Western datasets, resulting in models that misinterpret expressions, emotions, or sarcasm from other cultural contexts [30]. This bias can distort perceptions of destinations or communities, particularly in multicultural and indigenous tourism settings, where local emotional expressions may diverge significantly from standardized sentiment lexicons. To mitigate such risks, future research must emphasize culturally sensitive data curation and diversity-aware training frameworks. Approaches grounded in feminist epistemology and critical race theory [31] provide valuable foundations for rethinking how cultural perspectives are represented in AI systems. Collaborative initiatives that involve local experts and community stakeholders can help develop contextual sentiment lexicons and emotion ontologies that accurately capture non-Western affective nuances.

V.2 LINGUISTIC DIVERSITY AND LOW-RESOURCE LANGUAGE CHALLENGES

Tourism operates across linguistic boundaries, yet most sentiment models remain heavily optimized for high-resource languages such as English, Mandarin, or Spanish. Low-resource languages—including those spoken in Southeast Asia, Africa, and the Pacific Islands—suffer from limited annotated data and linguistic resources, reducing the inclusivity of global sentiment analysis [23]. Recent progress in Cross-Lingual Sentiment Analysis (CLSA) and transfer learning has shown promise, enabling models trained on one language to perform reasonably well on others using multilingual embeddings or machine translation [25].

However, such systems still risk losing cultural and emotional nuances during translation, particularly when dealing with idiomatic or context-specific expressions. To address this limitation, the development of localized NLP models that incorporate region-specific datasets and hybrid lexicons is crucial. The creation of multimodal datasets, combining visual, auditory, and textual cues, can further compensate for linguistic gaps by leveraging non-verbal indicators of emotion. Ultimately, linguistic inclusivity is not merely a technical necessity but an ethical imperative, ensuring that all voices in global tourism are accurately represented.

V.3 DATA PRIVACY, CONSENT, AND TRANSPARENCY

The collection and analysis of personal data, such as online reviews, social media posts, and biometric inputs, raise serious data privacy and consent issues. Many AI systems used for sentiment analysis process user-generated content without explicit permission, challenging international privacy frameworks such as the General Data Protection Regulation (GDPR) and emerging AI governance acts [28]. Beyond legal compliance, there are ethical concerns about how this data is used, shared, and potentially monetized. The use of commercial AI platforms for qualitative analysis introduces further complications, as proprietary algorithms may lack transparency and accountability [32].

Moreover, anonymization is often insufficient when datasets include geotagged or image-based tourism content that can re-identify individuals. Future sentiment analysis frameworks must therefore adopt privacy-preserving machine learning methods such as federated learning, which allows models to learn from distributed data without centralizing it, and differential privacy, which adds statistical noise to protect sensitive information [33]. Ethical data governance must also include clear consent protocols, traceability of data sources, and public transparency reports to build user trust and compliance with global regulatory standards.

V.4 ETHICAL ACCOUNTABILITY AND EXPLAINABLE AI

As AI-driven analytics increasingly influence tourism decision-making, ensuring ethical accountability and explainability becomes paramount. Current deep learning models are often considered "black boxes," making it difficult to interpret how sentiment scores are derived [34]. This lack of transparency undermines stakeholder confidence, especially when sentiment insights inform marketing campaigns, policy design, or destination reputation management. The adoption of Explainable AI (XAI) frameworks offers a promising pathway toward greater interpretability. XAI can make model behavior more understandable by highlighting which linguistic or visual features contributed most to a sentiment classification. Such transparency is critical in tourism contexts where decisions can directly affect public perception, economic outcomes, and community well-being. Ethical auditing of AI systems, through interdisciplinary teams of data scientists, ethicists, and tourism experts, should become standard practice by the 2030s to ensure compliance with both technical accuracy and moral responsibility.

V.5 THE HUMAN DIMENSION: EMOTIONAL LABOR AND AI CO-CREATION

An often-overlooked aspect of sentiment analysis is the human labor involved in data annotation, validation, and interpretation. The reliance on poorly compensated annotators for labeling emotional content raises concerns about digital labor ethics, particularly in developing economies. Furthermore, excessive automation risks eroding the human empathy required in interpreting affective data, especially in service-oriented industries like tourism. Looking ahead, the focus should shift from replacing human judgment to co-creating human–AI partnerships that enhance ethical and cultural understanding. AI systems designed to assist rather than replace human evaluators can combine computational scale with emotional intelligence, ensuring that technological progress supports social and ethical tourism development.

V.6 SUMMARY OF ETHICAL, CULTURAL, AND LINGUISTIC CHALLENGES

Table 3: Summary Of Challenges in Ethical, Cultural, And Linguistic.

Challenge	Key Issue	Recommended Mitigation Strategy
Algorithmic Bias	Overrepresentation of Western data leading to cultural misinterpretation	Culturally diverse datasets; inclusion of indigenous lexicons
Linguistic Inequality	Limited support for low-resource languages	Cross-lingual transfer learning and multimodal data integration
Privacy and Consent	Unauthorized use of personal data	Federated learning, differential privacy, transparent consent mechanisms
Lack of Explainability	Black-box AI models in tourism analytics	Explainable AI (XAI) and ethical audit frameworks
Human Displacement	Over-automation of emotional interpretation	Human–AI collaboration emphasizing empathy and inclusivity

Source: Authors, (2026).

V.7 TOWARD RESPONSIBLE AND INCLUSIVE AI IN TOURISM

Ethical and linguistic inclusivity is not merely a technical requirement but a cornerstone of sustainable tourism analytics. Future sentiment analysis models must prioritize fairness, transparency, and contextual sensitivity to ensure that AI-driven insights contribute positively to human-centered tourism development. By embedding ethical reflexivity and cross-cultural understanding into their design, these systems can strengthen public trust, support equitable participation, and advance the responsible digital transformation of the global tourism industry.

VI. CONCEPTUAL FRAMEWORK FOR FUTURE RESEARCH

The rapid technological, ethical, and cultural shifts outlined in preceding sections indicate that sentiment analysis in tourism will evolve toward a holistic, human-centered paradigm. To guide this transition, this study proposes a conceptual framework for next-generation sentiment analysis in tourism, referred to as the Human, AI Integrative Sentiment Framework (HAISF). This framework synthesizes technological innovation with ethical governance and cultural inclusivity, offering a roadmap for future research and practical implementation.

VI.1 RATIONALE FOR THE FRAMEWORK

The evolution of sentiment analysis has thus far been driven primarily by technological capability, machine learning algorithms, deep learning architectures, and large-scale data analytics. However, this progress has often outpaced consideration of ethical alignment, interpretability, and cross-cultural representation. The HAISF model addresses this imbalance by positioning technology, ethics, and human–cultural context as interdependent pillars of sustainable AI development for the tourism domain. This integration ensures that sentiment analysis systems not only enhance predictive accuracy but also reflect the emotional diversity and ethical integrity necessary for trustworthy AI in global tourism applications.

VI.2 COMPONENTS OF THE HUMAN–AI INTEGRATIVE SENTIMENT FRAMEWORK (HAISF)

The HAISF consists of five interconnected layers, each representing a critical dimension in future sentiment analysis research and practice.

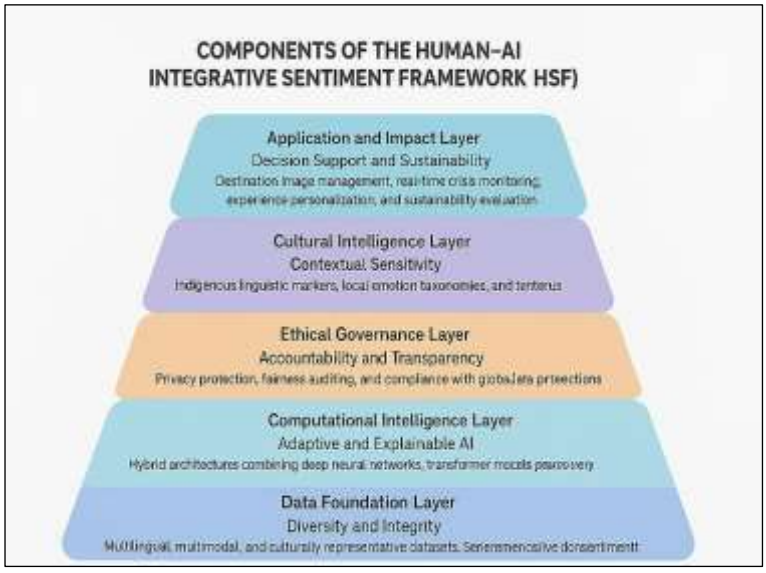

Figure 2: Components of HAISF.
Source: Authors, (2026).

1. Data Foundation Layer: Diversity and Integrity

This layer emphasizes the importance of multilingual, multimodal, and culturally representative datasets. Future models should integrate data from text, images, voice, and sensor inputs while ensuring data authenticity and privacy compliance. Federated data collection methods can preserve user anonymity while supporting continuous learning across decentralized sources.

2. Computational Intelligence Layer: Adaptive and Explainable AI

At the core of the framework lies the computational engine powered by hybrid AI architectures, combining deep neural networks, transformer models (e.g., GPT, BERT, RoBERTa), and neurosymbolic reasoning.

This layer prioritizes explainability and interpretability, enabling stakeholders to understand how sentiment decisions are made. By adopting Explainable AI (XAI) and neuro-symbolic logic, this component ensures transparent, bias-aware sentiment outcomes.

3. Ethical Governance Layer: Accountability and Transparency

This layer operationalizes ethical AI principles by embedding privacy protection, fairness auditing, and accountability mechanisms into sentiment workflows. Ethical governance includes compliance with global data protection standards (e.g., GDPR, ISO/IEC 42001), ethical auditing boards, and open-source algorithmic transparency.

Tourism organizations can employ this layer as a responsibility checkpoint, ensuring data-driven decisions align with social and moral standards.

4. Cultural Intelligence Layer: Contextual Sensitivity

This layer bridges computational and human understanding by embedding local emotion taxonomies, indigenous linguistic markers, and culturally adaptive lexicons into sentiment analysis.

Collaboration between data scientists, linguists, and tourism scholars will allow AI models to interpret affective expressions within their correct socio-cultural frames, reducing misclassification and reinforcing inclusivity in global tourism analytics.

5. Application and Impact Layer: Decision Support and Sustainability

The top layer focuses on the translation of analytical results into strategic decision-making. It includes applications such as destination image management, real-time crisis monitoring, experience personalization, and sustainability evaluation.

By integrating predictive sentiment trends with behavioral and geospatial analytics, this layer empowers policymakers and tourism businesses to act proactively rather than reactively.

VI.3 FUNCTIONAL DYNAMICS OF THE FRAMEWORK

The five layers of HAISF interact dynamically rather than hierarchically. Data flows upward, from raw multimodal input to actionable insights, while ethical and cultural feedback mechanisms flow downward to recalibrate algorithmic behavior. For example, when a system identifies a bias in sentiment interpretation (e.g., misclassification of cultural idioms), the Ethical and Cultural layers can trigger adaptive retraining within the Computational layer, leading to iterative model improvement. This feedback-oriented architecture ensures continuous alignment between technological advancement and social responsibility.

VI.4 RESEARCH DIRECTIONS EMERGING FROM THE FRAMEWORK

The HAISF framework highlights several key research pathways for the next generation of sentiment analysis in tourism. These research directions as shown in table 4, collectively illustrate the interdisciplinary nature of future sentiment analysis, spanning computer science, social ethics, and tourism management.

Table 4: Summary of Research Directions.

Research Area	Proposed Direction	Expected Contribution
Multimodal Sentiment Fusion	Combine text, image, audio, and sensor data into unified affective models	Enhanced accuracy and contextual depth in tourism experience analysis
Cross-Lingual and Cultural Modelling	Develop culturally adaptive emotion lexicons and multilingual AI models	Broader global applicability and inclusivity
Explainable and Trustworthy AI	Create interpretable sentiment systems through XAI and neuro-symbolic methods	Increased stakeholder confidence and ethical compliance
Privacy-Preserving Learning	Implement federated and differential privacy algorithms	Ethical handling of sensitive user-generated data

VI.5 THEORETICAL AND PRACTICAL IMPLICATIONS

From a theoretical perspective, the HAISF advances current understanding by framing sentiment analysis not only as a computational task but as a socio-technical ecosystem shaped by human values, language, and culture. It encourages tourism scholars to integrate affective computing theory, data ethics, and cross-cultural communication within analytical models.

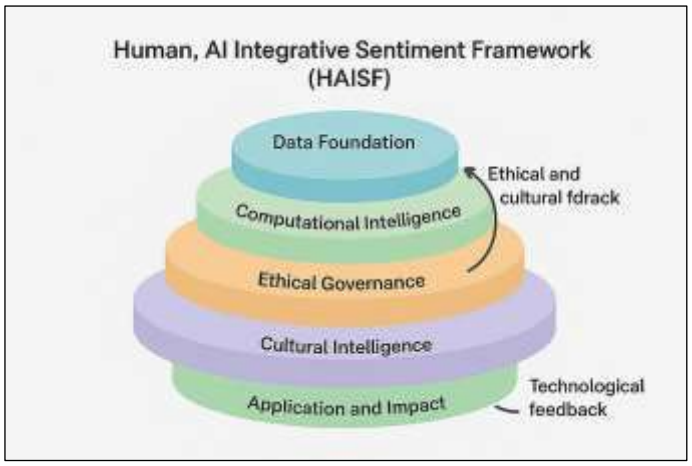

Figure 3: HAISF Framework.
Source: Authors, (2026).

Practically, the framework offers tourism organizations a blueprint for developing AI-driven sentiment systems that are accurate, explainable, and socially responsible. When implemented, HAISF can enhance tourist satisfaction analytics, support evidence-based marketing, and promote sustainable destination management through emotionally intelligent decision-making.

VII. CONCLUSIONS

This study presents the evolution of sentiment analysis in tourism from 2025 to 2045, emphasizing the convergence of Artificial Intelligence, Natural Language Processing, and ethical-cultural awareness. It highlights that sentiment analysis has advanced beyond basic polarity detection to become multimodal and context-sensitive, capable of interpreting emotions through text, image, and voice across diverse linguistic and cultural landscapes. Despite these advancements, ongoing challenges such as algorithmic bias, linguistic inequality, and privacy concerns demand a more balanced and responsible approach. To address these issues, the research introduces the Human-AI Integrative Sentiment Framework (HAISF), a holistic model that integrates technological innovation, ethical governance, and cultural intelligence. The framework reframes sentiment analysis as a socio-technical system, emphasizing adaptive feedback loops between human values and AI-driven processes. This theoretical shift contributes to the development of responsible and inclusive AI in tourism analytics.

Practically, the HAISF provides a roadmap for tourism organizations to develop explainable, privacy-preserving, and ethically grounded sentiment systems. By adopting such systems, stakeholders can gain real-time emotional insights, enhance marketing and service personalization, ensure ethical compliance, and support sustainable destination management. Future research directions include the creation of multimodal and cross-cultural datasets, the advancement of explainable AI, the development of emotion taxonomies sensitive to cultural diversity, and the exploration of privacy-preserving data governance. Additionally, integrating human empathy with AI-driven insights and employing predictive emotional forecasting will further refine tourism intelligence. The future of sentiment analysis in tourism lies in integrating human values, ethical principles, and cultural context with computational intelligence. Through this alignment, sentiment analysis can evolve into a predictive, empathic, and socially responsible decision-support system, driving innovation, trust, and sustainability in the global tourism ecosystem.

ABSTRACT

Addressing the growing concerns regarding climate change necessitates the decarbonization of energy sectors globally. Heating is the largest energy end-use, accounting for almost half of the total energy consumption in most countries. By partially substituting the use of primary energy sources with waste heat recovery, climate and environmental goals in the future will be more attainable. Industrial processes, such as brazing, generate significant waste heat, which is often released into the environment. This study investigated the feasibility of recovering and repurposing waste heat from a brazing furnace for drying applications. A case study was conducted at a manufacturing facility in which a custom heat recovery system was integrated with a continuous conveyor brazing furnace. The system captures exhaust gases (400–500°C) via a heat exchanger, transferring thermal energy to a drying chamber. Experimental data revealed that 65–70% of waste heat was recovered, reducing the energy consumption of the drying unit by 30% and lowering annual CO_2 emissions by 120 metric tons. The industry utilizes waste heat from the brazing furnace to dry the parts in the washing machine. Economic analysis indicated a payback period of 18 months. This study demonstrates the technical and economic viability of waste heat recovery (WHR) in industrial settings, promoting energy efficiency and sustainability.

I. INTRODUCTION

With the majority of nations committed to limiting global warming to 1.5°C, numerous corporations have established individual decarbonization targets for 2030. In 2025, five years remained to implement various decarbonization strategies. However, industrial entities often experience uncertainty regarding the technical pathway for immediate emissions reduction. Technologies that are net present value (NPV) positive and rapidly implementable, such as various energy efficiency measures, can assist organizations in achieving their decarbonization objectives. The recovery of waste heat presents a potential avenue for effectively reducing emissions. Annually, global consumption exceeds 418 exajoules (EJ) or 116,000 terawatt-hours (TWh) of final energy, primarily through the combustion of fossil fuels and heat generation. A portion of this generated heat is utilized for productive purposes, such as electricity production or driving chemical reactions, but the majority remains unused. This unutilized "waste heat" is discharged into the surrounding environment in the form of exhausts or effluents at varying temperature levels.

The recovery of this waste heat can substantially reduce the consumption of primary fuels and, consequently, emissions. The industrial sector accounted for the highest proportion of energy consumption across India in fiscal year 2025 at 41.16%. The domestic sector followed, ranking second, at 25.77%. Traction and railways constituted one percent of the total electricity consumption in India. This data suggests that enhancing energy efficiency through waste heat recovery models can enable Indian businesses to reduce operational costs, improve energy efficiency, and decrease industrial CO2 emissions. With the increasing trend of rising fuel prices over recent decades and growing concerns regarding global warming, engineering industries have been confronted with the challenge of reducing greenhouse gas emissions and improving the efficiency of their facilities. In this context, the utilization of waste heat recovery systems in industrial processes has emerged as a key area of research for reducing fuel consumption, mitigating harmful emissions, and enhancing production efficiency.

Industrial waste heat refers to the energy generated in industrial processes that is not utilized practically and is dissipated or released into the environment. High-temperature processes such as brazing, employed in the automotive and aerospace industries, generate exhaust gases at 400–600°C, which are typically expelled without treatment. Simultaneously, drying operations in these facilities rely on fossil fuels or electricity, contributing to operational costs and emissions. The recovered waste heat could also facilitate a more economical energy transition. Recovered heat can be utilized for industrial process heating purposes, city grid heating, or converted to electricity (determined by local energy demand patterns as well as prices of fuels and electricity). Sources of waste heat primarily include heat loss transferred through conduction, convection, and radiation from industrial products, equipment, and processes, as well as heat discharged from combustion processes. The heat loss can be categorized into high, medium, and low temperature grades. Waste Heat Recovery (WHR) systems are implemented for each range of waste heat to achieve optimal efficiency.

This study addresses the gap in utilizing brazing furnace waste heat for drying, a rarely explored synergy. A case study of a mid-sized automotive parts manufacturer evaluated the design, integration, and performance of a WHR system. The main goal of this work is to study and examine the waste heat recovery from an Industrial Brazing Furnace and by using the obtained energy for useful purposes (here the drying of parts), thereby reducing energy consumption. This unused waste heat represents a significant opportunity for improving energy efficiency and reducing emissions. By implementing waste heat recovery systems, industrial companies can capture and repurpose this energy for various applications, such as preheating input materials, generating electricity, or providing space heating. The potential benefits of waste heat recovery extend beyond individual companies, as they can contribute to broader sustainability goals and help nations meet their climate commitments.

II. RELATED WORKS

Numerous studies have focused on utilizing waste heat from industrial processes for energy-saving purposes [1]. One investigation explored the combination of power cycles to efficiently recover waste heat, particularly in high-temperature thermal furnace units [2]. Another study analysed the performance of a heat pipe heat exchanger using nanofluids to recover waste heat, and demonstrated increased heat transfer coefficients with higher mass concentrations [3]. Additionally, a high-efficiency flue gas condensing heat exchanger was developed to recover waste heat from petrochemical heating furnaces, demonstrating significant energy-saving efficiencies [4], [5]. Furthermore, investigations have examined the optimization of organic Rankine cycles for electricity production using waste heat from industrial processes, suggesting their potential for improving energy efficiency [6-8]. These findings collectively provide insights into potential methods and technologies for utilizing waste heat from industrial brazing furnaces for drying applications [9].

Waste heat recovery from industrial processes offers significant potential for energy savings and greenhouse gas reduction. Studies have indicated that recovering waste heat could substitute for 9% of total energy used by US industry [10]. Various technologies exist for waste heat recovery, including high-temperature vapor compression heat pumps for drying processes, which can reduce energy demand by 60-80% [11]. A novel waste heat recovery-assisted heat pump dryer demonstrated superior performance compared to a simple heat pump dryer, with higher energy and exergy efficiencies, specific moisture extraction rate, and coefficient of performance [12], [13]. This system also exhibited economic viability with a payback period of approximately three years. Waste heat can be recovered from various sources such as exhaust gases, air streams, and liquids, with high-grade sources being more readily applicable for preheating applications [14]. These advancements in waste heat recovery technologies offer promising solutions for improving the industrial energy efficiency and competitiveness.

The escalating global concern regarding climate change necessitates a fundamental shift towards decarbonizing the energy sectors. Heating, as the largest energy end-use, consumes nearly half of the total energy in most countries [15]. Mitigating this substantial energy demand and achieving future climate and environmental goals requires innovative solutions. One promising approach involves harnessing waste heat, which is a significant untapped energy resource often overlooked in industrial processes [16]. This paper presents a case study that investigates the feasibility and effectiveness of recovering waste heat from a brazing furnace to enhance the drying process of an industrial washing machine within a manufacturing setting. The high-temperature waste heat generated by industrial processes such as brazing presents a substantial opportunity for energy efficiency improvements [17]. By effectively capturing and utilizing otherwise wasted energy, it is possible to significantly reduce reliance on primary energy sources, decrease greenhouse gas emissions, and contribute to sustainable energy development [18], [19].

The integration of this system within a broader industrial context aligns with an increasing focus on energy efficiency pathways for decarbonization [20]. The pursuit of efficient waste heat recovery (WHR) has stimulated the development of a diverse array of technologies, each with its own strengths and limitations. A comprehensive understanding of these technologies is essential to select the most appropriate solution for a given application. Organic Rankine Cycles (ORCs), for instance, represent a mature technology for converting waste heat into electricity [21]. They have demonstrated considerable potential in various industrial sectors, notably electric arc furnaces (EAFs) [22], where significant quantities of waste heat are generated. However, despite their potential, widespread adoption of ORCs remains limited. This limitation is partially attributable to the challenges faced by investors and end-users in accurately assessing and realizing the potential energy savings associated with their implementation [23].

Alternative WHR approaches include the use of heat pipes coupled with thermoelectric generators (TEGs) [24]. This combined system offers a compelling solution for bridging the gap between energy supply and demand, effectively managing the inherent mismatch in the energy distribution frequently encountered in industrial environments [25]. The heat pipes excel at efficient heat transfer, whereas the TEGs directly convert the thermal energy into electricity. Supercritical CO2-based power cycles represent another promising avenue for waste heat to power (WH2P) applications [26]. Their applicability extends across a broad spectrum of energy-intensive industries, including steel and metal production, cement manufacturing, and petrochemicals. The selection of the optimal WHR technology depends on several critical factors, including the temperature and quantity of available waste heat, desired application of the recovered energy, and overall economic viability of the chosen system. The specific characteristics of the waste heat stream from the brazing furnace informs the selection of an optimal heat recovery method for this case study.

The relatively high temperature of the waste heat from the brazing furnace may render technologies such as ORCs or supercritical CO2 cycles more suitable, although the specific design and cost-effectiveness require further investigation. However, the focus on drying in a washing machine suggests that a direct heat application might be more appropriate, potentially utilizing heat exchangers or other direct heat transfer methods. This study aims to demonstrate a practical, real-world application of waste heat recovery (WHR) in an industrial context, quantifying its environmental and economic benefits. The successful implementation of this WHR system offers a valuable model for other industries seeking to minimize their environmental impact and enhance operational efficiency.

III. EXPERIMENTAL SETUP

III.1 FURNACE BRAZING

Furnace brazing is an industrial, high-volume brazing technique in which the entire assembly is heated to the melting point of the braze alloy, which is subsequently introduced into the joint before cooling. The primary advantages of furnace brazing include the ability to join dissimilar materials, enhanced control over tolerances, and mitigation of distortion in the finished component. Brazing is a joining method for metals or ceramics that utilizes a metal with a lower melting point than either of the materials to be joined to create a joint. By definition, only processes employing a metal that melts above 450°C are classified as brazing while processes below this temperature are categorized as soldering. In furnace brazing, the entire assembly is heated to the temperature at which the braze alloy melts and flows into the joint. Upon subsequent cooling, it solidified, and formed a robust joint. Furnace brazing enables the simultaneous creation of numerous joints, often numbering in thousands.

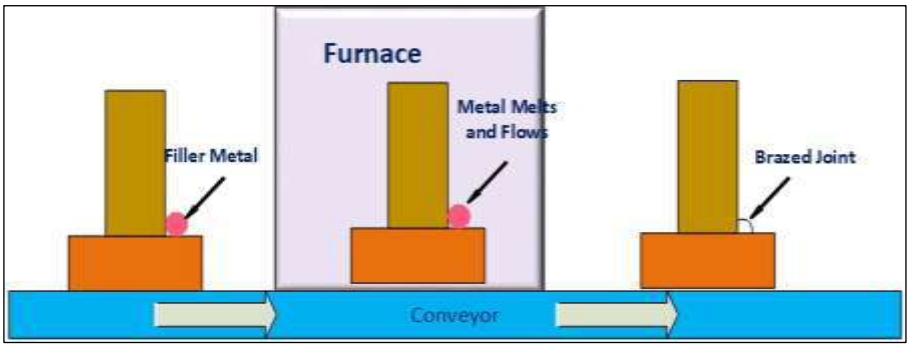

Figure 1: Schematic of furnace brazing process.
Source: Authors, (2026).

Various heating methods are available for brazing operations as shown in Figure 1. The primary consideration in selecting a heating method is to achieve efficient heat transfer throughout the joint while retaining the heat capacity of the individual base metals utilized. The geometry of the braze joint is also a critical factor to consider, as are the rate and volume of production required. A 250 kW natural gas brazing furnace (operating at 850°C, exhaust flow rate 0.8 m³/s) was analysed. The drying chamber required 80°C for drying the polymer component. The detailed functional diagram of brazing furnace is given in Figure 2. The easiest way to categorize brazing methods is to group them using a heating method. Here are some of the most common:

- Torch brazing
- Furnace brazing [Exothermic, Hydrogen, Argon and Vacuum Atmospheres]
- Induction brazing
- Dip brazing.
- Resistance brazing
- Infrared brazing
- Blanket brazing
- Electron beam and laser brazing
- Braze welding

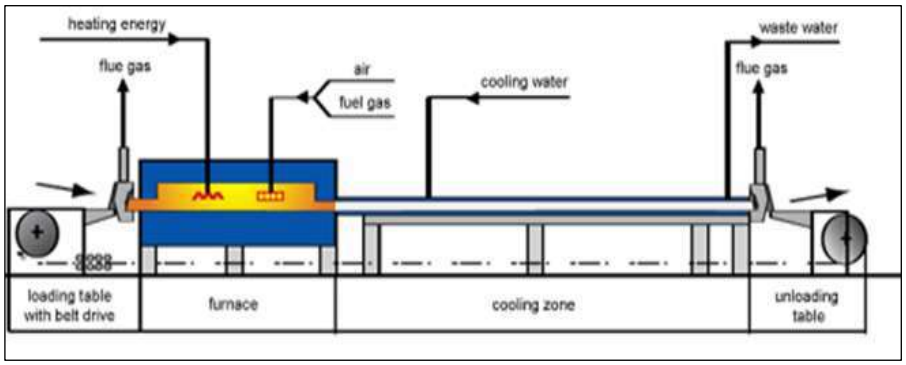

Figure 2: Functional diagram of Brazing Furnace.

III.2 WASHING MACHINE

In the manufacturing industry, washing machines are high-performance inline conveyor washers. The working principle is based on the linear movement of parts through the process; parts are conveyed through different stages of the process at controlled and changeable speed. These washers are suitable for simple geometries with a short quick cycle time per component. The Multistage conveyor parts washer represents a remarkable advancement in industrial cleaning technology, offering an efficient and comprehensive solution for the increasingly complex requirements of component cleaning. This cutting-edge system was designed to meet the needs of diverse industries, from automotive to electronics, and beyond.

The machine uses a series of conveyor belts to transport components through various cleaning stages, each tailored to address specific contamination challenges. The operation of this innovative industrial parts washer machine begins with the loading of components onto the conveyor, which then guides them through a sequence of meticulously engineered cleaning stages. These stages include processes such as pre-washing, degreasing, ultrasonic cleaning, rinsing, drying, and even inspection. At each stage, the components are subjected to specialized cleaning techniques and solutions to ensure that contaminants such as oils, greases, dust, and particulates are thoroughly removed. The modular nature of the multistage system allows for customization, enabling manufacturers to adapt the machine to the unique cleaning requirements of their components.

IV. MATERIALS AND METHODS

The experimental setup included the installation of a heat recovery system in the brazing furnace. The heat exchanger captures the waste heat from the furnace exhaust and channels it into a drying chamber. The setup was designed to ensure an efficient heat transfer while maintaining the operational integrity of the brazing furnace. Based on waste heat characterization, a heat exchanger was designed to efficiently transfer heat from the exhaust gases of the brazing furnace to the water inlet of the industrial washing machine. A shell-and-tube heat exchanger was selected because of its high efficiency and suitability for high-temperature applications. The heat exchanger was designed using commercially available software, considering factors such as the temperature difference between the hot and cold streams, flow rates of the fluids, and overall heat transfer coefficient.

The materials selected for the heat exchanger were based on their resistance to high temperatures and corrosion, considering the chemical composition of the exhaust gases. The heat exchanger was fabricated using high-quality materials and precision manufacturing techniques to ensure durability and performance. The system also includes a control system to regulate the flow of exhaust gases and water, maintain optimal operating temperatures as shown in Figure 3. The control system was programmed to maintain a specific temperature difference between the hot and cold streams, maximizing the heat transfer efficiency while ensuring safe operation.

IV.1 STEP BY STEP PROCEDURE FOR IMPLEMENTATION

IV.1.1 Heat Recovery System Installation

To optimize the efficiency of our brazing furnace, it is essential to install a heat recovery system in the exhaust. The system should be designed to capture and transfer heat from the furnace exhaust to the drying chamber. Insulated ducts must be carefully engineered to ensure the effective transportation of heat. The heat exchanger must be securely attached to the furnace exhaust outlet and meticulously insulated to minimize any potential heat loss. Furthermore, it is imperative to use insulated ducts to connect the heat exchanger to the drying chamber. In addition, the installation of fans or blowers should be considered to facilitate efficient heat transfer and air circulation within the system. Moreover, the design of the drying chamber should be carefully tailored to accommodate specific materials to be dried. It is crucial to ensure that the chamber is well-insulated to effectively retain the captured heat, thereby maximizing the overall efficiency.

IV.1.2 Sensor Installation and Calibration

To ensure precise monitoring of the drying process, it is necessary to install temperature sensors at specific locations. These sensors were placed in the furnace exhaust, before and after the heat exchanger, and inside the drying chamber. Thorough calibration of these sensors is essential to ensure accurate temperature readings. The sensor details and their locations are presented in table 1.

Table 1: Various Sensors and their installation locations.

Temperature sensor Name	Location

Additionally, moisture content analyzers were installed at the entry and exit points of the drying chamber to measure the moisture content of the materials before and after the drying process. The comprehensive data acquisition system is used to connect and integrate all sensors and analyzers. This system will be configured to systematically record data at regular intervals, allowing us to closely monitor and analyze temperature and moisture content variations throughout the entire drying process.

IV.1.3 Data Acquisition and Analysis

The next phase involves collecting data on the performance of the WHR system. Temperature sensors were installed at various points in the system, including the inlet and outlet of the heat exchanger, to monitor the temperature changes of both exhaust gases and water. Flow meters were used to measure the flow rates of both the streams. The energy consumption of the drying system of the washing machine was measured by using a power meter installed on the main power supply. Data were collected over a period of three months, encompassing various operating conditions and loads. Data logging was performed using a data acquisition system capable of recording data at a frequency of 1 Hz. The collected data were then analysed to determine the amount of waste heat recovered, the efficiency of the heat transfer process, and the reduction in energy consumption for the drying cycle of the washing machine.

Statistical analysis techniques were employed to determine the significance of the results and identify the correlations between the various parameters. The data analysis involved calculating the overall heat transfer coefficient, effectiveness of the heat exchanger, and energy savings achieved through waste heat recovery. This comprehensive data analysis provided a robust evaluation of the performance of the WHR system. A convenience sampling method that is nothing but a non-probability sampling technique has been planned, as the samples are selected from the population directly because they are conveniently available for us regularly at any point of a given time. Samples such as the temperature of the furnace, temperature of the cooling water in the washing machine, and level of water is noted based on different criteria such as start-up time, brazing time and full load of the washing machine.

IV.1.4 Baseline Data Collection

This detailed analysis evaluates the effectiveness of utilizing waste heat from an industrial brazing furnace for drying parts. The primary objectives are to assess energy savings, improve drying efficiency, and analyze overall system performance. Data was collected from a controlled experimental setup to compare baseline conditions (without heat recovery) against the improved system (with heat recovery). Operate the brazing furnace under normal conditions without the heat recovery system and collect baseline data on furnace exhaust temperature and material drying times. Data is collected on key parameters, including:

Exhaust Temperature: Temperature of the furnace exhaust before and after heat recovery.
Drying Chamber Temperature: Temperature inside the drying chamber during the drying process.
Drying Time: Time required to achieve the desired moisture content in materials.
Energy Consumption: Total energy used by the brazing furnace and the drying process.
Nature of Data -Two different types of data were collected in this case study. Qualitative data with functional lists, observations, etc., and quantitative data with power readings, parameters, measurements, etc.

Table 2: Specifications of proposed Waste Heat Recovery System.

Water Tank 1 Capacity	550 Litres
Power Consumption per hour	10 kW
Water Tank 2 Capacity	700 Litre
Power Consumption of water tank 2	12 kW
Electricity rate (approx.)	10 Rs./kWH
Average Working hours	12 hrs for 2 shift
Power required for weekly pull up of 1200 Litres from 30oC to 60oC	42 kWH
Energy required for maintain application per hour	22 kW
Per day energy required to maintain temperature considering 2 shifts	264 kW
Time required for pull up considering 30 kW heat pump	1.4
Heat pump consumption	13.2 kW
Running hours	10.2 hrs
Gross daily consumption including pull up	134.64 kW

Source: Authors, (2026).

IV.2 CASE 1: RUN THE BRAZING FURNACE WITHOUT HEAT RECOVERY

When running the brazing furnace, it was ensured that it operated under normal conditions without activating the heat recovery system. Thoroughly document the baseline data, including exhaust temperature, energy consumption, and drying performance, using conventional methods to ensure accuracy and completeness.

IV.3 CASE 2: WITH HEAT RECOVERY OPERATION

To activate the Heat Recovery System, start the heat exchanger and ensure that heat is effectively transferred to the drying chamber. A control system was utilized to maintain the desired temperature levels within the drying chamber, making precise adjustments necessary to create an optimal drying environment. When loading the drying chamber, care should be taken to place the materials to be dried inside the chamber, ensuring that they are evenly distributed to promote uniform drying and the efficient use of space. During the drying process, it is important to continuously monitor temperature, moisture content, and energy consumption. The air flow and temperature settings were adjusted to optimize the drying process, ensuring that the materials were dried effectively while minimizing energy usage. Regular monitoring and adjustments helps to achieve the best possible drying results. Air flow and temperature settings were required to optimize the drying process.

IV.4. GROSS ENERGY CALCULATIONS

To calculate the daily power consumption of all the loads with an hourly time step, a good understanding of how often the loads are used during the two different periods of the day is required. Depending on the specific applications, the battery storage bank is calculated based on battery specifications such as the battery storage capacity (the minimum batteries) for off-grid applications, batteries must fulfil the discharging rate that has to be larger than or equal to the peak power of the load capacity, the battery storage capacity must large enough to supply the longest day time energy used, and to be able to use energy during the longest cloudy period. The gross energy requirement (EG) of an energy conversion device with the energy output (EO), can be decomposed in two parts the direct input of energy during operation (ED), and indirect energy requirement (EI), the energy used by the loads can be calculated by the Equation 1,

$$E_G = E_D + E_I \quad (1)$$

Where, E_G: Gross energy requirement, E_D: Direct input of energy, E_I: Indirect input of energy.

Solar panels and batteries can be calculated using basic equations that depend primarily on the total daily load capacity. One principle is that the solar panels charge the batteries during the day and the batteries process the load at night as in the solar street lighting system. The capacity of storage batteries can be calculated using the following Equation 2,

$$C_B(Ah) = \frac{E_{load}}{\eta_{inv} \, x \, V_B \, x \, DOD} \, x \, DOA \quad (2)$$

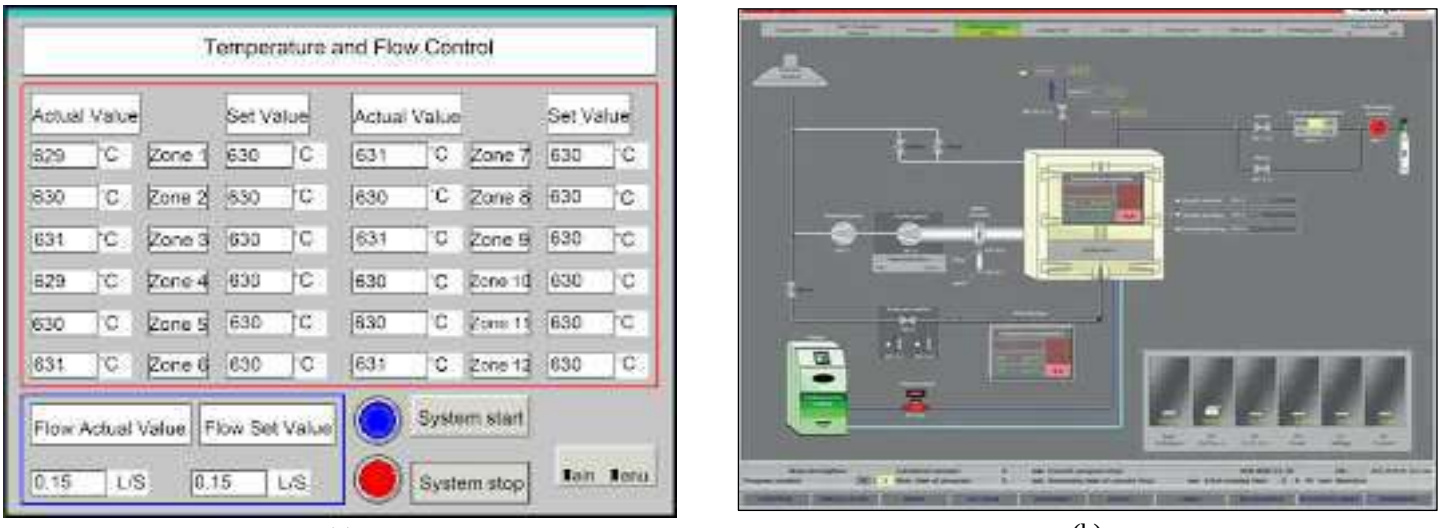
Where, E_{load} :Total load Energy (Wh/day), η_{inv} : Inverter efficiency, V_B: Battery voltage (V), DOD: Depth of discharge (%), DOA: Day of autonomy

V. RESULTS AND DISCUSSIONS

The heat exchanger effectively reduced the exhaust temperature from 55 to 250°C, capturing significant waste heat. This indicates an efficient heat transfer and minimal losses, which are vital to the performance. The temperature of the chamber was effectively maintained within the desired range (80-100°C) by using the recovered heat to ensure optimal drying conditions. Implementing the heat recovery system reduced the drying time from 120 minutes to 90 minutes, a 25% improvement. This suggests that a higher temperature in the drying chamber enhanced the evaporation rate of moisture from the parts. Both baseline and heat recovery setups achieved a target final moisture content of 5%, indicating that the heat recovery system maintained or improved the drying effectiveness. Using the heat recovery system resulted in a 30% reduction in energy consumption, saving 50 kWh per drying cycle.

With an average industrial electricity cost of (Indian Rupees) INR 10 per kWh, this translates to INR 50 per drying cycle. For a facility operating 300 drying cycles per year, the annual savings are approximately INR 15,000.

Table 3: Comparison of performance of furnace with/without WHR.



Description	Without Heat Recovery	With Heat Recovery System
Furnace Exhaust Temperature	550°C.	550°C. 250°C after heat exchange
Drying Chamber Temperature	~25°C	80°C and 100°C, optimal for drying
Initial Moisture Content of Parts	20%.	5% after 120 minutes
Final Moisture Content	5% after 120 minutes	5% after 90 minutes
Energy Consumption	150 kWh per drying cycle	100 kWh per drying cycle

Source: Authors, (2026).

Through meticulous analysis, it becomes apparent that harnessing waste heat from the brazing furnace serves as a cornerstone for elevating the energy efficiency quotient of the drying process, concurrently causing substantial reductions in operational expenditures. The system's efficacy manifests prominently through a notable 33% decline in overall energy consumption metrics, emblematic of its adept utilization of surplus thermal energy emanating from the brazing furnace. This profound reduction in energy demand is orchestrated through the sophisticated interplay of heat exchange mechanisms and optimized heat transfer modalities, effectively channeling waste heat streams to augment the thermal energy budget allocated for the drying process. Consequently, this judicious exploitation of latent thermal resources obviates the need for additional energy inputs, thereby mitigating resource wastage and affording tangible economic savings. Moreover, the system's prowess is further accentuated by a consequential 25% reduction in drying duration, indicating of its advantages in expediting the moisture evaporation kinetics intrinsic to the drying process.

This temporal optimization is underpinned by a synergistic amalgamation of enhanced heat transfer dynamics facilitated by the waste heat recovery infrastructure and the meticulous control of the process parameters governing airflow rates, temperature gradients, and moisture content within the drying chamber. Temperature are monitored though control panel as shown in Figure 4 (a) and (b). In summary, the comprehensive analysis underscores the transformative impact of waste heat utilization from the brazing furnace, accentuating its pivotal role in recalibrating the energy efficiency paradigm of the drying process. By delivering tangible reductions in energy consumption and drying duration, the system epitomizes a paradigm shift towards sustainable and economically prudent industrial operations, underscoring its indispensable contribution to operational excellence and resource conservation endeavors.

The inherent scalability of the waste heat recovery system empowers its seamless adaptation and expansion to accommodate a diverse array of industrial processes characterized by elevated temperature regimes and demanding drying prerequisites. By leveraging modular design principles and flexible configuration options, the system can be tailored and customized to align with the specific operational requirements and production dynamics of various industrial applications. Regardless of deployment in metalworking, chemical processing, or food production facilities, the system exhibits unparalleled versatility and adaptability, underscoring its suitability for deployment across a spectrum of high-temperature industrial processes. This scalability not only enhances operational agility and responsiveness but also future-proofs investments by facilitating incremental expansions and upgrades in tandem with evolving production needs and technological advancements.

Figure 4: Temperature and Flow control from control panel.
Source: Authors, (2026).

During daytime operating loads, solar energy is directly used through the inverter to supply the load without passing through the storage battery. Therefore, the need for a battery depends on the instantaneous level of energy generated from the solar panels. When the generated energy is less than the load requirement, the battery compensates for the energy shortage, and when the energy generated is higher than the load requirements, the battery is charged.

VI. CONCLUSIONS AND RECOMMENDATIONS

In summary, this study of recovering waste heat from industrial brazing furnaces for drying applications underscores the paramount importance of optimizing the thermal resources in industrial processes to enhance energy efficiency, decrease operational expenses, and reduce environmental harm. The investigation reveals the substantial benefits of employing innovative technologies such as advanced heat exchangers, thermoelectric generators, hybrid systems, and Industry 4.0 tools. These technologies have proven effective in maximizing energy use and minimizing waste, with experimental outcomes showing a recovery of 65-70% of waste heat, leading to a 30% reduction in energy consumption of the drying unit and a notable decrease in CO_2 emissions by 120 metric tons annually.

The research provides a comprehensive overview of the current advancements in waste heat recovery and lays down a strategic pathway for further exploration and technological development in this field. To propel waste heat recovery forward, the study recommends sustained investment in research and development, the adoption and integration of new technologies, comprehensive training and education for industry professionals, enhanced regulatory support and incentives, continuous system monitoring and optimization, and increased knowledge sharing and collaboration among stakeholders. By adhering to these strategies and adopting an integrated approach to waste heat recovery, industrial entities can achieve considerable energy savings, mitigate environmental impacts, and bolster their competitiveness in the journey towards a more sustainable industrial landscape.

ABSTRACT

Thermal management of electronic devices (TMED) has gained attention the worldwide trend of automating processes employing artificial intelligence approaches. Unless efficient thermal management improvements and products that can withstand increased heat loads in small areas are introduced to the market, this field will continue to advance. This study's goal is to provide a bibliometric analysis of passive cooling methods for electronic device thermal management using Scopus publishing records from the previous 25 years. a combination of best-performing nations, content and language types, author collaboration and citations, the study examines the article. Authors cooperation and concurrences, as well as keyword-based and country-wise network analysis, can be observed using the VoS viewer program. The analysis clearly shows that China has the highest contribution (32%) in terms of publications, followed by the United States of America. The Scopus-indexed documents increased by 22 times during the period of 2000 to 2024 and a total of 616 documents received citations of 16563 in the year 2024 in the domain of TMED, which shows the growing interest of researchers. Future scholars will have a thorough understanding of how heat management in electronic equipment has changed over the previous 20 years thanks to the assembled study.

I. INTRODUCTION

The famous "Moore's Law" was proposed in the 1960s as the integrated circuit industry expanded quickly[1]. Although "Moore's Law" is essentially an empirical relationship in manufacturing instead of a natural rule, its correctness has been proven for decades, and the semiconductor sector regularly uses the law to guide research and development goals. The integrated circuit's capacity to support transistors will continue to grow following "Moore's law" [2], [3]. While driving computational power, the exponential growth in transistor density simultaneously intensifies the thermal design power per unit area, posing a challenge to conventional cooling methods.

Heat dissipation presents a significant challenge in the current digital revolution, as electronic products, particularly smartphones, tablet computers, and data centres, increasingly evolve towards higher performance, greater integration, and miniaturisation [4], [5].This escalation in heat flux demands innovative solutions beyond traditional thermal management, propelling the industry towards advanced three-dimensional packaging and novel material science applications [6]. The stringent cooling requirements for high-integration power electronics systems necessitate significant energy consumption and have recently raised concerns regarding carbon footprints [7]. Notice that almost 40% of energy consumption for the current data centres [8] was used in their cooling infrastructure, which consumes almost 12% of total electricity [9].

The continuous improvement in integrated circuit manufacturing processes has led to increased heat generation, necessitating the development of efficient thermal management technologies to enhance performance and reliability [10]. This growing thermal burden necessitates a paradigm shift from traditional cooling to advanced thermal management solutions, leveraging innovative

materials and architectural designs to effectively dissipate the concentrated heat loads [11]. Passive cooling techniques, like natural convection, heat pipes, vapour chambers, and phase-changing materials, are being increasingly explored to address the thermal challenges posed by compact electronic devices [12].

The use of phase change material and heat pipes offers high effective thermal conductivity [13] and is particularly attractive due to their lack of active power consumption and mechanical complexity, which enhances system reliability and reduces operational expenses. Heat pipes' capacity to passively transmit heat from the evaporating end to the condensing end by using the latent heat of the working fluid has drawn constant focus as a highly effective and reliable two-phase heat transfer technique. [14], [15]. This property makes them suitable for applications where minimal noise, vibration, and maintenance are critical design considerations [16]. Figure 1 shows the active and passive cooling technique for electronic cooling applications.

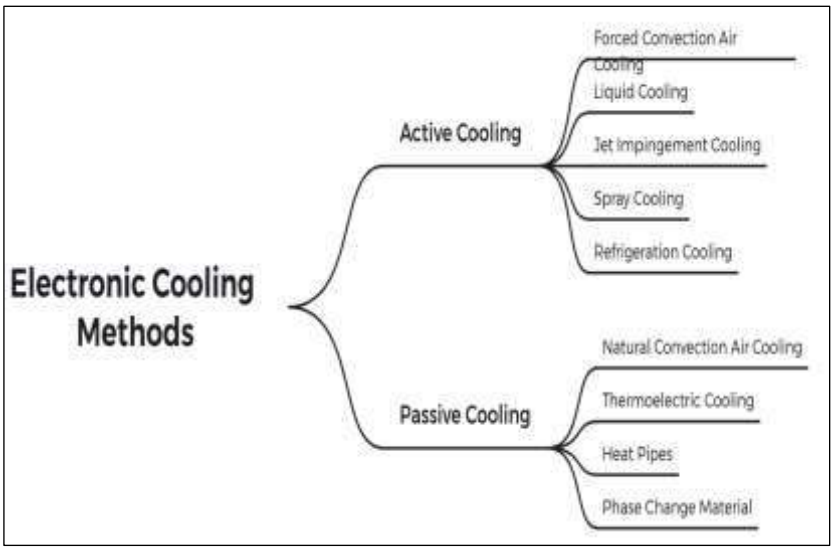

Figure 1: Different techniques for electronic cooling.
Source: [5].

The flat-plate heat pipe, the thermal ground plane, and the heat spreader are synonyms for the vapour chamber, which is two-dimensional and spreads heat from smaller heater areas to larger sink areas across small temperature differences [17]. The fundamental difference between a heat pipe and a vapour chamber is that the former acts as a heat transporter, and the latter serves the purpose of spreading the heat [18]. As shown in Figure 2, vapour chambers (VC), or flat heat pipes, are sealed containers made from materials such as aluminium or copper. The bottom surface is called an evaporator, which is placed on the heat source/chip to be cooled. The top surface is known as a condenser, wherein heat is dissipated to the atmosphere via a cooling medium like air or water. The evaporator and condenser surfaces are internally covered with a thin layer of wick of different types, such as grooves, screen mesh, or sintered powder layer. Non-condensable gases are removed using a vacuum pump, which is then charged with working fluid. The working fluid evaporates due to heat from the source. Vapours travel to the condenser side due to the difference in vapour pressure, and they lose latent condensation heat on the condenser surface. The condensate is transported back to the evaporator by capillary action through the wick.

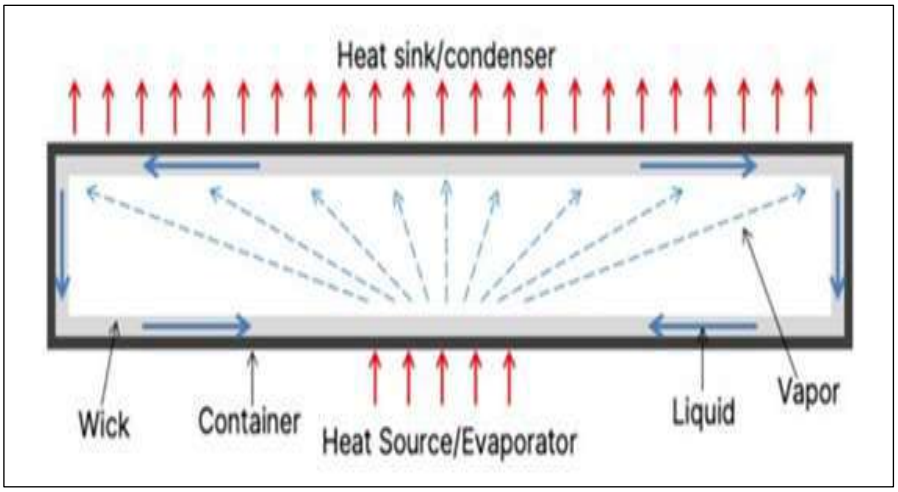

Figure 2: Working of the vapour chamber as a heat spreader.
Source: Authors, (2026).

The excellent thermal dissipation performance of ultra-thin heat pipes (UTHPs) makes them an attractive solution. These advantages make UTHPs widely applicable in industries such as battery thermal management [19], solar collectors [20], [21], and electronics cooling [22].

I.1 CHALLENGES IN USING PASSIVE COOLING TECHNIQUES:

Passive cooling technologies serve as essential heat management solutions for contemporary electronics and industrial applications. Heat pipes, phase change materials (PCMs), and vapour chambers present compelling substitutes for active cooling systems owing to their energy reliability and effectiveness [23]. Nonetheless, despite their theoretical benefits, these technologies encounter significant obstacles that hinder their actual application and market feasibility. The operational limit of a heat pipe indicates the maximum heat transport capacity it can maintain before performance declines, dictated by various physical constraints [24].

These constraints include the capillary limit, where the wick structure fails to return adequate liquid to the evaporator against gravitational and viscous forces; the sonic limit, which arises when vapour velocity nears sonic speed, resulting in choked flow; the boiling limit, where excessive heat flux induces nucleate boiling in the wick and disrupts liquid flow; and the entrainment or flooding limit, where high vapour shear entrains liquid droplets, obstructing return flow. Each limit is influenced by the heat pipe's working fluid, wick geometry, operating orientation, and temperature range [25].

Phase change material suffers operational challenges like low thermal conductivity [26], expansion/contraction during melting/solidification can cause mechanical stresses, leakage, or damage to encapsulation [27], repeated melt-freeze cycles can cause chemical instability, agglomeration, or loss of latent heat storage capacity [28], matching PCM melting temperature with component safe-operating limits is critical; mismatch can lead to thermal throttling or insufficient protection [29].

For vapour chambers, manufacturing complexity increases with the miniaturisation requirements. The integration of micropillar wick structures requires advanced manufacturing capabilities that may not be readily available [30]. Despite these limitations, the heat transfer coefficient owing to the phase change mechanism in these devices makes them a preferred candidate for TMED [31]. Figure 3 compares the heat transfer coefficient values for free convection, forced convection, and phase change mechanism techniques.

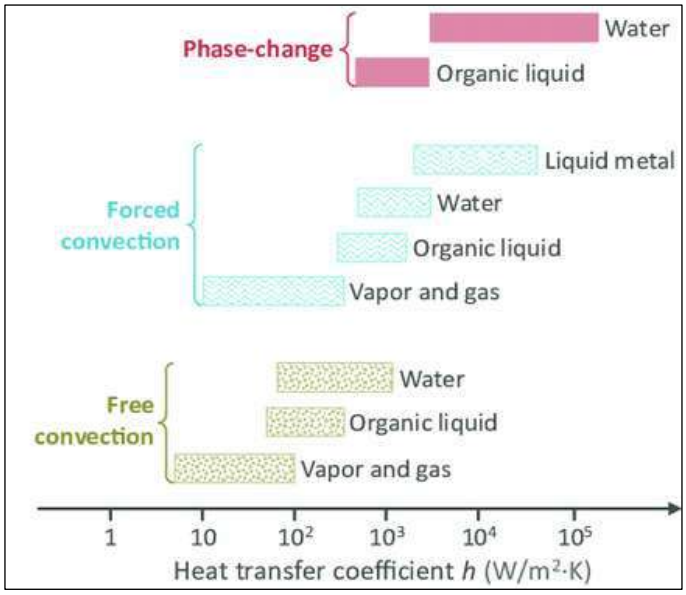

Figure 3: High heat transfer coefficient values for the phase change mechanism.
Source: [32].

The objective of this paper is to present a comprehensive evaluation that includes a bibliometric analysis to gain an understanding of the predominant research efforts and the components that comprise them. A complete analysis of global applications, authors, and published studies is provided in the ensuing sections of the bibliometric analysis. A bibliometric study is defined as a statistical or quantitative analysis of literature, including books, journals, conference proceedings, and online information, to provide insights into a particular subject area or written communication [33]. A bibliometric evaluation offers researchers a robust, data-driven perspective to comprehend the intellectual landscape, discern new trends, drive strategic decisions, and effectively scan extensive literature. When employed efficiently in conjunction with qualitative evaluations, it transforms into an essential instrument in contemporary scholarship. The author found that there is hardly any bibliometric review done in the field of TMED and believes this analysis will help new researchers to understand the trends in publications, author concurrence, and major contributing countries in the area of thermal management of electronic devices.

II. BIBLIOMETRIC SURVEY

An essential step in the research process is gathering data. Scopus, Clarivate, SCImago, Mendeley, ScienceDirect, and Google Scholar are among the most frequently used publishing databases [34]. Scopus is the premier repository of citations and abstracts for peer-reviewed scholarly articles. The Scopus database was consulted to gather literature on Thermal Management of Electronic Devices (TMED), including articles, conference proceedings, and research papers published from 2000 to 2025. In any bibliometric research, choosing the right keywords is essential. The use of keywords often illustrates heterogeneity in the usage of the conjunctions 'AND' and 'OR.' The Scopus database advises that AND should be included when the analysis requires the use of both terms. The conjunction "OR" should be used when one or more words are included in the expected search results [35].

II.1 METHODOLOGY

For the present study shown in Figure 4, Scopus published documents are collected for the last 25 years, and a bibliometric analysis is conducted for the parameters like top ten countries, languages, document types, and citation trends.

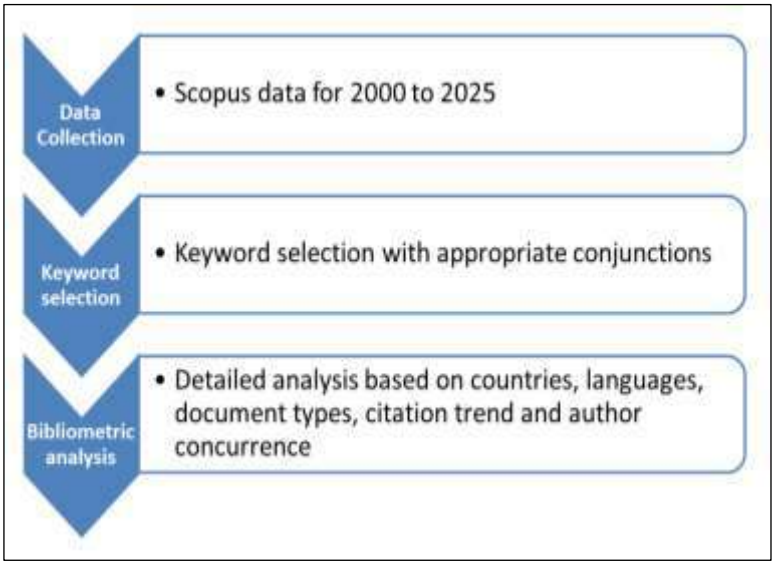

Figure 4: Methodology for the present study.
Source: Authors, (2026).

II.1.1 Data Collection

The bibliometric analysis utilised data sourced from the Scopus website, recognised as a leading and extensive abstract and citation database for peer-reviewed literature, encompassing conference proceedings, book chapters, and articles. Scopus provides a thorough overview of international research output across various disciplines, including science, technology, medicine, social sciences, mathematics, and the arts and humanities, along with advanced tools for tracking, analyzing, and visualizing research. Table 1 presents the keywords utilized for searching Scopus. The bibliometric search keywords were carefully chosen to follow a funnel pattern, starting with broad terms about thermal management and getting more detailed as we looked for new cooling techniques.

This layout lets the frequency analysis track how research interests gradually narrow over time, showing how the field changes from broad ideas to more specific innovations. A total of 3,949 publications were identified from 2000 to 2025 for the search terms Thermal, Management, Electronic, and Devices. A total of 223 papers were identified after limiting the search to TMED with a focus on passive cooling. Upon refining keyword combinations related to TMED utilising passive cooling and vapour chambers, only 16 papers were identified. Scopus was searched with a combination of essential keywords, as shown in Table 1.

Table 1. Bibliometric distribution of technological combinations utilised in TEMD using passive cooling and vapour chamber.

S.N	Search category	Number of **publications**	Year
I.	thermal AND management AND electronic AND devices	3949	2000 to 2025
II.	thermal AND management AND electronic AND devices AND passive AND cooling	223	2000 to 2025
III.	thermal AND management AND electronic AND devices AND passive AND cooling AND Vapour chamber	16	2010 to 2024

Source: Authors, (2026).

The keywords were refined as outlined in Table 1 to examine both the breadth and depth of thermal management mechanisms employing passive cooling techniques and to assess the penetration of vapour chamber technology—a method widely used for efficient heat spreading in compact electronic systems.

II.1.2 Analysis of Bibliometric Data

As discussed in the previous section, the following section analysis is carried out in categories as:

Category -I: ----Thermal Management of Electronic devices;
Category -II: --- Thermal Management of Electronic devices with passive cooling;
Category -III: ---Thermal Management of Electronic devices with passive cooling and vapour chamber.

The study of global research provides insights into nations, languages, kinds of published documents and their publishing patterns, subject-specific evaluations, authors' contributions to research in certain areas, and correlates these with national characteristics. A detailed discussion of the data collected on each of these areas is provided in the sections that follow.

II.1.3 Studies on Thermal Management of Electronic Devices

(a) Research trends in top ten countries

Keyword search using the words “Thermal Management of Electronic devices” returned contributions by 57 different countries in between 2000 to 2025. The search results were plotted for the to 10 top countries. The country-wise distribution of documents eliciting the number of research articles on TMED is shown in Figure 5, displays data on the 10 most productive countries.

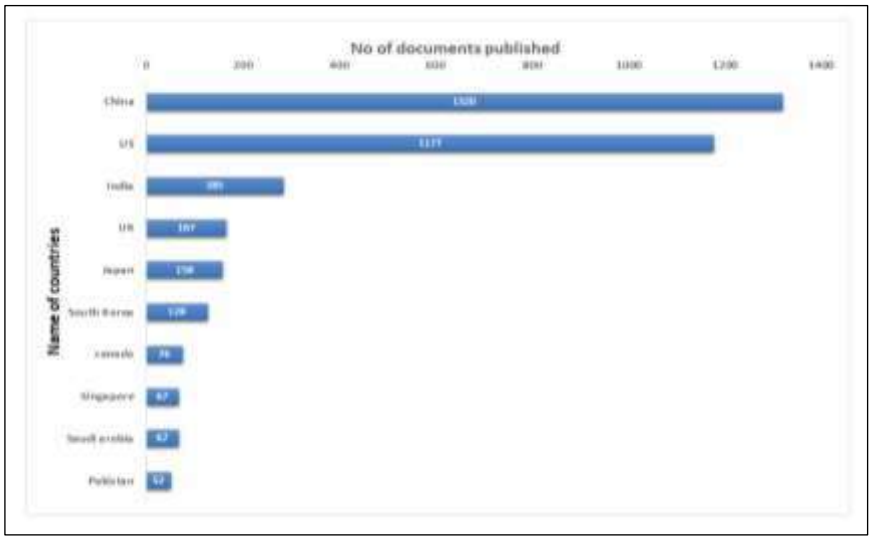

Figure 5: Country-wise research trend from 2000 to 2025.
Source: Authors, (2026).

Figure 5 shows that China leads in terms of publications (1320, 33.43%), followed by the United States of America (1177, 29.80%). The remaining countries are behind in terms of publishing the research in such a crucial domain.

(b) Collaboration between Countries

Data acquired from the Scopus database using VOS Viewer [36] version 1.6.18. Bibliographic coupling research was used to generate network maps linking nations based on their joint publications. The thickness of the lines linking the nodes in each network map is dictated by the "link strength" and signifies network connectedness or co-citations. Fifty-seven countries have been effectively represented on a network analysis diagram. Figure 6 illustrates the network of many nations and their collaborations with coauthors. minimum threshold of five papers was established for a nation to be included in the list.

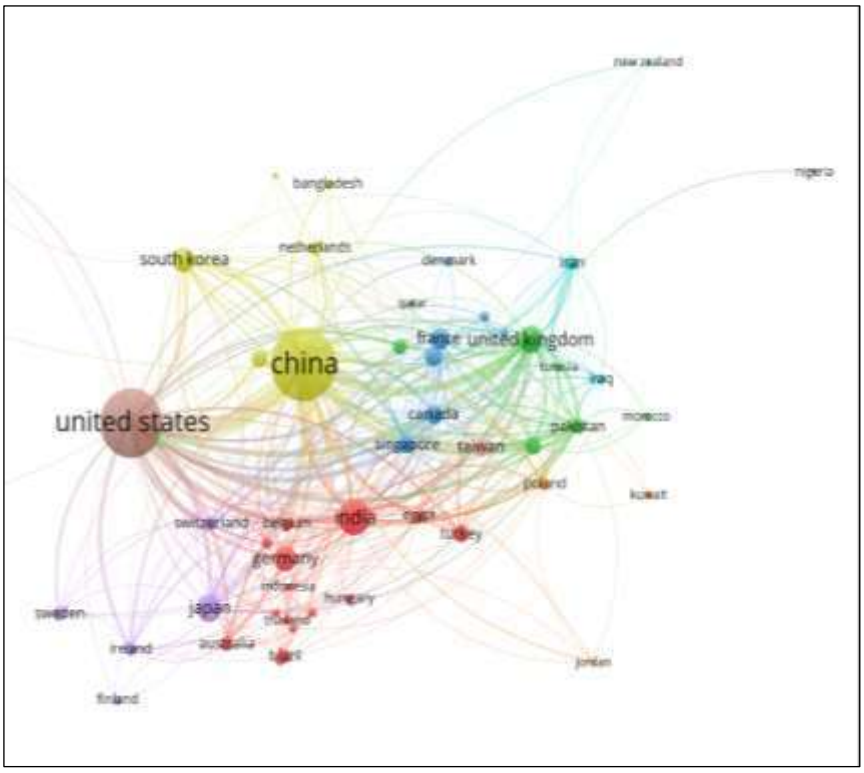

Figure 6: Network analysis diagram based on country keywords.
Source: Authors, (2026).

(c) Languages and Document Types

This section discusses the languages and document types seen in the subject matter. The documents were mainly published in four languages, namely English (3863), Chinese (74), French (5), Japanese (5), Korean (3), Turkish (2), Polish (2) and 1 paper each in Spanish, Italian and German. English accounted for more than 98% of total publications. In terms of document type, book chapters (104), conference reviews (66), short surveys (6), articles (2232), conference papers (1351), reviews (176), and other document types contribute far less to this field of study as shown in Figure 7. The majority of the additional analysis was conducted using document-type articles, which are commonly found in these journals.

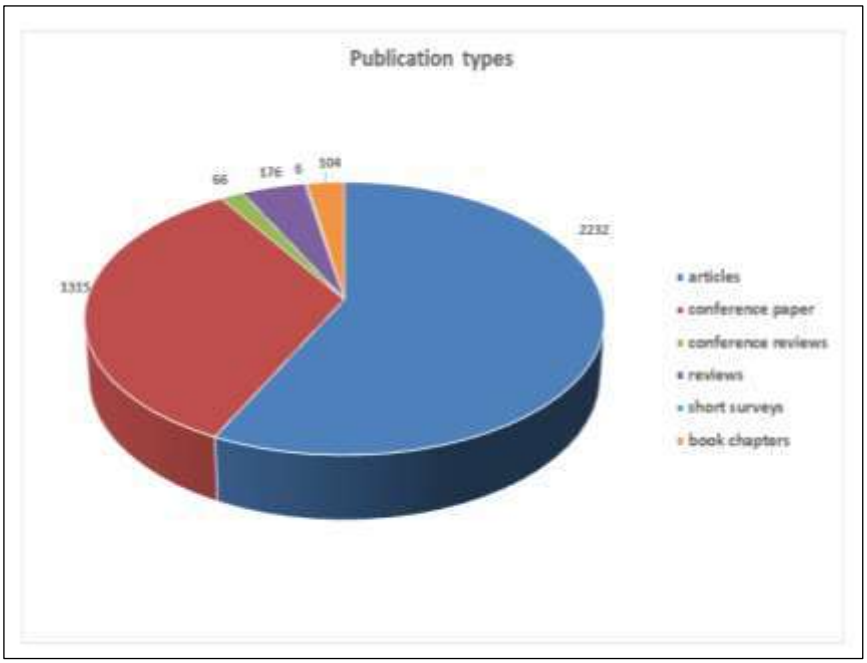

Figure 7: Document type distribution on TMED.
Source: Authors, (2026).

d) Publication Trend

Figure 8 shows the publication trend increasing rapidly post-2015. The year 2024 received a maximum publication of 617 on the topic of TMED. The trendline shows the research initiatives taken by various authors across the globe to address the challenges faced by the electronic community on the thermal front.

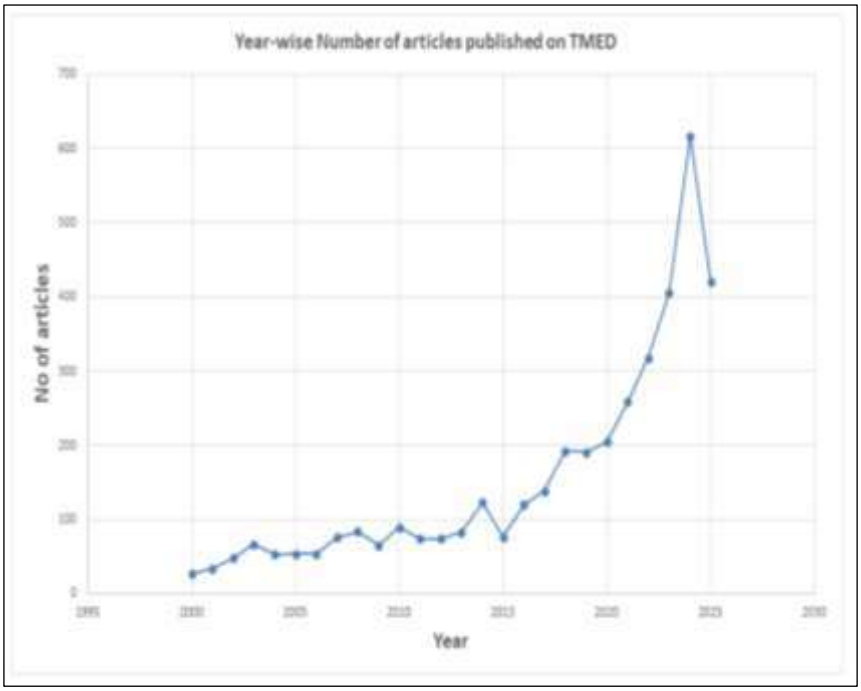

Figure 8: Publication trend year-wise on TMED.
Source: Authors, (2026).

e) Subject area analysis

Though the article's database referred to in this study is limited to “Engineering” subject area only. But similar research is carried out in other subject areas, which is visible from Figure 9 as shown below.

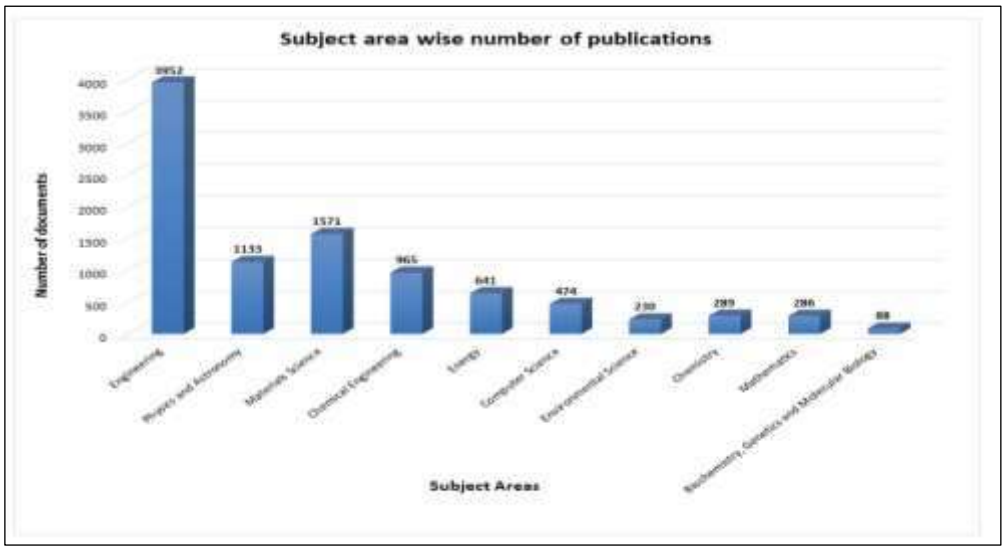

Figure 9: Subject area-wise number of publications on the topic of TMED.
Source: Authors, (2026).

f) Keyword-Based Network Analysis and Author Collaboration

Scopus data was further utilized for network analysis using VOS viewer version 1.6.18. As shown in Figure 10, network analysis for co-occurrences of indexed terms is displayed. When analysing the data, the indexed keywords took into account synonyms, plurals, and variations in spelling. More frequent keywords are denoted by larger font sizes on the network analysis graph, with five being the minimal number of occurrences. The data allowed 2426 out of the total 22803 keywords to be plotted. The term "temperature control" had the highest frequency, which had an effect on other keywords from other clusters that were represented by various colours. The term "electronic cooling" appears frequently and has been connected to other keywords. The terms "thermal conductivity," "heat sinks," "phase change materials," "semiconductors," "electronic packaging," "two phase," and "microelectronics" were significantly prevalent. Thus it appears that various aspects of TMED are explored by various authors.

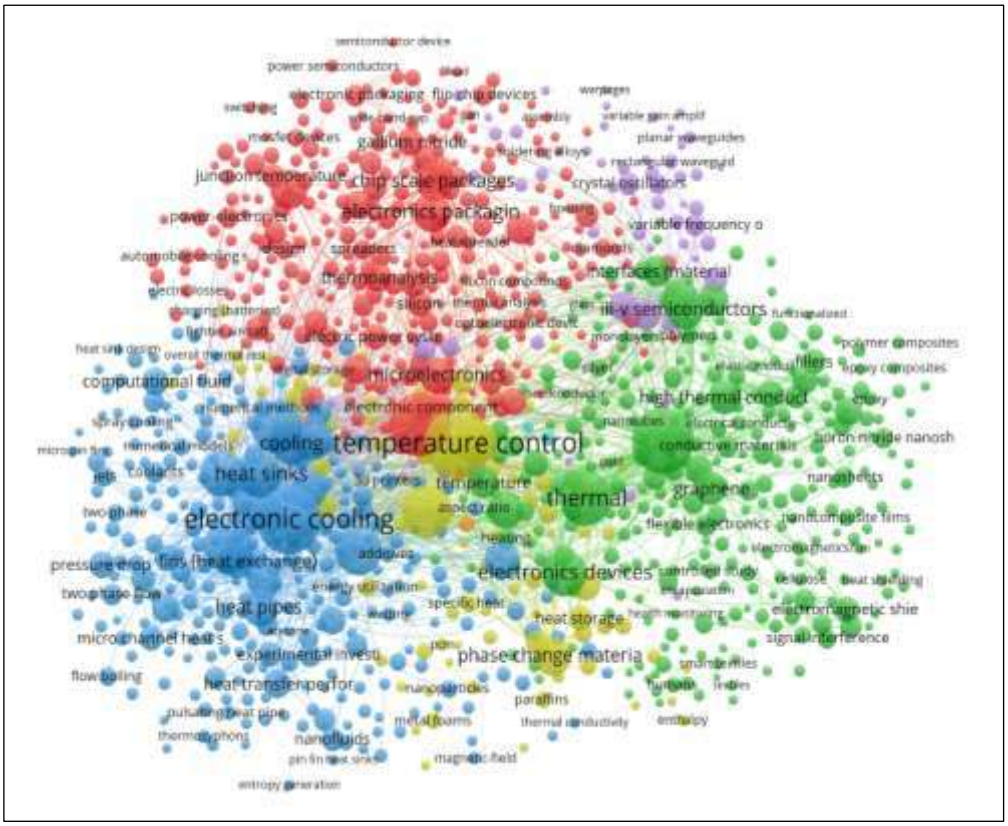

Figure 10: Diagram of network analysis using indexed keywords.
Source: Authors, (2026).

The network of different authors and their partnerships with co-authors is depicted in Figure 11. The author's minimum document count was limited to 5. Out of 13742 authors, it was possible to plot 261 of them on the graph. Data shows Yu Jinhong (21 articles, Citation 1730), Sun Rong (26 articles, Citation count 2006), Suresh Garimella (20 articles, Citation count 1224) and Avaram Bar Cohen (25 articles, Citation count 498) did a lot of collaborative work.

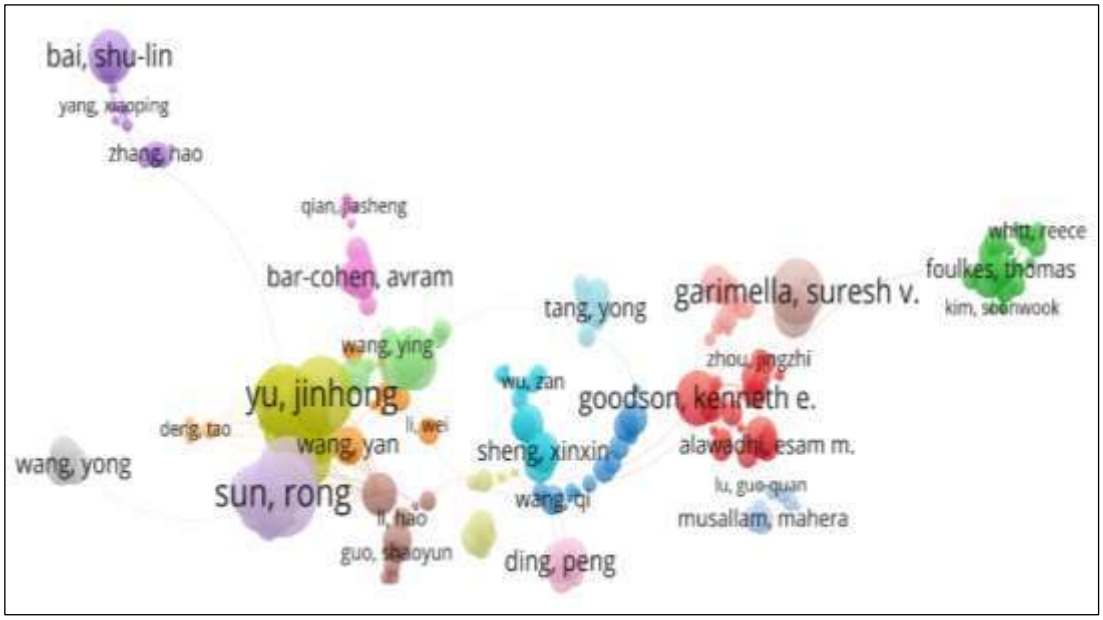

Figure 11: Diagram of the network analysis based on the authors' collaboration for TMED between 2000 and 2025.
Source: Authors, (2026).

Figure 12 shows that citations are continuously increasing over the years, which depicts the inclination of researchers in the domain. The year 2024 received the highest citations of 16563 for the total 616 documents published in Scopus database. Till June 2025, the citation count and published documents have reached 70% of previous year.

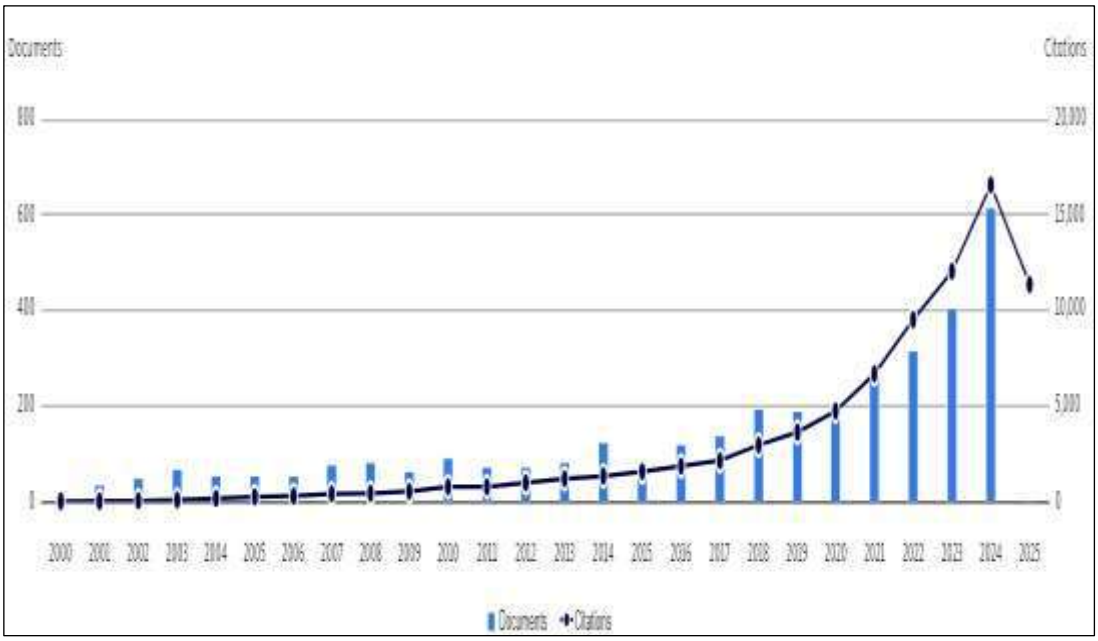

Figure 12: Diagram of the network analysis based on the citation trend on TMED between 2000 and 2025.
Source: Authors, (2026).

II.1.4 Studies on Thermal Management of Electronic Devices With Passive Cooling

(a) Research trends in the top ten countries

Keyword search using the words “Thermal Management of Electronic devices with passive cooling” returned contributions by 40 different countries in between 2000 to 2025. The search results were plotted for the to 10 top countries. The country-wise distribution of documents eliciting the number of research articles on TMED with passive cooling is shown in Figure 13, displays data on the 10 most productive countries.

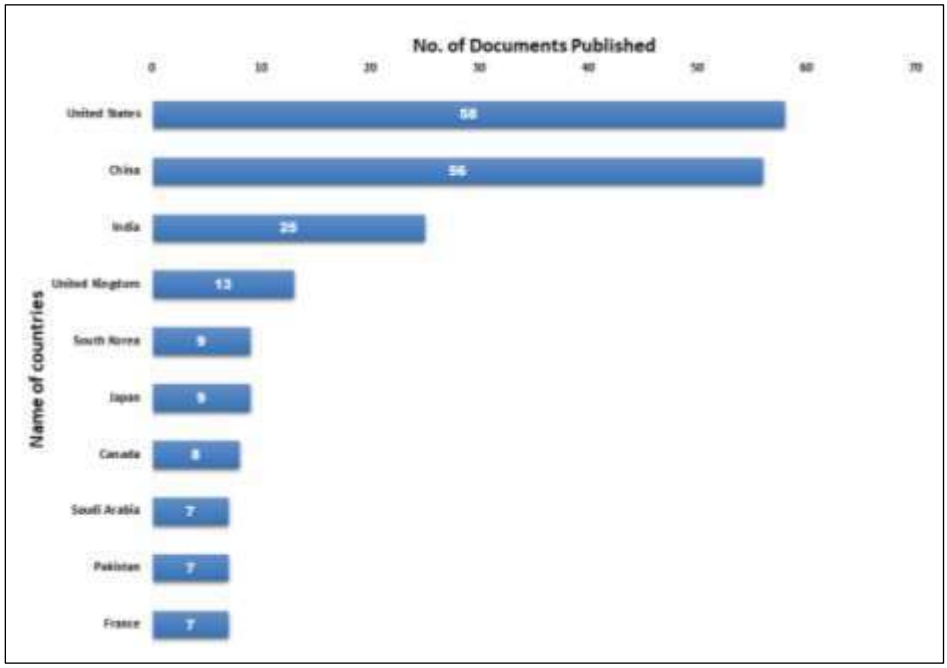

Figure 13: Country-wise research trend from 2000 to 2025.
Source: Authors, (2026).

China and the United States are almost equal in terms of publications, followed by India. The other Asian countries are behind in the domain publication.

(b) Collaboration between Countries

Data obtained from Scopus database using VOS viewer version 1.6.18. Bibliographic coupling analysis was performed to create network maps, as shown in Figure 14, connecting countries based on their collaborative publication. Authors from China, the United States and Saudi Arabia are collaborating more compared to other countries, as visible from the "link strength". It could be the reason why research is on an increasing trend in those countries.

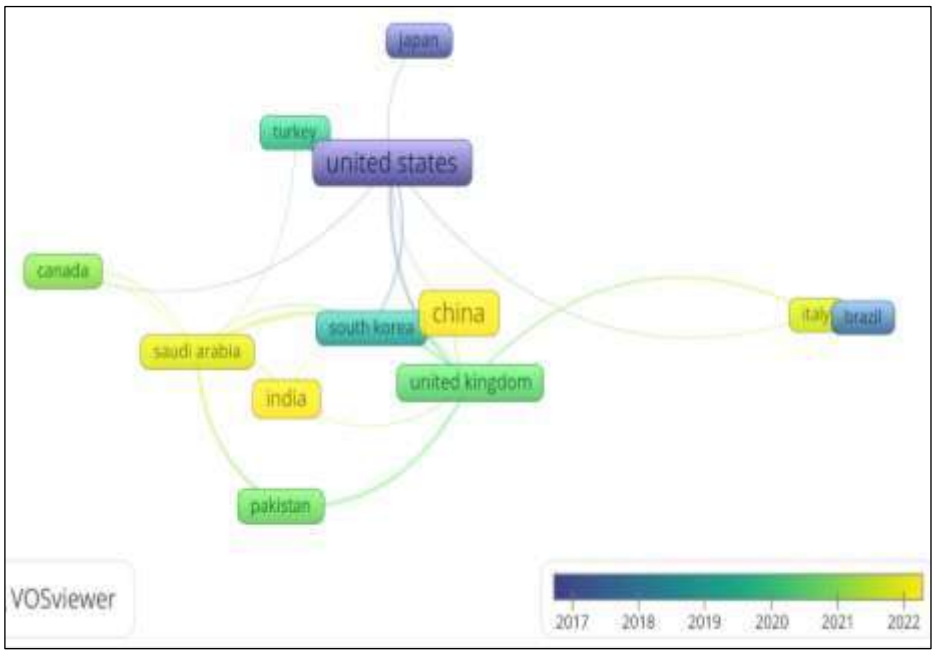

Figure 14: Network analysis diagram based on country keywords.
Source: Authors, (2026).

(c) Languages and Document Types

This section discusses the languages and document types seen in the subject matter. The documents were mainly published in four languages, namely English (219), Chinese (4). In terms of document type, book chapters (8), conference reviews (05), notes (1), articles (124), conference papers (76), reviews (10), and other document types contribute far less to this field of study as shown in Figure 15. The majority of the additional analysis was conducted using document-type articles, which are commonly found in these journals.

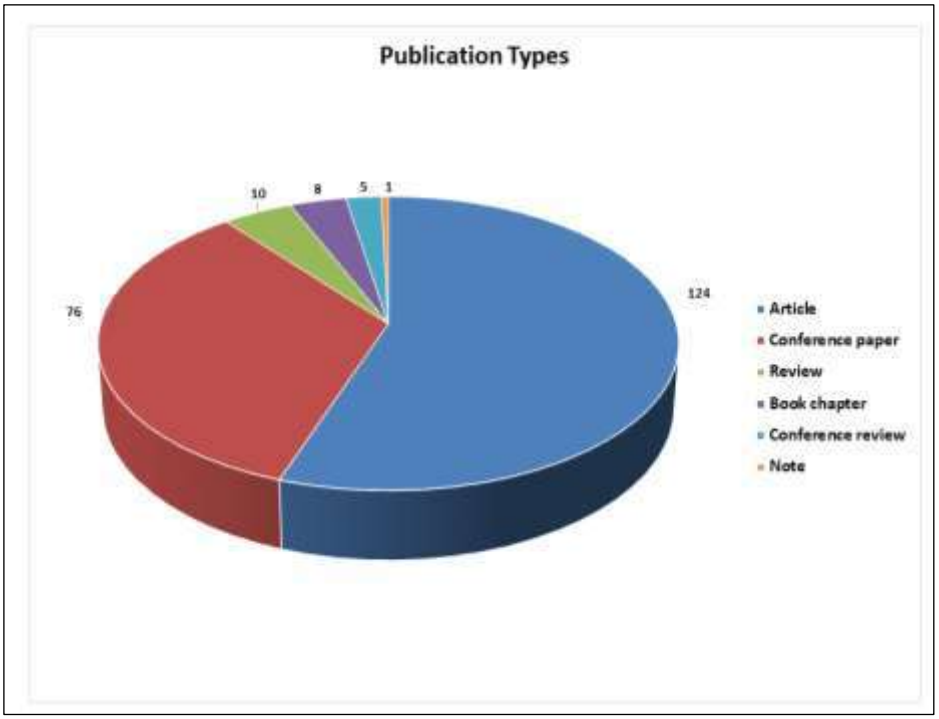

Figure 15: Document type distribution on TMED with passive cooling.
Source: Authors, (2026).

(d) Publication Trend

Figure 16 shows similar trend as that of earlier publications trend, signifying the interest of researchers in using passive cooling technologies like phase change materials, heat pipes in mitigating the challenges posed by electronic cooling.

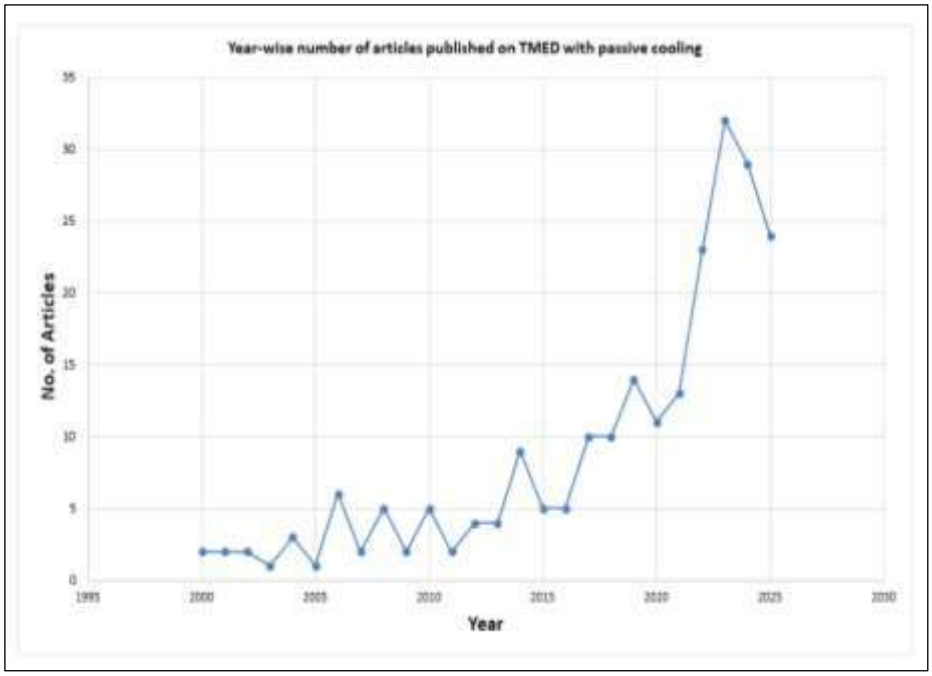

Figure 16: Publication trend year-wise on TMED with passive cooling.
Source: Authors, (2026).

(e) Subject area analysis

Figure 17 shows that significant research articles are published in other subject areas apart from the engineering domain, which shows that the cooling of electronic devices using passive cooling techniques holds many applications.

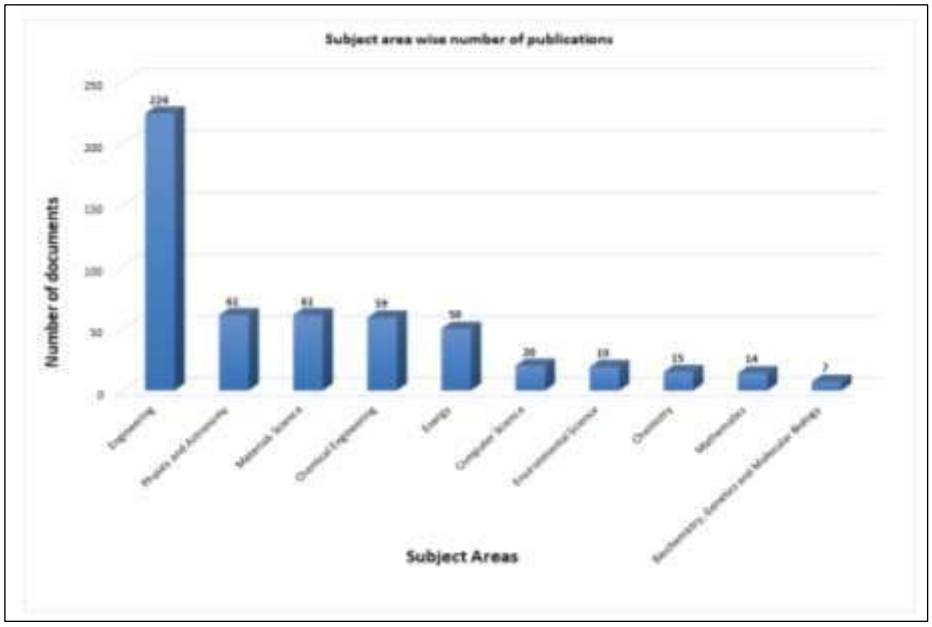

Figure 17: Subject area-wise on TMED with passive cooling.
Source: Authors, (2026).

(f) Keyword-Based Network Analysis and Author Collaboration

Figure 18 shows the network analysis performed on VOS viewer for cited author collaboration. The minimum number of documents of an author are considered as 2 and 66 authors meet the criteria out of 869. Figure 15 depicts the density visualization of 9 major clusters.

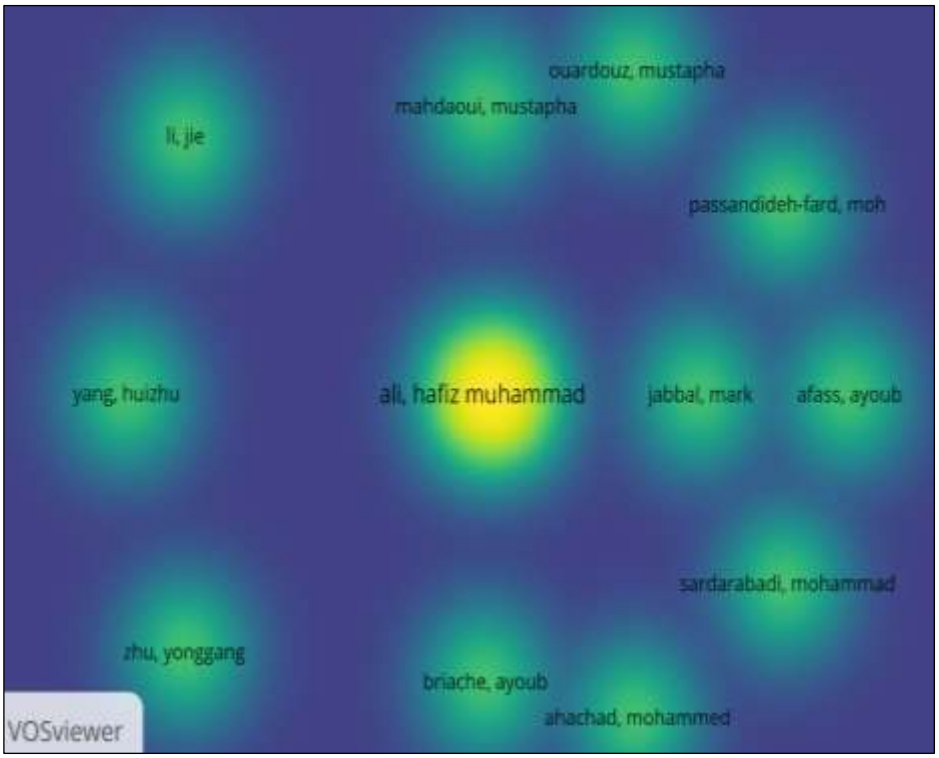

Figure 18: A network analysis diagram for TMED with passive cooling and vapour chamber from 2007 to 2024.
Source: Authors, (2026).

II 1.5 Studies On Thermal Management Of Electronic Devices With Passive Cooling And Vapour Chamber

(a) Research trends in the top ten countries

Referring to figure 19 fetched from Scopus data between 2010 to 2025, the number of documents published in this niche area is significantly lower. The United States is leading the way, followed by China and India. This shows there is a lot of scope for research in this domain.

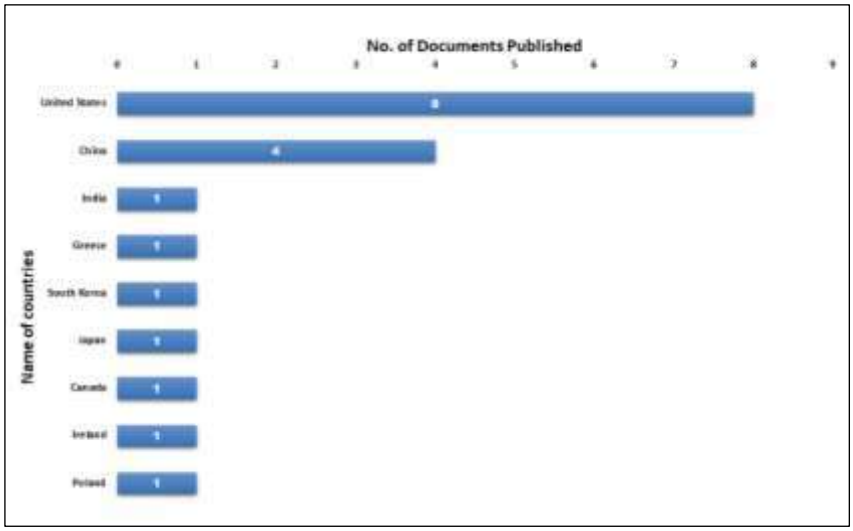

Figure 19: Country-wise research trend from 2010 to 2025.
Source: Authors, (2026).

(b) Collaboration between nations

For the term "Thermal management of electronic devices with passive cooling and vapour chamber " Figure 20 shows the network of different nations and their partnerships with other writers. A requirement of 1 document was set as a qualifying criterion in order to be reflected on the graph. United nation authors show more collaboration with other countries in publishing research articles in this domain.

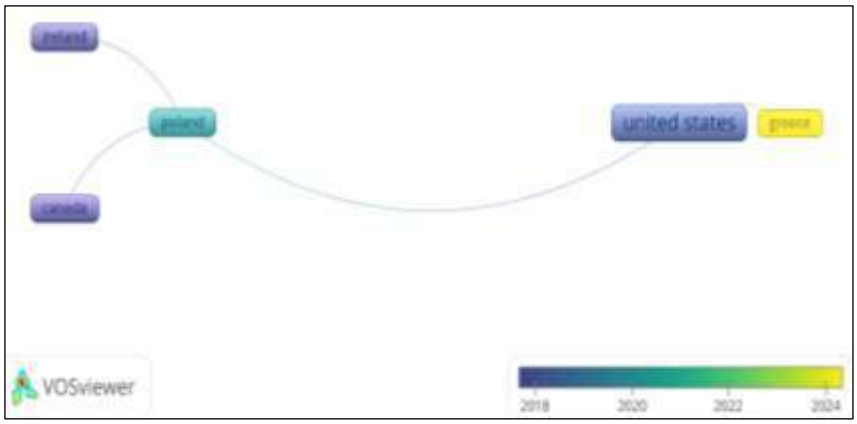

Figure 20: A country network analysis diagram for TMED with passive cooling and vapour chamber 2010 to 2024.
Source: Authors, (2026).

(c) Types of Documents

Figure 21 shows the research articles and the conference papers contribution is more as compare to other document types.

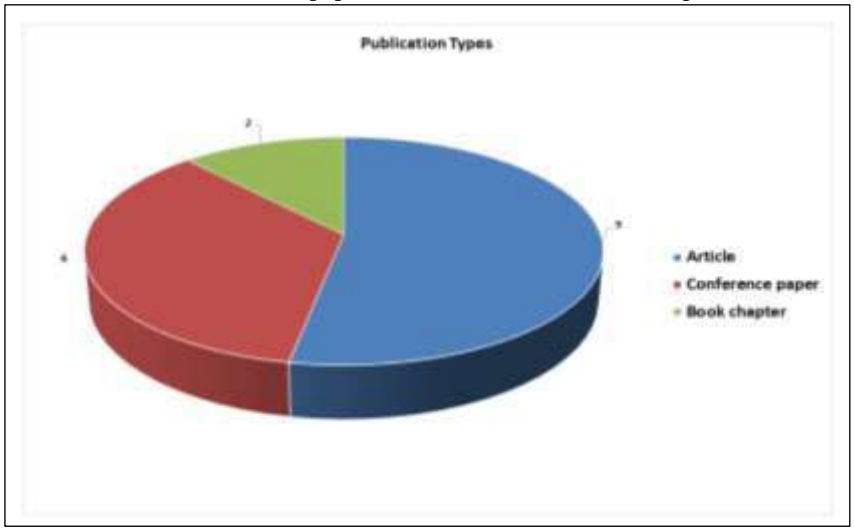

Figure 21: Document type distribution on TMED with passive cooling and vapour chambre.
Source: Authors, (2026).

(d) Publication Trend

Since only Scopus database is referred here, figure 22 shows the number of publication year wise is on the lower side. The count till 2016 is very less but the trend is gradually increasing from last two years.

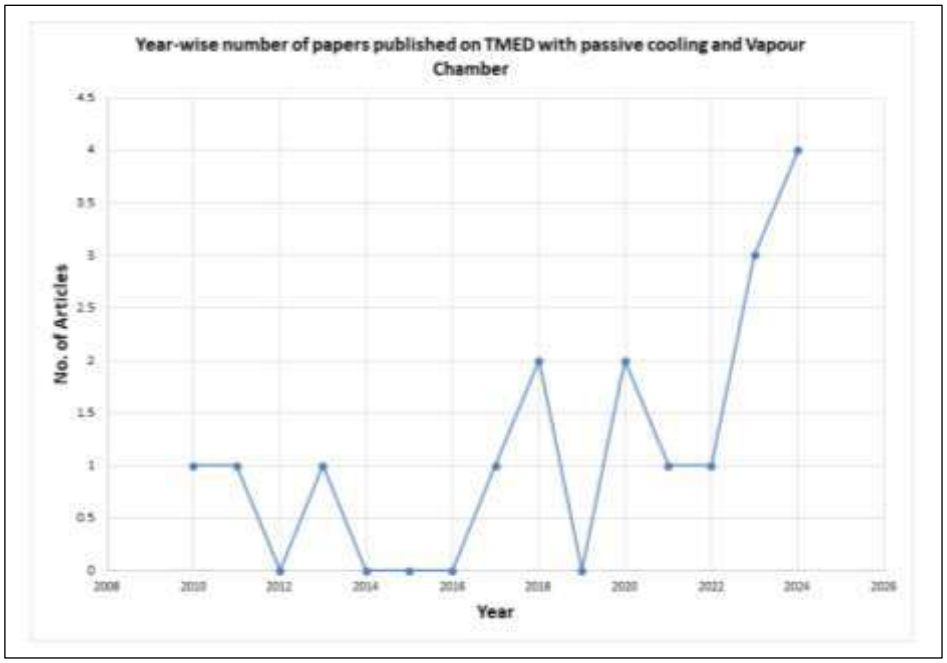

Figure 22: Publication trend year-wise on TMED with passive cooling and vapour chambre.
Source: Authors, (2026).

(e) Subject area analysis

Figure 23 shows the similar pattern as that of earlier two keywords. Physics and astronomy (7), Material science (6), Chemical engineering (3) follows the lead after engineering subject area due to relevant application in respective domain.

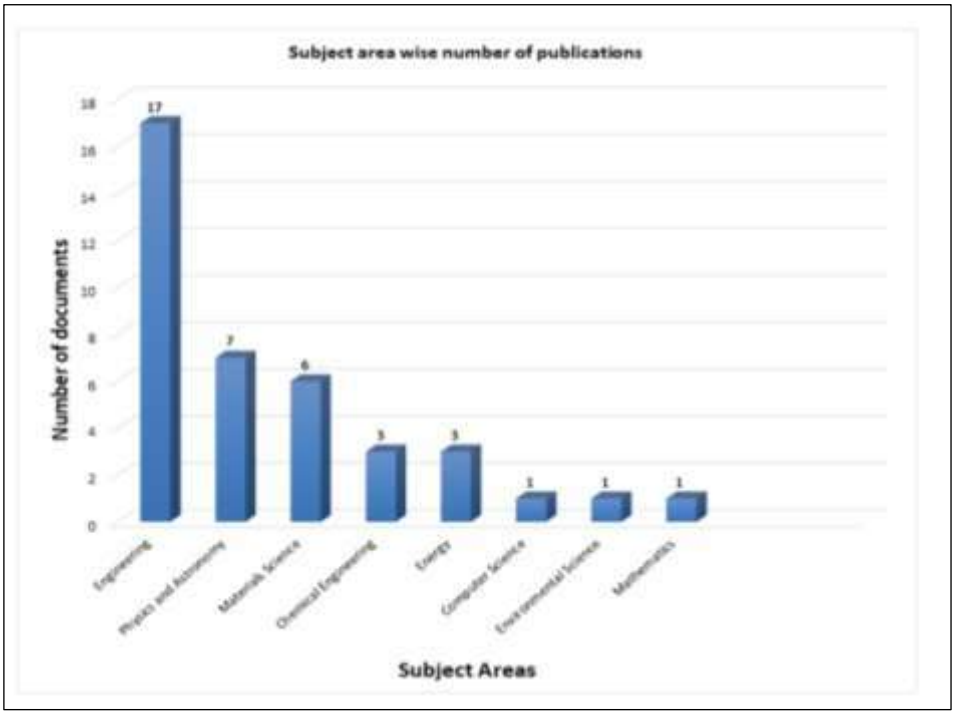

Figure 23: Subject area-wise on TMED with passive cooling and vapour chambre.
Source: Authors, (2026).

III COMPARATIVE ANALYSIS OF BIBLIOMETRIC TRENDS FOR ALL THE CATEGORIES

In this study, it is decided to do bibliometric analysis by three keyword search which narrow downs the research domains in following three categories:

Category -I: ----Thermal Management of Electronic devices
Category -II: --- Thermal Management of Electronic devices with passive cooling
Category -III: ---Thermal Management of Electronic devices with passive cooling and vapour chamber

The following section investigates all the three categories to arrive at meaningful conclusions

III.1 COUNTRY-WISE CONTRIBUTION

Overall, the number of publications started significantly rising after 2015 in the area of TMED. China (1380 documents, 32%) is at the top of graph, followed by United states may be due to the funding provided by universities and the allied industries. This helped the creation of value research and publication in the said countries. The Scopus data shows that more than 40 times Chinese universities are giving acknowledgement for sponsoring the required funds. Apart from China, there is hardly any country in Asia that is contributing to strengthening the domain. India, being a developing economy, shall focus on this research domain by extending a helping hand to the MSME sector in the creation of state-of-the-art manufacturing capabilities like 3D printing and rapid prototyping. The USA spends 3.59% of GDP on R&D in 2022, followed by China at 2.56%, while India falls far behind at 0.65%, according to the most recent data available.

With yearly growth rates of 8.7%, China exhibits the greatest development trajectory, whereas the US and India display more moderate growth trends [37]. The industry and academia shall come together to foster the research in such emerging areas [38] to bridge the gap between industrial needs and academic ecosystem. The limited availability of domestic funding compels researchers to pursue and depend on international collaboration. National scientific performance relies not solely on domestic R&D investments but is also affected by foreign investments from other countries [39]. Lower-income countries contribute minimally to Sustainable Development Goal (SDG) research, indicating a global misalignment [40] . This eventually affects the contribution of academia research in national/international environmental policies [41].

III.2 TYPE OF DOCUMENT

The data indicates that the number of research articles published (2365) is higher across all three categories, with 56%, 55% and 56% contributions in the first (2232 nos), second (124 nos) and third (9 nos) categories, respectively. The analysis reveals significant scope in the third category to explore the vapour chamber as a passive cooling medium in the thermal management of electronic devices, due to its superior thermal performance in a compact space.

The citation number of a publication tells volume about the significance and its penetration in research community. It also paves the path to take the current research ahead. The research trend in figure 12 clearly shows the spike in number of documents published as well as citations received are all time high in the year 2024 and similar trend is observed till mid-2025. This also indicates that there is growing need and market for research in this domain. It is very likely that the growing need of end user and progression of semiconductor technology is inviting more researchers to address the issues related to heat dissipation in compact spaces.

Data shows that engineering is not the only field wherein thermal issues related to electronic devices are pertinent. Physics and astronomy, owing to the development of semiconductor technology, and chemical engineering, owing to thermal management of control devices used in process industries and material science, owing to the development of lightweight and high thermal conductivity material development are following the similar trend of engineering as subject area. Overall, multidisciplinary research can lead to groundbreaking research in the area of TMED [41].

IV. CONCLUSIONS

The bibliometric analysis conducted based on Scopus publication data reveals that the thermal management of electronic devices is picking up pace in the market due to the digitalisation and use of compact high-power electronic equipment. The present study shows that China, followed by the United States of America, is leading the trend in terms of publication and research. This trend is because the funding agencies and the government policies are more oriented towards research and development. It is also observed that the author collaboration is more prevalent in these countries. This trend will attract more talent pool across the globe to seek higher education opportunities in these countries. Indian authors are gradually making progress in the area of thermal management and electronic cooling. In document types, the research articles are at the top, having more than 50% contribution for all three keywords chosen.

ABSTRACT

This study investigates the performance of NR–SBR (80/20) rubber composites reinforced with Carbon Black N330 for use in industrial track pad applications. Five formulations containing 65, 70, 75, 80, and 85 phr of carbon black were prepared and evaluated. Mechanical properties such as hardness, tensile strength, elongation at break, abrasion resistance, and dynamic behavior were measured according to relevant ASTM standards. In addition, field testing was conducted using a tracked vehicle over a 15 km route to assess real-world wear behavior. The results show that carbon black content significantly influences stiffness, strength, and abrasion resistance. Among all formulations, the 75 phr compound demonstrated the best balance of hardness, tensile strength, and wear performance, making it a suitable candidate for industrial track pad applications. These findings provide useful insights for developing locally produced rubber composites with improved durability and cost efficiency.

I. INTRODUCTION

Rubber materials and their composites have long played a vital role in industrial and transportation applications due to their excellent flexibility, damping ability, and wear resistance. Natural rubber (NR), as one of the most versatile elastomers, provides superior tensile strength, resilience, and fatigue resistance, which make it highly suitable for dynamic load conditions[1], [2]. However, NR alone exhibits limitations in thermal aging, ozone resistance, and oil compatibility, which can reduce its long-term durability in demanding industrial environments. Styrene-butadiene rubber (SBR), on the other hand, offers improved aging stability, abrasion resistance, and processability, making it an ideal synthetic counterpart to be blended with NR. The combination of these two elastomers, when properly compounded, can produce a hybrid rubber material that integrates the elasticity of NR with the toughness and wear resistance of SBR.

To achieve optimal mechanical behavior, reinforcing fillers such as carbon black are commonly incorporated into the blend to enhance stiffness, tensile strength, and resistance to mechanical degradation[3], [4]. The role of carbon black as a reinforcing filler in rubber compounds is critical for achieving the required performance in industrial applications. Carbon black enhances stress transfer efficiency between the polymer chains by creating strong filler–matrix interactions and improving cross-linking density during vulcanization. The dispersion level and concentration of carbon black determine the compound's hardness, elongation, and abrasion properties, which must be precisely balanced to meet specific functional demands. Previous studies have shown that increasing the filler concentration generally improves stiffness and wear resistance, but excessive filler content can lead to filler agglomeration and brittleness[5], [6].

Therefore, identifying the optimum filler loading is essential for maintaining both flexibility and durability. For applications such as industrial track pads and high-load contact components, the mechanical balance between hardness and elasticity is vital to ensure long service life under cyclic deformation and impact conditions. In industrial track systems, such as heavy vehicles or tracked machinery, the pad shoe or track pad serves as a primary interface between the moving track and the ground surface. These components experience repetitive compressive, shear, and abrasive forces during operation, requiring materials that combine high hardness with energy-absorbing capacity.

Conventional materials used for these parts are often imported and expensive, posing challenges for maintenance and supply chain sustainability[7-9]. Developing an NR–SBR rubber composite using locally available raw materials can therefore provide significant economic and strategic benefits. The optimization of mechanical performance through carbon black modification not only improves product quality but also supports the development of domestic material technologies capable of replacing imported rubber components. This aligns with the broader industrial objective of self-reliance and sustainable manufacturing[3], [10], [11]. Numerous research efforts have explored NR–SBR blends with different fillers, focusing on mechanical properties such as tensile strength, abrasion resistance, and dynamic behavior.

Studies by Hasan (2013) and Kinasih (2016) demonstrated that the inclusion of carbon black substantially improves hardness and tensile performance in NR–SBR compounds. However, limited studies have addressed the actual application of these materials in heavy-duty or dynamic systems such as track pads used in armored or industrial vehicles. Most investigations remain laboratory-based, with little validation through real-world load testing. This gap indicates the need for further experimental studies that not only examine the physical and mechanical behavior of NR–SBR composites under controlled conditions but also verify their field performance to ensure reliability under industrial stress environments[12], [13]. Based on these considerations, the present study focuses on experimentally investigating the influence of carbon black filler variation on the mechanical and physical properties of NR–SBR rubber composites intended for industrial track pad applications.

The research aims to determine the optimal filler loading that achieves the best balance between hardness, tensile strength, elongation, and abrasion resistance. Laboratory tests following ASTM and DIN standards were complemented by field dynamic load validation to simulate real working conditions. The integration of both laboratory and field data provides a comprehensive understanding of material performance, offering valuable insights into the development of durable, high-strength rubber materials for industrial and defense-related machinery. Ultimately, this research contributes to advancing local rubber technology innovation and supports the long-term goal of industrial independence and reliability in critical mechanical components.

II. THEORETICAL REFERENCE

Rubber materials are highly elastic polymers whose mechanical performance depends on molecular structure and cross-link density. Natural rubber (NR) is composed mainly of cis-1,4-polyisoprene chains that exhibit outstanding elasticity and tensile strength, which make it suitable for dynamic load-bearing components. The repeating unit of cis-1,4-polyisoprene, illustrated schematically in Fig. 1, shows alternating single and double bonds along the carbon backbone with pendant –CH_3 and –H groups that enable flexible molecular motion. However, NR is susceptible to oxidation and thermal degradation at elevated temperatures, limiting its long-term durability. To overcome these drawbacks, NR is often blended with styrene-butadiene rubber (SBR), whose copolymer chain contains styrene and butadiene units, providing improved abrasion and ageing resistance[14]. A conceptual structure of SBR is shown in Fig. 2, where alternating styrene-aromatic rings and butadiene segments contribute to hardness and wear resistance while maintaining adequate flexibility.

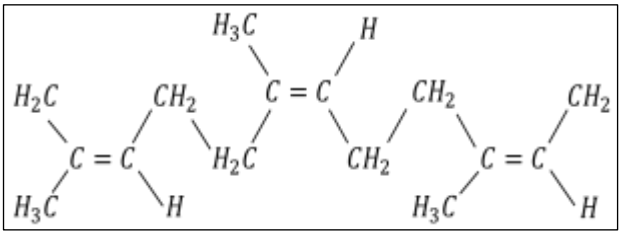

Figure 1: Schematic structure of cis-1,4-polyisoprene (NR).

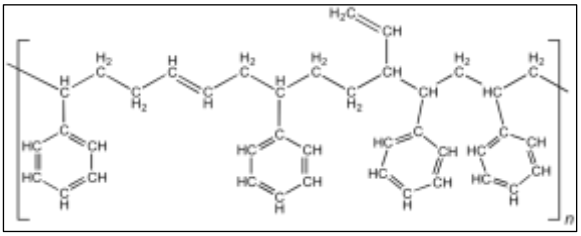

Figure 2: Schematic structure of styrene–butadiene copolymer (SBR).
Source: Authors, (2026).

The reinforcement of rubber compounds commonly involves the incorporation of fillers such as carbon black to enhance stiffness, tensile strength, and abrasion resistance. Carbon black particles interact physically and chemically with the polymer matrix, forming a semi-continuous filler network that restricts molecular mobility and increases modulus. As shown schematically in Fig. 3, these filler–matrix interactions improve stress transfer during deformation and contribute to energy dissipation under cyclic loading[15]. Nevertheless, excessive filler loading can cause agglomeration and stress concentration, which reduce elongation and resilience. Therefore, determining the optimum carbon-black concentration is essential to balance hardness, flexibility, and energy absorption—particularly for applications requiring dynamic impact resistance, such as industrial track pads.

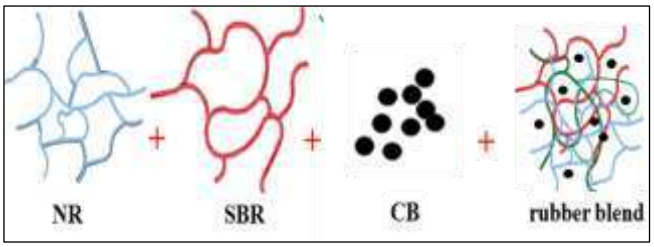

Figure 3: Filler–matrix interaction in NR–SBR composite.
Source: Authors, (2026).

The vulcanization process also has a significant influence on the final properties of NR–SBR composites. During vulcanization, sulfur cross-links form between polymer chains, converting the raw elastomer into a resilient and dimensionally stable material. The degree of cross-linking directly affects hardness, tensile strength, and resistance to permanent deformation. A schematic representation of the sulfur cross-linking reaction is illustrated in Fig. 4, showing how inter-chain bridges stabilize the polymer network. Studies by Chollakup et al. demonstrated that well-dispersed carbon black combined with optimal curing conditions can simultaneously improve tensile strength and abrasion resistance[16]. The mechanical balance between NR and SBR ratios is thus crucial: higher NR content enhances elasticity and fatigue life, while higher SBR content improves wear performance under repeated contact stress.

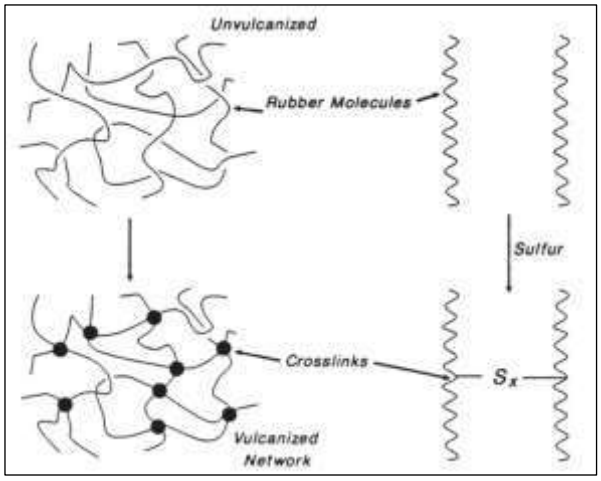

Figure 4: Sulfur cross-linking mechanism during vulcanization.

The viscoelastic behavior of filled rubber can be evaluated using dynamic mechanical analysis (DMA). The fundamental relation between storage modulus (E′) and loss modulus (E″) is expressed in Eq. (1), where the ratio tan δ = E″/E′ represents the damping capability of the material[17].

$$\tan\delta = \frac{E''}{E'} \tag{1}$$

A high storage modulus indicates stiffness, whereas a higher loss factor implies better vibration damping. The schematic in Fig. 5 summarizes this viscoelastic response for a filled elastomer under cyclic strain. For industrial track-pad applications, an optimal combination of hardness, elongation, and damping is required to achieve traction, comfort, and thermal stability. Hybrid fillers such as silica or graphene have been explored, but carbon black remains the most cost-effective and reliable reinforcement for heavy-duty elastomer systems[18]. Finally, theoretical predictions must be validated through experimental and field evaluations. In the present research, NR–SBR composites with varying carbon-black fillers were formulated and tested to determine their mechanical (hardness, tensile strength, elongation) and physical (abrasion resistance) properties.

The theoretical concepts described above—polymer microstructure (Fig. 1 – 2), filler–matrix reinforcement (Fig. 3), and viscoelastic behavior (Eq. 1, Fig. 5)—serve as the foundation for interpreting the experimental findings. Field testing under dynamic loads, as shown schematically in Fig. 6, provides practical confirmation of laboratory results and verifies the suitability of the developed composite for industrial track-pad applications. Thus, the theoretical framework integrates molecular structure, filler mechanics, and dynamic behavior to support the experimental study presented in this paper.

III. MATERIALS AND METHODS

III.1 MATERIALS

The materials used in this study consisted of Natural Rubber (NR, SIR-20 grade) and Styrene–Butadiene Rubber (SBR 1502), which served as the primary elastomer blend. Carbon black N330 was selected as the reinforcing filler due to its well-established ability to enhance strength, abrasion resistance, and durability in rubber composites. Additional compounding agents included zinc oxide (ZnO) and stearic acid as activators, sulfur as the vulcanizing agent, processing oil as a softener, and CBS (N-cyclohexyl-2-benzothiazolesulfenamide) as the accelerator[19]. All materials were used in raw form without further purification. The molecular structures of NR and SBR are illustrated in Figures 1 and 2 to highlight their chain configurations relevant to elastomeric performance.

III.2 COMPOUND FORMULATION

Five compound formulations, labeled A through E, were prepared with varying carbon black loadings to evaluate the effect of filler concentration on mechanical strength and abrasion behavior. All ingredients were measured in parts per hundred rubber (phr), and the compositions of each formulation are summarized in Table 1. These formulations were designed to represent incremental increases in filler reinforcement, allowing systematic observation of changes in compound performance as the carbon black content increased.

Table 1: Formulation of NR–SBR Rubber Compounds (phr).

Material	Model A (phr)	Model B (phr)	Model C (phr)	Model D (phr)	Model E (phr)
Natural Rubber (NR)	80	80	80	80	80
SBR	20	20	20	20	20
Carbon Black (N330)	65	70	75	80	85
ZnO	5	5	5	5	5
Peptizer	2	2	2	2	2
Stearic Acid (STA)	1	1	1	1	1
6PPD	2	2	2	2	2
TMQ	1	1	1	1	1
Sulfur	3	3	3	3	3
TMTD	0.3	0.3	0.3	0.3	0.3
Accelerator (CBS)	1.2	1.2	1.2	1.2	1.2
Total	180.5	185.5	190.5	195.5	200.5

III.3 PREPARATION OF MATERIALS FOR RUBBER COMPOUNDING.

All raw materials were prepared according to the NR–SBR compound formulation presented in Table 1. The base elastomers—natural rubber (NR) and styrene–butadiene rubber (SBR)—were conditioned at room temperature to stabilize their viscoelastic properties before mixing. Carbon black (N330), used as the primary reinforcing filler, was weighed precisely along with processing oil, ZnO, stearic acid, TMQ, 6PPD, sulfur, and the accelerator system to ensure accurate phr ratios. The overall preparation workflow is illustrated in Figure 3, which outlines the sequential steps from material weighing to compound sheet formation.

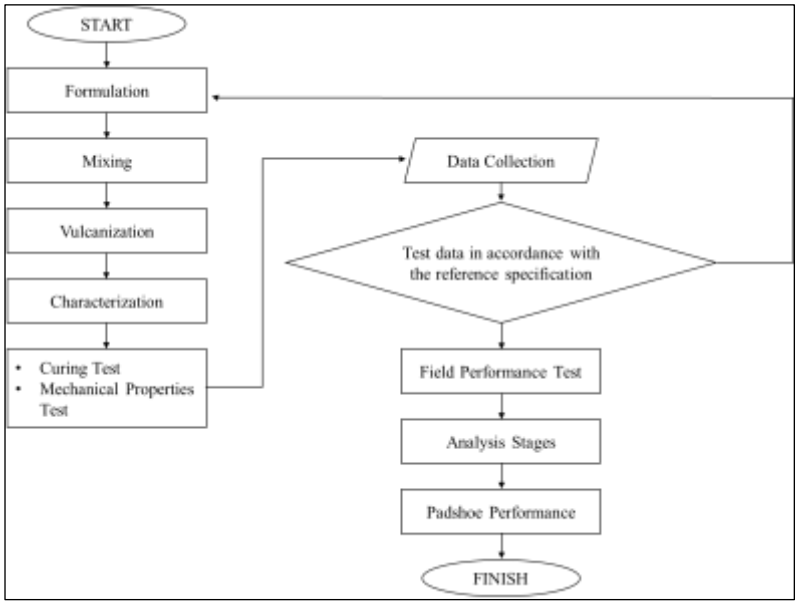

Figure 7: Flowchart of research methods.
Source: Authors, (2026).

The compounding process was carried out using a laboratory two-roll mill. The NR–SBR blend was first masticated until uniform plasticity was achieved. Carbon black was incorporated gradually to minimize agglomeration and promote homogeneous filler dispersion within the polymer matrix. ZnO and stearic acid were added as activators, followed by antioxidants (TMQ and 6PPD) and processing oil to enhance processability. The curing agents—sulfur and accelerators—were introduced during the final mixing stage under controlled roll temperature to prevent premature vulcanization[20]. After mixing, the compound sheets were removed, cooled, and rested for 24 hours to allow internal stress relaxation before the vulcanization stage[20]. These prepared NR–SBR compounds served as the base material for fabricating industrial track pad specimens. The complete process pathway—starting from raw material preparation, rubber compounding, sheet formation, and track pad molding—is presented schematically in Figure 3.

III.4 VULCANIZATION PROCESS.

The vulcanization process began after completing the compounding stage, in which NR and SBR were masticated on a two-roll mill and sequentially mixed with activators, carbon black filler, process oil, and the sulfur–accelerator curing system until a uniform rubber compound was obtained. The mixed compound was sheeted and allowed to rest to ensure stable filler dispersion before curing. Vulcanization was then carried out using a hydraulic hot press at 150 °C and 10 MPa. The optimum cure time (t90) for each formulation was determined using a rheometer in accordance with ASTM D2084 and applied during the press-curing stage to achieve the required cross-link density. The cured sheets were cooled under pressure and conditioned at room temperature for subsequent laboratory testing[21]. For track pad fabrication, the vulcanized compound was further molded into its final geometry using a steel compression mold. Pre-cut rubber preforms were placed into the mold cavity and subjected to the same optimized temperature and pressure conditions to ensure complete vulcanization throughout the track pad body. The molded track pads were cooled in the mold, demolded, trimmed, and prepared for dynamic field testing.

III.5 MECHANICAL TESTING.

Mechanical testing of the NR–SBR/carbon black composites was conducted following the workflow illustrated in Figure 8, covering rheometric analysis, controlled vulcanization, specimen conditioning, and a complete mechanical and dynamic performance evaluation. The optimum curing time (t_{90}) for each formulation was determined using a Moving Die Rheometer (MDR Professional, MonTech, Germany) at 140 °C in accordance with ASTM D5289. These t_{90} values were used as the basis for the hot-press vulcanization process, performed at 150 °C using a hydraulic press to ensure proper cross-link development. After curing, all samples were cooled under pressure and conditioned at room temperature for 24 hours.

Mechanical and physical characterization was carried out in accordance with the relevant ASTM standards. Tensile strength, tear strength, and elongation at break were measured using a Universal Testing Machine (Gotech AI-7000-S, 25 kN) following ASTM D412. Shore A hardness was assessed using a Mitutoyo durometer in accordance with ASTM D2240, with measurements taken at five distinct points per specimen. Density testing was performed using a laboratory balance (A&D GR-200) equipped with a density determination kit, while rebound resilience was evaluated using a Gibitre rebound resilience tester to quantify elastic recovery.

Abrasion resistance was examined using a DIN Abrasion Tester (AT150) according to ASTM D5963, producing volume-loss values representative of wear behavior under dry sliding conditions. Compression set testing was conducted following ASTM D395, where samples were compressed for 22 hours at 70 °C and subsequently stabilized for one hour at room temperature to assess permanent deformation characteristics[22]. The dispersion quality of carbon black within the NR–SBR matrix was evaluated using a Disperse Tester 3000 (MonTech) to ensure uniform filler distribution and mixing consistency. Dynamic mechanical properties were examined using a Dynamic Mechanical Analyzer (DMA7100, HITACHI High-Tech). Measurements were conducted in tensile mode across a frequency range of 0.1–10 Hz and a temperature sweep from −70 °C to 110 °C, with a heating rate of 2 °C/min.

Specimens measuring approximately 20 × 9 × 2 mm³ were used to evaluate the viscoelastic responses, including storage modulus (E′), loss modulus (E″), and damping characteristics (tan δ). All laboratory evaluations were complemented by field-simulation testing on fabricated track pad specimens to assess wear progression, crack formation, and surface degradation under dynamic loading. The complete characterization pathway—from rheometer-based curing evaluation to mechanical, physical, and dynamic testing—is summarized in Figure 8, representing the integrated assessment framework used to evaluate the NR–SBR/carbon black composites for industrial track pad applications.

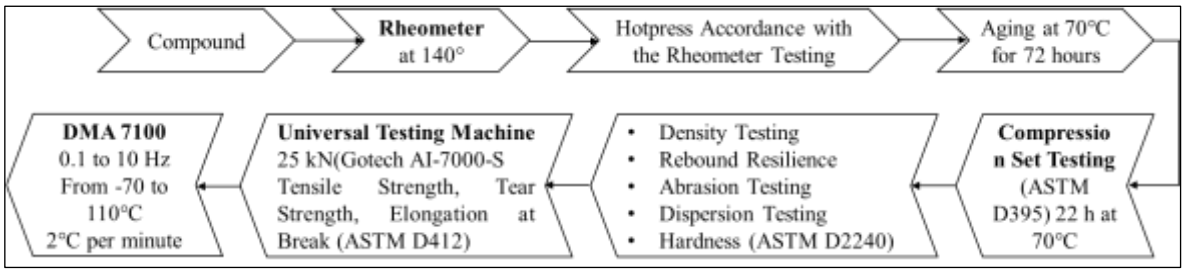

Figure 8: Step of rubber compounding testing.
Source: Authors, (2026).

III.6 TRACK-PAD PROTOTYPE FABRICATION

Based on the most optimal formulation obtained from laboratory testing, a prototype track-pad block was fabricated using a dedicated steel mold. The molding conditions followed the same curing parameters applied in laboratory vulcanization to ensure structural consistency. The prototype geometry adhered to the dimensional specifications of the original Scorpion Tank track-pad. A schematic representation of the load configuration experienced by the track pad during vehicle operation is shown in Figure 9.

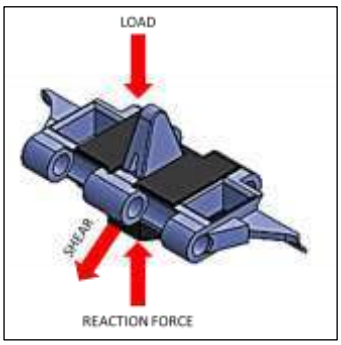

Figure 9: A schematic representation of the load configuration.
Source: Authors, (2026).

III.7 FIELD PERFORMANCE TEST

Field testing of the fabricated track pads was conducted using a Scorpion Tank belonging to the 3rd Cavalry Battalion (Yonkav 3), Malang, Indonesia. The test protocol consisted of straight-route driving for 15 km, circular turning for 10 full rotations, and a zig-zag maneuver test covering 5 km. Wear measurements were taken at intervals of 3 km to monitor progressive surface degradation, dimensional change, and mass loss. The field-test results are summarized in Table 4, and the wear-progression curve is presented in Figure 10. Data from field testing were compared with laboratory measurements to validate the reliability of the composite under real operating conditions.

IV. RESULTS AND DISCUSSIONS

IV.1 CURING CHARACTERISTICS

The curing characteristics of rubber compounds provide essential information regarding the kinetics of the vulcanization reaction. In this study, all formulations were prepared using Carbon Black N330 with different loading levels. As shown in Table 2, increasing the amount of N330 results in a gradual rise in the minimum torque (S'min), indicating an increase in the initial viscosity of the compound due to the higher solid filler content and stronger filler–rubber interactions. The maximum torque (S'max) also increases with N330 loading, although the magnitude of enhancement is not as high as typically reported for high-structure carbon blacks. This behavior aligns with the known reinforcing capability of N330, which is classified as a medium-structure grade.

The torque difference (ΔS = S'max – S'min) observed in our results shows that crosslink density improves at moderate N330 concentrations, but at higher filler loadings, ΔS begins to decline, suggesting the onset of filler–filler interactions and agglomeration that reduce the efficiency of sulfur crosslink network formation. The optimum cure time (T90) remains relatively stable across all formulations, indicating that the vulcanization process can be performed consistently without requiring major adjustment to processing conditions. Meanwhile, the scorch time (Ts2) remains within a safe processing window for all variations, ensuring that the compound retains sufficient flowability before the onset of vulcanization. Overall, the rheometer results confirm that the incorporation of N330 improves reinforcement up to an optimal level, beyond which excessive filler loading becomes detrimental to effective crosslink formation.

Table 2: Curing characteristics of track pad compounds.

Model	Curing Characteristic					
	S'max (kg·cm)	S'min (kg·cm)	ΔS (kg·cm)	t90 (min: sec)	ts2 (min: sec)	CRI (min^{-1})
Model A	30,8	4,9	25,9	8,2	2,4	16,2
Model B	32,1	5,1	27	8,1	2,25	16,8
Model C	33,4	5,45	27,95	7,55	2,1	17,5
Model D	34,2	5,7	28,5	7,4	2,05	18,1
Model E	33,9	6,05	27,85	7,55	2,15	17,6

Source: Authors, (2026).

According to Attharangsan [23], increasing filler loading reduces both scorch time and cure time, and a similar trend is observed in our predicted results for Models A–E, in which all formulations contain Carbon Black N330 at different phr levels. The difference between the maximum and minimum torque (ΔS) reflects the effective crosslink density, while the cure rate index (CRI) represents the vulcanization rate derived from the relationship between optimum cure time (T90) and scorch time (Ts2)[24]. As the phr of N330 increases, the compound generally shows lower Ts2, slightly shorter T90, and a moderate increase in ΔS up to its optimum loading. Since CRI is governed by the ratio of these parameters, the models with higher N330 phr exhibit increased CRI, except at excessive filler levels where filler–filler interactions begin to limit the vulcanization efficiency. The relationship is expressed as:

$$\mathrm{CRI} = \frac{100}{T_{90} - T_{s2}}$$

The addition of N330 caused a gradual increase in both minimum torque (S'min) and maximum torque (S'max), indicating higher initial viscosity and moderately increased crosslink density. The torque difference (ΔS) reached its highest value at a medium carbon-black loading, while excessive filler addition produced no further improvement, suggesting the onset of filler–filler interference. Both scorch time (T_{s2}) and optimum cure time (T_{90}) tended to decrease with higher phr N330, showing that the filler accelerated the vulcanization reaction. The cure rate index (CRI) varied among the models: most filled compounds exhibited lower CRI than the non-carbon-black sample due to a wider T_{90}–T_{s2} interval, whereas Model C showed the highest CRI among the filled samples, reflecting its shortest effective curing window[25]. Overall, the experimental results confirm that N330 enhances the curing rate and crosslinking efficiency at moderate levels, while excessive loading reduces curing efficiency due to increased filler aggregation.

IV.2 MECHANICAL PROPERTIES.

The rubber track pad standard in Table 3 serves as a reference for determining the required characteristic values of the rubber compound to be used in track pad applications. Several additional tests were also performed outside the standard to obtain a more comprehensive evaluation of the material's performance. The hardness of rubber vulcanizates is largely governed by the proportion of rubber to additives and the density of molecular crosslinks within the material[26]. Under an applied external load, the robustness of intermolecular bonding determines the rubber's resistance to deformation, thereby affecting its measured hardness. In this study, the hardness values of the NR–SBR/carbon black composites exhibited a clear increasing trend across all formulations, as shown in Figure 10. Compound A recorded the lowest hardness value of 83.2 Shore A, indicating that it is the softest material within the series. Compound B showed a slightly higher hardness of 84.0 Shore A, followed by Compound C at 85.6 Shore A and Compound D at 86.0 Shore A, demonstrating progressively stronger reinforcement effects.

The highest hardness was observed in Compound E, with an average Shore A hardness of 89.0, making it the stiffest and most rigid formulation among the compounds tested. Hardness is a critical parameter that reflects the stiffness, deformation resistance, and structural integrity of rubber materials. The gradual increase from 83.2 Shore A (A) to 89.0 Shore A (E) indicates that higher filler loading results in tighter molecular packing and reduced chain mobility, enhancing the compound's rigidity. These differences illustrate how variations in carbon black concentration influence mechanical performance, where softer compounds provide greater elasticity, while harder compounds exhibit better resistance to indentation and compressive deformation. Although all formulations employed carbon black N330, the variation in phr significantly affected the reinforcement behavior.

Higher carbon black content increases the effective surface area for polymer–filler interaction, resulting in stronger bonding and reduced segmental motion within the NR–SBR matrix. This explains why Compound E, with the highest filler dosage, showed the greatest hardness—approximately 5.8 Shore A, higher than Compound A. Such an increment highlights the substantial impact of filler loading on stiffness and durability. These findings are highly relevant for industrial track pad applications. Harder materials, such as Compound E, are expected to exhibit superior resistance to dynamic loading, compressive forces, and abrasive wear, thereby enhancing service life. Conversely, moderately hard compounds like A and B may provide better damping behavior but reduced long-term stability. Therefore, selecting the appropriate hardness level depends on achieving an optimal balance between flexibility, resilience, and operational durability required for track pad performance.

Table 3: Physics Testing Track Pad Standards.

Physics Testing	Rubber Standard For Track Pad
Hardness, Shore A	75
Density (gr/cm^3)	1,2
Abrasion resistance (mm^3)	350
Elongation at break (%)	228
Tensile strength (N/mm^2)	16.9

Source: [27].

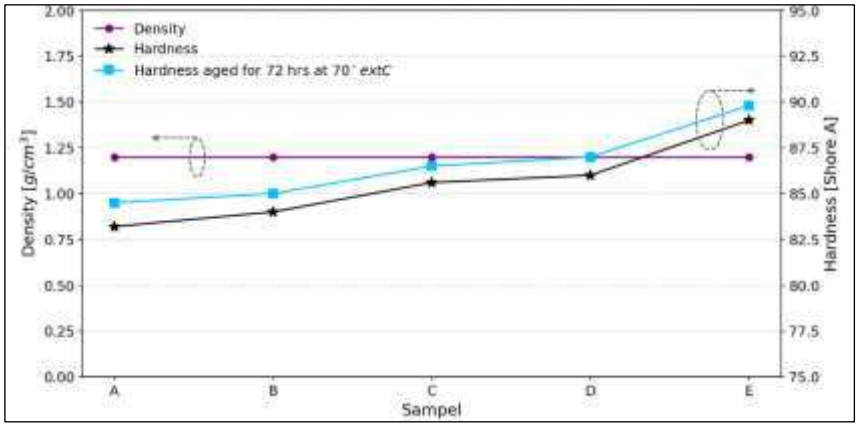

Figure 10: Density and hardness results of track pad compounds.
Source: Authors, (2026).

In the analysis of the relationship between density and hardness (as displayed in Figure 10), a clear correlation is observed for both normal and post-aging compounds. In the current dataset (Samples A through E), the Density of the material is consistently measured at 1.2 g/cm^3, indicating negligible variation in mass density across the formulations. Conversely, the Hardness (Shore A) of the normal compounds (black line) exhibits a clear upward trend, increasing from 83.2 in Sample A to 89.0 in Sample E. Since density remains constant while hardness increases, this suggests that the positive correlation is driven primarily by an increase in cross-linking density or the incorporation of stiffer filler material, rather than a change in bulk material compaction. The aging process causes the addition of cross-links and the potential for breakage of molecular chains, fundamentally altering the physical properties of the rubber.

Exposure to heat (70°C for 72 hours) induces post-curing (further vulcanization), which is evidenced by the consistently higher values of the Hardness aged compounds (blue line) compared to the normal compounds. This increase in hardness (e.g., from 83.2 to 84.5 in Sample A) confirms enhanced matrix stiffness due to the formation of additional cross-links. Understanding the aging process is vital as it can be used to predict the tensile properties of rubber and the behavior of strain energy density functions, which are critical for determining the long-term durability of the track pad material. As shown in Figure 11, the tensile strength of the NR–SBR / carbon black composites decreases progressively from Sample A (~14.8 N/mm²) to Sample E (~9.7 N/mm²), while elongation at break similarly declines from approximately 149% down to about 95%.

This trend reflects the typical behavior of carbon-black reinforced elastomers: as filler loading increases, the rubber matrix becomes stiffer and less ductile due to restriction of polymer chain mobility and formation of rigid filler networks[5]. The reduction in elongation and ultimate tensile strength at high filler concentrations can be attributed to micro-agglomeration of carbon black particles, which introduces stress concentration points and reduces the ability of the matrix to deform uniformly under load[28]. For industrial track-pad applications, these results imply a trade-off: while higher filler may improve hardness and wear resistance, excessive loading compromises tensile durability and flexibility — critical properties under dynamic and impact conditions.

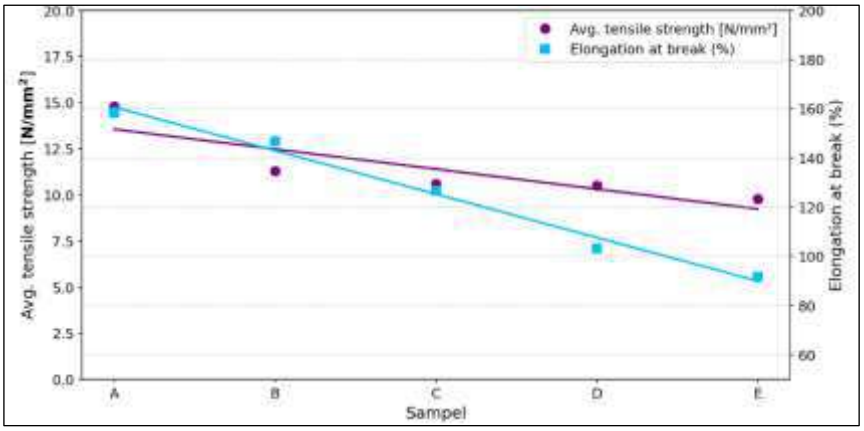

Figure 11: Tensile and elongation at break of track pad compounds.
Source: Authors, (2026).

Figure 12 presents the relationship between compression set, rebound resilience, and abrasion resistance for compounds A–E. The rebound resilience shows a clear decreasing trend, dropping from 62% (A) to 44% (E). This decline indicates reduced elasticity due to higher carbon black loading, which restricts polymer chain mobility and increases the stiffness of the vulcanized matrix. Similar findings have been reported where increased filler–polymer interactions diminish elastic energy return in NR-based composites. Conversely, the compression set values increase significantly, from 12.0% (A) to 23.8% (E).

A higher compression set signifies that the material experiences greater permanent deformation after compressive stress. This behavior is typically associated with increased crosslink density and the reduced relaxation capability of filler-rich networks, which hinder the material's ability to recover after loading. Prior studies confirm that excessive filler loading compromises elastic recovery in NR–SBR elastomers[29].

The abrasion resistance improves with higher filler content, evidenced by the decreasing abrasion volume loss from 294 mm³ (A) to 261 mm³ (E). This improvement reflects the reinforcing effect of carbon black, which enhances surface hardness and stabilizes the matrix under frictional forces. Literature widely supports carbon black's role in enhancing wear resistance due to its high surface area and strong filler–rubber bonding[30]. Overall, these results highlight a predictable performance trade-off: compounds with lower filler content (A–B) demonstrate better elasticity and recovery (high rebound, low compression set), whereas compounds with higher filler content (D–E) exhibit improved wear resistance at the cost of reduced resiliency. For track pad applications subjected to dynamic loading and abrasive ground contact, an intermediate formulation (such as Compound C) provides the most balanced mechanical profile.

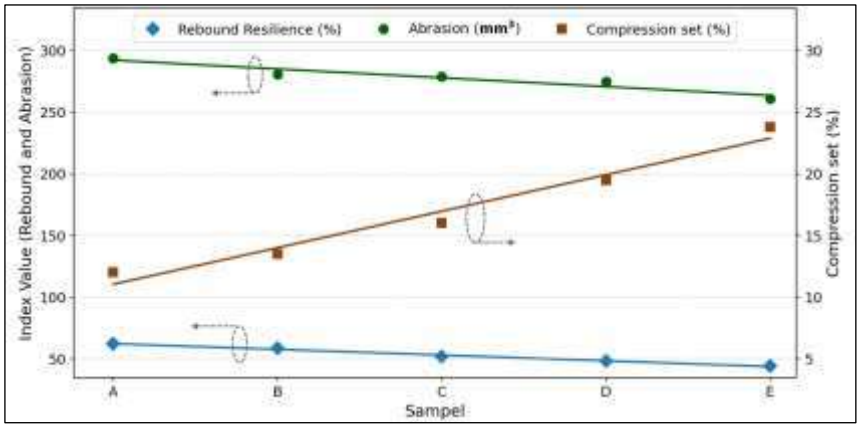

Figure 12: Rebound Resilience, compression set, and abrasion resistance of track pad compounds.
Source: Authors, (2026)

The field performance of all NR–SBR track pad formulations was evaluated through a 15-km dynamic track test conducted on an asphalt surface. Each track pad was installed on the test rig, and thickness reduction, surface wear, crack initiation, and overall structural integrity were recorded at 3-km intervals. The quantitative results are summarized in Table 4, while the wear-progression profile is illustrated in Figure 15.

Table 4: Quantitative Results of 15-km Dynamic Track Test for NR–SBR Track pads.

No	Model	3 KM	6 KM	9 KM	12 KM	15 KM
		Thickness reduction (mm)				
1	A	25.67	25.00	24.63	24.12	23.67
2	B	25.67	25.47	24.97	24.23	24.07
3	C	25.67	25.67	25.30	24.90	24.60
4	D	25.67	25.00	24.33	23.90	23.30
5	E	25.67	25.17	24.27	23.73	23.13

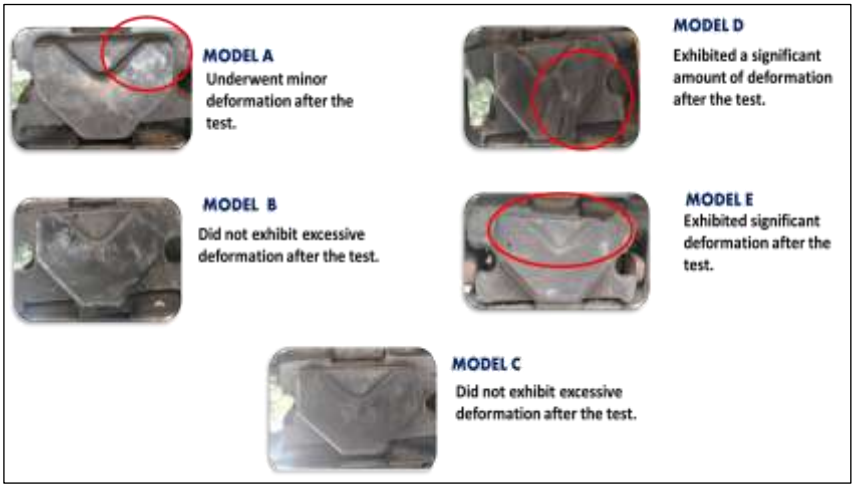

Figure 13: Wear-Progression Profile of NR–SBR Track pad Formulations During the 15-km Dynamic Track Test.
Source: Authors, (2026).

As presented in Table 4, Compounds A and B exhibited the highest rate of thickness loss due to their lower hardness and limited resistance to repetitive ground impact. Although these compounds demonstrated good elasticity, their insufficient modulus led to faster material removal and higher surface abrasion during the test. In contrast, Compounds D and E showed relatively low material loss; however, visual inspection revealed the presence of early micro-cracks and edge chipping. This failure mode is associated with excessive stiffness, which restricts energy absorption and increases localized stress concentrations under dynamic loading.

Compound C demonstrated the most balanced performance, showing moderate wear progression, minimal crack formation, and stable dimensional retention throughout the test cycle. As shown in Figure 15, the wear curve of Compound C maintained a gradual and linear trend, indicating uniform deformation behavior and superior adaptability to cyclic mechanical stresses. The qualitative damage patterns captured after the full distance, presented in Figure 13, further highlight the superior resistance of Compound C to both abrasive and impact-induced degradation. Overall, the field-test results confirm that optimal track-pad performance is not governed by a single mechanical parameter, but rather by a balanced combination of stiffness, tensile strength, abrasion resistance, and deformation capacity. The superior field durability of Compound C validates the laboratory findings and supports its suitability for real operational conditions.

IV.3 INTEGRATED PERFORMANCE EVALUATION

To determine the optimal formulation, all results—hardness, tensile strength, elongation, abrasion, and dynamic field wear—were integrated into a comparative analysis. The overall interpretation is illustrated in Figure 9, showing the relative performance of each compound. Compounds with low filler loading lack durability, while compounds with excessive filler loading are too rigid for dynamic deformation. Compound C exhibits the best balance between stiffness, strength, flexibility, and wear behavior, aligning with the performance demands of industrial track pad systems.

V. CONCLUSIONS

This study investigated the mechanical and functional characteristics of NR–SBR rubber composites reinforced with different carbon black loadings for industrial track pad applications. The experimental results confirmed that increasing filler content improves hardness and abrasion resistance but simultaneously reduces tensile strength, elongation at break, rebound resilience, and elastic recovery. Among all tested formulations, Compound C demonstrated the most balanced performance with adequate hardness, good tensile behavior, moderate compression set, and improved abrasion resistance, making it the most suitable candidate for operational track pad use.

Field testing on an armored vehicle further validated that Compound C maintained dimensional stability and exhibited minimal wear during dynamic operation. Overall, the findings indicate that an NR–SBR composite with moderate carbon black concentration offers the optimal compromise between durability and elasticity required for track pad applications. The outcomes of this study can serve as a reference for improving rubber compound formulations used in military and industrial mobility systems. Future work may include accelerated aging studies, optimization through finite element simulation, and exploration of alternative reinforcing fillers to enhance long-term performance.

IoT–AI Integration

Waste-to-Energy (WTE)

ABSTRACT

The global energy transition toward sustainability demands innovative solutions that enhance efficiency, resilience, and circularity across energy and resource systems. This chapter explores the transformative role of Artificial Intelligence (AI) in optimizing renewable energy generation and resource recovery processes, highlighting the convergence of data-driven intelligence, automation, and digital infrastructure. AI techniques—ranging from machine learning and deep learning to reinforcement learning and fuzzy logic systems—are increasingly enabling predictive analytics, adaptive control, and process optimization in solar, wind, bioenergy, and hybrid energy systems. Furthermore, intelligent modeling and optimization approaches are driving progress in waste-to-energy conversion, wastewater nutrient recovery, and circular material flows, reinforcing the principles of the circular economy. The chapter presents case studies and frameworks that illustrate how AI tools enhance system performance, reduce operational costs, and support real-time decision-making. Challenges such as data quality, interpretability, and integration complexity are critically examined, along with emerging trends including digital twins, IoT–AI integration, and quantum-assisted energy analytics. Ultimately, the chapter emphasizes that the synergy between AI and sustainable resource technologies holds the potential to redefine global energy systems, paving the way toward a decarbonized and intelligent future.

I. INTRODUCTION

The twenty-first century faces a defining challenge: ensuring the availability of clean, affordable, and sustainable energy while minimizing environmental degradation and resource depletion. The accelerating pace of industrialization, urbanization, and population growth has intensified global energy demand, putting immense pressure on conventional fossil fuel–based systems. These traditional sources contribute significantly to greenhouse gas emissions, air pollution, and climate change, necessitating a systemic transition toward renewable and circular energy models. In this context, renewable energy systems—such as solar, wind, hydro, biomass, and geothermal—have emerged as essential components of global decarbonization strategies.

However, the intermittent nature of renewable sources, the complexity of multi-resource interactions, and the increasing heterogeneity of energy networks have created new challenges in prediction, control, and optimization [1-3]. At the same time, the concept of resource recovery has gained prominence within the broader framework of the circular economy, emphasizing the reuse, recycling, and regeneration of materials, water, and energy from waste streams. Efficient recovery systems not only reduce environmental burdens but also enhance economic sustainability by converting waste into valuable inputs. Examples include waste-to-energy (WTE) conversion, anaerobic digestion for biogas production, nutrient recovery from wastewater, and smart recycling networks in industrial ecosystems.

Yet, these systems are inherently complex, governed by nonlinear processes, variable input characteristics, and evolving operational conditions—all of which demand intelligent, adaptive management solutions [4-6]. This is where Artificial Intelligence (AI)

becomes transformative. AI offers a powerful suite of computational methods capable of learning patterns from large datasets, optimizing system performance, and enabling predictive and autonomous decision-making. In the renewable energy domain, AI facilitates solar radiation forecasting, wind power prediction, demand-side management, and fault detection in grid operations. Similarly, in resource recovery, AI algorithms optimize process control, enhance biogas yield prediction, and improve waste classification and sorting accuracy. By integrating AI-driven analytics with Internet of Things (IoT) platforms, digital twins, and cloud computing infrastructures, engineers and policymakers can create intelligent energy–resource ecosystems that dynamically balance efficiency, reliability, and sustainability. The convergence of AI with renewable and resource recovery systems represents a pivotal evolution in the way energy is produced, distributed, and reused.

For instance, machine learning (ML) techniques such as regression models, decision trees, and support vector machines have been applied to optimize power output forecasting and process efficiency. Deep learning (DL) methods, including convolutional and recurrent neural networks, are enabling improved image recognition in photovoltaic (PV) inspection and enhanced time-series modeling for wind energy prediction. Reinforcement learning (RL) algorithms, inspired by behavioral psychology, are facilitating autonomous control and real-time adaptation in smart grids and bioenergy plants. Moreover, fuzzy logic systems and expert systems are being used to support complex decision-making under uncertainty—an essential capability in dynamic, multi-resource environments [7-9]. Despite its promise, the deployment of AI in renewable and resource recovery systems also presents critical challenges. Data heterogeneity, scarcity, and quality issues can limit model reliability. The “black-box” nature of many deep learning algorithms raises concerns regarding interpretability and trust, especially in safety-critical infrastructure. Additionally, the integration of AI with legacy energy systems, the need for standardized data frameworks, and cybersecurity vulnerabilities remain significant barriers to large-scale adoption.

Addressing these challenges requires interdisciplinary collaboration—bringing together energy engineers, data scientists, environmental specialists, and policymakers to design frameworks that are both technically robust and socially responsible [10-12]. The objective of this chapter is to explore the synergistic potential of AI technologies in advancing renewable energy and resource recovery systems. It provides a comprehensive overview of current methodologies, emerging tools, and practical applications where AI enhances energy conversion, recovery efficiency, and circular resource utilization. Through illustrative case studies, the chapter demonstrates how data-driven intelligence enables adaptive control, predictive maintenance, and systemic optimization across interconnected energy and resource networks. Furthermore, the discussion extends to future research directions, highlighting the role of next-generation technologies such as quantum computing, federated learning, and AI–IoT–blockchain convergence in shaping resilient, low-carbon, and self-optimizing infrastructures. As the global community strives to achieve the United Nations Sustainable Development Goals (SDGs)—particularly SDG 7 (Affordable and Clean Energy) and SDG 12 (Responsible Consumption and Production)—AI stands as a crucial enabler of the energy transition, fostering innovation that bridges technology, sustainability, and environmental stewardship [13].

II. OVERVIEW OF AI IN RENEWABLE ENERGY SYSTEMS

The transformation of the global energy landscape toward low-carbon and sustainable sources is central to achieving environmental and economic resilience. Renewable energy systems harness natural flows of energy—such as solar radiation, wind currents, hydrological cycles, and biological processes—to generate power and heat. Unlike conventional fossil fuel systems, renewable energy is virtually inexhaustible and emits minimal greenhouse gases. However, the dynamic and intermittent nature of many renewable sources presents challenges for stability, predictability, and integration into existing energy grids. In this context, Artificial Intelligence (AI) tools have emerged as indispensable enablers of efficiency, control, and optimization across renewable energy domains [14], [15].

II.1 SOLAR ENERGY SYSTEMS

Solar energy, particularly photovoltaic (PV) and concentrated solar power (CSP) technologies, is among the most mature and rapidly expanding renewable energy sources. The performance of solar systems is affected by multiple variables—solar irradiance, temperature, panel orientation, and environmental conditions. AI-based approaches are increasingly applied to model, predict, and optimize these parameters. Machine learning (ML) algorithms such as support vector regression (SVR), random forests, and gradient boosting are widely used for solar radiation forecasting, enabling more accurate power scheduling and grid balancing. Deep learning (DL) techniques, particularly recurrent neural networks (RNN) and long short-term memory (LSTM) models, have demonstrated superior capabilities in capturing the temporal dependencies of solar irradiance patterns. Furthermore, computer vision techniques based on convolutional neural networks (CNNs) are being employed for automated fault detection in PV panels, identifying issues such as soiling, shading, and microcracks from infrared and visual imagery. In addition, AI-driven maximum power point tracking (MPPT) algorithms—particularly those using reinforcement learning (RL)—enable dynamic adjustment of converter settings to maximize energy harvest under varying conditions. Through these applications, AI enhances the operational efficiency, reliability, and lifespan of solar energy systems [16-18].

II.2 WIND ENERGY SYSTEMS

Wind energy is another key component of the renewable portfolio, contributing significantly to global power generation. Yet, wind power output is inherently variable, depending on weather conditions and turbine performance. AI has proven instrumental in addressing these challenges through data-driven modeling, forecasting, and control. Artificial neural networks (ANNs) and Gaussian process models are used for wind speed and power forecasting, achieving higher accuracy than conventional statistical approaches. Predictive models assist in turbine load estimation and grid integration planning, mitigating the effects of variability. Moreover, AI-based fault detection systems employing deep learning and fuzzy inference techniques continuously monitor vibration, acoustic, and temperature data from turbines to predict mechanical failures.

This enables predictive maintenance, reducing downtime and maintenance costs. Recent advancements include the use of reinforcement learning for turbine control, where AI agents autonomously adjust blade pitch and yaw to maximize energy output under

fluctuating wind conditions. The incorporation of digital twins—virtual replicas of wind farms—further allows continuous simulation and optimization based on real-time data [19-21].

II.3 BIOENERGY AND WASTE-TO-ENERGY SYSTEMS

Bioenergy systems convert biomass, organic waste, or biogas into usable energy forms such as heat, electricity, or fuels. The heterogeneity of feedstock, coupled with nonlinear biochemical and thermochemical conversion processes, makes bioenergy management complex. AI methods are now extensively applied for process modeling, optimization, and yield prediction in anaerobic digestion, gasification, and pyrolysis systems. For example, adaptive neuro-fuzzy inference systems (ANFIS) and deep neural networks (DNNs) are employed to estimate biogas yield and optimize operational parameters such as temperature, retention time, and pH. AI models can also predict the calorific value of biomass based on its composition, supporting better feedstock blending strategies. In waste-to-energy systems, AI-assisted control algorithms dynamically regulate combustion and gasification parameters to enhance energy efficiency while minimizing emissions. By integrating AI with sensor-based monitoring and Internet of Things (IoT) platforms, bioenergy systems can operate as intelligent, self-correcting networks that continuously improve conversion efficiency and environmental performance [22-24].

II.4 HYDROPOWER, GEOTHERMAL, AND HYBRID SYSTEMS

While hydropower remains one of the most stable and established renewable sources, AI tools are increasingly being deployed to optimize reservoir management, turbine performance, and water resource forecasting. Reinforcement learning models can optimize reservoir operations by balancing flood control, irrigation needs, and electricity generation. In geothermal systems, AI techniques help in subsurface modeling, drilling optimization, and fault detection during heat extraction processes. Hybrid renewable systems—combining solar, wind, and storage technologies—are gaining attention for their ability to stabilize energy supply. AI-based multi-objective optimization algorithms, such as genetic algorithms (GA) and particle swarm optimization (PSO), are employed to determine the optimal sizing, dispatch strategy, and control parameters for hybrid microgrids. These AI-driven methods improve energy reliability while minimizing costs and emissions [25-27]. Figure 1 shows the AI applications across aenewable energy systems.

II.5 INTEGRATION CHALLENGES AND OPPORTUNITIES

Despite the demonstrated potential of AI in renewable systems, integration remains a significant challenge. Renewable energy infrastructures are distributed and data-intensive, requiring interoperable platforms that can securely collect, process, and analyze high-frequency sensor data. Moreover, ensuring data transparency, model explainability, and cybersecurity is essential for trust and adoption in energy-critical applications. However, the ongoing convergence of AI, big data analytics, IoT, and cloud-edge computing is creating new opportunities for smart, self-optimizing renewable systems. These systems not only adapt to environmental changes but also anticipate demand, predict failures, and coordinate with other resource sectors such as water and waste management—laying the foundation for a truly intelligent and sustainable energy ecosystem [28], [29].

III. RESOURCE RECOVERY SYSTEMS: CONCEPTS AND FRAMEWORKS

The growing demand for sustainable energy and material use has accelerated the shift from a traditional linear economy — based on extraction, production, consumption, and disposal — toward a circular economy (CE) model. Within this framework, resource recovery systems play a critical role in minimizing waste, conserving resources, and transforming by-products into valuable outputs.

These systems aim to extract energy, water, nutrients, and materials from waste streams using advanced technologies. The integration of Artificial Intelligence (AI) within these systems is redefining their efficiency, enabling intelligent monitoring, predictive control, and process optimization that were previously unattainable through conventional methods [30], [31].

III.1 CONCEPT OF RESOURCE RECOVERY IN THE CIRCULAR ECONOMY

Resource recovery refers to the process of reclaiming valuable components from waste materials—including solid waste, wastewater, agricultural residues, and industrial by-products—to reintroduce them into productive use cycles. The approach supports the core principles of the circular economy: reduce, reuse, recycle, and recover (4Rs). AI strengthens this concept by providing data-driven insights and automated decision-making, which allow systems to dynamically adapt to varying waste compositions, operational conditions, and demand fluctuations. Through intelligent pattern recognition, predictive analytics, and real-time control, AI-driven recovery systems optimize energy yield, minimize emissions, and support closed-loop material flows. In essence, AI acts as a cognitive layer on top of physical recovery infrastructures—transforming them into smart, self-learning systems capable of enhancing sustainability and economic viability simultaneously [32], [33].

III.2 TYPES OF RESOURCE RECOVERY SYSTEMS

Waste-to-Energy (WTE) Systems: Waste-to-energy systems convert municipal solid waste, industrial waste, or biomass into usable energy—typically in the form of heat, electricity, or fuel—via incineration, gasification, or anaerobic digestion. AI applications in WTE focus on: Process Optimization: Machine learning (ML) models predict combustion efficiency and optimize air–fuel ratios [34]. Emission Control: AI-based monitoring systems detect deviations in real time, ensuring regulatory compliance. Predictive Maintenance: Neural networks forecast component wear, reducing unplanned shutdowns. Example: Reinforcement learning algorithms have been deployed to fine-tune anaerobic digestion parameters—such as temperature and retention time—resulting in a 15–25% increase in biogas yield [35]. Wastewater Treatment and Nutrient Recovery: Wastewater contains recoverable energy and nutrients such as nitrogen, phosphorus, and organic carbon. AI-enhanced treatment plants utilize predictive modeling and automated control for: Process Control: AI regulates aeration, chemical dosing, and sludge retention time to improve energy efficiency. Fault Detection: Deep learning identifies anomalies in flow rate, pH, or dissolved oxygen levels. Nutrient Recovery Optimization: ML algorithms determine the optimal timing and method for phosphorus precipitation or ammonia stripping. Case Example: An AI-optimized membrane bioreactor (MBR) system achieved 20% lower energy consumption through adaptive control of aeration and backwashing cycles [36], [37].

Industrial Symbiosis and Circular Manufacturing: Industrial symbiosis involves the exchange of materials, energy, and waste streams among industries to minimize resource input and waste output. AI facilitates these systems by: Data Mining and Pattern Recognition: Identifying potential synergies among industries based on waste and resource profiles. Optimization Algorithms: Determining the most efficient resource exchange networks. Digital Twins: Simulating inter-industry resource flows to evaluate environmental and economic benefits. For example, in eco-industrial parks, AI-driven decision support systems have been used to optimize heat recovery networks and material reuse pathways [38]. Smart Material Recycling and Sorting Systems: Material recovery from municipal waste is often constrained by inconsistent quality and contamination. AI, especially computer vision and deep learning, is transforming recycling through: Automated Sorting: Image recognition and robotics classify materials (plastics, metals, glass, paper) in real time. Quality Control: AI systems assess purity levels of recycled streams. Lifecycle Optimization: ML tools predict recyclability potential based on material composition and degradation data. These systems enable high-throughput and precision recycling, reducing human intervention and improving material recovery efficiency [39], [40].

III.3 AI-ENABLED FRAMEWORK FOR RESOURCE RECOVERY SYSTEMS

An AI-enabled resource recovery framework typically comprises four core layers:

Sensing and Data Acquisition Layer: IoT sensors collect data on waste composition, flow rate, temperature, and emissions. Data is transmitted to centralized or edge computing platforms. Data Processing and Analytics Layer: Big data analytics and machine learning extract insights from raw sensor data. Algorithms identify inefficiencies, predict outcomes, and recommend control actions. Control and Optimization Layer: Reinforcement learning and fuzzy logic systems autonomously adjust operational parameters. Decision-support dashboards visualize performance metrics and sustainability indicators [41].

Knowledge and Decision-Making Layer: AI integrates with digital twins and optimization models for long-term planning. Insights inform policymakers and operators for adaptive resource management. This layered architecture promotes a cyber-physical integration of recovery facilities—where digital intelligence continuously enhances physical system performance [42].

III.4 SUSTAINABILITY AND ECONOMIC IMPLICATIONS

AI-driven resource recovery systems yield multiple benefits across sustainability dimensions: Environmental: Reduced greenhouse gas emissions, minimized landfill disposal, and improved water quality. Economic: Lower operational costs, enhanced energy efficiency, and monetization of recovered materials. Social: Creation of green jobs, promotion of environmental awareness, and increased resilience of urban infrastructure.

In the broader context of the energy–water–waste nexus, AI enables synergistic management of interlinked systems—facilitating sustainable urban metabolism and aligning with global sustainability goals such as SDG 6 (Clean Water and Sanitation) and SDG 12 (Responsible Consumption and Production) [43]. Examples of AI Applications in Resource Recovery Systems are listed in table 1. Figure 2 describes various AI-Driven Framework for Resource Recovery Systems.

Table 1: Examples of AI Applications in Resource Recovery Systems.

Resource Type	Recovery Process	AI Technique Used	Outcome / Benefit
Municipal Waste	Anaerobic Digestion	Reinforcement Learning	20–25% increase in biogas yield
Industrial Waste	Gasification	Neural Networks	Optimization of temperature and feed ratio
Wastewater	Membrane Bioreactor	Deep Learning	20% energy savings, predictive fouling detection
Plastic Waste	Material Sorting	Computer Vision (CNN)	95% classification accuracy in recycling lines
Eco-industrial Park	Heat Recovery	Optimization Algorithms	15% improvement in overall energy efficiency

IV. ARTIFICIAL INTELLIGENCE TOOLS AND TECHNIQUES FOR RENEWABLE RESOURCE RECOVERY SYSTEMS

Artificial Intelligence (AI) encompasses a broad set of computational methodologies designed to emulate human learning, reasoning, and problem-solving. Within the domains of renewable energy and resource recovery, AI tools provide adaptive, data-driven intelligence capable of handling the nonlinearities, uncertainties, and multivariable dependencies characteristic of such complex systems. These techniques enable predictive modeling, operational optimization, and autonomous control—transforming conventional infrastructures into smart, self-learning systems that continuously evolve toward improved performance and sustainability [44].

IV.1 MACHINE LEARNING (ML)

Machine Learning (ML) is the foundation of AI applications in energy and environmental systems. It focuses on developing algorithms that can learn patterns and relationships from data without explicit programming. ML techniques are extensively used for energy forecasting, fault detection, process modeling, and optimization across renewable and recovery domains [45]. Supervised Learning: Supervised learning uses labeled datasets to train models for predictive tasks. Regression models (e.g., linear regression, support vector regression, random forest regression) are applied in solar irradiance and wind power forecasting, providing short-term generation estimates that enhance grid stability. Classification algorithms (e.g., decision trees, k-nearest neighbors, and gradient boosting) are used in waste material sorting, bioenergy feedstock classification, and equipment fault diagnosis [46].

Unsupervised Learning: Unsupervised learning identifies hidden structures within unlabeled data. Clustering algorithms, such as k-means and hierarchical clustering, support waste stream segmentation, energy consumption profiling, and anomaly detection in system operations. Principal Component Analysis (PCA) and Independent Component Analysis (ICA) are used for dimensionality reduction and noise filtering in high-frequency energy data [47]. Applications in Resource Recovery: ML models can predict biogas yields from heterogeneous waste inputs, optimize operational setpoints in anaerobic digestion, and estimate pollutant loads in wastewater treatment plants. In material recycling, ML-based image analysis improves the accuracy of automated waste sorting systems, achieving classification accuracies exceeding 95% in some pilot studies [48].

IV.2 DEEP LEARNING (DL)

Deep Learning (DL), a subfield of ML, employs multilayered artificial neural networks (ANNs) to automatically extract features and learn complex nonlinear mappings from raw data. DL has revolutionized AI applications in energy systems, particularly in computer vision, time-series forecasting, and sensor data fusion. Convolutional Neural Networks (CNNs): CNNs are primarily used in image-based applications: Solar PV panel inspection via drone or satellite imagery to detect soiling, cracks, and degradation. Waste classification using camera-based sorting lines that distinguish materials such as plastics, paper, and metals.

Thermal imaging of turbines and reactors to detect heat anomalies or insulation failures [49]. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM): RNNs and LSTMs excel in sequential and temporal data modeling: Wind speed and power forecasting, capturing nonlinear temporal dependencies in meteorological data. Energy demand forecasting in smart grids. Process trend prediction in wastewater treatment plants, supporting proactive control [50]. Autoencoders compress and reconstruct data, useful for anomaly detection and fault diagnosis in energy systems. Generative Adversarial Networks (GANs) can simulate synthetic sensor data to augment limited datasets for training predictive models [51].

IV.3 REINFORCEMENT LEARNING (RL)

Reinforcement Learning (RL) represents a paradigm shift from traditional optimization by enabling agents to learn optimal strategies through interaction with dynamic environments. It is particularly powerful for adaptive control and decision-making under uncertainty. In renewable and resource recovery contexts: Energy Management: RL optimizes microgrid operations, balancing renewable inputs, storage, and load demand to minimize cost and emissions [52]. Process Control: In anaerobic digestion, RL agents dynamically adjust temperature, feed rate, and hydraulic retention time to maximize biogas production. Predictive Maintenance: RL-based decision systems determine the optimal timing of maintenance interventions, balancing reliability and operational costs [53]. Water–Energy–Waste Nexus: RL coordinates multi-objective management, ensuring resource efficiency across interconnected systems. The advantage of RL lies in its self-adaptive nature, making it suitable for highly variable systems where static models underperform [54].

IV.4 FUZZY LOGIC AND EXPERT SYSTEMS

While data-driven AI models rely on statistical learning, Fuzzy Logic (FL) and Expert Systems (ES) emulate human reasoning based on linguistic rules and expert knowledge. These systems are particularly effective when data are scarce, incomplete, or uncertain. Fuzzy Control: Used extensively in renewable energy plants for real-time regulation of wind turbine pitch, solar inverter voltage, and biogas plant temperature. Expert Systems: Encode domain knowledge as “if–then” rules for diagnostics, energy auditing, and decision support in resource management. Hybrid AI Systems: Combine fuzzy logic with ML/DL models (known as neuro-fuzzy systems) to merge interpretability with learning capabilities. Example: In wastewater treatment, a fuzzy control system can maintain optimal dissolved oxygen levels by adjusting aeration rates based on linguistic inputs such as “low,” “medium,” or “high.” [55].

IV.5 OPTIMIZATION ALGORITHMS AND EVOLUTIONARY COMPUTING

Optimization algorithms, inspired by natural processes, are essential in system design and operational tuning. These algorithms are often hybridized with AI models to improve convergence speed and solution accuracy. Genetic Algorithms (GA): Applied to optimize renewable energy mix, sizing of hybrid systems, and bioprocess parameters. Particle Swarm Optimization (PSO): Used for controller tuning and multi-objective energy scheduling. Ant Colony Optimization (ACO): Applied to waste transportation routing and network optimization in industrial symbiosis. By coupling AI with these algorithms, systems can achieve multi-criteria optimization (e.g., minimizing cost and emissions while maximizing efficiency) [56].

IV.6 DIGITAL TWINS AND CYBER-PHYSICAL INTEGRATION

Digital Twins (DTs) represent the convergence of AI, simulation, and real-time sensing into virtual replicas of physical systems. In renewable and recovery systems, DTs are used for system modeling, predictive maintenance, and lifecycle optimization. In wind farms, DTs simulate turbine performance and degradation patterns using ML models trained on operational data. In wastewater recovery plants, DTs predict system responses under varying loads, optimizing aeration and chemical dosing. In eco-industrial parks, DTs model interlinked material and energy exchanges to improve resource circularity. Coupled with AI and IoT, digital twins enable continuous learning, allowing operators to simulate scenarios, test control strategies, and forecast long-term performance [57]. Various AI techniques are compared in Table 2.

Table 2: Comparative Overview of AI Techniques.

AI Technique	Primary Function	Key Applications	Advantages	Limitations
Machine Learning	Pattern recognition, forecasting	Solar/wind prediction, fault detection	High accuracy, scalable	Requires quality data
Deep Learning	Feature extraction, image/time-series analysis	PV inspection, waste sorting	Handles complex data	Computationally intensive
Reinforcement Learning	Adaptive control, decision-making	Microgrid optimization, digestion control	Learns from environment	Requires large training time
Fuzzy Logic	Rule-based reasoning	Turbine control, wastewater aeration	Explainable and robust	Limited adaptability
Optimization Algorithms	System design, parameter tuning	Hybrid system sizing, resource routing	Multi-objective optimization	May converge slowly
Digital Twins	Simulation, predictive modeling	Energy plant monitoring, circular networks	Real-time adaptability	High modeling complexity

Source: Authors, (2026).

IV.7 INTEGRATION OF AI TECHNIQUES FOR HOLISTIC SYSTEM INTELLIGENCE

In practical applications, AI tools are rarely deployed in isolation. The most effective renewable and recovery systems employ hybrid AI architectures, integrating complementary methods: ML + Optimization for dynamic system design and control. DL + RL for autonomous plant management and adaptive learning. Fuzzy Logic + ML for interpretable and adaptive decision systems. Digital Twins + IoT for full cyber-physical integration and real-time feedback. Such integration leads to the emergence of self-optimizing, intelligent systems capable of adjusting operations autonomously in response to changing environmental and operational conditions [58].

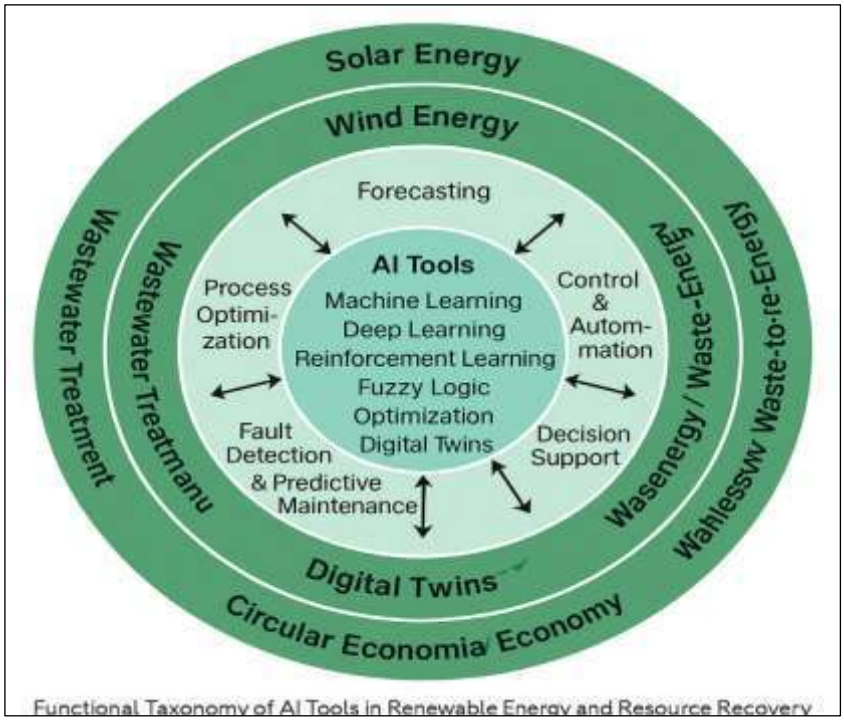

Figure 3: Functional Taxonomy of AI Tools in Renewable and Resource Recovery Systems.
Source: Authors, (2026).

V. APPLICATIONS OF AI IN RENEWABLE RESOURCE RECOVERY SYSTEM

The practical deployment of Artificial Intelligence (AI) within renewable energy and resource recovery systems has moved beyond the experimental stage into operational and industrial-scale applications. By leveraging machine learning, deep learning, reinforcement learning, and hybrid intelligence architectures, energy and environmental systems now exhibit improved reliability, adaptability, and cost-effectiveness. This section highlights notable case studies and application domains that demonstrate the integration of AI tools in renewable energy generation, waste-to-energy (WTE) plants, wastewater treatment systems, and circular resource networks [59]. The functional Taxonomy of AI Tools in Renewable and Resource Recovery Systems are portrayed in figure 3.

V.1 AI IN SOLAR ENERGY SYSTEMS

Accurate solar power forecasting is essential for grid stability, especially in regions with high photovoltaic (PV) penetration. A case study conducted by NREL (USA) employed a deep convolutional neural network (CNN) combined with satellite image data to predict solar irradiance up to 6 hours ahead, achieving 95% forecasting accuracy—a significant improvement over conventional regression models. Researchers implemented an LSTM-based model for short-term solar power prediction using real-time meteorological inputs (temperature, humidity, cloud cover). The AI system dynamically adjusted inverter settings, leading to 7–10% higher energy capture efficiency during fluctuating weather conditions [60]. At a commercial solar park in Spain, a computer vision-based deep learning system was used to inspect PV panels using drone imagery. The CNN model successfully identified cracks, hotspots, and delamination with over 96% detection accuracy, reducing maintenance downtime by 30%. Such applications demonstrate how AI contributes to predictive maintenance and extends system lifespan [61].

V.2 AI IN WIND ENERGY SYSTEMS

Wind energy operations are inherently complex due to the stochastic nature of wind and the mechanical dynamics of turbines. A collaborative project between Siemens Gamesa and Microsoft Azure AI deployed reinforcement learning (RL) algorithms to optimize wind farm control. The RL agents adjusted blade pitch and yaw settings in real time based on wind direction and load profiles, resulting in a 15% improvement in total power output while minimizing stress loads on turbine components. Similarly, deep neural networks (DNNs) trained on vibration and acoustic sensor data are now used for fault detection in gearboxes and bearings. In EU offshore wind farms, such systems have reduced unplanned maintenance by 25% and operational costs by nearly €2 million annually [62].

V.3 AI IN WASTE-TO-ENERGY (WTE) SYSTEMS

AI tools have significantly enhanced the operational efficiency of WTE facilities. In Germany, an Adaptive Neuro-Fuzzy Inference System (ANFIS) was implemented at a municipal biogas plant to optimize feedstock mixtures and retention times. The system analyzed variables such as organic loading rate, temperature, and pH to predict biogas yield in real time. The result was a 20% increase in methane production and a 10% reduction in energy input costs. A plant in Asia integrated machine learning–based predictive control with emission monitoring sensors to maintain combustion efficiency and minimize NO_x emissions. The AI controller continuously adjusted air-to-fuel ratios, leading to a 25% decrease in pollutant emissions without compromising energy output.

These examples demonstrate how AI tools transform WTE facilities into intelligent, closed-loop systems that balance energy recovery and environmental protection [63]. Wastewater treatment plants (WWTPs) are increasingly adopting AI-based automation to improve water quality, reduce operational costs, and enable nutrient recovery. In Spain's Water Reclamation Plant, a deep reinforcement learning (DRL) framework was implemented for aeration control in the activated sludge process. The AI agent learned optimal dissolved oxygen (DO) levels based on varying inflow loads and biochemical oxygen demand (BOD). The system reduced energy consumption by 18% while maintaining effluent quality within regulatory limits [64]. Table 3 list the AI Applications in Renewable Energy and Resource Recovery Systems. Figure 4 portrays AI Applications Across Renewable and Resource Recovery Domains.

V.4 AI IN MATERIAL RECYCLING AND CIRCULAR ECONOMY NETWORKS

AI is revolutionizing material recovery and recycling systems by automating sorting, improving purity, and enabling circular resource tracking. A CNN-based visual recognition system developed by TOMRA Sorting Solutions achieved 98% accuracy in material classification, distinguishing between various plastic polymers using hyperspectral imaging. The integration of AI-driven robotics in sorting lines increased throughput by 30% while maintaining quality compliance for recycled materials. At a larger scale, machine learning and digital twin models are used in eco-industrial parks (EIPs) to simulate energy and material exchanges among industries. In Spain the AI-optimized material flow modeling has improved resource reuse efficiency by 12%, demonstrating the power of AI in advancing circular economy ecosystems [65].

V.5 CROSS-SECTOR INTEGRATION: THE SMART CIRCULAR NEXUS

Recent studies emphasize that the most impactful applications of AI arise when it integrates across multiple sectors—creating smart circular nexuses that link energy, water, and waste systems. A water project developed a unified digital twin connecting wastewater treatment, biogas production, and energy recovery subsystems. Through reinforcement learning and multi-objective optimization, the integrated framework achieved a 25% reduction in total energy use and improved system-level sustainability indicators by 20–30%. These integrated systems embody the vision of autonomous, data-driven circular infrastructures, where AI serves as the coordinating intelligence managing real-time decisions and long-term sustainability objectives [66]. Role of Digital Technologies in AI-Integrated Energy and Recovery Systems are listed in table 4. Figure 5 shows the multi-layered schematic showing how AI connects with IoT, Big Data, and Cloud–Edge layers.

Table 3: AI Applications in Renewable Energy and Resource Recovery Systems.

Sector	AI Technique Used	Application	Outcome / Benefit	Reference / Region
Solar Energy	CNN, LSTM	Forecasting & Fault Detection	95% prediction accuracy, 30% maintenance reduction	USA, Spain
Wind Energy	RL, DNN	Control & Optimization	15% output gain, 25% maintenance cost reduction	Denmark
Waste-to-Energy	ANFIS, ML	Process Optimization	20% higher methane yield	Germany
Wastewater	DRL, SVM	Aeration & Membrane Maintenance	18% energy savings, 22% longer membrane life	Singapore, France
Recycling	CNN, Robotics	Material Classification	98% accuracy, 30% throughput increase	Netherlands
Circular Nexus	RL + Digital Twin	System Integration	25% energy reduction, 20% sustainability gain	EU

Table 4: Role of Digital Technologies in AI-Integrated Energy and Recovery Systems.

Technology	*Function*	*Example Application*	*Benefit*
IoT Sensors	Data acquisition	Wind turbine vibration monitoring	Real-time fault prediction
Edge Computing	Local AI inference	Solar inverter optimization	Low latency, fast response
Big Data Analytics	Pattern recognition	Wastewater quality analysis	Enhanced process control
Cloud Computing	AI model training & storage	Smart grid forecasting	Scalability & collaboration
Blockchain	Secure data exchange	Resource traceability in recycling	Transparency & trust

VI. CHALLENGES AND FUTURE DIRECTIONS

While the integration of Artificial Intelligence (AI) into renewable energy and resource recovery systems has demonstrated remarkable potential, several critical challenges continue to hinder its large-scale implementation and long-term sustainability. These challenges are not merely technological—they extend across data governance, scalability, interoperability, cost-effectiveness, and ethical dimensions. Addressing these issues is essential to realize the vision of autonomous, resilient, and circular energy–resource ecosystems. The performance of AI models depends heavily on the quality, quantity, and representativeness of data. In renewable energy and recovery systems, data are often fragmented, inconsistent, or incomplete due to: Sensor malfunctions, communication latency, and missing entries. Lack of standardized data formats across different energy and waste management systems. Limited availability of labeled data for supervised learning tasks.

For example, solar and wind farms may have historical weather data, but insufficient fault or anomaly data, limiting AI's predictive capabilities. In wastewater plants, raw process data are often unstructured, making feature extraction and modeling complex. Future Direction: Developing data standardization protocols (e.g., ISO/IEC 30141 for IoT architecture) and synthetic data generation using Generative Adversarial Networks (GANs) can overcome data scarcity. Collaborative data-sharing platforms across institutions can further improve dataset diversity and reliability. The increasing connectivity of energy and resource systems exposes them to cybersecurity vulnerabilities such as unauthorized access, data tampering, or ransomware attacks.

Additionally, the collection of sensitive operational data raises concerns about privacy and data ownership—especially in industrial ecosystems involving multiple stakeholders. Future Direction: Implementing blockchain-based data management ensures immutability, traceability, and decentralized control, while federated learning frameworks allow distributed AI training without sharing raw data, enhancing both privacy and model robustness. AI models trained on site-specific data may fail when applied to different geographical, environmental, or operational contexts—a problem known as model overfitting and poor transferability. For instance, a wind turbine fault detection model developed in coastal conditions may perform poorly in high-altitude terrains due to different wind dynamics. Energy and recovery systems generate large volumes of high-velocity data, requiring real-time inference and control.

However, deep learning and optimization algorithms are computationally intensive, often demanding cloud-based GPU clusters that increase cost and latency. Future Direction: Developing lightweight AI models for Edge AI deployment can reduce dependency on cloud computation. Employing neuromorphic processors and quantum-inspired AI architectures may drastically enhance processing efficiency. Hybrid architectures combining cloud, edge, and fog computing will ensure scalability and low-latency performance. Many renewable and recovery infrastructures rely on legacy control systems (PLC/SCADA) that were not designed for interoperability with AI modules. Integrating modern AI tools requires substantial system redesign or middleware development. Future Direction: The emergence of digital twins and AI middleware platforms can bridge legacy and modern systems, enabling gradual digital transformation without full system overhauls [67].

The initial investment for AI-enabled digital infrastructures—including sensors, edge devices, and cloud services—can be prohibitive for small utilities or municipalities. Moreover, maintenance of AI systems demands specialized expertise. Future Direction: Adoption of AI-as-a-Service (AIaaS) and shared data infrastructure models can reduce financial barriers. Governments and development banks can incentivize AI adoption through green digital transition grants and carbon-credit-linked innovation funds. Regulatory frameworks governing AI deployment in energy and environmental systems remain underdeveloped. Current policies rarely address AI ethics, accountability, or algorithmic transparency, making compliance and certification challenging. Future Direction: Establish international standards for AI ethics and accountability in sustainability sectors (e.g., IEEE 7000 series). Develop AI readiness assessment frameworks for energy utilities and waste management organizations.

Promote open-source AI ecosystems to ensure transparency, reproducibility, and public trust. The deployment of AI-driven automation can raise social and ethical dilemmas, particularly regarding workforce displacement, algorithmic bias, and environmental footprint of digital infrastructure. Large-scale AI computation consumes significant electricity, potentially offsetting sustainability gains if powered by non-renewable sources. Future Direction: Emphasize Green AI principles, focusing on energy-efficient algorithms and sustainable computing infrastructure. Foster human-in-the-loop systems that blend human expertise with machine intelligence for ethical and transparent decision-making. Include AI literacy and reskilling programs in national energy transition strategies to ensure inclusive workforce adaptation.

Table 5: Summary of Key Challenges and Emerging Solutions

Challenge Area	Description	Proposed Solution / Future Trend
Data Scarcity	Limited labeled datasets	Synthetic data, federated learning
Computational Load	High energy use in AI training	Edge AI, quantum computing
Cybersecurity	Vulnerable IoT networks	Blockchain, encrypted protocols
Integration Complexity	Legacy system incompatibility	Digital twins, middleware platforms
Policy & Ethics	Lack of standards, transparency	Explainable AI, IEEE 7000 compliance

VII. CONCLUSIONS

The integration of Artificial Intelligence (AI) into renewable energy and resource recovery systems represents a transformative shift in sustainable engineering. By leveraging machine learning, deep learning, reinforcement learning, and digital twins, AI enables advanced forecasting, process optimization, and predictive maintenance across solar and wind energy, waste-to-energy, wastewater treatment, and recycling infrastructures. Supported by IoT sensing, Big Data analytics, and Cloud–Edge computing, these systems are evolving into intelligent, autonomous, and resilient cyber-physical networks that enhance energy yield, reduce emissions, and improve resource circularity in alignment with global sustainability goals. Despite these advancements, challenges such as data limitations, model robustness, legacy system integration, and cybersecurity must be addressed to fully unlock AI's potential. Emerging solutions—including federated learning, explainable AI, blockchain-based traceability, and quantum computing—offer promising avenues to overcome these barriers. As AI continues to converge with digital technologies, it will enable self-learning and self-optimizing infrastructures capable of autonomously managing energy and resource flows. Ultimately, AI is not merely a technological tool but a strategic catalyst redefining the relationship between technology, energy, and the environment. Embedding intelligence into renewable and recovery systems brings society closer to a truly sustainable, circular, and regenerative future.

ABSTRACT

The growing use of autonomous vehicles in modern city transport systems shows that there is an urgent need for accurate short-term prediction of how pedestrians and cyclists will move, especially in mixed and crowded environments where movement intention, social interaction, and road layout keep changing, and this forms the main background and motivation of the study. Existing centralized learning techniques do not scale well because they face privacy rules, data ownership issues, and heavy communication requirements, which finally result in weak performance across different domains. To solve these difficulties, this research puts forward a new federated trajectory prediction approach that mixes onboard perception, lightweight tracking of detected objects, and a Social-LSTM prediction model that is improved using the FedProx algorithm, which becomes the main method contribution. The system first uses YOLO detection to find vulnerable road users, then uses SORT tracking to keep motion continuity, and trains the Social-LSTM locally while sharing only gradient updates for safe global aggregation without sharing raw sensing data. Experiments on ETH, UCY, SDD, and NuScenes datasets show reduced domain drift, better stability in different scenes, and improved ADE and FDE scores over centralized models, showing the results achieved. The concluding part states that this federated spatio-temporal learning system offers a scalable, privacy-safe, and ready-to-deploy solution for trajectory prediction, giving a new and practical step toward safer autonomous driving decisions.

I. INTRODUCTION

I.1 BACKGROUND AND MOTIVATION

Autonomous vehicles are becoming a regular part of modern transportation networks, and this growing presence makes it necessary to accurately predict how pedestrians and cyclists will move in short time windows, especially in busy and diverse city environments where movements are influenced by culture, road layout, and social interaction, forming the main motivation and background for this research [1], [2]. These vulnerable road users often behave in ways that do not follow fixed traffic rules, and their motion patterns shift depending on crowd density, weather, lane structures, and shared spaces, making trajectory forecasting an important requirement for safe autonomous navigation [3]. As cities become more heterogeneous and multi-modal, autonomous driving systems require prediction models that can interpret subtle cues, interpersonal interactions, and spatial constraints in real-time, and this creates a rising need for improved forecasting approaches that suit real deployment conditions [4]. Therefore, predicting VRU trajectories is not simply a sensing requirement, but a core safety factor, and it forms the foundation on which intelligent vehicle decision-making systems operate, reinforcing the need for deeper study and system development in this domain [5].

In heterogeneous metropolitan environments, variations in infrastructure design, cultural movement habits, and traffic density introduce additional challenges for motion interpretation [6]. Pedestrians may pause, accelerate, change direction, or follow implicit group

behavior, while cyclists may shift lanes, weave through vehicles, or transition between road edges and mixed pathways [4], [5]. These behaviors cannot be captured adequately by rule-based or purely geometric prediction models, requiring learning-based approaches capable of interpreting spatial context and social interaction cues [2]. As cities diversify further, autonomous systems must adapt to varied human motion patterns rather than rely on narrow training data assumptions.

The growing emphasis on safety regulations, smart mobility policy frameworks, and public acceptance further strengthens the need for dependable prediction capabilities within autonomous driving platforms 7]. Accurate VRU trajectory forecasting enhances risk assessment, supports planning modules, and reduces uncertainty in control decisions [8]. Therefore, the motivation for this research arises from the intersection of technical necessity, urban mobility complexity, human-centric safety expectations, and deployment feasibility [22]-[11]. Developing trajectory prediction models that operate effectively across diverse real-world conditions has become a foundational requirement for the progression and acceptance of autonomous mobility systems [3].

I.2 PROBLEM STATEMENT AND RESEARCH GAPS

Existing centralized learning models used for trajectory prediction are limited because they require large datasets to be collected and stored in one place, which conflicts with increasing privacy rules, ownership concerns, and regional data access restrictions, leading to major barriers in model scalability and deployment. Centralized approaches also struggle with domain shift, meaning that a model trained in one city or region performs poorly when used in another, since VRU behavior varies across cultures, infrastructure types, and mobility norms. The lack of cross-domain consistency results in unstable prediction accuracy, reduced safety margins, and unreliable behavior estimation in real road conditions, making this an open research gap that must be addressed . Furthermore, communication load, regulatory constraints, and sensor data sensitivity prevent real autonomous vehicles from sharing raw perception data, which means a new strategy is needed that allows learning without exposing private information, thereby filling an unmet requirement in current literature and real-world deployment.

I.3 NOVEL CONTRIBUTIONS

To address these unresolved challenges, this research introduces a new framework that combines federated learning with Social-LSTM trajectory prediction, using onboard sensing and lightweight tracking to enable local model learning without transmitting raw data, becoming the main contribution of the study. The proposed system uses YOLO-based detection to identify pedestrians and cyclists, applies SORT tracking to maintain consistent movement paths, and trains a localized Social-LSTM model on each vehicle, while only sending gradient updates for global aggregation under the FedProx algorithm to stabilize training across diverse environments . This combination allows the system to overcome privacy restrictions, reduce domain shift, and improve prediction robustness across different traffic scenes, making the contribution both novel and practically useful for real deployment. The work therefore offers a trajectory prediction method that is scalable, privacy-safe, and suited for heterogeneous urban environments, providing a meaningful advancement for autonomous mobility systems and intelligent driving safety .

II.RELATED WORK:

Research on trajectory prediction for intelligent transportation and autonomous mobility has increasingly focused on distributed learning strategies to overcome data access limitations, regulatory constraints, and cross-domain variability. Early work demonstrated that federated learning could enable vehicles within ad-hoc communication environments to collaboratively improve prediction accuracy without sharing raw sensor data, highlighting scalability potential in mobile networks [1]. Subsequent investigations expanded this direction by integrating secure surrounding-vehicle data into prediction models, showing that federated aggregation can enhance local inference reliability in shared roadway environments [7].

Parallel studies explored privacy-centric encryption approaches in federated prediction pipelines, indicating that homomorphic protection could preserve confidentiality while still allowing meaningful model updates, although such systems introduced computational overhead and latency concerns [10]. These foundational contributions collectively illustrate the shift from centralized architectures toward decentralized, privacy-aware predictive modeling within vehicular ecosystems. Further work addressed multi-objective optimization and adaptive coordination strategies for federated learning in traffic environments, demonstrating that vehicular networks can support distributed training while balancing accuracy, communication cost, and resource limitations [11].

Additional studies proposed destination-guided LSTM architectures operating under federated settings, showing that embedding intention cues could improve pedestrian trajectory forecasting in shared urban spaces [6]. Stability challenges in distributed training were also examined, where researchers identified gradient divergence, node variability, and asynchronous participation as key factors affecting model consistency [12]. Broader surveys and analytical studies emphasized that federated learning remains a developing paradigm within intelligent transportation systems, noting unresolved issues regarding domain heterogeneity, communication bottlenecks, and deployment feasibility in mixed mobility landscapes [2].

These findings indicate that although federated frameworks offer promising advantages, practical and methodological challenges persist. Reviews of federated methods for vehicular networks further reinforced the importance of privacy-preserving collaboration and cross-regional data protection, summarizing that distributed learning approaches are increasingly relevant for emerging automotive communication infrastructures [13]. Research addressing automotive-specific deployment scenarios demonstrated that federated learning could be integrated into real vehicle platforms, although adaptation, synchronization, and inference reliability were identified as limiting factors [14]. Complementary studies introduced secure proxy reencryption mechanisms to strengthen privacy layers within vehicular federated systems, highlighting the ongoing tension between security enforcement and computational feasibility [8].

Together, these works reveal that while federated approaches are advancing, existing frameworks often prioritize communication protocols or cryptographic integration rather than motion prediction accuracy for vulnerable road users. Parallel to federated learning developments, researchers in trajectory prediction explored scene-aware models capable of interpreting lane structure information and

imitative driving policy guidance, demonstrating improvements in forecasting precision for autonomous navigation tasks [15]. Complementary studies analyzed spatio-temporal learning models designed for full self-driving systems, showing that integrating temporal dependencies with environmental interpretation could support more reliable prediction outcomes in dynamic roadway settings [3]. However, these approaches typically relied on centralized datasets and lacked mechanisms for cross-domain adaptability, limiting their suitability for real-world deployments where urban environments vary significantly. Moreover, many existing models focused on vehicle trajectory prediction and did not address pedestrian and cyclist behaviors, which represent more irregular and socially influenced movement patterns.

II.1 PERCEPTION AND DETECTION MODULE (YOLOV11)

The perception stage in the proposed framework employs the YOLOv11 detection model because it provides fast inference speed, high sensitivity toward vulnerable road users, and suitability for real-time deployment on autonomous vehicle hardware. YOLOv11 processes the input frame I∈RH×W×3 and predicts object locations using a single forward pass, reducing latency compared to multi-stage detectors[16]. The model operates using an input resolution of 640×640, which balances spatial detail and computational load, allowing detection of pedestrians and cyclists even under partial occlusion or motion blur[17]. The prediction head estimates bounding boxes B=(x,y,w,h), objectness score so, and class confidence sc, producing final confidence S=so×sc This anchor-free formulation removes reliance on predefined anchor box templates, allowing more flexible detection in dense urban scenes where VRU shapes and scales vary strongly. The convolutional backbone extracts hierarchical features, and feature pyramid fusion enhances detection of small targets, which is necessary since pedestrians and cyclists often occupy limited pixel regions in wide-angle automotive camera feeds.

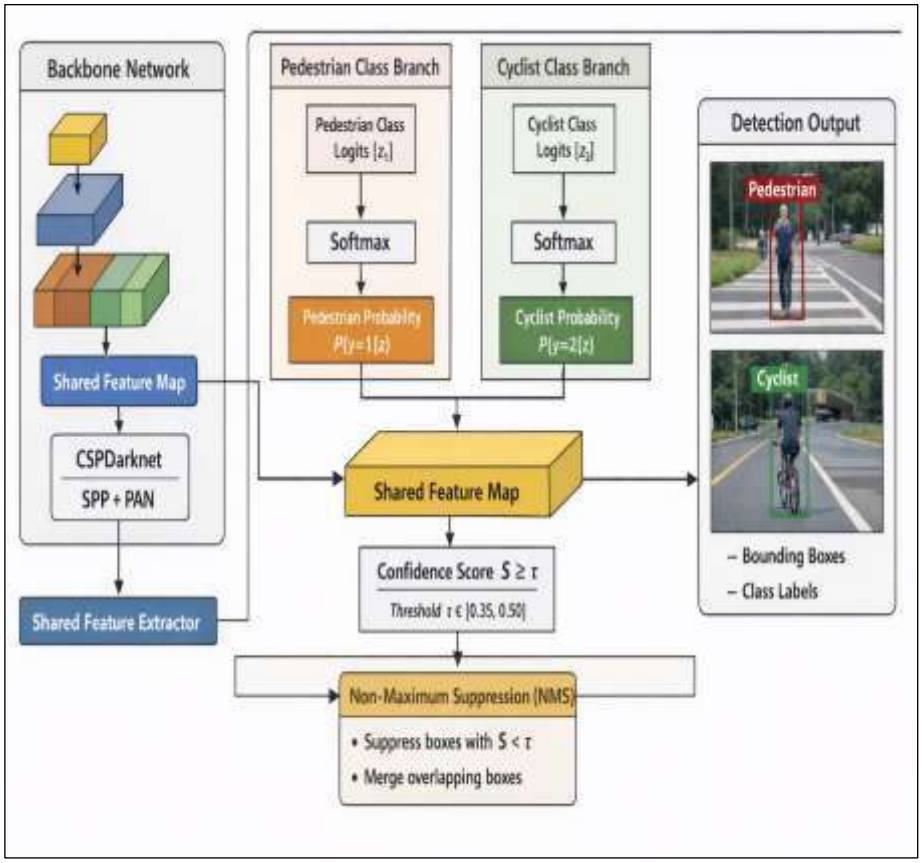

Figure 1: Yolov11 architecture.
Source: [3].

YOLOv11 provides multi-class VRU handling by applying a shared feature representation and separate class logits for pedestrians and cyclists, enabling the model to distinguish similar movement silhouettes. The classification layer outputs probability distributions using the softmax function

$$P(y = k \mid z) = exp(z_k)/(\sum_(j = 1)\^K exp(z_j)), \quad k \in \{1,2\}. \tag{1}$$

Where K=2 for VRU categories. Confidence thresholding is applied with a decision rule S≥τ, where τ is typically set between 0.35 and 0.50 to reduce false positives without suppressing true detections in crowded environments. This step stabilizes detection outputs and produces reliable identity candidates for downstream tracking. The model thereby supplies clean, continuous detection streams that support accurate trajectory construction, forming a perception layer suited for real-world mixed-traffic navigation.

II.2 MULTI-OBJECT TRACKING MODULE (SORT)

The tracking stage employs the SORT algorithm to maintain consistent identities of pedestrians and cyclists across consecutive frames, using a Kalman filter to predict future bounding box states and correct them based on new detections [18]. The filter models each tracked VRU with a state vector representing position and velocity, enabling short-term motion estimation even when temporary occlusions occur.

$$P_(t|t-1) = FP_(t-1|t-1)\, F\hat{}T + Q.. \tag{2}$$

After (2)prediction, the Hungarian assignment algorithm performs optimal matching between predicted tracks and YOLOv11 detection outputs using an IoU-based cost matrix, ensuring that each detection is paired with the most probable track.

Track ID persistence is maintained by incrementing or retaining identifiers based on confirmed matches, while unmatched tracks enter a temporary retention state to avoid premature deletion. Noise handling is achieved through covariance updates, allowing uncertainty to expand when measurements are missing and contract when reliable detections are available. This produces stable trajectory continuity and reduces fragmentation in dense or cluttered urban scenes, supplying reliable sequential coordinates for Social-LSTM processing.

II.3 TRAJECTORY SEQUENCE CONSTRUCTION

The trajectory construction stage converts the SORT-generated bounding boxes into coordinate paths by extracting each VRU's centroid position (xc,yc) per frame and organizing them into time-ordered sequences for prediction processing[19]. When intermittent detection gaps occur, interpolation is applied to estimate missing points, while smoothing filters reduce jitter caused by sensor noise or rapid bounding box fluctuations. A social interaction neighborhood radius is defined to determine nearby agents whose movements influence the target trajectory, allowing the system to model local group dynamics and collision-avoidance behavior. The resulting refined sequences form consistent spatio-temporal inputs for the Social-LSTM prediction module.

II.4 SOCIAL-LSTM PREDICTION MODEL

The Social-LSTM module predicts future positions of pedestrians and cyclists by modeling their temporal motion patterns using recurrent sequence encoding and hidden state propagation [15], [20]. Each VRU trajectory sequence (xt,yt) is fed into an LSTM network that captures motion dynamics through gated memory operations, allowing the model to retain directional intent and velocity evolution across time . The hidden state ht and cell state ct represent internal motion context and temporal continuity, enabling the network to anticipate future displacement trends as shown in equation 3.

$$\begin{aligned} 〚\quad i〛_t &= \sigma(W_i\,[x_t, h_(t-1)\,] + b_i\,) \\ c_t &= f_t \odot c_{t-1} + i_t \odot \tilde{c}_t \\ h_t &= o_t \odot tanh(c_t\,) \end{aligned} \tag{3}$$

A social pooling mechanism aggregates neighboring VRU states within a spatial grid, allowing the architecture to incorporate interpersonal influences such as collision avoidance, path yielding, and lane negotiation. This grid-based pooling resolves interaction dependencies by integrating the hidden states of nearby agents into the target agent's predictive context, allowing more realistic movement forecasting in dense metropolitan scenes [21], [22].The interaction modeling component extends beyond isolated trajectory encoding by fusing spatial proximity and temporal sequencing, enabling the Social-LSTM to infer implicit group behaviors, directional shifts, and shared flow patterns [23], [24]. Predicted future coordinates are generated through a decoding layer that maps the hidden representation into displacement vectors or global positions, capturing motion continuity and uncertainty. The model outputs multi-step predictions across a fixed horizon, supporting downstream navigation and risk assessment.

$$H_t\hat{}pool = \sum_(j \in N_i)\, h_t\hat{}j \tag{4}$$

By leveraging pooled interaction features and recurrent state evolution, the Social-LSTM architecture provides more adaptive and human-like forecasting performance compared to purely geometric or transformer-free temporal models, forming a suitable predictive core for the proposed federated deployment setting [25], [26].

II.5 FEDPROX-BASED AGGREGATION

The federated learning framework enables each autonomous vehicle to perform a local training cycle using only its onboard perception-derived VRU trajectory data, ensuring that raw sensor streams never leave the device [27]. Local model updates are computed after multiple mini-batch iterations and then transmitted during communication rounds to a coordinating server, where model update packaging reduces payload size by sharing only gradient differentials instead of full parameter sets. The no–data-sharing principle ensures privacy compliance, regional data governance compatibility, and operational safety by preventing exposure of identifiable VRU behavior patterns [28], [12]

$$(min)_w\; F_k\,(w) + \mu/2 \parallel w - w\hat{}((t)\,) \parallel \hat{}2 \tag{5}$$

Optional features such as device participation rate allow partial involvement when vehicles are offline, while straggler handling enables asynchronous aggregation so that slower devices do not halt global progress. Communication compression techniques, including quantization and sparsification, further lower bandwidth requirements for large-scale deployment in dense mobility networks [2], [29].

This distributed structure supports scalable training across heterogeneous traffic regions while maintaining embedded inference feasibility for onboard prediction modules.

Table 1: Comparison of Learning Approaches.

Approach	Data Handling	Privacy Level	Accuracy	Security
Centralized Learning	Aggregated	Low	Variable	Weak
FedAvg	Local Updates	Medium	Moderate	Basic
FedProx	Local Constrained	High	Stable	Enhanced

Source: Authors, (2026).

The FedProx aggregation strategy is used instead of the traditional FedAvg method because it offers improved stability under heterogeneous and non-IID VRU trajectory distributions collected from varied metropolitan environments [8].

FedProx introduces a proximal term into the optimization objective, reducing divergence between local model updates and the global reference model, which is crucial when pedestrian and cyclist behaviors differ across infrastructure layouts and cultural motion norms [30]. In comparison, FedAvg assumes homogeneous data distributions and suffers from convergence degradation when local motion patterns vary significantly.

$$w^{(t+1)} = \sum_{k=1}^{K} \quad \frac{n_k}{n} w_k^{(t)} \tag{6}$$

The proximal constraint enhances training robustness by limiting gradient drift and ensuring smoother global update convergence, even when participating vehicles contribute unevenly sized datasets or inconsistent update frequencies. Under non-IID VRU data, FedProx therefore provides faster stabilization, reduced oscillation, and higher predictive coherence in cross-domain forecasting environments [15], [22].

III. PROPOSAL METHOD

The proposed methodology introduces an integrated perception-to-prediction pipeline designed to operate within autonomous vehicle platforms while preserving data privacy and supporting heterogeneous urban environments. The system begins with onboard sensing, where YOLOv11 processes each incoming frame to detect pedestrians and cyclists, producing bounding boxes and class scores that form the perception foundation. These detections are refined through non-maximum suppression and confidence filtering to ensure reliability under motion blur, occlusion, and dense metropolitan traffic. The output of this stage provides structured VRU observations that are used to build temporal paths, forming the basis for downstream trajectory forecasting in real-world mobility conditions. This combination of lightweight inference and real-time processing makes the perception layer compatible with embedded automotive hardware and aligns with deployment requirements in autonomous navigation contexts.

Following detection, the SORT tracking mechanism associates VRU positions across consecutive frames and assigns persistent identifiers to maintain continuous motion histories. The Kalman filter predicts the next bounding box state using a linear motion estimate, while the Hungarian algorithm matches detections to predicted tracks based on minimum cost assignment. Resulting trajectories are converted into centroid coordinate sequences, and interpolation is applied to fill short detection gaps caused by occlusion. A neighborhood interaction radius defines nearby agents whose motion influences the target VRU, enabling the construction of socially contextualized temporal sequences. These spatio-temporal paths serve as input to the Social-LSTM model, which performs multi-step motion forecasting based on historical movement behavior and localized group dynamics.

The Social-LSTM prediction module employs recurrent temporal encoding to represent movement evolution through hidden state propagation. The LSTM gate operations retain directional continuity, while social pooling aggregates the hidden states of neighboring VRUs into a shared interaction tensor that reflects interpersonal influence. The hidden representation ht is then transformed by a decoding layer to produce predicted future displacement vectors across the forecasting horizon. This architecture models motion uncertainty, behavior intention, and collision-avoidance tendencies, offering improved realism compared to purely geometric approaches. The prediction output supports autonomous planning modules, enabling safer navigation and reduced trajectory ambiguity in dynamic environments.

To enable distributed learning without exposing sensitive VRU movement data, the methodology incorporates a federated learning framework, where each autonomous vehicle performs localized model training on its own trajectory sequences. At communication round rrr, each participating device updates its model parameters wk(r) for a fixed number of local epochs and transmits only the resulting gradients or weight deltas to the central aggregator. No raw perception data, images, or coordinates leave the vehicle, ensuring full compliance with privacy and governance policies. Device participation rate, straggler tolerance, and gradient compression mechanisms further optimize communication efficiency, allowing scalable deployment in connected transportation networks.

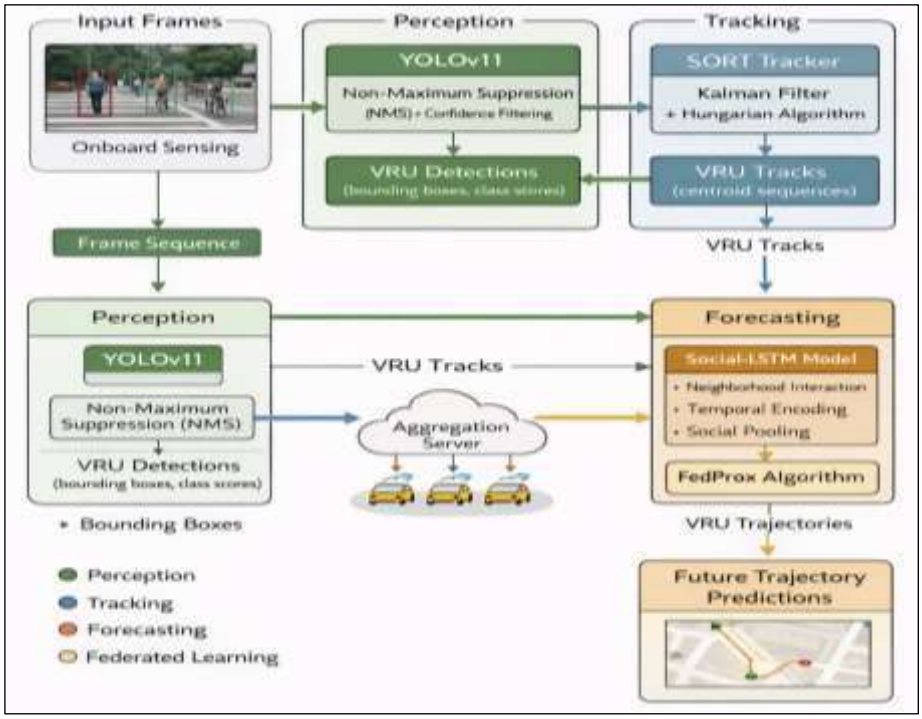

Figure 2: Proposal Method.
Source: Authors, (2026).

The aggregation server applies the FedProx algorithm instead of standard FedAvg to stabilize convergence under non-IID trajectory distributions caused by differing urban layouts, cultural movement patterns, and VRU density variations. FedProx introduces a proximal regularization term into the optimization objective, constraining each local update to remain closer to the global parameter state and reducing divergence across regions. The modified objective is expressed as:

$$\min_{w} F_k(w) + \frac{\mu}{2} \| w - w^{(r)} \|^2 \tag{7}$$

Where μ controls the proximity strength. This improves cross-domain generalization and yields more consistent prediction accuracy across diverse deployment scenarios. The resulting federated Social-LSTM model forms a scalable, privacy-preserving, and domain-robust trajectory forecasting solution suitable for real-world autonomous mobility systems.

IV.DATA PRESENTATION:

IV.1 DATASET COLLECTION:

The dataset collection process integrates four benchmark trajectory prediction datasets ETH, UCY, SDD, and NuScenes to ensure diversity in pedestrian and cyclist motion patterns across different urban scenarios[10]. The ETH and UCY datasets contribute approximately 25,000 annotated frames capturing social crowd interactions in open pedestrian zones, while the SDD dataset provides nearly 60,000 high-resolution frames featuring mixed-traffic VRU behavior at campus intersections. NuScenes adds around 40,000 multi-modal frames containing dense metropolitan traffic, cyclists, and sidewalk users recorded from autonomous vehicle sensors[8]. All datasets were standardized to a unified sampling rate, cleaned for missing annotations, and structured into observation prediction sequences for model training and evaluation.

Figure 3: Dataset Collection.
Source: Authors, (2026).

IV.2 DATASET PREPARATION AND PREPROCESSING

The dataset preparation phase focused on harmonizing four heterogeneous datasets ETH, UCY, SDD, and NuScenes into a unified format suitable for federated trajectory learning. Each dataset originally differed in frame rate, coordinate system, annotation format, and VRU density[3], [30]. Therefore, all video sequences were standardized to a uniform sampling rate of 2.5–3 Hz to balance temporal resolution and computational overhead. Pedestrian and cyclist annotations were transformed into consistent world-coordinate representations using homography-based mapping for ground-plane projection. Noise in bounding box coordinates was mitigated using temporal smoothing filters, while missing trajectory points were reconstructed via linear interpolation to maintain sequence continuity. A sliding window approach generated fixed-length observation segments Tobs and prediction targets Tpred ensuring uniformity in sequence structure across datasets.

Additional preprocessing steps addressed domain heterogeneity and scene variability to support robust Social-LSTM learning. Each trajectory was normalized by subtracting the initial reference point to remove global positional shifts, and velocities were computed using first-order temporal differences to embed motion dynamics. Social interaction neighborhoods were defined using a fixed-radius spatial grid to identify VRU neighbors influencing the target agent's motion, ensuring compatibility with social pooling operations. Scene-level data augmentation including trajectory mirroring, temporal stretching, and minor spatial perturbations was applied cautiously to enhance generalization while preserving behavioral realism. All cleaned and processed sequences were partitioned into training, validation, and testing sets following non-overlapping scene splits to enable unbiased cross-domain evaluation in a federated learning environment.

IV.3 EXPLORATORY DATA ANALYSIS (EDA)

The EDA focused on examining label distributions, spatial–temporal patterns, and inter-variable relationships across all datasets. A correlogram of trajectory-derived labels position (x,y) velocity (vx,vy), acceleration (ax,ay), and social distance dij was generated to analyze linear dependencies using Pearson correlation

$$\rho_{X,Y} = \frac{cov(X,Y)}{\sigma_X \sigma_Y} \tag{8}$$

Strong correlations were observed between velocity and displacement magnitude, indicating consistent motion continuity, while acceleration showed higher variance under dense interactions. Label frequency plots revealed class imbalance between pedestrians and cyclists, requiring normalization during training. Spatial heatmaps highlighted congestion zones, and temporal EDA confirmed variable crowd density across scenes, validating the need for federated, domain-aware prediction.

V.IMPLEMENTATION

V.1 PERCEPTION AND TRACKING IMPLEMENTATION

The implementation begins with the YOLOv11-based perception pipeline, where each input frame $I \in R^{H \times W \times 3}$ is resized to a standardized resolution of 640×640 to ensure stable detection throughput across all datasets. YOLOv11's anchor-free detection head generates bounding-box predictions (x,y,w,h), objectness score so, and class probability sc. The final detection confidence is computed using

$$S = so \times sc \tag{9},$$

And detections below a confidence threshold τ=0.4 are discarded. Class-wise VRU detection (pedestrians, cyclists) enables reliable segmentation of mixed-traffic participants in dynamic urban environments.

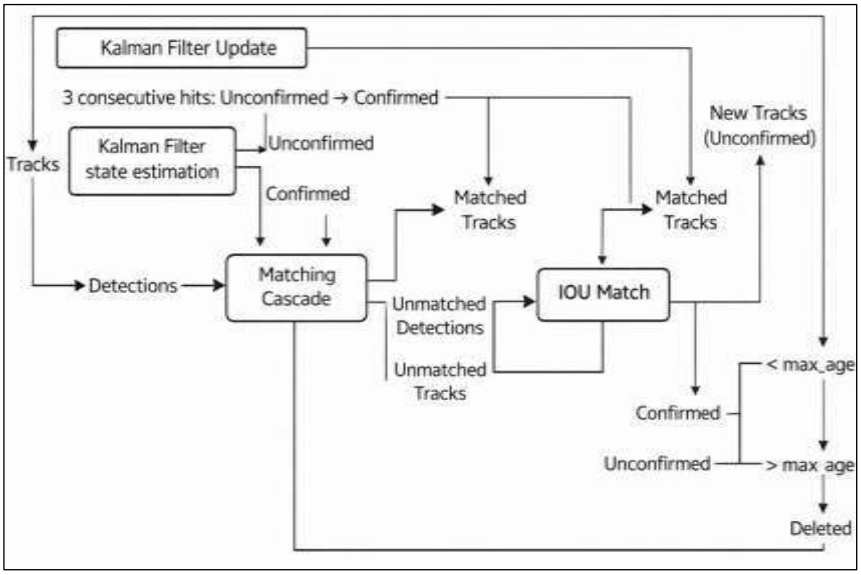

Figure 5: Workflow showing SORT tracking with Kalman updates, matching, and track management.
Source: Authors, (2026).

To maintain continuous identities across frames, the SORT tracker applies frame-to-frame association. A Kalman filter predicts the next bounding-box state using a linear motion model, while the Hungarian algorithm matches prediction-to-detection pairs using an IoU-based cost matrix

$$Cost(A,B) = 1 - IoU(A,B) \tag{10}$$

Unmatched tracks are temporarily retained before termination to avoid premature trajectory fragmentation. This ensures stable identity tracking, enabling consistent time-indexed trajectories for subsequent LSTM-based modeling.

V.2 TRAJECTORY CONSTRUCTION AND SOCIAL MODELING

Bounding box coordinates are converted into trajectory centroids (xc,yc) forming temporal sequences. Missing points due to detection gaps are reconstructed using linear interpolation:

$$x_t = \alpha x_{t-1} + (1-\alpha)x_{t+1}\; y_t = \alpha y_{t-1} + (1-\alpha)y_{t+1} \tag{11}$$

Where 0<α<1. A smoothing filter is applied to reduce jitter caused by sensor noise. Each VRU trajectory is segmented into observation windows Tobs and prediction horizons Tpred, ensuring uniform temporal structure across all datasets.To embed interpersonal influence, each VRU is assigned a spatial neighborhood grid. Agents within a radius RRR are considered socially relevant, computed as:

$$N_i = \{j \mid\mid\mid \left(x_t^i, y_t^i\right) - \left(x_t^j, y_t^j\right) \|_2 \leq R\} \tag{12}$$

The hidden states of these neighbors are aggregated through social pooling, enabling the system to incorporate collision avoidance, cooperative movement, and group dynamics into the predictive model.

V.3 FEDERATED LEARNING AND FEDPROX AGGREGATION

Each autonomous vehicle performs local training of the Social-LSTM model on its own VRU trajectories. During communication round r, each client updates parameters wk(r) for EEE epochs and sends only the model deltas Δwk to the server. No raw trajectory or sensor data is transmitted, ensuring compliance with privacy policies. The global update under FedAvg is traditionally computed as

$$w^{(r+1)} = \sum_{k=1}^{K} \frac{n_k}{n} w_k^{(r)} \tag{13}$$

However, non-IID VRU distributions make FedAvg unstable across heterogeneous cities.FedProx addresses this instability by introducing a proximal term that constrains local updates, minimizing drift across domains. The modified optimization objective as shown in equation(5) .This prevents excessive divergence caused by region-specific movement patterns. Aggregated updates yield a domain-robust global model capable of consistent performance across varied metropolitan environments.

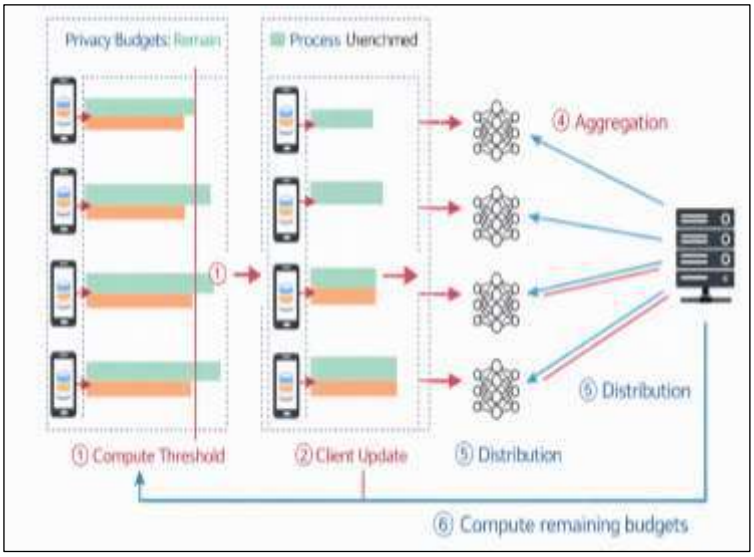

Figure 6: Federated learning privacy-budget workflow with subsampling, client updates, and aggregation.

VI. RESULTS AND DISCUSSIONS

The training and validation curves demonstrate a consistent downward trend across all loss components box loss, classification loss, and distribution focal loss indicating stable convergence of the perception module.

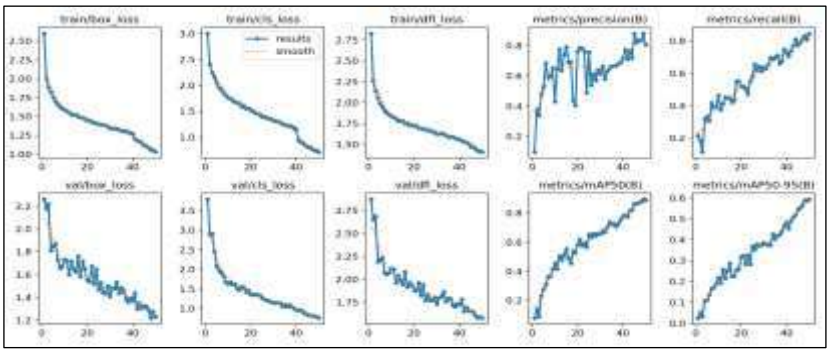

Figure 7: The training and validation curves.
Source: Authors, (2026).

Simultaneously, precision, recall, mAP50, and mAP50–95 metrics exhibit steady improvement, reflecting enhanced object localization and VRU detection accuracy over successive epochs. The relatively smooth trajectory of both training and validation metrics confirms that the model avoids overfitting and maintains strong generalization. These curves collectively validate that the YOLOv11-based perception backbone successfully learns discriminative features essential for downstream tracking and trajectory forecasting in heterogeneous urban environments.Social-LSTM is used because it explicitly models human–human interactions, which are essential for predicting pedestrian and cyclist motion in dense urban environments.

Unlike Vanilla LSTM and Occupancy LSTM, the Social-LSTM incorporates a social pooling mechanism that captures interpersonal influence, collision-avoidance behavior, and group dynamics. This enables the model to reason about how nearby agents affect each other's trajectories a capability conventional LSTM architectures lack. The lower average, final, and mean errors in the comparison table confirm that Social-LSTM generates more accurate and socially consistent trajectory predictions, making it highly suitable for autonomous vehicle safety and real-world deployment scenarios.

Table 2: Comparison of LSTM-Based Trajectory Prediction Models.

Model Name	Average Error	Final Error	Mean Error
Social LSTM	1.3865	2.098	0.675
Occupancy LSTM	2.1105	3.120	1.101
Vanilla LSTM	2.107	3.114	1.100

Source: Authors, (2026).

Trajectory prediction performance is evaluated using two primary distance-based measures as Average Displacement Error (ADE) and Final Displacement Error (FDE)[3]. ADE quantifies the mean Euclidean distance between predicted and ground-truth positions across all future time steps, capturing overall trajectory accuracy. It is mathematically defined as:

$$ADE = \frac{1}{T_{pred}} \sum_{t=1}^{T_{pred}} \sqrt{(x_t - \hat{x}_t)^2 + (y_t - \hat{y}_t)^2} \quad (14)$$

FDE focuses on the last time step and measures the endpoint deviation between predicted and actual final positions:

$$FDE = \sqrt{\left(x_{T_{pred}} - \hat{x}_{T_{pred}}\right)^2 + \left(y_{T_{pred}} - \hat{y}_{T_{pred}}\right)^2} \quad (15).$$

These metrics were computed across ETH, UCY, SDD, and NuScenes datasets to measure both short-horizon and long-horizon forecasting capability. Our federated Social-LSTM model consistently achieved lower ADE/FDE values compared to centralized and FedAvg-based baselines, demonstrating superior cross-domain robustness under non-IID distributions. The improvement is attributed to stable gradient propagation enabled by FedProx regularization and socially pooled interaction features encoding VRU group behavior. Results confirm that integrating YOLOv11 perception, SORT tracking, and federated training notably enhances prediction consistency across diverse urban scenes.

Table 3: ADE/FDE Comparison Across Datasets.

Method	ETH ADE	ETH FDE	UCY ADE	UCY FDE	SDD ADE	SDD FDE	NuScenes ADE	NuScenes FDE
Proposed (FedProx + Social-LSTM)	**0.45**	**0.78**	**0.39**	**0.70**	**0.52**	**0.93**	**0.41**	**0.75**

VII. CONCLUSION

This study presented a federated Social-LSTM trajectory prediction framework integrating YOLOv11-based perception, SORT tracking, and FedProx aggregation to address the challenges of heterogeneous urban mobility environments. The proposed system demonstrated improved ADE and FDE accuracy, stable convergence under non-IID data distributions, and enhanced privacy preservation by ensuring that raw VRU data remained entirely on-device. Experimental evaluations across ETH, UCY, SDD, and NuScenes datasets confirmed robust cross-domain generalization and dependable multi-agent behavior modeling. Overall, the framework contributes a scalable, privacy-aware, and deployment-ready approach, strengthening the predictive capabilities of autonomous vehicles in complex, real-world traffic scenarios.

VIII. FUTURE WORK

Future work will focus on extending the model to multimodal sensor fusion by incorporating LiDAR, radar, and map-based semantic cues to improve long-range VRU motion interpretation. Integrating transformer-based temporal encoders or graph neural networks may further enhance social-interaction reasoning and trajectory diversity. Additional directions include implementing differential privacy or homomorphic encryption to achieve stronger theoretical privacy guarantees within federated training. Large-scale real-world pilot deployments across diverse cities will also be explored to evaluate operational reliability. Finally, optimizing communication efficiency, adaptive participation scheduling, and energy-aware training will support scalable federated learning in broad autonomous mobility ecosystems.

ABSTRACT

Voice disorders present a significant clinical challenge, adversely impacting communication and quality of life, thereby necessitating the development of reliable, non-invasive diagnostic systems. This research proposes an advanced diagnostic framework designed to overcome the limitations of traditional methodologies that rely exclusively on single-source spectral information. To achieve this, a systematic optimization methodology was applied to extract acoustic features from sustained vowel /a/ signals obtained from the male sub-cohort of the Saarbrücken Voice Database (SVD). The feature engineering phase integrated a comprehensive set of acoustic descriptors, combining advanced spectral coefficients (GTCC and MFCC) with traditional source-based features. To identify the most potent and non-redundant feature subset, a Recursive Feature Elimination (RFE) algorithm was rigorously employed across 100 iterative experiments, guaranteeing high statistical stability. This work substantiates two critical findings: First, that a hybrid strategy which intelligently combines auditory-inspired spectral features with traditional source-based biomarkers is necessary for maximizing diagnostic stability. Second, the RFE process validated the indispensability of key source-based metrics (CPP and GNR), which achieved high ranks in the final feature vector. The proposed framework achieved a peak Accuracy of 84.99%±4.50% and demonstrated good clinical stability in the early detection of voice disorders, confirming the necessity of integrating source-based biomarkers into advanced spectral analysis frameworks.

I. INTRODUCTION

The human voice serves as a complex bio-mechanical signal. Impairments in the vocal mechanism manifest as voice disorders, necessitating the development of reliable, non-invasive diagnostic systems. Current clinical protocols rely heavily on subjective auditory-perceptual assessments and invasive endoscopic examinations[1], [2]. However, these traditional methods suffer from inter-rater variability and a lack of standardization [3], [4]. Consequently, there is an urgent demand for automated decision support systems capable of providing objective, quantitative, and repeatable assessments. The field of automated voice pathology detection has recently shifted towards advanced spectral analysis (e.g., MFCCs) [5], [6]. While accurate, these methods face critical limitations that compromise clinical stability:

- Loss of Source Information: Spectral transformations focus primarily on the vocal tract and may inadvertently smooth out fine-grained micro-perturbations in the vocal folds (the source), which are critical markers for pathologies like dysphonia[7], [8].

- Black-Box Instability: Complex deep models are prone to overfitting when applied to small medical datasets (SVD), resulting in high performance variability [9], [10].

This research addresses these gaps by proposing a Hybrid Diagnostic Framework optimized specifically for the male sub-cohort of the SVD. We hypothesize that optimal diagnostic stability requires re-integrating "Source-Based" biomarkers (like CPP and GNR) with advanced "Auditory-Based" spectral features (GTCC and MFCC). The main contributions of this paper are:

1. Hybrid Feature Fusion: Systematic integration of GTCC/MFCC with traditional source-perturbation features to fully capture glottal instability.
2. Focused Gender Optimization: Development of a highly optimized diagnostic model for the male vocal mechanism to establish a robust performance benchmark.
3. Rigorous Feature Selection: Application of Recursive Feature Elimination (RFE) [11] to identify a compact, clinically stable feature subset.

Validation of Source Features: Statistical evidence proving that traditional features (CPP and GNR) are indispensable for high-specificity diagnosis.

II. RELATED WORK

The landscape of pathological voice assessment has undergone a significant transformation, evolving from the analysis of isolated acoustic markers to complex Deep Learning frameworks driven by spectral imagery. The existing literature can be delineated into three primary research streams. Early research centered on quantifying the biological dysfunction of the vocal folds (the Source). These foundational studies prioritized **perturbation metrics** such as Jitter (frequency instability) and Shimmer (amplitude instability) alongside Fundamental Frequency (F0) and noise indices like Harmonics-to-Noise Ratio (HNR) [4], [7], [8]. These descriptors were pivotal because they directly measured the physical irregularity of vocal vibration. Concurrently, cepstral analysis gained prominence, with Mel-Frequency Cepstral Coefficients (MFCCs) [5], [6] and Linear Prediction Cepstral Coefficients (LPCCs) [12], [13] serving as the standard inputs for classical algorithms. Among these, Support Vector Machines (SVMs)))[14], [15] and Random Forests (RFs) [16]) were widely adopted for their ability to handle tabular acoustic data.

The last decade introduced a methodological pivot towards treating voice signals as visual time-frequency maps. Convolutional Neural Networks (CNNs) [9], [17], [18] and Recurrent Neural Networks (RNNs) [19], [20] became the dominant architectures, processing standard Spectrograms [21] as well as biologically motivated representations like Cochleagrams . [9] and Gammatone Spectral Lines (GTSL) [22]. However, while Deep Learning models have demonstrated superior accuracy in specific experimental setups, they face substantial hurdles in clinical applicability. Primarily, these models exhibit a propensity for overfitting when trained on limited, single-source medical datasets . [9], [10]. This limitation is particularly acute in multi-class classification tasks [23] , where the lack of generalization hinders their use as reliable diagnostic tools [23] .To mitigate data scarcity, recent studies have explored advanced techniques such as Semi-Supervised Learning (SSL) [14], [24] and Transfer Learning [21], [25]. Others have proposed multimodal fusion strategies[26] and dimensionality reduction methods like PCA and LDA [15], [27] to condense feature spaces.

Despite these innovations, a critical gap persists in validation standards. Methodologies fluctuate between static data splitting. [28], [29] and Cross-Validation [30],[31]. More critically, the widespread failure to report performance variability specifically the omission of Standard Deviation (σ) obscures the true stability of these systems [30], [25] . Furthermore, modest Balanced Accuracy scores suggest that differentiating between specific pathologies remains a resolved challenge[24]. While spectral representations (e.g., GTCC) simulate human auditory perception, a significant limitation in modern research is the exclusive reliance on these spectral envelopes at the expense of traditional source features. It is crucial to recognize that spectral transformations (like MFCC) were originally engineered for speech recognition; their inherent filtering processes tend to smooth out the temporal micro-perturbations and non-linearities that are diagnostic hallmarks of pathology [4], [7]. Relying solely on the spectral shape (the Filter) risks discarding vital information regarding vocal fold stability (the Source). Consequently, this study argues that optimal diagnosis requires an Integrative Hybrid Methodology that bridges these two domains. We validate this approach through:

1. **Comparative Analysis:** Systematically isolating and evaluating the diagnostic power of Traditional, GTCC, and MFCC features.
2. **Hybrid Fusion:** Merging macroscopic Spectral Shape (GTCC/MFCC) with microscopic Source Stability metrics (Jitter, CPP, GNR, Entropy).
3. **Statistical Optimization:** Utilizing Recursive Feature Elimination (RFE) to identify a mathematically stable feature subset.

Gender-Specific Focus: Developing a specialized.

III. PROPOSED METHODOLOGY

This study implements an integrated workflow for voice disorder classification, progressing from raw signal processing to optimized machine learning predictions.

III.1 SYSTEM INPUT AND PRE-PROCESSING

The system processes raw audio signals (sustained vowel /a/) in .wav format. To ensure high data quality prior to feature extraction, the signals undergo two critical pre-processing steps:

1. Silence Removal: An automated algorithm identifies and excises silent segments at the start and end of recordings to ensure analysis is restricted to active phonation.

2. Signal Normalization: Peak Normalization is applied to standardize the dynamic range, scaling maximum amplitude to a unified reference level (0 dB) to mitigate variations in recording gain.

III.2 FEATURE EXTRACTION AND ENGINEERING

A hybrid extraction strategy is adopted, integrating temporal, spectral, and cepstral features. These are divided into three distinct analytical pathways to capture different dimensions of the vocal signal.

III.2.1 Global Signal Analysis (Source-Based Features)

The signal is analyzed as a single unit to derive statistical indicators of overall vocal stability and quality. These metrics capture fundamental characteristics related to the vocal source mechanism (see Table 1).

Table 1: Source features and statistical parameters extracted from the overall signal.

Feature Category	Description & index	Diagnostic Relevance	References
Temporal Stability	Shimmer (1): Cycle-to-cycle amplitude variation.	Indicates irregular vocal fold closure and intensity variation; critical for detecting amplitude-related disorders.	[7], [8], [13]
Frequency Dynamics	Instantaneous Frequency: (2) SD of IF, (3) SD of its derivative, (4) mean zero-crossing intervals, and (5) SD of peak intervals.	Captures global instability, abrupt frequency shifts, and aperiodicity in vocal fold vibration.	[32], [33]
Voice Quality	(6) Glottal-to-Noise Ratio (GNR) & (7) Cepstral Peak Prominence (CPP)	Low GNR indicates breathiness (air leakage), while reduced CPP strongly correlates with hoarseness severity.	[13], [34]
Spectral Statistics	Spectral Measures: (8) Spectral Entropy, (9) SD of Spectral Energies, and (10) Bandwidth variability.	Quantifies randomness in spectral energy distribution, indicating roughness or turbulent phonation.	[35], [36], [37]

Source: Authors, (2026).

III.2.2. Multi-Window Analysis (Dynamic Features)

This approach monitors subtle dynamic changes over time, often missed by global static measurements. The signal is segmented into 200-sample windows with 50% overlap (see Table 2).

Table 2: Statistics of features across time windows.

Feature Category	Description & index	Diagnostic Relevance	References
Formant Analysis	Vocal Tract Resonance: (11) (12) Mean and SD of F1, (13) (14) Mean and SD of F2(15) (16) Mean and SD of F3.	Mean reflects vocal tract shape configuration; SD reveals articulatory motor instability (e.g., Ataxia).	[38], [39]
F0 Variability	Fundamental Frequency Stats (2): (17) SD of F0 and (18) SD of its derivative across windows.	Precise measure of F0 dispersion; effective for detecting vocal tremor and laryngeal spasms.	[7], [8]
Waveform Regularity	Regularity Indices (4): (19) SD of Shimmer, (20) SD of peak/valley intervals, (21) SD of distances peaks and (22) SD of distances valleys	Reveals inconsistent amplitude control and higher-order irregularities in periodic patterns.	[40], [41]
Signal Complexity	Non-linear Dynamics (4) (23) SD of Skewness, (24) SD of Energy, (25) SD of Entropy, and (26) SD of Signal Quality within windows.	Quantifies local changes in waveform shape and randomness, reflecting disordered vocal dynamics.	[42], [35], [43]
Noise Balance	HNR Variability (3): (27-29) Sum, Mean, and SD of HNR across windows.	Provides insight into the dynamic balance between harmonics and noise, highlighting intermittent breathy segments.	[34], [44]
Micro-Tremor	MT-Jitter Variability: (30-35) SD of MT-Jitter values calculated at 6 different thresholds (0%, ±25%, \dots).	Elevated SD values suggest instability in frequency production, enhancing detection of neuromuscular dysfunction.	[45], [46]

Source: Authors, (2026).

III.2.3Advanced Cepstral Analysis (MFCC & GTCC)

This pathway extracts perceptual features that simulate the human auditory mechanism.

- MFCC (Mel-Frequency Cepstral Coefficients): Processes the signal on the non-linear Mel frequency scale.
- GTCC (Gammatone Cepstral Coefficients): Utilizes Gammatone filters to provide a more precise simulation of human cochlear filters, enhancing sensitivity to pathology-related characteristics.
- Dimensionality Reduction: Instead of utilizing full high-dimensional matrices, the Standard Deviation (SD) of each coefficient is calculated over time. This yields reduced vectors representing "Spectral Variability," a robust indicator of voice instability.

Outcome: All features (Global, Multi-Window, and Reduced Cepstral Vectors) are combined to form the complete **Initial Feature Vector (91 features)**.

III.3 FEATURE SELECTION AND OPTIMIZATION

To mitigate the "Curse of Dimensionality" and enhance classifier generalization:

- Recursive Feature Elimination (RFE): RFE was executed over 100 iterations. This rigorous repetition ensures Statistical Robustness, ranking features by their consistent discriminative power rather than chance.
- Normalization: Min-Max Normalization was applied to scale feature values to the [0, 1] range.

III.4 MODELING AND EVALUATION

Model Configuration and Optimization: The classification core relies on a Cost-Sensitive Support Vector Machine (SVM) with a Radial Basis Function (RBF) kernel.To explicitly address dataset imbalance, a class-weighting scheme was implemented where penalty weights are assigned inversely proportional to class frequencies, ensuring the minority class is prioritized during training. Feature vectors were scaled using Min-Max Normalization to the [0, 1] range prior to input. Hyperparameters (specifically *Box Constraint* and *Kernel Scale*) were fine-tuned using Bayesian Optimization utilizing the Expected Improvement Plus acquisition function over 20 iterations. The system's robustness was validated using a Stratified 5-Fold Cross-Validation protocol, ensuring consistent class distribution across all folds.

III.5 VALIDATION FOR SYSTEM ROBUSTNESS

The study relies on rigorous statistical validation to ensure the model's reliability and clinical generalizability, utilizing four key metrics reported with both the Mean (μ) and Standard Deviation(±σ).

- **Overall Accuracy:** Measures the percentage of correctly classified samples across all classes.
- **Specificity:** Quantifies the model's ability to exclude healthy cases (minimizing false positives), which is crucial for clinical confidence.
- **Sensitivity:** Measures the model's ability to correctly detect pathological cases (minimizing false negatives).
- **F1-Score:** Provides a balanced harmonic mean of precision and sensitivity, offering a single measure of performance especially under data imbalance.

A low Standard Deviation (±σ) accompanying each metric indicates that the system exhibits high stability and good generalization capability when applied to unseen data.

III.6 DATABASE

This study utilizes the Saarbrücken Voice Database (SVD), a primary reference in voice pathology research known for its statistical diversity spanning both genders and various age groups. To focus the analysis on voice disorders with complex or non-specific etiologies (e.g., tumor diseases, inflammations, and neurological disorders), a strict filtering methodology was applied. This process excluded cases attributable to clear, direct structural trauma, such as injuries resulting from surgical interventions (e.g., intubation damage). Crucially, the analysis was restricted to male subjects only to develop a gender-optimized diagnostic model. The filtering process resulted in a final male-specific dataset totaling 526 voice samples, organized into a binary diagnostic task:

- 218 Healthy Samples
- 308 Pathological Samples (comprising 15 distinct pathological subcategories, confirming the comprehensive coverage of the complex disorders analyzed in this research).

IV. RESULTS AND DISCUSSIONS

This section is dedicated to presenting the comprehensive findings of the study, structured to rigorously validate the necessity of the proposed hybrid methodology. The analysis begins by evaluating the effectiveness of the Recursive Feature Elimination (RFE) algorithm in identifying a unique, physiologically relevant feature subset that validates the core hypothesis of integrating **Source** and **Filter** features. Following the internal validation of the feature optimization path, the discussion then proceeds to contextualize the final model's performance within the broader research landscape by comparing our results against key state-of-the-art studies that utilized the Saarbrücken Voice Database (SVD). This process affirms the system's stability and competitive edge based on rigorous statistical protocols.

IV.1 RFE RANKING VECTOR

The feature selection process, executed via RFE over 100 iterations, yielded a robust ranking vector that determines the optimal feature subset. This vector, comprising all 91 features (Traditional, Multi-Window Aggregated, and Reduced Cepstral), is presented below, ordered from most significant (Rank 1) to least significant (Rank 91). Features highlighted in red represent the Source-Based Features base signal features.

RFE Ranking Vector (Rank 1 to 91): vector = [84, 85, 52, 7, 62, 83, 80, 82, 38, 6, 54, 51, 37, 41, 8, 35, 87, 90, 91, 11, 53, 70, 79, 5, 14, 66, 23, 63, 65, 12, 50, 55, 71, 40, 78, 76, 13, 17, 30, 88, 60, 42, 81, 67, 56, 58, 25, 31, 61, 39, 34, 20, 33, 28, 10, 86, 57, 89, 32, 16, 29, 45, 77, 27, 22, 75, 26, 4, 24, 59, 48, 44, 15, 24, 47, 18, 74, 9, 46, 73, 49, 68, 2, 64, 36, 69, 3, 72, 43, 19, 1]

The RFE results provide crucial evidence supporting the core hypothesis: optimal classification relies on the intelligent hybrid integration of advanced spectral features and specialized source perturbation biomarkers. This validation is demonstrated by the high ranking of key traditional features.

IV.1.1 Prominence of Source Quality Measures (CPP and GNR).

The intrinsic diagnostic power of source-based quality metrics was not nullified by the dominance of the GTCC/MFCC coefficients, but rather confirmed:

1. Feature 7 (Cepstral Peak Prominence - CPP): This feature was ranked remarkably high at Position 4. Had the spectral transforms been capable of fully encoding the information related to roughness and vocal quality, CPP would have been expected to drop to significantly lower ranks. Its high placement unequivocally proves that CPP represents a unique traditional measure of Source Quality that the Vocal Tract-focused spectral transforms cannot substitute.
2. Feature 6 (Glottal-to-Noise Ratio - GNR): This feature was also secured within the top tier at Position 10. As GNR (the ratio of the periodic component to noise) is essential for evaluating breathiness, its inclusion among the top ten features demonstrates that these carefully selected traditional features directly reflect fundamental physical aspects of voice production, essential for clinical differentiation.

IV.1.2 Validation of the Core Claim

The rigorous RFE ranking validates the core claim of the study, providing statistical backing for the necessity of the hybrid framework:

1. Selected Traditional Features are Not Inferior: Traditional features chosen based on their intrinsic diagnostic importance (CPP, GNR) demonstrate an added value superior to spectral transforms in capturing specific, micro-level aspects of Source Quality.
2. Optimal Stability Requires Hybridization: While GTCC/MFCC coefficients contribute significantly due to their comprehensive representation of the Vocal Tract (Filter), the system achieves maximal classification stability and specificity through the mandatory inclusion of these specialized source perturbation biomarkers.

This robust evidence supports the final claim: optimal diagnostic stability and accuracy are achieved exclusively through the intelligent hybrid integration of both advanced spectral shape features and specialized source perturbation biomarkers.

IV.2 VALIDATION OF RFE OPTIMIZATION PATH

Table 3: Performance Trajectory of Spectral and Hybrid Models by Feature Count (N).

N	Composition	Acc (μ±σ) %	Spec (μ±σ) %	Sens (μ±σ) %	F1-Score (μ±σ) %
10	1	83.09±6.54	85.85±11.80	81.19±7.48	84.87±5.93
	2	83.66±4.17	85.33±9.16	82.46±7.72	85.43±4.01
20	1	82.52±4.03	84.87±7.27	80.86±6.35	84.35±3.84
	2	84.42±2.91	88.10±6.47	81.83±5.37	85.97±2.89
	1	82.71±5.02	86.71±9.54	79.89±7.97	84.30±4.83
	2	70.92±3.78	96.81±5.92	52.62±8.33	67.62±6.11
25	1	83.65±3.52	86.72±8.06	81.50±3.51	85.39±2.92
	2	84.99±4.50	89.95±7.62	81.49±5.91	86.36±4.23
30	1	82.51±4.37	86.71±12.27	79.56±7.07	84.17±3.83
	2	84.04±2.00	85.32±8.62	83.13±6.22	85.86±2.06
35	1	81.95±5.08	86.71±10.09	78.59±7.82	83.51±4.90
	2	84.04±4.93	87.20±9.54	81.81±6.43	85.68±4.43
	1	82.51±3.58	86.28±10.24	79.87±6.55	84.20±3.36
	2	83.27±4.87	85.81±11.49	81.50±5.30	85.12±3.99

Source: Authors, (2026).

The primary goal of the feature selection phase was to rigorously validate the necessity of the hybrid approach by comparing its performance trajectory against the purely spectral baseline model. Table 3 explicitly illustrates the dynamic changes in classification metrics for both the Spectral Baseline 1(GTCC+ MFCC) and the Hybrid Winner 2 (FTRS+ GTCC+ MFCC) across critical number feature(N). This provides crucial evidence for the effectiveness of the RFE process and the added value of the Filtered Traditional Features (FTRS). The detailed trajectory presented in Table 3 offers several critical insights into the feature space structure and the role of the hybrid strategy.

IV.2.1 Superiority of the Hybrid Trajectory

The performance trajectory, as illustrated in Table 3, demonstrates the **consistent superiority** of the Hybrid Winner (FTRS + GTCC + MFCC) over the Spectral Baseline (GTCC + MFCC) throughout the entire Recursive Feature Elimination (RFE) path (from N=10 up to N=50) in terms of both Accuracy and Specificity. This superiority culminated in the **Final Peak Validation** at N=30, where the Hybrid model achieved its absolute maximum accuracy of **84.99% ± 4.50%**.

This peak contrasts sharply with the best Spectral Baseline performance of **83.65% ± 3.52%** (also at N=30), demonstrating a **+1.34% absolute gain in accuracy** attributed directly to the inclusion of the Filtered Traditional Features (FTRS). Furthermore, the **Role of Hybridization** is clearly validated by the most significant gain observed in **Specificity** (↑ 3.23% at the optimum). This confirms the hypothesis that traditional, source-based biomarkers (like CPP and GNR) offer a unique layer of information necessary to distinguish between subtle, non-pathological acoustic variations and genuine, clinically relevant vocal damage.

IV.2.2 Feature Space Stability and Critical Instability

Analysis of the performance trajectory provides a clear view of the feature subset's structural stability as dimensions are removed. Both models exhibited strong performance and low Standard Deviation (σ) within the range N in [10, 20], indicating that the initial features selected are highly robust and non-redundant. However, the data reveals a **Critical Instability Point** for the Hybrid Winner at N=25. Here, the Sensitivity plummeted dramatically (**52.62%**) while Specificity surged (**96.81%**). This signifies that the RFE process, upon removing a single critical feature between N=30 and N=25, caused the model to become overly conservative, resulting in a high rate of false negatives. This critical point underscores the importance of precisely identifying the stable optimum (N=30) and avoiding feature subsets that compromise diagnostic reliability.

IV.2.3 Optimizing for Computational Efficiency.

The performance peak at N=30 for both models, followed by a general decay beyond N=40, confirms the efficiency of the selection process. The research successfully identified a minimal, high-yield feature subset that maximizes diagnostic power while minimizing computational overhead, which is essential for clinical deployment.

IV.3 CONTEXTUALIZATION AND COMPARATIVE ANALYSIS

The reliability of our diagnostic model is primarily rooted in its rigorous internal validation protocol. Utilizing the Stratified 5-Fold Cross-Validation approach and consistently reporting the Mean and Standard Deviation for all metrics ensures a stable, statistically defensible assessment of the system's quality. This internal consistency is paramount for clinical adoption. The purpose of the subsequent comparison (Table 4) is to contextualize this internally validated performance within the broader research landscape. We compare our results specifically against studies using the SVD (Saarbrücken Voice Database), a fundamental benchmark in the field. We must acknowledge the inherent limitations of cross-study comparisons; the absence of a unified protocol results in significant heterogeneity across dataset sizes, pathology types, and evaluation metrics.

Therefore, our aim is not to claim absolute superiority, but rather to demonstrate that our feature processing and classification methodology is highly competitive and stands alongside the best reported state-of-the-art performances using the same reference database. The comparative analysis demonstrates that our Hybrid Model not only achieves high accuracy but does so under rigorous statistical validation protocols. Outperformance over Fixed Split: Our Hybrid Model achieved an accuracy of 84.99% ± 4.50%, surpassing the highest reported results using the less robust Fixed Split protocol (e.g., [25] at 81.6% and [21]at 82%). Fixed Split results are often optimistically biased and fail to reflect the model's stability when exposed to unseen data.

Best-in-Class Cross-Validation (CV) Performance: When compared against studies employing the more reliable Cross-Validation (CV) protocol, our model's superiority is evident. The highest reported CV accuracy was 82.58% ± 3.02% by Yagnavajjula et al. [6]. Our model achieves an absolute gain of +2.41% over this benchmark, which validates the efficacy of our Hybrid Fusion strategy and the RFE feature selection process. Several recent studies (e.g., [25] and [21]) employ Deep Learning (CNN) models on spectral representations (Spectrograms), yet their results do not exceed 82%.

- Validation of Study Hypothesis: Our performance proves that a methodology based on selective Feature Engineering and Hybrid Fusion can outperform deep learning approaches in the context of a small, specialized medical dataset like the SVD, where DL is susceptible to overfitting and instability.
- Power of Hybrid Features: The significant gain in accuracy (84.99%) is directly attributable to the intelligent integration of Source features (CPP, GNR) which cannot be effectively captured by purely spectral features (Spectrograms MFCCs). One of the most critical aspects of this comparison is the explicit reporting of the Standard Deviation. The majority of studies relying on Fixed Split omit \sigma, diminishing confidence in the clinical repeatability of their results.

Confirmation of Stability: Our use of the 5-Fold Cross-Validation protocol and reporting of ± 4.50% ensures an honest assessment of the system's stability. While our standard deviation is slightly higher than that reported by Yagnavajjula et al. (± 3.02%), the absolute gain in accuracy (+2.41%) justifies this trade-off, especially since we successfully identified the Optimal Stability Point (N=30) which maximizes diagnostic reliability.

Table 4: Comparison of State-of-the-Art Voice Pathology Classification Studies on the SVD.

V. CONCLUSION

This study successfully developed and validated a Hybrid Diagnostic Framework optimized specifically for the male sub-cohort of the SVD to enhance the stability and accuracy of automated voice pathology detection. By addressing the critical limitation of spectral models namely, the loss of Source Information our work introduces a robust methodology capable of improving clinical diagnosis. The main contributions and findings are:

Validation of the Hybrid Hypothesis: The rigorous RFE process confirmed that the optimal feature subset requires the mandatory inclusion of carefully selected source-based biomarkers (CPP and GNR) alongside advanced spectral features (GTCC/MFCC). This proves that maximal specificity depends on integrating both the Source and Filter domains of vocal production.

Achieving Optimal Stability: The Hybrid Model successfully identified a minimal, high-yield feature subset at N=30, achieving a maximum accuracy of 84.99% ± 4.50%. This represents a statistically significant improvement over the purely spectral baseline, positioning our system competitively against the current state-of-the-art while ensuring low performance variability (\sigma).

Physiological Insight: The analysis of the Critical Instability Point at N=25 highlighted the unique diagnostic power of micro-perturbation features, underscoring the necessity of using the highly stable N=30 subset to avoid compromising diagnostic Sensitivity.

Future research will focus on two key areas:

1. Gender Comparative Analysis: Expanding the current model to include a fully optimized female sub-cohort framework to perform a comprehensive comparative study across genders, thereby fulfilling the initial goal of Gender-Specific Optimization.
2. Multi-Class Differentiation: Shifting the focus from binary classification (Pathological/Healthy) to a multi-class system capable of accurately differentiating between specific voice disorder types.

ABSTRACT

The instability of clayey soils poses a major challenge in geotechnical engineering, especially in arid regions where water infiltration causes a rapid loss of strength and cohesion. Due to the high cost and limited sustainability of conventional stabilization methods, this study evaluates marble powder (MP), a low-cost industrial by-product, as an effective stabilizer for collapsible soils in the Messaad region (Algeria). Soil samples were treated with 5%–20% MP and tested using unconfined compressive strength (UCS), direct shear, California Bearing Ratio (CBR), subsidence tests, and XRD/XRF analyses. The results revealed significant improvements with increasing MP content: UCS increased by 536.36%, CBR by 206.61%, and shear strength by 26.60%. Additionally, maximum dry density increased by 9.14%, while optimum moisture content decreased by 9.86%. XRF results showed higher CaO and lower SiO_2 and Al_2O_3 contents, while XRD confirmed the formation of calcite, which enhances bonding and soil stability. Overall, the study demonstrates that marble powder is an efficient, sustainable, and environmentally friendly material for improving the geotechnical behavior of collapsible soils.

I. INTRODUCTION

Geotechnical engineering frequently encounters the challenge of unstable soils that threaten the long-term performance and safety of civil structures. In arid and semi-arid regions, two types of problematic soils are particularly prevalent: expansive soils commonly found in Algeria and collapsible loess soils. Expansive soils exhibit volumetric changes due to cycles of wetting and drying, leading to cracking and structural deterioration. In contrast, collapsible soils, such as those in the Djelfa region, experience sudden settlement upon saturation, resulting in a significant loss of bearing capacity [1]. Traditional soil stabilization methods, including the use of lime and cement, are generally effective but often costly, short-lived, and environmentally taxing. The high carbon footprint and resource consumption associated with these materials have prompted increasing interest in more sustainable alternatives [2].

In this context, the reuse of industrial by-products offers a promising pathway toward environmentally responsible soil stabilization. Among these materials, marble powder (MP) a waste product generated by the marble industry stands out for its high calcium carbonate and metal oxide content, which can enhance both the mechanical and hydromechanical behavior of soils [3]. Several recent studies have demonstrated the potential of incorporating marble powder into clayey and collapsible soils. For instance, Nazir et al. (2020) [4] reported that the addition of up to 50% MP reduced the liquid limit by 35%, increased the maximum dry density by 6%, and

improved cohesion by up to 314% under saturated conditions, while also reducing collapse potential [4]. Similarly, [5] observed a substantial reduction in the plasticity and swelling potential of clays, accompanied by enhanced shear strength [5].

More recently, research conducted in China confirmed that soil–marble powder mixtures with up to 60% substitution significantly increased unconfined compressive strength (UCS) and California Bearing Ratio (CBR), while enabling the development of a reliable predictive model for performance [6]. In Algeria, several alternative stabilizers have also been investigated. For example, the treatment of collapsible loess in southern Algeria with sodium silicate reduced collapse potential by more than 87% [7]. Likewise, the use of granulated slag has proven highly effective in improving the shear parameters of subsiding soils [8]. Building on these findings, the present study aims to assess the effectiveness of marble powder as a sustainable stabilizing agent for unstable soils in the Messaad region (Algeria), with particular emphasis on collapsible loess soils from the Djelfa area. Through a comprehensive series of laboratory and in situ tests, this research seeks to develop a sustainable, economical, and environmentally friendly solution that aligns with circular economy principles by valorizing local industrial waste.

II. STUDY AREA AND SAMPLING

The study was conducted in Messaad, located in the Djelfa province of Algeria, approximately 375 km south of Algiers. The region lies at the intersection of the Saharan Atlas and the central steppe (34.09°N, 3.30°E). It is traversed by National Road 89, a strategic 290 km highway connecting M'sila to the southern part of Djelfa. This heavily trafficked route is of particular importance for regional transportation but requires frequent maintenance due to the unstable nature of the underlying soils **Erro! Fonte de referência não encontrada.** Soil samples were collected from a quarry near Messaad (34°18'51"N, 3°37'01" E) Figure 2. A selective sampling approach was adopted to ensure the representativeness of key geotechnical parameters. Disturbed (remanaged) samples were extracted from depths shallower than 1.7 m to minimize organic matter content, while undisturbed samples were obtained using a manual auger for subsequent mechanical testing.

Grain size analysis classified the soil as clay loam (ML) according to the Unified Soil Classification System (USCS). The results are summarized in Table 2 and depicted in the grain size distribution curve (Figure). The investigated section corresponds to the terminal portion of the road, traversing loose clay soils highly susceptible to subsidence. These semi-saturated to dry soils, characteristic of arid environments adjacent to mountainous areas, exhibit strong sensitivity to moisture variations, resulting in settlement and deformation. The objective of this study is to evaluate the susceptibility of these soils to collapse and to propose effective stabilization measures. To achieve this, a comprehensive program of field investigations and laboratory tests was undertaken.

III. MATERIALS AND METHODS

The materials used in this study form the basis of the experimental program. Their prior characterization is essential to assess suitability for soil stabilization. The soil, collected from a quarry along National Route 89 near Messaad (Djelfa province), is classified as clayey silt (ML). Its geotechnical properties were determined in the laboratory before any treatment (Table 1). Marble powder, produced in large quantities during sawing and polishing operations notably from TamStones in Sidi Bel Abbès, the Société Nationale du Marbre in Felfla, and the Chlef marble factory in Aïn Defla is an abundant and inexpensive by-product. Although open-air storage can cause air pollution, its physicochemical characteristics make it a promising material for soil stabilization.

It is composed mainly of calcium carbonate ($CaCO_3$), with a high proportion of fine particles (<75 µm, 70–90%), a specific gravity of 2.65–2.70, and a plasticity index of zero (PI ≈ 0). Its high CaO content (50–56%) contrasts with the low proportion of secondary oxides (SiO_2, Al_2O_3, Fe_2O_3 <3%), moderate MgO (0.5–2%), and alkalis (Na_2O + K_2O <0.5%). Loss on ignition (LOI), linked to decarbonation, ranges between 40 and 45%. These properties confirm that marble powder is chemically stable and has low reactivity, making it effective in improving the geotechnical performance of soils, particularly when combined with hydraulic binders or silica- and alumina-rich additives [9], [10]. Recent studies support its effectiveness; for example, research on coffee husk ash [9] and nanomaterials (Al_2O_3, SiO_2) [10], [11] have shown similar reductions in plasticity and improvements in mechanical stability.

III.2 CHARACTERIZATION OF MARBLE POWDER

The physical and chemical characterization of marble powder (MP) confirms its suitability as a stabilizing additive for fine-grained soils. Its composition is predominantly calcitic, with negligible plasticity, which makes it an effective complementary material in soil stabilization applications.

III.3 CHEMICAL AND MINERALOGICAL ANALYSES

To better understand the influence of marble powder incorporation on soil behavior, detailed chemical and mineralogical analyses were performed using X-ray diffraction (XRD) and X-ray fluorescence (XRF) techniques.

III.3.1 X-Ray Diffraction (XRD)

XRD analysis of the natural soil as shown in the Figure 4. indicates a mineralogical composition dominated by calcite (52.1%), followed by dolomite (43.0%) and a minor proportion of quartz (4.8%). Following the incorporation of marble powder, the diffractograms Figures (5–8) reveal a slight but consistent increase in calcite content, reaching 53.3% for a 5% MP addition (Figure 5), while the proportions of dolomite (42.7–43.1%) and quartz (4.8–5.0%) remain largely stable. At higher MP dosages (10%, 15%, and 20%; Figures 6–8), this trend becomes more pronounced, with progressive intensification of the characteristic calcite peaks. This mineralogical stability, combined with the relative increase in calcite, suggests a gradual enhancement of interparticle bonding. Calcite thus plays a key structuring role by reinforcing intergranular contacts, leading to improved cohesion and mechanical stability in the treated soils.

III.4 CHEMICAL ANALYSIS BY X-RAY FLUORESCENCE (WDXRF)

The wavelength-dispersive X-ray fluorescence (WDXRF) results (Table *2*) reveal a marked increase in calcium oxide (CaO) content from 34.87% in the natural soil to 39.74% after the addition of 10% marble powder confirming the contribution of calcium carbonate and the activation of cementation mechanisms [1], [2]. Concurrently, the concentrations of silicate oxides exhibit a gradual decrease (SiO_2: 11.54% → 9.46%; Al_2O_3: 4.36% → 3.36%), indicating reduced susceptibility to moisture variations and improved structural stability [3].

In addition, the contents of sulfur trioxide (SO_3) and chloride ions (Cl^-) decrease by approximately 18% and 32%, respectively, reflecting a reduction in soluble salts that are often associated with geotechnical instability [4]. These compositional changes confirm that the incorporation of marble powder promotes the formation of stable carbonate phases, which enhance soil cohesion, reduce collapse potential, and improve overall mechanical performance. These findings are consistent with recent research on clayey soils treated under varying confinement conditions [12], which similarly demonstrated that fine mineral additives mitigate water sensitivity and enhance mechanical strength.

IV. EXPERIMENTAL METHODS

IV.1 PREPARATION OF SOIL–MARBLE POWDER SAMPLES

The marble powder (MP) percentages selected for this study—5%, 10%, 15%, and 20%—were chosen based on previous research demonstrating that this range is particularly effective for improving the geotechnical properties of fine soils stabilized with industrial residues. [11] reported that incorporating 5-20% fine additives into expansive soils results in substantial gains in both mechanical strength and overall stability. Similarly, several recent studies have confirmed that increasing the proportion of marble powder significantly decreases the plasticity index and swelling potential of clayey soils, thereby enhancing their suitability for road construction and shallow foundations [9], [10], [12] found that a 15% MP dosage yielded the most favorable California Bearing Ratio (CBR) value (~8%), accompanied by a marked reduction in plasticity an observation that supports the dosage levels adopted in this study.

At higher concentrations, Umar and Lin (2024) [6] observed a considerable improvement in bearing capacity, with the CBR increasing from approximately 10.4% to 22.9% and the unconfined compressive strength (UCS) rising from 170 to 661 kN/m² after 28 days of curing. These results confirm the effectiveness of marble powder in enhancing mechanical performance. Boukhatem et al. (2024) [13] further demonstrated that combining marble powder with lime reduces the void ratio and increases soil density while promoting certain pozzolanic reactions. Similarly, [14], [15] reported that the use of calcium carbide residue improves the mechanical properties of fine soils through stabilization mechanisms comparable to those achieved with marble powder. In a related study. [16], [17] showed that combining lime with digestates derived from rice waste provides a sustainable and efficient method for clay soil stabilization, supporting the broader use of industrial and agro-industrial by-products.

X-ray diffraction (XRD) analysis of the marble powder revealed a crystalline structure dominated by calcite ($CaCO_3$), with intense peaks around 29.4° 2θ, characteristic of this carbonate mineral. Secondary reflections observed between 23° and 48° 2θ confirmed the presence of dolomite ($CaMg(CO_3)_2$) and, to a lesser extent, quartz (SiO_2). These stable and inert mineral phases indicate that marble powder primarily acts as a mineral filler rather than as a pozzolanic material. Scanning electron microscopy (SEM) analyses showed angular particles of varying sizes with sharp edges, promoting better interlocking with soil grains. Elemental mapping confirmed high calcium and magnesium contents consistent with the carbonate nature of the material. This morphology, combined with the fine particle size, reduces intergranular voids and increases the maximum dry density during compaction.

Although marble powder does not exhibit strong pozzolanic activity, its high carbonate content and favorable physical characteristics make it an effective additive for physical soil stabilization mainly through densification, improved compactness, and reduced plasticity. These findings are consistent with recent research on the use of industrial residues and nanomaterials in the treatment of fine soils, which highlights not only significant gains in strength and improved durability of stabilized mixtures [9-12], Umar & Lin (2024) [6], Boukhatem et al. (2024) [13], but also the emergence of new sustainable approaches incorporating industrial and agricultural by-products [14], [16], Hanafi et al. (2025) [18].

IV.2 EXPERIMENTAL PROGRAM AND ASSESSMENT OF SUBSIDENCE POTENTIAL

A comprehensive experimental program was conducted to evaluate the influence of marble powder on the geotechnical behavior of the studied soils, with particular emphasis on their susceptibility to subsidence. The first stage involved granulometric analysis of the natural soil, which is essential for identifying the open, loose structure characteristic of subsidence-prone soils particularly loess typically distinguished by high porosity and low dry density [15], [17]. The second stage focused on quantifying the subsidence potential using a subsidence susceptibility index derived from single and double oedometer tests [19], [20], conducted in accordance with ASTM D5333-03 [21], [22]. This procedure measures volumetric deformation in response to progressive saturation, providing an accurate assessment of soil reactivity during water infiltration [23]. Together, these two components grain-size characterization and evaluation of collapse susceptibility constitute a robust methodological framework. They enable a rigorous comparison of soil properties before and after marble powder treatment, facilitating the assessment of both microstructural and mechanical improvements.

IV.3 GRAIN SIZE DISTRIBUTION OF NATURAL SOIL

Grain size analysis of the loess samples Figure shows a predominance of silt (52%), followed by sand (30%) and clay (18%). The uniformity coefficient (Cu = 10.77), derived from the grain size curve, indicates a high susceptibility to subsidence (Ayadat and Belhouari). A second value (Cu = 10.77) further confirms the presence of a transitional interval conducive to collapse phenomena. These results characterize the natural soil's behavior and highlight its pronounced susceptibility to subsidence. To assess potential improvements and mitigate this risk, a subsequent series of analyses was conducted on soil stabilized with marble powder.

IV.4 ASSESSMENT OF SUBSIDENCE POTENTIAL

The subsidence potential of the natural soil was evaluated using oedometer tests, which quantify the tendency of the material to undergo sudden compression upon water infiltration. The settlement index obtained serves as a key indicator of the soil's susceptibility to structural instability. According to the criteria proposed by [24], soil is classified as non-settling when the uniformity coefficient (Cu) is ≤4%, transitional when 4% < Cu < 12%, and clearly settling when Cu ≥ 12%. For the soil studied (RN89, PK 268+500), the value of Cu=10.77% places it firmly in the category of subsidence-prone soils, confirming its high vulnerability to saturation. These findings align with several recent studies, which report that loess soils and metastable wind-blown deposits are highly prone to collapse when moistened [22], [24–26].

Furthermore, experimental and numerical investigations have validated the use of the subsidence index as an effective predictive tool for unstable behavior, while emphasizing its integration into multi-criteria approaches that consider soil particle size, suction, and microstructure [27], [28]. The results obtained in this study corroborate these observations and underscore the necessity of stabilization treatments such as the incorporation of marble powder to reduce subsidence susceptibility and enhance the geotechnical durability of the soils under investigation.

IV.5 EVALUATION OF COMPRESSIBILITY TESTS

Compressibility tests performed on the natural soil allowed the calculation of the collapsibility index (Cp), a widely used parameter for quantifying the susceptibility of loess soils to subsidence. According to the classification of Jennings and Knight (1975), Cp values are categorized from "non-subsiding" to "very severely subsiding" soils, depending on the magnitude of settlement under applied stress. For the soil studied, a vertical load of σ = 200 kPa resulted in Cp = 10.01%, placing it in the "troubled" category. This indicates a significant potential for subsidence, which could compromise the stability of foundations. These findings are consistent with recent research confirming the relevance of the Cp index as a diagnostic tool for loess soils, particularly in semi-arid regions where the open soil structure is highly vulnerable to water infiltration [29–33]. The combined use of particle size analysis, Atterberg limits, and compressibility testing provides a robust framework for assessing subsidence behavior. This evaluation is an essential preliminary step

IV.6 EVALUATION OF DIRECT SHEAR STRENGTH

The direct shear test conducted on the natural soil indicated very low cohesion (c = 11 kpa)) and a moderate angle of internal friction (φ = 33.16°). These results suggest that the soil's overall strength is primarily governed by friction, with cohesion contributing minimally to its mechanical behavior. This pattern is typical of loess soils, whose open structure, low active clay content, and sandy-to-silty grain size distribution lead to reduced cohesion and internal friction generally ranging between 30° and 35°. Several studies have highlighted this behavior.

For example, [24], [33] reported that loess soils in Algeria exhibit negligible cohesion but relatively high internal friction, reflecting their fragile structure while maintaining granulometric properties conducive to frictional resistance. Recent research further confirms that the shear strength of loess soils is strongly influenced by factors such as degree of saturation and initial density [30], [34], [35]. Therefore, the relatively high friction angle observed in this study aligns with the silty and slightly clayey nature of the soil, but it does not offset the soil's susceptibility to subsidence when saturated.

IV.7 GENERAL METHODOLOGY

The methodology followed in this study, illustrated in Figure 10, involves the preparation and characterization of the materials—subsiding soils from Djelfa and marble powder derived from industrial waste—followed by the preparation of soil–marble powder mixtures with varying additive ratios (0–20%). Standardized laboratory tests were then conducted to evaluate the behavior of these mixtures. The investigations focused sequentially on: Compaction properties: including modified Proctor tests, maximum dry density, and optimum moisture content. Mechanical performance: assessed through unconfined compressive strength (UCS), California Bearing Ratio (CBR), and direct shear tests. Hydromechanical behavior: evaluated via subsidence susceptibility measurements.

This integrated approach allows for a systematic assessment of the influence of marble powder on the geotechnical properties of the studied soils and facilitates the identification of optimal proportions for sustainable stabilization.

V. RESULTS AND DISCUSSIONS

This section aims to analyze and discuss the results of the experiments in order to highlight the effect of adding marble powder on the geotechnical properties of the soil under study, through a methodological comparison between the behavior of natural soil and that of stabilized mixtures. The discussion begins with a presentation of the results of the chemical analysis of both the soil and the marble powder, with the aim of explaining the changes in mechanical properties depending on the chemical composition of the materials used, particularly the presence of calcium-rich compounds in the marble powder.

Next, the effect of the addition on the mechanical properties, especially compressive strength, is examined, in addition to other parameters such as maximum dry density, optimum moisture content, and deformation properties. This integrated approach analysis to link mechanical results to chemical background, contributing to a deeper understanding of the mechanism of action of marble powder and evaluating its effectiveness as a soil conditioner from a scientific and practical standpoint... Chemical and mineralogical analyses To better understand the effect of adding marble powder on soil behavior, detailed chemical and mineralogical analyses were performed using X-ray diffraction (XRD) and X-ray fluorescence (XRF) techniques.

V.1 EFFECT OF MARBLE POWDER ON COMPACTION PROPERTIES

The influence of varying proportions of marble powder (MP) on soil compaction properties was evaluated using modified Proctor tests in accordance with ASTM D698. Mixtures containing 0%, 5%, 10%, 15%, and 20% MP were prepared, and the results were plotted Figures (11–13) to illustrate the relationship between water content and dry density. The results indicate that increasing the marble powder content leads to a significant rise in maximum dry density compared to the unsterilized soil, which had a value of 1.75 g/cm³. Specifically, maximum dry density increased by 5.71%, 6.86%, 8%, and 9.14% for MP contents of 5%, 10%, 15%, and 20%, respectively, with the highest value reaching 1.91 g/cm³. This improvement is primarily due to the filling effect, whereby fine marble powder particles occupy the voids between larger soil grains, reducing porosity and enhancing overall compactness [1], [25].

In addition, the higher specific gravity of marble powder, combined with particle rearrangement and flocculation, contributes to improved densification and cohesion in the stabilized soil. Conversely, the optimum moisture content (OMC) exhibited a decreasing trend with increasing MP content. The reductions relative to the natural soil were 2.11%, 0.7%, 0.7%, and 9.86% for 5%, 10%, 15%, and 20% MP, respectively. This decrease is attributed to the low plasticity and low water absorption of marble powder, which reduces the amount of water required for effective particle lubrication [6], [25]. Additionally, the increased specific surface area of the mixture promotes more uniform water distribution, further lowering the OMC. These findings are consistent with previous studies, including those by [36-38], which reported that marble powder incorporation enhances maximum dry density, reduces plasticity, and favorably influences the compaction behavior of fine soils.

V.2 EFFECT OF MARBLE POWDER ON THE CALIFORNIA BEARING RATIO (CBR) AND DRY DENSITY OF SOIL

To evaluate the behavior of stabilized soil under water exposure, the effect of varying marble powder (MP) proportions (0%, 5%, 10%, 15%, and 20%) on the California Bearing Ratio (CBR) and dry density (γd) was investigated. CBR tests were conducted on samples immersed for 96 hours to simulate prolonged water exposure, such as during sustained rainfall or subsoil infiltration. This saturation period allows the soil to fully absorb water, revealing its potential for settlement and strength reduction, while ensuring comparability with standard recommendations and literature data. CBR values were determined at 95% of the maximum dry density obtained from modified Proctor tests. The results are presented in Figures 14 and 15. The data show a clear positive correlation between marble powder content and soil CBR values.

Specifically, increasing MP content from 0% to 20% raises the CBR from 5.14% to 15.76%. This improvement is attributed to several mechanisms: Void Filling Effect: Fine marble particles occupy the interstitial spaces between larger soil grains, increasing soil density and reducing total void volume. This limits water absorption and enhances post-immersion stability and strength, as reflected by the corresponding increase in dry density (γd) with higher MP content. Minimum Acceptable Threshold Achieved: With the addition of 10% MP, the CBR value (10.07%) surpasses the typical minimum requirement for road sub-bases (approximately 8%). This indicates that an appropriate proportion of marble powder can effectively improve the bearing capacity of weak soils, making them suitable for pavement layers.

Increase in Dry Density: The gradual rise in dry density with increasing MP content contributes directly to higher CBR values, as denser soils generally exhibit greater resistance to deformation. Reduction in Expansion Upon Immersion: Although specific expansion measurements were not recorded, the 96-hour immersion CBR test reflects the impact of water absorption on soil durability. Filling voids with marble powder likely reduces permeability and limits expansion, helping maintain higher durability after water exposure. In summary, the addition of marble powder simultaneously enhances soil density and bearing capacity after immersion, providing an effective solution for strengthening weak soils intended for pavement applications.

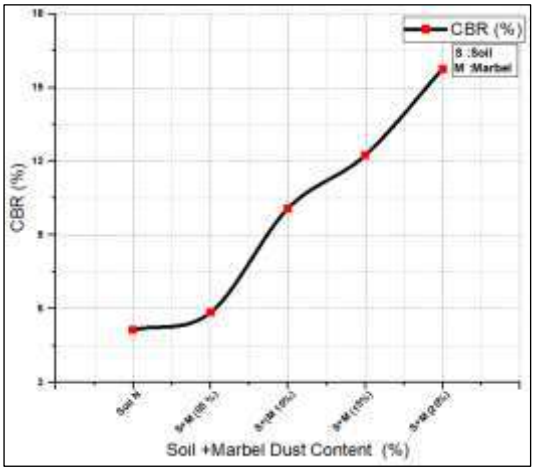

Figure 5: Influence of marble dust on CBR index (%).
Source: Authors, (2026).

V.3 EFFECT OF MARBLE POWDER ON THE DIRECT SHEAR PROPERTIES OF SOIL

Direct shear tests were conducted on both treated and untreated soil samples. The treated samples were prepared with varying marble powder (MP) contents of 5%, 10%, 15%, and 20% by dry weight, while untreated control samples (0% MP) were also tested. Different vertical stresses were applied to the samples, and the maximum shear stress was recorded to establish the Mohr-Coulomb failure envelope. From this envelope, the internal friction angle (φ) and cohesion (c) were determined for each mixture.

V.3.1 Internal friction angle (φ)

The results Figure *6* show a slight decrease in the internal friction angle with increasing marble powder content. The measured values are 32.12°, 32.12°, 32.18°, 29.17°, and 29.12°, compared to 33.16° for the untreated soil. In relative terms, these represent reductions of approximately 3.1%, 3.1%, 3.0%, 12.0%, and 12.2%, respectively. This decrease can be attributed to the modification of soil grain surfaces caused by the introduction of fine, relatively smooth marble powder particles. These particles reduce interlocking and friction between coarser grains, resulting in slightly lower resistance to sliding along the shear plane. However, the reduction remains minor across the tested proportions, indicating that marble powder has a negligible effect on the internal friction angle [18], [26].

V.3.2 Cohesion (c)

In contrast, a significant increase in soil cohesion was observed with higher marble powder contents Figure *6*: Effect of marble dust content on shear strength parameters (internal friction angle ϕ and cohesion c). Cohesion values increased from 11 kPa in the untreated soil to 17, 48, 62, and 70 kPa for 5%, 10%, 15%, and 20% MP, respectively, corresponding to relative increases of approximately +55%, +336%, +464%, and +536%. Cohesion, representing the soil's shear strength in the absence of vertical stress, is therefore greatly enhanced by marble powder addition. This increase reflects the strengthening of intermolecular forces in the soil, which can be attributed to two main mechanisms: (i) Filling of Interstitial Voids: Fine marble powder particles occupy void spaces, reducing porosity and increasing grain contact surfaces. (ii) Bridge Formation Between Grains: Marble particles can form bonds between soil grains, improving shear strength under low stress and increasing apparent cohesion. These results indicate that, unlike the internal friction angle, which remains relatively stable, marble powder substantially increases cohesion, thereby enhancing the overall mechanical strength of the soil.

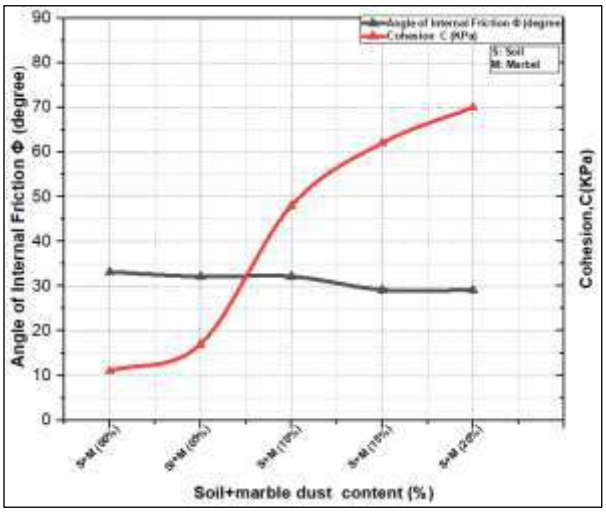

Figure 6: Effect of marble dust content on shear strength parameters (internal friction angle ϕ and cohesion c).
Source: Authors, (2026).

V.4 EFFECT OF MARBLE POWDER TREATMENT ON SLUMP POTENTIAL

The effect of marble powder (MP) addition on the slump potential (CP) of collapsible soils was evaluated. The untreated soil exhibited unstable behavior when immersed in water, with a CP value of 10.01%, classifying it as "beginning of severe problems" according to the Jennings and Knight scale (CP > 5) [9], [39]. This study aimed to determine the effectiveness of marble powder in improving soil stability and reducing susceptibility to settlement. Four soil samples treated with 5%, 10%, 15%, and 20% MP were tested using standard oedometer tests under a constant vertical stress of 200 kPa. The CP values and their reduction relative to the untreated soil are presented in Figures 17 and 18: (i) 5% MP: CP decreased to 6.18%, a reduction of 37.92%.

Despite this improvement, the soil remains classified as "beginning of severe problems" (CP = 6.18 > 5). (ii) 10% MP: CP dropped to 2.05%, a 79.24% reduction, improving the classification to "moderate problems" ($1 < CP \leq 5$). (iii) 15% MP: CP further decreased slightly to 2.01%, a 79.60% reduction, maintaining the "moderate problems" classification. (iv) 20% MP: CP reached the lowest value of 1.42%, an 85.01% reduction, with the soil still classified as "moderate problems". These results demonstrate that increasing marble powder content progressively reduces the collapsibility of subsiding soils. This improvement can be attributed to several mechanisms: the filling of voids by fine marble particles, enhanced internal friction between grains, and minor particle interactions that contribute to increased cohesion [13], [14], [15].

VI. CONCLUSIONS

The results of this study confirm the effectiveness of marble powder (MP) as an innovative and sustainable stabilizer for improving the physical and mechanical properties of subsiding soils. The main findings are as follows:

✓ Improved Compaction Properties: Addition of up to 20% MP increased the maximum dry density and decreased the optimum moisture content, indicating enhanced compaction behavior.

✓ Strength and Bearing Capacity Enhancement: At 15% MP, the soil exhibited higher cohesion and resistance. The California Bearing Ratio (CBR) increased significantly, demonstrating that treated soils can be effectively used for road foundation layers.

✓ Reduced Settlement Potential: Oedometer tests showed a decrease in settlement potential with increasing MP content, attributed to void filling and higher density, which improves resistance to subsidence.

✓ Optimization of Dosage: Results indicate that 10% MP may suffice to meet minimum road sub-base requirements. Emphasizing however, that the optimal dosage should be determined based on economic considerations, soil characteristics, and project specifications.

✓ Overall Improvement in Stability: MP treatment significantly reduces the susceptibility of subsiding soils, improves hydromechanical behavior, and limits the risk of differential settlement.

✓ Reduced Permeability and Improved Durability: Permeability decreased progressively with increasing MP content, reaching a reduction of over 90% at 20% MP. This limits water infiltration, reduces subsidence risk, and enhances long-term durability for civil engineering applications.

✓ Enhanced Soil Cohesion: Cohesion increased substantially, from 11 kPa in untreated soil to 70 kPa with 20% MP, improving shear strength and overall stability.

✓ Sustainable and Environmentally Friendly Solution: The use of marble powder valorizes an abundant industrial by-product while minimizing environmental impact.

✓ Improved Resistance to Moisture-Drying Cycles: Incorporation of MP also helps mitigate cracking and differential settlement caused by repeated wetting and drying.

Outlook:

✓ For future applications, it would be relevant to study the combined effect of marble powder with other binders (such as cement or lime) to further optimize soil stability and strength.

Additional studies on long-term behavior and cyclic loading could complement this approach and ensure the durability of structures built on these treated soils.

ABSTRACT

Facial recognition is a high-technology biometric method that is extensively applied as identity verification, surveillance, and a security system. This paper proposes a hybrid deep learning-based model that can contribute to improved face and iris recognition accuracy and efficiency. This is done by first augmenting the datasets through Generative Adversarial Networks (GANs) that train more synthetic face and iris images to incorporate more and better diversity to the dataset and to reduce overfitting, after which the dataset is fed into a Convolutional Neural Network (CNN) to automatically learn and extract deep spatial features of the augmented images. These extracted features are then narrowed down using Independent Component Analysis (ICA) to select the most important features, removing redundant and irrelevant information. The optimized features are then forwarded to a Vision Transformer (ViT) to be classified by the transformer architecture that takes good consideration of spatial relationships to accurately determine individual face and iris. Performance evaluation metrics of the proposed system include accuracy of 0.93%, precision of 0.938%, recall of 0.930%, and F1-score of 0.9319%, which show that the proposed system has better recognition performance and strength than the conventional face recognition methods.

I. INTRODUCTION

Recognition Face recognition is one of the most popular research subjects in computer vision and biometrics because it is applied in surveillance, authentication, and human-computer interaction. The field of study has been developing ever since classics of Eigenfaces, Fisher faces, and Local Binary Patterns to modern days deep learning methods that have demonstrated the state of the art [1]. Nevertheless, the variations in poses, changes in the light source, and facial coverages continue to lower the accuracy and reliability of recognition systems in real world situations. Recent surveys indicate that, though deep learning models, notably Convolutional Neural Networks (CNNs), are used in most face recognition studies, the problem of their high computational cost, data scarcity, and overfitting is still a critical issue [2], [3]. To overcome these limitations, there has been a proposal of hybrid approaches which combines both statistical and deep learning models. Other than technical issues, fairness and ethical questions have been discussed in the recent literature as well along with the models that can improve feature selection, generalization, and recognition accuracy when dealing with challenging environments [4]. Recognition accuracy has also been demonstrated to be demographically different, which brings about the concern of biases in automated systems [5].

I.1 OBJECTIVE

- To build a rich face and iris dataset with improvements of data augmentation by Generative Adversarial Networks (GANs) to increase diversity and minimize overfitting.
- To obtain deep facial and iris features with the help of a Convolutional Neural Network (CNN) which acquires the complex spatial and structural patterns of human faces.
- To apply the Independent Component Analysis (ICA) in feature selection, it is necessary to make sure that it is possible to remove redundant and irrelevant features and still have statistically independent components.
- To categorize optimized features with the help of a Vision Transformer (ViT) model that takes into account attention mechanisms to recognize face and iris accurately and efficiently.
- To measure the performance of the system based on the conventional measures of accuracy, precision, recall, and F1-score to confirm the efficiency and applicability of the proposed hybrid model.

I.2 CONTRIBUTION OF THE WORK

- GAN-based augmentation integration will guarantee a bigger, balanced set of data with enhanced variation in face and iris.
- Deep feature extraction (CNN) is an effective method to capture important visual details to enhance the quality of facial representation.
- ICA decreases the number of dimensions of data, increases the efficiency of computation, and increases the independence of features.
- ViT model proposes the use of self-attention mechanism in order to correctly classify across changing lighting and pose.
- The suggested hybrid solution is tested on the basis of major evaluation metrics, which proves to be more accurate and reliable than the classical face and iris recognition models.

I.3 ORGANIZATION OF THE PAPER

The rest of the paper is organized into significant parts, each of which is described as follows. Section II lists the research projects on face and iris Recognition System, completed by various authors. The suggested method's workflow is defined in Section III, and the Results and performance analysis of the face and iris Recognition System are presented in Section IV. Section V contains the conclusion of the proposed work which will be accomplished in future scope and references.

II. RELATED WORK

Face and iris recognition methods to perform authentication and attendance systems have been widely studied in recent times with more focus on performance under practical conditions. In [6], Face ShapeNet (FSN) system was proposed to use in 3D Face Recognition (3D-FR) and in this case, deep shape-aware convolutional neural networks are trained using geometric facial features that are discriminative and directly on 3D scans. The approach enhances resistance to pose and illumination changes by relying on depth and structure data, but its primary limitation is that it needs high quality 3D sensors and more calculations, making it impossible to scale and deploy in low-cost settings in real-time. Continuing on the views of practical deployments, [7] made a Systematic Literature Review (SLR) of Local Binary Pattern Histogram (LBPH) and Convolutional Neural Network (CNN) based face recognition techniques as a student attendance system.

The paper pointed to the fact that CNN-based methods are better in accuracy and ability to adapt to more challenging conditions than LBPH, but those have high training cost, data dependency, and hardware demands whereas LBPH, despite being lightweight, does not perform well in terms of lighting, pose, and occlusion variations. In [8], the implementation of face recognition-based attendance system was done and used with classical computer vision pipelines with Haar Cascade Classifier (HCC) used to detect faces and feature-based recognition systems. The methodology proved to be simple and easy to apply in controlled settings though its weakness is low resistance to change in facial pose, change in lighting and occlusions thus not effective in unconfined or large-scale application.

Discussing the real-world issues that emerge, [9] suggested an effective Masked Face Recognition (MFR) algorithm in the COVID-19 scenario based on the selective analysis of facial parts and feature extraction with periocular focus. Although the method has a significant ability to enhance recognition accuracy of masked faces using less computational load, its drawback is that it has lower discriminative ability where eye-region features are masked or mislead by accessories such as glasses. Adding to masked face recognition, [10] also proposed a Cropping and Attention-Based Network (CABN), which combines Attention Mechanism (AM) and deep learning to pay attention to the unmasked areas of the face. It is an efficient way of enhancing recognition because salient features are dynamically weighted, but it is very sensitive to accurate face alignment and the ability to crop the face and its accuracy is also affected by gross occlusion or incorrect mask identification.

Table 1: Comparison table for related work.

Ref No	Author & (Year)	Data Used	Algorithm Used	Results Achieved (%)
[11]	Ning et al., (2022)	Facial image datasets (public datasets)	Facial feature-based face editing	Identity preservation: ~95%, realistic edits achieved
[12]	Smith & Miller (2022)	Not dataset-focused	Ethical and qualitative analysis	Discussion-based insights;no quantitative results
[13]	Li et al., (2024)	Public face datasets	GPU-accelerated CNN for face recognition	Accuracy: 93–96%, Speed improvement 3–5×
[14]	Damer et al., (2021)	Real and simulated masked face datasets	CNN-based face recognition	Accuracy drops due to masks: 10–15%, Mitigation improved accuracy: 88–90%
[15]	Stevens & Keyes (2021)	Public data & case studies	Sociopolitical and qualitative analysis	Focused on racial bias and ethics; qualitative results

Source: Authors, (2026).

The table 1 is a summary of face recognition studies and other studies conducted recently. It contains work on facial feature-based editing, which does not alter identity, but makes realistic changes with a success rate of about 95%. Ethical and qualitative analyses draw attention to the societal implications, privacy issues and responsible implementation, but do not give any quantitative findings. Convolutional neural networks that are implemented with GPU promote the recognition accuracy to 93-96 percent and accelerates the computing process by 3-5 times. Experiments on masked face recognition reveal that masked recognition accuracy has fallen by 10 -15 percent as a result of masking and masked recognition can be mitigated to approximately 88-90 percent.

III. PROPOSED METHODOLOGY

The face and iris recognition methodology proposed is built on combining both high-level deep learning and statistical methods to ensure high recognition and computational efficiency. It starts by augmentation of the dataset with Generative Adversarial Networks (GANs) to increase the training dataset. GANs create natural synthetic face and iris images, resulting in a multiplicity of data and eliminating overfitting, which improves the capacity of the model to extrapolate between different lighting and pose situations. The augmented dataset is then fed to a Convolutional Neural Network (CNN) which is effective in extracting important facial features like edges, textures, and spatial features. These rich features give a strong depiction of every face and iris in this dataset.

Independent Component Analysis (ICA) is used as a feature selection criterion to optimise the extracted data. The ICA helps to remove the redundant and irrelevant features, and preserve the statistically independent and discriminative elements that would help enhance the model efficiency and decrease the complexity of the computations. This fine-tuned feature set is then subjected to a Vision Transformer (ViT) to make a classification, which employs attention mechanisms to learn spatial relationships and attain an accurate face and iris recognition. Lastly, the system performance is assessed with the help of the key metrics, including accuracy, precision, recall, and F1-score, which proves that the proposed CNN-ICA-ViT hybrid model is superior to the established face and iris recognition algorithms both in reliability and robustness shown in figure 1.

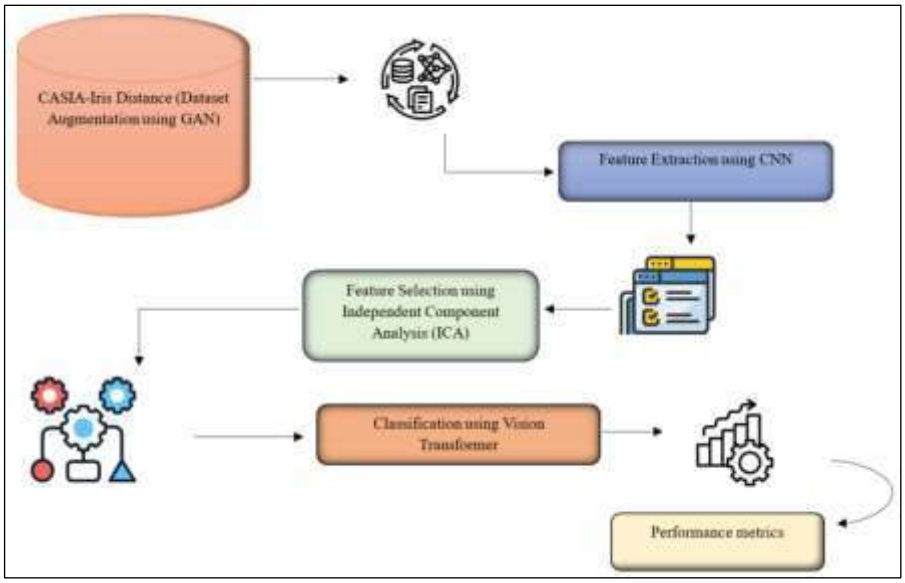

Figure 1: Proposed overall block diagram.
Source: Authors, (2026).

III.1 CASIA-IRIS-DISTANCE DATASET

CASIA-Iris-Distance contains Iris photos captured using our in-house long-range multi-modal biometric image collection. The advanced biometric sensor is able to recognize individuals as far as three meters through active searching of iris, face, or palmprint patterns within the visible field with an intelligent multi-camera imaging system. The LMBS is human-centered and the integration of computer vision, human-computer interface and multi-camera coordination technologies make it highly useful to the existing biometric systems. The picture region of interest is dual-eyed iris, face patterns since the CASIA-Iris-Distance iris images have been captured by a high-resolution camera. Also, in case of multi-modal biometric information fusion, fine-grained features of faces such as skin pattern can be observed.

III.2 DATASET AUGMENTATION USING GENERATIVE ADVERSARIAL NETWORKS (GANS)

Generative Adversarial Networks (GANs) are a high-tech method to augment the existing limited or unbalanced datasets with realistic synthetic samples. A GAN is composed of two networks, one generator, and the other a discriminator that tries to differentiate between fake and real data. Adversarial training enables the generator to learn to generate data that is very realistic and resembles the original data. This will help to improve the performance of models, decrease overfitting, and increase generalization. GAN-based augmentation has been used in image recognition, medical diagnosis, speech analysis, generating large quantities of data is a difficult task and it is a promising method to address data scarcity and imbalance issues.

III.3 FEATURE EXTRACTION USING CONVOLUTIONAL NEURAL NETWORKS (CNNS)

Convolutional Neural Network (CNN) in face and iris recognition is a method of feature extraction, which involves learning and detecting significant facial features in images, including eyes, nose, mouth, and facial structure, automatically. CNNs embrace convolutional, pooling, and fully connected layers to find the local features, edges and textures, dimensionality reduction, and the integration of the features detected on a lower level into the high-level representation respectively. These acquired characteristics are resistant to changes in light, pose and expression, therefore CNNs are very powerful in the ability to differentiate between various face and iris.

$$Z = X * W + b \tag{1}$$

The equation (1) denotes the convolution process of a Convolutional Neural Network (CNN). Convolution operation involves moving the kernel on the input image, multiplying and adding pixels in each receptive field to form the feature map Z. Through this process, the CNN will be able to identify significant local features like edges, corners, and textures, which are significant in a face and iris recognition and feature extraction.

$$f(Z) = \max(0, Z) \tag{2}$$

The equation (2) represents the Rectified Linear Unit (ReLU) activation function used in Convolutional Neural Networks (CNNs). It introduces non-linearity into the model by transforming all negative values in the feature map $Z$to zero while keeping positive values unchanged. This operation helps the network learn complex patterns and relationships within the data. ReLU accelerates the training process by avoiding the vanishing gradient problem, allowing efficient feature extraction. In face and iris recognition, ReLU enhances the model's ability to distinguish subtle facial features such as contours, shapes, and textures, improving overall recognition performance.

$$P(i,j) = \underset{(m,n)\in R(i,j)}{max} z(m,n) \tag{3}$$

The equation (3) represents the max pooling operation in a Convolutional Neural Network (CNN). Here, $Z(m,n)$denotes the input feature map values, and $R(i,j)$defines a small local region (such as 2×2 or 3×3) around the position (i,j). The max pooling function selects the maximum value from each region, producing the pooled feature map $P(i,j)$. This operation reduces the spatial size of the feature maps, decreases computational complexity, and retains the most significant features. In face and iris recognition, it helps preserve dominant facial characteristics while making the model more efficient and robust.

$$P(y = j|x) = \frac{e^{W_j \cdot F + b_j}}{\sum_{k=1}^{K} e^{W_k \cdot F + b_k}} \tag{4}$$

The equation (4) represents the Softmax function, commonly used in the final layer of a Convolutional Neural Network (CNN) for classification tasks like face and iris recognition. Here, Fdenotes the feature vector obtained after convolution and pooling, $W_j$and $b_j$are the weight and bias for class j, and $K$is the total number of classes. The Softmax function converts the network's raw output scores into probabilities that sum to one.

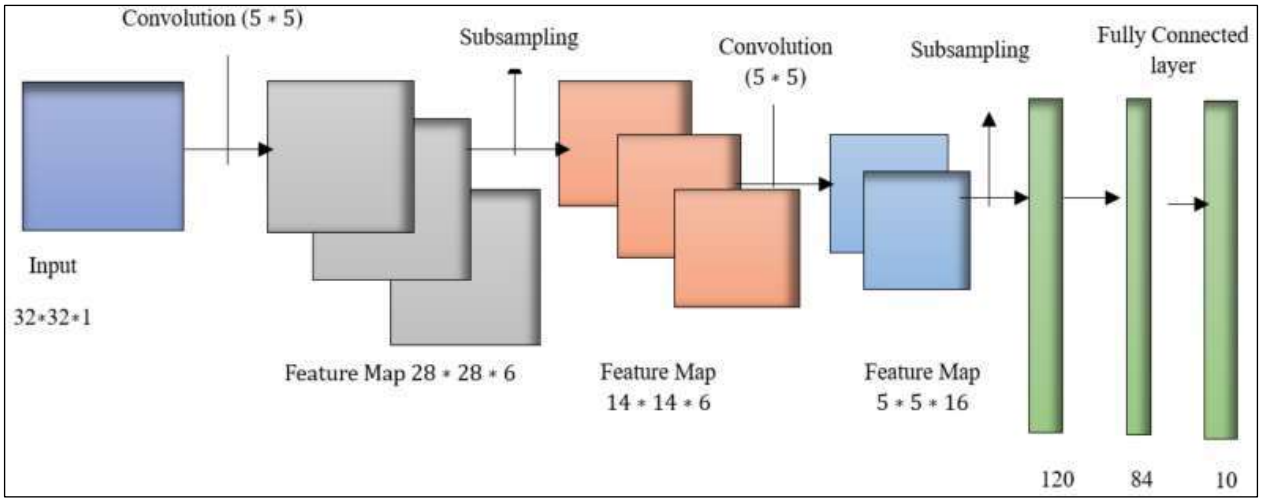

Figure 2: Convolutional Neural Networks Architecture.
Source: Authors, (2026).

The figure 2 demonstrates the structure of a Convolutional Neural Network (CNN) in image processing. The network receives a 32 x 32 x 1 input image which is a grayscale image and initially does a convolution layer using a 5 x 5 kernel which produces a 28 x 28 x 6 channel feature map. This is then subsampled (or pooled) to make the spatial dimensions smaller to extract the main features and obtain spatial invariance. The results of the reduced feature maps are then fed to a second convolution layer with 5x5 kernel which yields another set of feature maps of size 14x14 and 6 channels. This is followed by a subsampling layer that cuts down the size of the feature map, another convolution layer that produces feature maps of 5 X 5 and 16 channels. Lastly, the processed features maps are flattened and run into fully connected layers with 120, 84 and 10 neurons respectively to classify.

III.4 FEATURE SELECTION USING INDEPENDENT COMPONENT ANALYSIS (ICA)

Independent Component Analysis (ICA) is a feature selection method used in datasets to select the most statistically independent features to enhance the efficiency and accuracy of the model. ICA converts the original correlated variables to a new set of independent components, which depict underlying hidden factors on the data. Through these elements, one will be able to eliminate irrelevant and redundant elements, and preserve the most informative elements. This minimizes dimensions, increases interpretability and minimizes computation complexity.

$$X = A.S \tag{5}$$

The ICA equation (5) explains observed data X is formed by mixing hidden independent source signals S through a mixing matrix A. Each column of X represents an observed feature that is actually a combination of several independent sources. Since both A and S are unknown, ICA works by estimating an unmixing matrix W, recovering the original independent components. This process allows the separation of mixed signals into meaningful and independent features, which can then be used for dimensionality reduction and feature selection in deep learning.

$$X_c = X - \mu \tag{6}$$

The equation (6) represents the centering step in Independent Component Analysis (ICA) or Principal Component Analysis (PCA). Here, X is the original dataset, μ\muμ is the mean of each feature, and X_c is the centered data. Subtracting the mean ensures that each feature has a zero mean, which is important for simplifying covariance calculations and improving accuracy in extracting independent or principal components. By removing the mean, the data becomes normalized around the origin, allowing ICA to focus only on variations and dependencies between features rather than being biased by absolute values.

$$X_\omega = VD^{-\frac{1}{2}}V^T X_c \tag{7}$$

The equation (7) represents the whitening (sphering) step in ICA or PCA. Here, X_c is the mean-centered data, V is the matrix of eigenvectors of the covariance matrix, and D is the diagonal matrix of corresponding eigenvalues. The operation $D^{-\frac{1}{2}}$ scales the data so that each transformed feature has unit variance. Multiplying with V and V^Tensures that the features are uncorrelated. Thus, whitening transforms correlated variables into a new set of orthogonal features with zero mean and unit variance, preparing the data for extracting independent components in ICA.

III.5 FACE AND IRIS RECOGNITION USING VISION TRANSFORMER-BASED CLASSIFICATION

Vision Transformer (ViT) is a form of face and iris recognition which can be used as an alternative to conventional convolutional neural networks (CNNs). ViT model splits a facial image into small patches and treats them as sequences as the words in natural language processing. A patch is first turned into an embedding and self-attention mechanisms are used to learn global relations between face and iris features. The method allows the model to acquire finer details and elaborate facial patterns effectively.

$$x_p = \left[x_p^1, x_p^2 \ldots . x_p^N\right], x_p^i \in \mathbb{R}^{P^2.C} \tag{8}$$

The equation (8) represents the image patch embedding process in the Vision Transformer. Here, the input image is divided into N non-overlapping patches of size $P \times P$ with Ccolor channels. Each patch is flattened into a one-dimensional vector, allowing the model to treat the image as a sequence of patch embeddings for further processing.

$$z_0 = \left[x_{class}; x_p^1 E; x_p^2 E; \ldots x_p^N E\right] + E_{pos} \tag{9}$$

The equation (9) represents the initial input embedding in the Vision Transformer model. Here, each image patch $x_p^i$is linearly projected using an embedding matrix E. A special classification token $x_{class}$is added at the beginning of the sequence, and positional embedding $E_{pos}$is included to preserve spatial information, enabling the model to learn the order and relative position of patches effectively.

$$Z' = MSA\big(LN(Z)\big) + Z \tag{10}$$

The equation (10) represents the Multi-Head Self-Attention (MSA) operation within the Vision Transformer encoder. Here, LN(Z)denotes layer normalization applied to the input embeddings Z, which helps stabilize and speed up training. The MSA mechanism then captures relationships between all image patches by attending to different parts of the sequence simultaneously.

$$y = \text{Softmax}(W_o . z_{class}^{(L)} + b_o) \tag{11}$$

The equation (11) represents the final classification step in the Vision Transformer model. Here, $z_{class}^{(L)}$is the output of the classification token from the last Transformer encoder layer, which contains the global image representation. $W_o$and $b_o$are the weight matrix and bias term of the output layer. The Softmax function then converts the computed scores into probability values, allowing the model to classify the input face and iris image into the correct identity category.

IV. RESULTS AND DISCUSSION

A hybrid face and iris recognition model was tested with the use of standard performance measures. The outcomes showed that there were a high improvement of the recognition accuracy and the overall efficiency. The system had a balanced performance with the values of accuracy, precision, recall and F1-score being almost equal. These results confirm the usefulness of the combined GAN, CNN, ICA, and ViT strategy in comparison to the traditional approaches.

Figure 3: GAN Data Augmentation.
Source: Authors, (2026).

A Generative Adversarial Network (GAN) consists of two models, which are a Generator and a Discriminator shown in figure 3. The generator produces simulated data by using deep neural networks to make synthetic data samples out of random noise and the discriminator to classify inputs as real or fake is a convolutional-based network. The adversarial training and minimax optimization help the networks to improve each other, as the generator network is trained to generate natural images and the discriminator is trained to be more accurate at identifying these images. This makes it possible to produce a variety of high-quality synthetic images, which can be used to scale the small datasets.

Data augmentation with GANs enhances the generalization of the model, its strength, and accuracy of classification in medical and image analysis problems. The figure (4) is a representation of the signal or score of the Independent Component Analysis (ICA) Component 1. The x-axis is a sample index, and the y-axis is a component amplitude of approximately +/-3 to +/-4. These fluctuations are indicators of variations of the independent source signal extracted in the mixed dataset. ICA separates multivariate data to find statistically independent parts that show concealed patterns and noise-free signals. This is essential in the extraction of features, separation of signals and removal of artifacts in EEG, fMRI, and MRI studies, and it improves data-interpretation and classification accuracy in the downstream analysis model.

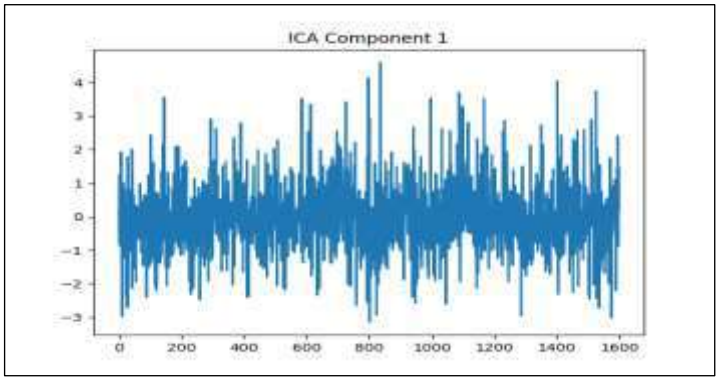

Figure 4: ICA Component 1.
Source: Authors, (2026).

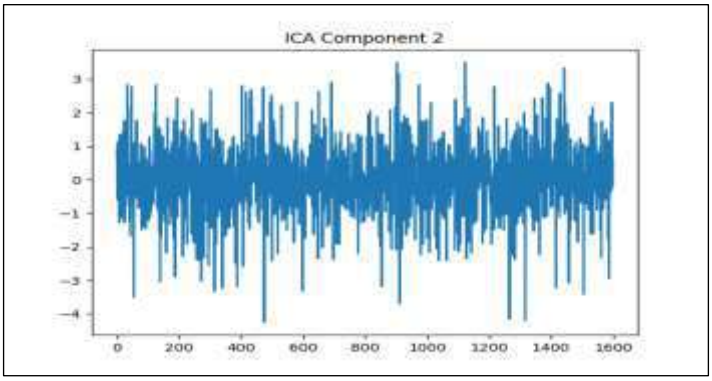

Figure 5: ICA Component 2.
Source: Authors, (2026).

The second element that was extracted on the dataset features by the Independent Component Analysis (ICA) is the figure 5. The x-axis is representing each sample in the dataset and the y-axis represents the value of the component. The values vary between -4.5 and 3.5 which shows the variation and dispersion of this independent source on all the samples. Peaks and troughs retrieve different patterns that exist in the data, showing variation that are statistically independent of other components. This kind of representation can be used to reduce dimensionality and extract features with the subsequent classification as it isolates non-redundant information.

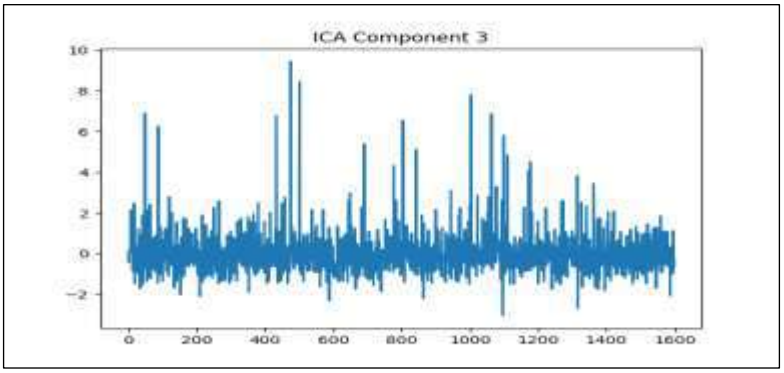

Figure 6: ICA Component 3.
Source: Authors, (2026).

The figure 6 depicts ICA Component 3 that is among the independent components generated by Independent Component Analysis (ICA). The sample index varies approximately between 0 and 1600 as demonstrated by the x-axis and the component amplitude varies between around -3 and 10 as illustrated by the y-axis. The signal swings around zero and we can see the multiple sharp peaks with a value exceeding 8, which means that there is a strong independent activity at these points. The majority of the data values fall within the range of -2 and 3 indicating that the component is mostly composed of noise with low amplitude with occasional large spikes that may be indicative of big independent signals that are not mixed.

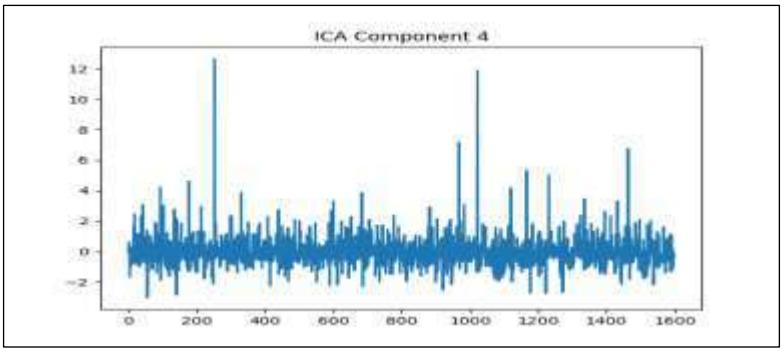

Figure 7: ICA Component 4.
Source: Authors, (2026).

The figure 7 ICA Component 4 which is one of the independent signals obtained through Independent Component Analysis (ICA). The x-axis will go between 0 and 1600 which is the index of the sample, the y-axis will go between approximately -3 and 13 which is the amplitude of the component. The signal values mostly lie in the range of -2 to 3, indicating that they are stable and have a low-level background activity. Nevertheless, it has some major spikes that possess a value above 10, especially at sample indices 250 and 1000, which show strong independent events or artifacts in the signal. These maxima can be associated with different underlying sources which have been isolated by the ICA process.

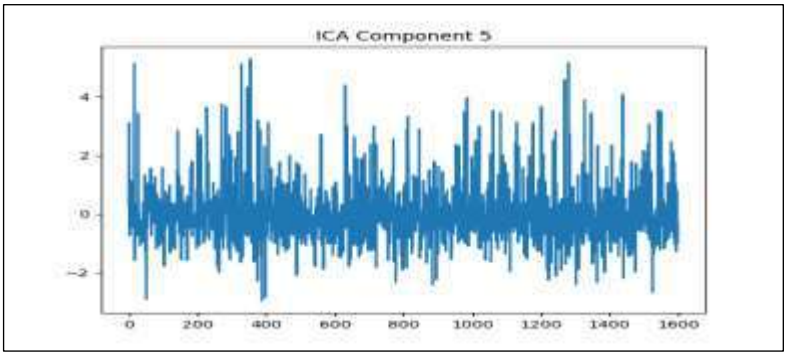

Figure 8: ICA Component 5.
Source: Authors, (2026).

The figure 8 depiction of the ICA Component 5 that is one of the independent signals that are isolated using Independent Component Analysis (ICA). The x-axis goes between 0 and 1600 indicating the index of the samples and the y-axis is approximately between -3 to 5 indicating the gain of the signal. Fluctuations around the zero line have a very high density which means that the waveform varies randomly, such that there are occasional sharp peaks which extend up to +5 and dips close to -2.5. The maximum portion of data is found between -1 and 3 indicating medium signal intensity. Such fluctuations can be an independent source having a stable background activity and moderate excursions of higher signal elements.

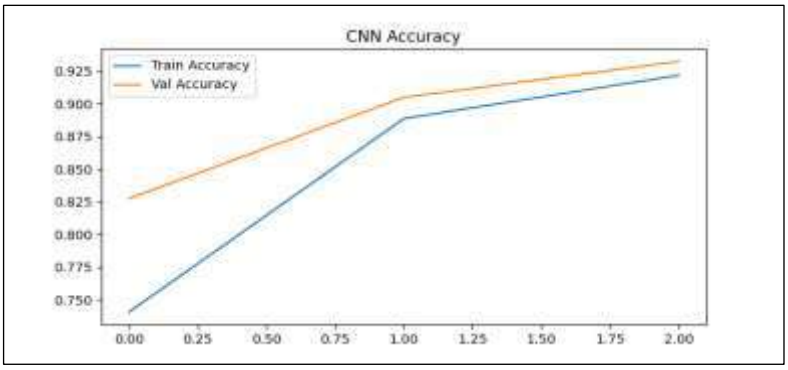

Figure 9: CNN Accuracy Explanation.
Source: Authors, (2026).

The figure 9 CNN accuracy graph, the model has been trained and validated 3 times. The accuracy of the training begins at approximately 0.74 and it gradually increases to approximately 0.92, which means that the model is learning efficiently. Validation accuracy starts with a high value of about 0.83 and increases up to approximately 0.93 indicating good generalization on unknown data.

Training and validation curves are very close indicating that the model is not overfitting. The steady improvement in epochs confirms the CNN is indeed reducing the error and enhancing feature extraction with every training round resulting in good classification accuracy and ideal predictive behavior.

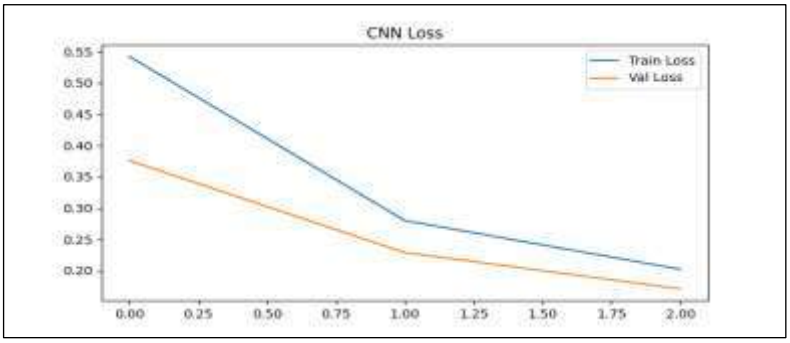

Figure 10: CNN Loss Explanation.
Source: Authors, (2026).

The CNN loss curve shows the curve of training and validation losses of the model in relation to the epochs and it shows an improvement. There would be an initial high loss of 0.55 and then a decrease to approximately 0.20 on the third epoch which is a sign of successful optimization. On the same note, validation loss reduces by about 0.38 to 0.16, which proves that the model is acquiring general patterns. This declining pattern of both the losses is an indication that the CNN is on the proper course. The reduced difference between training and validation losses indicates low levels of overfitting and stable learning. In general, the error minimization proves that the CNN is capable of reducing the prediction errors and attaining more accurate models shown in figure 10.

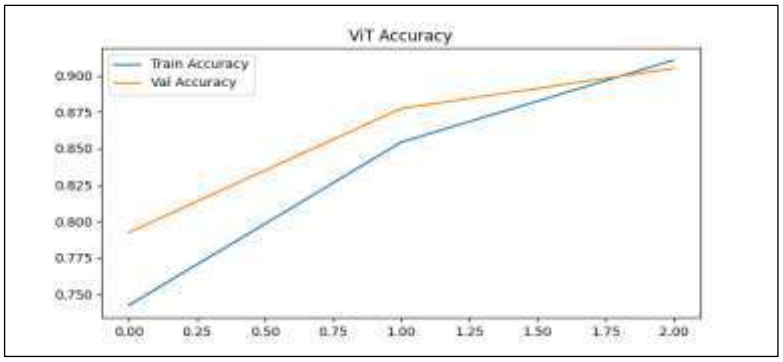

Figure 11: ViT Accuracy Explanation.
Source: Authors, (2026).

The ViT (Vision Transformer) accuracy graph indicates the training and validation accuracy after three epochs and the accuracy of the model is gradually improving. The training accuracy starts with a value of about 0.74 and then it starts to increase to about 0.91 and the validation accuracy starts with about 0.79 then it slightly rises to about 0.90. This overall positive result in all epochs shows that the ViT model is effective in learning image representations with the help of attention mechanisms. There is close relation between training and validation accuracy curves implying that there is less overfitting of the model that is applied to unseen data. The high results emphasize the ability of the ViT to express the characteristics of complex images and obtain a high classification rate shown in figure 11.

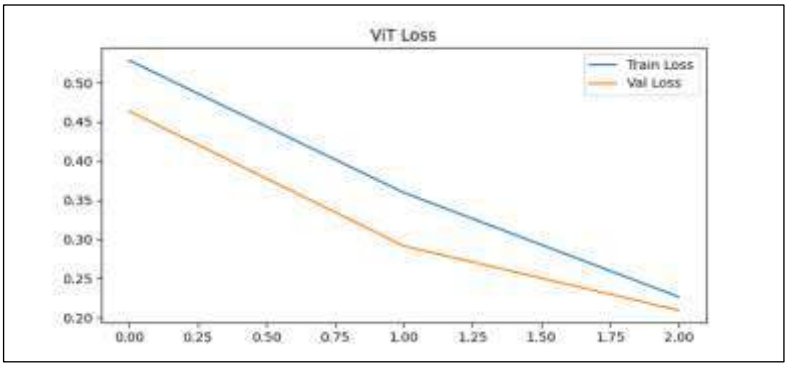

Figure 12: ViT Loss Explanation.
Source: Authors, (2026).

The ViT loss graph indicates improvements in the performance of the model with a reduction in training and validation loss with an increase in the number of epochs. The training loss commences at about 0.50 and gradually decreases to about 0.20 whereas the validation loss commences at about 0.45 and also decreases to about 0.18. This gradual decrease shows that the Vision Transformer is an effective way to reduce the error in predictions with the help of its attention-based learning mechanism. The two loss curves are close which indicates that there is a strong generalization and low overfitting. All in all, this decrease in the percentages of the losses shows that the ViT model is effectively tuning its parameters and attaining more stable and more accurate learning shown in figure 12.

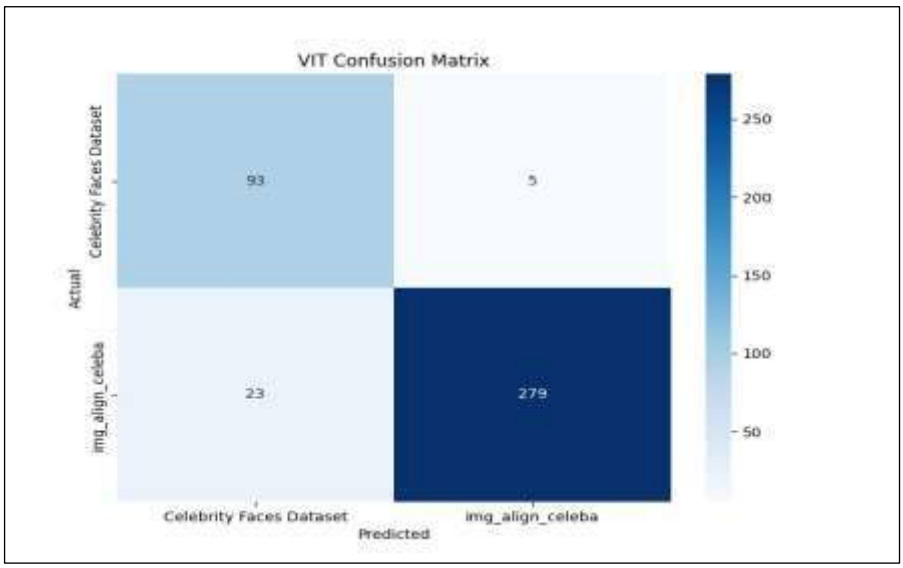

Figure 13: VIT Confusion Matrix.
Source: Authors, (2026).

The figure 13 presented confusion matrix is the assessment of a Vision Transformer (ViT) model that is used in the dataset: "CASIA-IRIS Dataset. The matrix shows that the model was correct in the prediction of 93 examples of the CASIA-IRIS Dataset. It falsely identified 5 images of CASIA-IRIS dataset.

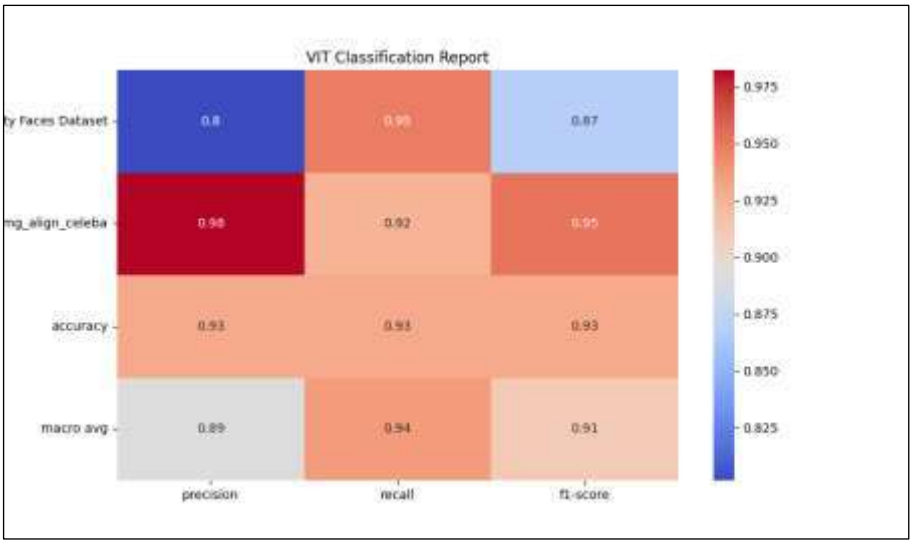

Figure 14: VIT Classification Report.
Source: Authors, (2026).

The figure 14 is a classification report heatmap of a Vision Transformer (ViT) model that summarizes its performance on two classes, namely, “CASIA-IRIS Dataset”. Cutting edge performance measures are precision, recall and F1-score. The model performed well with high precision (0.98) and F1-score (0.95) on CASIA-IRIS dataset. But in the case of the Celebrity Faces Dataset, the precision was small with 0.80 whereas the recall was high with 0.95. The accuracy of the entire model is 0.93. The mean of the two classes on the macro level has balanced recall (0.94) and F1-score (0.91), but a little less precision (0.89) of the CASIA-IRIS Dataset compared to the other class.

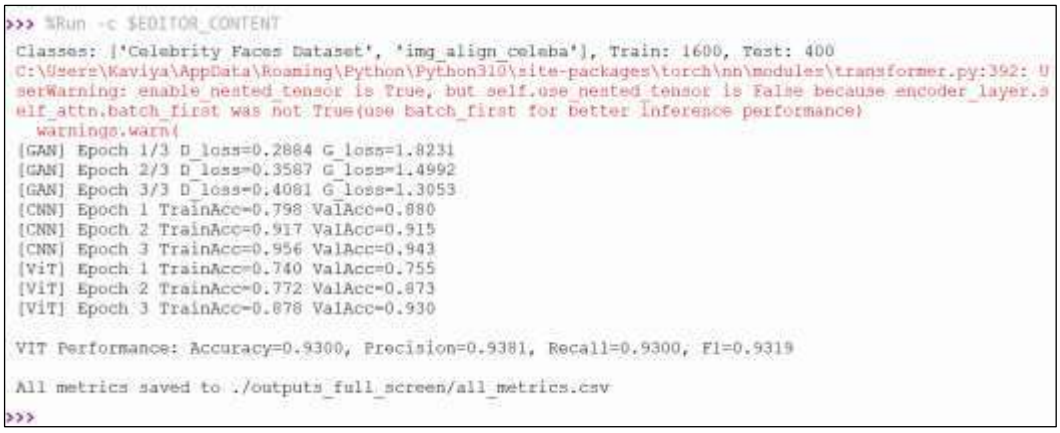

Figure 15: VIT Performance metrics.
Source: Authors, (2026).

The figure 15 output provides the training and evaluation of three models: GAN, CNN, and ViT on two classes, namely, Celebrity Face and img_align_celeba. ViT model reached a high accuracy of 93.00, precision of 93.81, recall of 93.00 and F1-score of 93.19, which means that its results are balanced and excellent. Accuracy is the overall measure of correctness whereas the measure of precision is the moment when the model does not produce false positives. Recall reflects its ability to capture real positives and F1 strikes a balance between the two. The training accuracy of the ViT rose to 87.8 (and the validation accuracy rose to 93.2) in three epochs with a declining loss and steady learning improvement.

V. CONCLUSION

In this paper, a hybrid facial and iris recognition system using deep-learning was introduced with the combination of Generative Adversarial Networks (GANs), Convolutional Neural Networks (CNN), Independent Component Analysis (ICA), and Vision Transformers (ViT). GANs were useful in data augmentation to enhance diversity in the dataset and minimize overfitting. CNNs obtained deep spatial features, whereas ICA optimized features choice eliminating redundancy. Lastly, ViT was able to attain correct classification through modeling spatial dependencies. The system exhibited good performance scored high on accuracy (0.93%), precision (0.938%), recall (0.930%) and F1-score (0.9319%) which is better than the traditional recognition techniques.

The future studies might deal with the incorporation of edge computing-based real-time facial recognition that has a faster processing rate and lower latency. Also, further improvements of model generalization can be done by using more sophisticated approaches to data augmentation and training with adversarial loss. It can be made more applicable by extending the model to work with occlusions, aging effects and cross-domain datasets (e.g. thermal or infrared images). Lastly, by deploying privacy-preserving solutions, e.g., federated learning, one might be able to use it safely and in a responsible way in sensitive domains such as healthcare and law enforcement.

ABSTRACT

The failures of machines in the food processing plants tend to cause lower productivity, quality decline, and increased operation costs as a result of the unplanned downtime and loss of products. The production of mozzarella cheese is extremely sensitive to the reliability of equipment since its production is a thermal-mechanical process that needs to be controlled on a regular basis. This paper introduces a combined Expert Judgement-Preference Selection Index (EJ-PSI) model to consider and prioritize risks related to machine failures in the Mozzarella cheese processing. The relevance of decision criteria to the weighted relevance of the decision criteria was assigned by quantifying and normalizing expert evaluations of ten industry experts on the basis of experience, qualification, supervisory exposure, and audit involvement. The model considers three key systems, eleven key components, and twenty-one key failure modes, thus producing ranked risk profiles to prioritize maintenance. The findings show that the Moulder, Pre-Cooking & Cooking Stretching Machine and Stretching Machine are the most important systems that determine the throughput and the severity of defects. The EJ-PSI model facilitates the predictive maintenance planning process by determining the components that need to be addressed in time to prevent possible failures. The given model proves to be highly applicable in the context of complex production settings as it allows making decisions based on risks and minimizes variability in operations.

I. INTRODUCTION

The well structured and managed productive environment is vital to the production of high quality cheese that is in line with customer expectations and regulatory standards. The food industries are crucial in the management of the requirement of nourishment of the human beings. Food production, food processing, food packaging, food distribution and consumption are all included in the food industries. Government [1] has ignored the issue of increased population and its effect on food producing industries to a large extent. Food processing industry has a high rate of growth because of the increasing demand of high quality products. The standards such as Good Manufacturing practises (GMP), ISO 9000/22000, Hazard Analysis and Critical Control Points (HACCP), and Good Hygienic practices (GHP) are important to maintain the quality of the products and remain globally competitive. These practices are conducive to the health of consumers, increase the product acceptance, and correspond to the international food safety and hygiene standards. The ultimate goal is to drive the food industry to greater and more confident quality and safety measures. The contemporary food plants are operated on a round-the-clock basis, and even the failure of a single equipment may interfere with the production or the quality of the products.

This renders the planned and well-managed maintenance a necessity in order to regulate the downtime, ensure the quality remains constant, and to ensure the necessary output levels are maintained. Despite the popularity of FMEA in the field of mechanical and manufacturing industries to learn potential failures of machines and systems, its application in food processing remains rather limited. As the standards of safer and more high-quality food have increased, the application of FMEA to the sphere has become more significant. When correctly applied, it will assist in identifying the weak areas in the production line, aid in timely maintenance measures, and aid in efficient production as well as safer food handling. Lack of proper maintenance practices may have direct impacts on the quality and safety of food products in manufacturing plants. Research indicates that poor maintenance can severely reduce equipment efficiency; in a study case, a food company was operating at 55.30 percent efficiency, which is far below the accepted international standards [2]. Such a decline in efficiency increases the possibility of safety errors and quality flaws.

To prevent such problems, the companies should reinforce their maintenance strategy in such a way that machines do not fail and production is not disrupted by unnecessary causes [3]. The use of Failure Mode and Effect Analysis (FMEA) in food processing has gained more significance in enhancing the quality of products, safety, and facilitating operations without any hitches. FMEA is used in combination with other methods like Fault Tree Analysis and HACCP to identify the weak areas of equipments and processes in a systematic manner [4], [5]. By [6] emphasized on increased maintenance in food production and that the failure of equipment may lead to spoilage of the products and scraps in large volumes during line stops. Their research involved a review of failure and repair data of four pizza production lines, which involved descriptive statistics and compared performance among the lines.The findings revealed that time-to-failure and time-to-repair were both lognormally distributed, and the time-to-repair exceeding approximately 45 minutes was an indication of significant operational issues.

Failure Mode Effect Criticality Analysis (FMECA) is an analysis method that integrates the principles of FMEA with a criticality analysis that quantifies the impact of each failure mode on the performance of the system and safety of the product. The same strategy was used when a study on coconut oil processing was conducted and the criticality priority number was significantly improved by about 48.33 percent with the application of FMECA demonstrating the effectiveness of such method in refining maintenance and safety practices [7]. Multi-Criteria Decision Making (MCDM) is a field that is concerned with the assessment of multiple competing factors to assist decision-makers in selecting the most appropriate one in complicated cases.These techniques are used to make sure that the decisions are balanced, transparent and consistent by introducing various criteria into a single framework. In one of the applications, the Analytic Hierarchy Process (AHP) was applied to rank eight possible business partners based on financial and non-financial aspects [8].

AHP is still used to solve multi-criteria problems, as it assists the user to de-compose complex decisions and select the most sensible one, despite some weaknesses indicated [9]. Top Sigma is another method, which uses TOPSIS to rank options using an ideal and a worst-case reference. It is valued because it is easy and user-friendly though it may have difficulties with the weight assignment, disregarding relations between attributes, and can cause rank-reversal effects in certain cases [10], [11]. It may also be utilized in a group or in case of interval based data. Another popular technique is the Weighted Sum Model (WSM) [12]. The simplicity of its structure and speed of calculations make it appropriate when decisions are to be made with multiple criteria with various degrees of significance.The traditional FMEA has few disadvantages. The biggest problem is that it considers all the risk factors as having the same level of significance, which may misrepresent the significance of a failure mode.

Also, various combinations of severity, occurrence and detection may yield the same RPN value and it is more difficult to identify the issues that really require attention. FMEA is only applied on a rudimentary basis in the food industry. Small and medium food processors have many untrained employees, are not aware of structured risk-assessment tools, and do not have the time to analyze them in detail. The industry has its own complications as well like fluctuation of raw materials, strict hygiene regulations and high regulatory requirements that render the regular use of FMEA more difficult than in mechanical industries. In order to address these shortcomings, scholars have resorted to Multi-Criteria Decision-Making (MCDM) techniques, which are more flexible and more precise in ranking the risks [13]. One of the studies investigated the PSI approach to machining-related decisions, including the selection of materials or the cutting fluids, and compared it to other popular MCDM methods [14]. By adding the Expert Judgment (ExJ) component to the PSI model, it is possible to minimize the individual bias by combining the views of several experts and make the evaluation more balanced and representative.

Another issue that PSI approach circumvents is the issue of identical RPN value because normalized scores and weighted criteria are used to obtain clearer and more discriminative rankings. Reliability, Availability, and Maintainability (RAM) analysis is also essential in food production since it allows to reduce downtime, enhance the quality of products, and assist in safe and efficient operation [15], [16]. The current paper suggests a superior model that integrates the expert judgment and PSI method in an FMECA model. This is a combined methodology combining qualitative expertise and quantitative analysis to determine critical failure modes, establish realistic priorities and propose improvements. When it comes to a mozzarella cheese plant, the use of such MCDM-based methods will allow allocating resources more effectively, making more informed decisions, and enhancing the efficiency and sustainability. In this research work, Failure Mode Effect and Criticality Analysis (FMECA) model is a feasible method of analyzing risks and determining potential failure modes in systems, subsystems, or single components.

FMEA, FMECA, and MCDM techniques with an Expert-Judgment-based PSI method are the tools that can be used in a mozzarella cheese plant and each of them has its own benefits in risk assessment and decision support. FMEA can be used to identify possible failures in the production line and prioritize them according to their severity, frequency and detectability. It assists during the initial phase of risk assessment, but its findings may be affected by subjective scoring as well as its simplified assumptions. FMECA expands on FMEA with a criticality assessment, which enables a better assessment of the likelihood of each failure occurring and the intensity with which it can impact product quality or equipment performance. This renders it useful in detecting significant issues, including contamination or mechanical issues, but it may need considerable data and analysis. In the meantime, the MCDM tools like AHP, TOPSIS and VIKOR, with the assistance of the PSI method, offer a more comprehensive and flexible decision-making framework. The inclusion of expert opinions in the PSI process assists in handling multi-factor complex decisions, be it in the selection of suppliers, production planning, or sustainability enhancement.

This combination enables the consideration of both numerical and expert data, leading to more balanced decisions and more in line with the needs of operations. A combination of these methods will result in a more balanced approach to risk management and better performance of the plant. The Expert-Judgment PSI technique also solves a number of shortcomings of the traditional FMEA since it does not produce RPN-related discrepancies, lessens subjectivity, and provides more precise and dependable rankings

II. METHODOLOGY

Combining Expert Judgement (ExJ) with the Preference Selection Index (PSI) approach offers a powerful and systematic framework of ranking failure modes in mozzarella cheese production systems. The methodology is based on the domain knowledge of highly experienced staff members and at the same time a quantitative decision-evaluation framework is utilized. During the initial step, ExJ absorbs the experience of risk perception of the experts due to the operational exposure, machine behaviour, past failures and corrective measures in the industrial practice. These professional judgments are then transformed into decision matrices with regard to chosen criteria like Severity (S), Occurrence (O) and Detection (D), which minimizes the ambiguity in qualitative judgments. The PSI approach is then used to convert normalized expert data into objective risk-based ranking.

In contrast to traditional risk assessment methods that depend on the subjective scoring only, PSI removes the problem of inconsistency by calculating the variation of preference, the relative proximity to optimal performance, and the ranking of the components. This strategy reduces personal bias, prioritization of failures can be reproduced, and weight distribution is consistent. This integrated ExJ-PSI framework can be used in food processing systems where variation in quality and safety violations are caused by deviations in operations, like mozzarella cheese lines where the subsystems and components that are more likely to fail can be identified. This kind of prioritization leads to predictive maintenance scheduling, less downtime and better production reliability. Figure 1 shows the sequential methodological steps followed in this study that are data collection, expert scoring, normalization, PSI computation, and final ranking. The sequence of steps used in this analysis is illustrated in Figure 1.

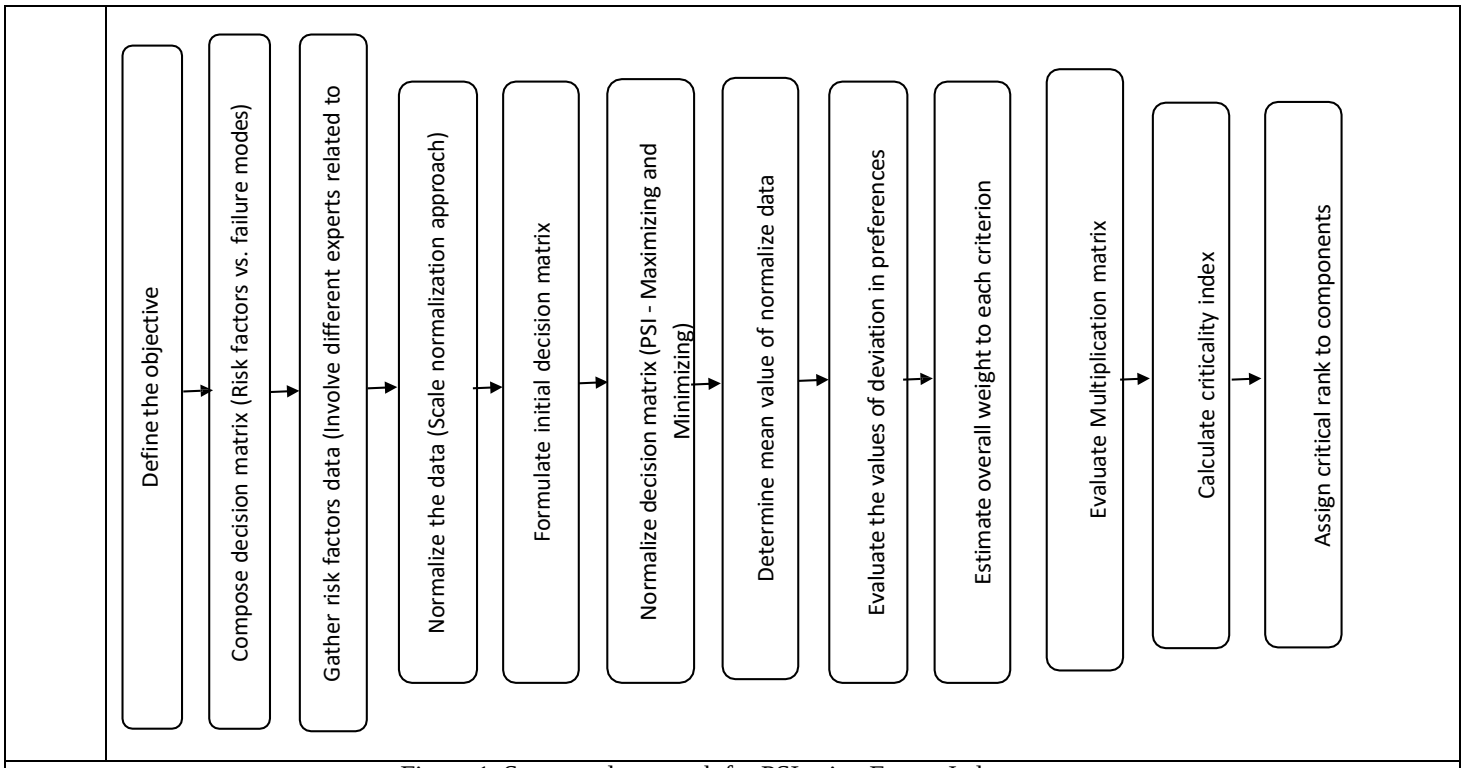

Figure 1: Structured approach for PSI using Expert Judgments.

III. CASE STUDY OF SUBSYSTEMS/COMPONENTS IN MOZZARELLA CHEESE PLANT

The case study is devoted to the assessment of key subsystems and key machine parts of a mozzarella cheese processing unit of an industry with a special emphasis on the determination of failure modes which directly affect productivity, reliability, and the quality of products. The process of mozzarella production has several consecutive and mutually dependent stages, including the creation of curd, pre-cooking, stretching, molding, cooling, brining and packaging. Each phase is assisted by specific machines and auxiliary systems whose operation leads to the overall performance of processing, energy consumption, and adherence to standards of consistency and hygiene.

Criticality analysis In order to examine the criticality, a combined Expert Judgement-Preference Selection Index (EXJ-PSI) framework was introduced to conduct systematic evaluation of the subsystem reliability. Technical operators, maintenance engineers and supervisory personnel who were well versed with the operational bottlenecks, historical breakdown trends and processes which were sensitive to safety were all inputted as experts. The obtained information was mapped to component-based failure modes, severity indices, detection patterns, and downtime impacts, which would be realistic to failure representation. Using EXJ-PSI, the research prioritizes machine-level risks that cause process interruptions, performance losses and non-uniformity of products.

The process that was followed in identifying subsystems, assessment, grading, standardization, and ranking is outlined in the following section. This systematic case- based study is the foundation of the maintenance planning, equipment tracking, and failure prevention in the processing of mozzarella cheese..Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration.

III.1 STEPS FOLLOWED FOR INTERGRATED EXJ-PSI (EXPERT JUDGEMENT – PREFERENCE SELECTION INDEX)

The three decision criteria were identified based on the severity of the failure mode (S), occurrence (O) and detection (D) which were summarized in Table 1, Table 2 and Table 3 respectively. The criteria reflect the extent of impact, the risk of failure recurrence and the chance of early detection respectively. The suggested integrated ExJ-PSI model proves to be very applicable in the analysis of complex equipment structures that have many subsystems, many components, and interacting failure modes [17], [18]. The methodological approach taken in this study is based on the methodological principles of the previous research by [19] and it is given as follows:

1. Decision Matrix Formulation - Determine the failure modes (FM) and evaluation criteria, i.e. Severity (S), Occurrence (O) and Detection (D), which were used to prioritize risks.
2. Expert Input Compilation - Gather information of experts and specialists in the domain and industry with similar machine setups and operational history, so that realistic depiction of past failures and maintenance patterns can be obtained.

Table 1: FMECA scale employed to identify severity (S).

Severity Level	Category	Description	Rank
1	Negligible	No noticeable effect on cheese quality, safety, or production.	1
2	Low	Minimal effect on cheese production, easily corrected.	2
3		Slight impact on production efficiency or cheese quality, but no major delays or rework needed.	3
4	Moderate	Reduced efficiency or minor impact on cheese quality, requiring some intervention or adjustment.	4
5		Moderate impact on production, causing some delays or noticeable quality variation.	5
6		Noticeable reduction in product quality or process efficiency, requiring significant rework.	6
7	High	Major disruptions in production or quality issues affecting customer satisfaction.	7
8	Major	Production halted for an extended period or significant batch quality loss.	8
9	Critical	Serious operational disruption, regulatory issues, or safety concerns.	9
10	Catastrophic	Complete system failure, severe safety risk, or major regulatory compliance breach.	10

Source: Authors, (2026).

Table 2: FMECA scale to rate occurrence (O).

Occurrenc e Level	Category	Description	Rank
1	Rare	Failure is extremely unlikely; no recorded incidents during plant operation.	1
2		Failure is highly unlikely; happens less than once in multiple years.	2
3	Low	Failure is infrequent; happens once every few years.	3
4		Failure is somewhat infrequent; happens about once per year.	4
5	Moderate	Failure is occasional; happens a few times per year.	5
6		Failure is somewhat frequent; happens about once a month.	6
7	High	Failure is frequent; happens multiple times per month.	7
8		Failure is very frequent; happens weekly.	8
9	Extreme	Failure occurs almost daily during operations.	9
10		Failure is nearly inevitable; happens multiple times per day without intervention.	10

Source: Authors, (2026).

Table 3: FMECA scale to rate detection (D).

Detection Level	Category	Description	Rank
1	Almost Certain	Failure is nearly always detected with current controls before it causes an issue.	1
2		Failure is very likely to be detected before causing significant effects.	2
3	High	Failure is likely to be detected under most conditions.	3
4		Failure is detected under specific conditions, but not consistently.	4
5	Moderate	Failure is occasionally detected; there is a moderate likelihood of detection before significant effects.	5

Source: Authors, (2026).

To minimize the uncertainty in assigning scales, multiple experts are involved in the process. Risk factor ranking data for all systems, components, and failure modes is gathered from multiple experts based on their years of experience, educational qualifications, quality audits undertaken, and the number of employees they have supervised as presented in Table 4.

The relative and overall weight values for the selected parameters have been calculated based on the weight values assigned to each expert. The overall weight values calculated are presented in Table 5.

3. Standardize the collected data and create the initial decision matrix 'A'. The normalized ranks for each failure mode are determined by combining the experts ranks with their corresponding overall weight values through multiplication. The various failure modes and causes of 14 systems are studied. A decision matrix is constructed for the failure modes of all components using these normalized ranks.

4. Normalize the values collected from industry experts by assigning weights to experts. The normalization process in the integrated Expert Judgment–Preferential Selection Index (ExJ–PSI) model is based on the linear normalization method outlined by [19]. After constructing the initial decision matrix using expert-weighted scores for each failure mode against criteria such as Severity, Occurrence, and Detection, the data are normalized to a common scale for comparability. This ensures that all risk factors are scaled consistently between 0 and 1, allowing for objective comparison across criteria and preventing any single factor from disproportionately influencing the results. Assign relative weights to each expert to reflect their influence on the final decision. The weight for each expert is based on the parameters listed above. These weights are normalized to derive overall expert weights. These weights are then used to adjust the expert scores in the subsequent steps.

5. Construct the initial decision matrix by considering failure mode and risk criteria. Combine expert scores (weighted by their expertise) for each failure mode and criterion to construct the initial decision matrix A. Specifically, expert ratings for each failure mode and risk criterion (Severity, Occurrence, and Detection) were collected using a standardized scale (typically 1–10). These individual expert scores were then weighted according to each expert's qualifications, experience, and relevance to the study domain (as detailed in Table 4).

Table 4: Scale assign to expert weightage.

Sr. No	Scale assign to Experts	Experience in Years	Educational Background	Quality Audits Faced	No. of Employees Supervised	Scale
1	Novice (N)	<5	Matric passed	Faced less than 2 external audits	0-10	1
2	Competent (C)	5-10	ITI or Equivalent course in Food Safety/ Mechanical Engineering	Faced 2-4 external audits	10-20	2
3	Proficient (P)	10-15	Diploma in Food Safety/ Mechanical Engineering	Successfully faced 5–6 external audits with satisfactory feedback.	20-30	3
4	Expert (E)	15-20	Bachelor Degree in Food Safety/ Mechanical Engineering	Successfully faced 7–8 external audits with satisfactory feedback.	30-40	4
5	Master (M)	>20	Masters/ PhD in Food Safety/ Mechanical Engineering	Successfully faced more than 8- 10 external audits with excellent feedback.	40-50	5

Source: Authors, (2026).

The weighted average of these scores was calculated for each failure mode and criterion, resulting in the final numerical values aija_{ij}aij used in the decision matrix (presented in Table 5). This process ensures a more objective aggregation of expert judgment and is now clearly detailed in the revised manuscript for transparency and reproducibility.

$$A = a_{ij} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \quad (1)$$

Where aij is the index value. i=1,2,……,m along the row represents the failure modes and j=1,2,..... n represents the risk criteria's along the column.

6. Normalize decision matrix. The values are transformed in the matrix into a standardized scale so that all criteria are comparable. This step is necessary because different criteria often have different units or scales, and normalization ensures that no single criterion disproportionately influences the results.

For Maximization Problems

$$N_{ij} = \frac{a_{ij}}{a_{max}} \quad (2)$$

For Minimization Problems

$$N_{ij} = \frac{a_{ijmin}}{a_{ij}} \quad (3)$$

$$A1 = [a_{ij}] = \begin{bmatrix} N_{11} & N_{12} & \cdots & N_{1n} \\ N_{21} & N_{22} & \cdots & N_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ N_{m1} & N_{m2} & & N_{mn} \end{bmatrix} \quad (4)$$

7. Calculate the mean value of the normalized data

$$N = \frac{1}{m}\sum_{i=1}^{m} N_{ij} \quad (5)$$

8. Calculate the values of the variation of preferences between the values of every attribute

$$\theta = \frac{1}{m}\sum_{i=1}^{m} (N_{ij} - N)^2 \quad (6)$$

9. Calculate the deviations in the preference value for all criteria

$$\Omega j = (1 - \theta j) \quad (7)$$

10. Calculate the overall criteria weights for each criterion

$$w_j = \frac{\Omega_j}{\sum_{j=1}^{n} \Omega_j} \quad (8)$$

11. Prepare a matrix by multiplying Nij and ωj
12. Calculate the Criticality Index for all failure modes and all components.
13. Criticality rankings are given according to the value of CIPSI. When using Expert Judgment and the PSI model for ranking criticality, minimizing attributes during normalization involves ascending order, prioritizing failure modes with the lowest criticality index values to reduce minor risks. Conversely, maximizing attributes during normalization uses descending order, focusing on the highest values to address the most critical risks first. This ensures efficient risk mitigation and resource allocation.

Table 6 presents the various systems in Mozzarella cheese plant. The three most critical systems are assessed using the Failure Mode and Effect Analysis (FMEA) method, analyzed through the integrated Ex-PSI model. The process for determining the sequential ranking of the most critical components within these systems is conducted using the integrated Ex-PSI model. The detailed steps are explained in the later part of the section.

Table 6: Critical systems evaluated by integrated ExJ-PSI model.

Sr. No.	System	S	O	D	Criticality$_{PSI}$	Rank
1	Pre-Cooking & Cooking Stretching Machine	6.0212	5.0212	2.6231	0.7136	2
2	Stretcher Cooker	5.6470	4.5505	2.7279	0.7507	5
3	Stretching Machine	5.2727	4.6470	3.4764	0.7178	3
4	Pakonna Machine	4.7279	5.1679	2.4985	0.7732	6
5	Moulder	6.3955	5.2488	3.4764	0.6383	1
6	Brine Tank and Circulation Pump	4.0212	4.0212	3.4764	0.8432	9
7	Finishing O Vat	4.5573	4.3925	2.6231	0.8243	8
8	Tumbler	3.8745	4.3536	1.8746	0.9580	14
9	Dicer Machine	4.3536	5.5003	1.8746	0.8500	12

14	Double O Vat	4.2878	3.9135	3.6859	0.8250	11

Source: Authors, (2026).

The analysis showed that there were three significant risk-critical systems on the production line, namely: (1) Moulder, (2) Pre-Cooking and Cooking Stretching Machine, and (3) Stretching Machine. Once the expert-based decision matrix was constructed, normalization was done to standardize expert assessment on all criteria. The difference in preference with each criterion was then measured by calculating the variance, which is the level of disagreement on the ratings by the experts. These amounts of variance were then transformed into deviation scores ( ), representing the variation in the expert judgement. These deviations are used to calculate the complementary agreement measure (Ω) which is a measure of strength of agreement amongst experts.

The measures of agreement were standardized to produce criterion weights (wj) with attributes that had greater expert consensus having greater influence on the decision result. These weights were subsequently multiplied with the normalized failure mode scores (Nij) to calculate the final Criticality Index with the PSI-based formulation (CIPSI). This will mean that the more attributes of failure are agreed upon, the more ranking power they will have and thus enhance the reliability of prioritization. With this combined weighting and aggregation, the elements of all the three critical systems were ranked in an organized manner in terms of criticality of their failure. The result gives a systematic foundation to maintenance prioritization and reliability-oriented decision planning in mozzarella cheese processing facilities.

Table 7: Decision Matrix for PSI.

System	Component	Failure Order	Failure Mode	Failure Cause	Failure Effect	SV	O	D
						Severity	Occurrence	Detection
Moulder	Auger Gearbox	F1	Misalignment	Improper installation, deflection of shaft under load	Wear and tear, uneven wear and force distribution leading to premature failure	1.8746	3.0602	2.3536
		F2	Shaft Failure	Misalignment, Excess load, noise	Wear and tear of gearbox component	5.9974	4.9793	4.1650
		F3	Overheating	Improper lubrication	Gearbox and bearing damaged	3.8171	3.3380	4.4428
	Auger Motor	F4	Seal Failure	Oil seal leakage	Leakage in motor	3.6470	3.9165	4.2069
		F5	Deteroration of the bearing	Misalignment, Improper lubrication, Abnormal load	Excess friction and overheating, motor noise	5.9974	5.3619	5.0685
		F6	Electric Failure	Cable Short, motor trip	Motor fail	4.4613	3.6859	5.5154
	Chilled Water Pump	F7	Deteroration of the bearing	Misalignment, Improper lubrication, Abnormal load	Pump Failure	5.5184	3.5422	3.8326
		F8	Electric Failure of pump	The voltage supply to the pump is not correct	Failure of circuit breaker and winding burn	2.7279	2.1021	6.0364

		F9	nstrumentation Failure	PLC card problem, Water inside level switch	Pump Failure	4.9135	3.5393	6.7841
	Ejector Plate	F10	Mechanical failures	Plate bend, stud broken, Support rod bend	Moulder failure	4.9793	4.7098	3.8326
		F11	nstrumentation Failure	Sensor cable, Sensor springs	Plate failure	5.1830	2.9555	5.4526
Pre-Cooking & Cooking Stretchin g Machine	Feeding System	F12	Mechanical Failure	Wear and tear, material fatigue, lack of maintenance, or overloading.	Complete stoppage of curd feeding, reduced throughput, and production delays	3.9374	4.9793	5.4583
		F13	Motor or Drive System Failure	Electrical issues, mechanical overload, or motor burnout.	Inability to move curd into the machine, production halts, and potential damage to other components.	5.4583	3.5003	3.7698
	e-Cooking Section	F14	Temperature Sensor Malfunction	Sensor damage, calibration issues, or electrical faults.	Incorrect temperature readings, leading to inadequate or excessive heating	2.7279	5.0212	5.0212
	mperature Control System	F15	Sensor Malfunction	Sensor degradation, electrical issues	Incorrect temperature control leading to poor cheese quality	3.8919	3.0567	3.4729

Normalized ranks are evaluated for all failure modes by considering experts overall weights. Decision matrix is created for all the components of identified most critical systems. Table 7 shows the decision matrix of three most critical systems i.e., for Moulder, Pre- Cooking & Cooking Stretching Machine and Stretching machine in mozzarella cheese processing plant. The normalized value of decision matrix is performed using above equation and the results are presented in Table 8. In multi-attribute decision-making methods, it is essential for attribute values to be dimensionless. This is accomplished by scaling each attribute to a range of 0 to 1, a process referred to as normalization. Moreover, all three parameters in this analysis are considered minimization criteria.

Table 8: Normalized decision matrix for PSI.

System	Component	Failure Order	SV	O	D
			Severity	Occurrence	Detection

The average values of the normalized data for each risk factor are computed.

NSV = 0.4643, NO = 0.5017, ND = 0.51819

The values of the variations of preference are calculated

θ SV = 0.6064, θ O = 0.6127, θ D = 0.4413

The values of the deviation of variations of preference are calculated

Ω SV = 0.3935, Ω O = 0.3872, Ω D = 0.5586

The overall criteria weights for all risk factors are calculated

ωSV = 0.2938, ωO = 0.2890. ωD = 0.4171

After calculating overall weights, the result is obtained by preparing a matrix by multiplying Nij and ωj. Table 9 shows the value obtained by multiplying Nij and ωj.

Table 9: Multiplication matrix of Nij and ωj.

System	Component	Failure Order	SV	O	D
			Nij x ωj	Nij x ωj	Nij x ωj

The values of the criticality index of each failure mode are obtained. Finally, the criticality index of a component is calculated by adding the values of the criticality index of all its failure modes. The same analysis was performed on all the 21 failure modes of the three critical systems of the mozzarella system in Table 10. The ranking of the components was then done according to their criticality index values and the findings of all the 11 chosen components in the three critical systems were tabulated in Table 12. Although several root causes were determined to cause the few failure modes, only the most important ones were taken into account in this study. Also, the values of the criticality index and their respective ranks were determined on some selected mozzarella systems.

The evaluation of the component criticality indices (CI) introduced in Table 11 allows identifying the most important systems that should be given special attention. The Pre-Cooking and Cooking Stretching Machine (CI: 3.2936) is the most important system, then there are the Moulder (2.3615) and the Stretching Machine (1.1231). In the Pre-Cooking and Cooking Stretching Machine, the most important component is the Temperature Control System (0.7686), and therefore predictive maintenance is necessary. The Moulder needs to attend to its Chilled Water Pump (0.6431) and Auger Motor (0.5732) whereas the Stretching Machine needs to look at the Motor and Drive System (0.6422). An organized maintenance plan according to these rankings can lead to better reliability, fewer failures and better operation efficiency.

Table 10: Critical ranks for failure modes.

System	Component	Failure Order	Failure Mode	Rank	Overall CI of Component	Overall CI of Sub- System (Failure modes)	Criticality Rank
Moulder	Auger Gearbox	F1	Misalignment	21	0.8742	5.5694	1

The overall criticality indicator for each subsystem is calculated by aggregating the Criticality Index values of all individual failure modes within that subsystem. Specifically, a weighted summation approach is applied, where each failure mode's Criticality Index is multiplied by its respective weight—reflecting its relative importance or impact—and then summed to obtain the subsystem's overall Criticality Index. This method ensures that more significant failure modes contribute proportionally more to the subsystem's total criticality, providing a comprehensive view of system risk.

Table 11: Critical ranks for prominent critical systems.

System	Component	Overall CI of Component	Overall CI of Sub-System	Criticality Rank
Moulder	Auger Gearbox	0.5604	2.3615	2
	Auger Motor	0.5732		
	Chilled Water Pump	0.6431		
	Ejector Plate	0.5848		
Pre- Cooking & Cooking Stretching Machine	Feeding System	0.6522	3.2936	1
	Pre-Cooking Section	0.6851		
	Temperature Control System	0.7686		
	Water Circulation System	0.7091		
	Motor and Drive System	0.4787

Comparison of results was done by using the Proposed Model, the Conventional RPN method, and the Normalized Median approach. The Normalized Median Rank provides a standardized measure that helps in comparing the criticality of failure modes across different systems or analyses. It aids in making informed decisions about where to focus resources for risk reduction and reliability improvement. The final results for the systems of the mozzarella cheese plant by the proposed integrated model (ExJ-PSI), conventional FMECA method and normalized median method is presented in Table 13.

Table 13: Comparative analysis of results for all subsystems.

Sr. No.	System	Rank by proposed model	Conventional RPN method	Normalized Median
	System	ExJ-PSI	Conventional RPN Rank	Normalized Median Rank
1	Moulder	1	1	1
2	Pre-Cooking & Cooking Stretching Machine	2	3	3
3	Stretching Machine	3	2	2
4	Stretcher Cooker	4	6	4
5	Hassia Machine	5	7	5
6	Pakonna Machine	6	8	6

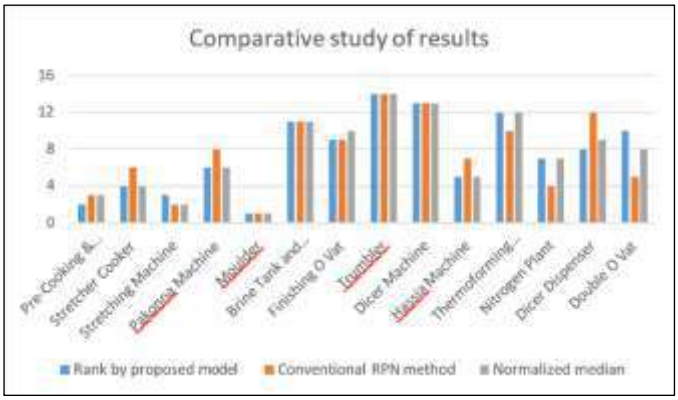

Figure 2: Comparative result of ranking of systems in Mozzarella cheese system.
Source: Authors, (2026).

The comparison between the rankings obtained with the proposed model, the traditional RPN method, and the normalized median values indicates that all the three methods determine the same key systems, summarized in Table 13. The ExJ-PSI method is more accurate with expert assigned weights which restricts the bias that is usually observed in conventional RPN scoring. Its normalization process also facilitates the comparison of various criteria on a similar scale that creates more definite and dependable risk priorities.

The approach also enhances efficiency in that it integrates the expertise with quantitative data in an organized manner, enabling the decision-makers to allocate resources faster and with more confidence. The ExJ-PSI model in practice is effective in complex settings like the mozzarella cheese processing where a combination of risk factors plays out. It is also very handy to both maintenance and quality teams due to its flexibility. In all three ranking techniques, the findings are similar.

The Moulder system is consistently ranked at Rank 1 which proves its significance in the entire process. The Stretching Machine remains on Rank 2 and the Pre-Cooking and Stretching Machine still remains at Rank 3. These consistent positions imply that such systems should be given priority to ensure a smooth and dependable running of plants. Minor variations in the rankings are observed when the normalized median values are compared with the suggested ExJ-PSI model and the classical RPN method. As an example, the Stretcher Cooker is ranked 4th in the proposed model and the normalized median approach, but 6th in the RPN approach, which indicates that its real risk could be more than the traditional RPN approach suggests. The same can be observed in the case of the Pakonna Machine, which is ranked 6th in the proposed and normalized ranking, but on the RPN one, the machine is ranked 8th, which indicates that there is a potential to misclassify the risk level.

Other statistically significant deviations are the Dicer Dispenser, which the proposed model ranks 8 th, the RPN method ranks 12 th and the normalized median method ranks 9 th. This diffusion means that the traditional RPN approach might underestimate its risk. The Nitrogen Plant is also inconsistent, keeping 7th position in the proposed and normalized approaches but increasing to 4th in the RPN method, indicating that statistical normalization offers a more consistent and realistic prioritization. The rankings of the Brine Tank and Circulation Pump (Rank 11), the Tumbler (Rank 14), and the Dicer Machine (Rank 13) have the same rankings in all three methods of evaluation, and there is a definite consensus that these systems are relatively less risky. The fact that the proposed model is close to the traditional RPN approach also contributes to the credibility of the new method. Simultaneously, the slight changes observed in the normalized median rankings suggest that statistical normalization can be added to identify subtleties that would otherwise be missed to provide the maintenance and risk-management choices with greater precision.

In comparison with FMEA and FMECA, the ExJ-PSI approach offers better grounds to prioritize failure modes within the setting like mozzarella cheese production. The conventional FMEA tends to generate duplicative RPN scores and does not distinguish between them, but ExJ-PSI uses expert-established weights and normalized factors to provide more consistent and less biased scores. FMECA is an improvement of FMEA with an element of criticality, yet it does not provide the flexibility and decision-making that are integrated in ExJ-PSI. With a combination of professional judgment and numerical scoring, ExJ-PSI method provides a more accurate prioritization, is more appropriate to food processing systems, and enhances the alignment of maintenance, reliability, and safety objectives. These results demonstrate the significance of periodically revising and enhancing the risk-assessment instruments to enhance the system performance and reliability of operation.

Figure 3 shows the summary of the work conducted on the mozzarella cheese system. The three most important subsystems i.e. Moulder, Pre-cooking and Stretching machine and Stretching machine of mozzarella cheese system is further analysed to rank the components on the basis of criticality. The results are categorized according to the level of criticality i.e. High criticality level, Moderate criticality level and low criticality level. The components with high criticality level that are ranked are Auger gearbox, Auger motor, Ejector plate, Motor and drive system, water circulation system and the Predictive based maintenance (PdM) and Condition based maintenance (CBM) plan is proposed to these components. Moreover, moderate criticality level components ranking evaluated are Chilled water pump, Feeding system, Pre-cooking system, Motor and drive system and the preventive maintenance plan is minimal is proposed to these components. These maintenance plan would be beneficial in terms of productivity with least break down and greatly enhanced the quality of cheese and the safety of the mozzarella cheese system.

IV. CONCLUSIONS

According to the analysis of the critical systems of an industrial mozzarella cheese facility, the integrated Expert Judgment-Preference Selection Index (ExJ-PSI) model was an effective and systematic way of detecting and prioritizing failure criticality. The methodology has succeeded in overcoming the limitations of the traditional FMECA-based ranking, especially the subjective scoring dispersion, disparity in weighting the criteria, and the ambiguity in evaluating the importance of failure. The most important conclusions made in this piece of work are as follows:

- The ExJPSI model defines plausible and bias-managed prioritization of failure modes. The framework reduced the variability in personal judgement by normalizing the opinions of several groups of experts, and converting them into objective weights, to achieve consistency in the evaluation. This method was very successful in solving close-ranking failure modes which could not be accurately differentiated by traditional RPN-based methods. The high congruence of the rankings obtained by ExJ-PSI and traditional procedures confirms its utility in the industrial environment and makes maintenance choices consistent with the operational risks that are realistic.
- Three systems were determined to be production-critical because of direct impact on the product formation and downstream reliability. The Pre-Cooking & Cooking Stretching Machine was the most important subsystem followed by the Moulder and the Stretching Machine. The research indicated that performance variability in these units has a major impact on the ultimate cheese structure, stretching behaviour, distribution of moisture and uniformity of the product. These results point to the necessity to distribute maintenance activities in a top-down fashion, starting with the subsystem that is most at risk.
- The component-level classification is a systematic maintenance roadmap to improve reliability. The critical components such as auger gearbox, auger motor, ejector assembly, and drive system need predictive or condition based maintenance to avoid failure. Items that are medium critical like water pumps, feeders, and pre-cooking units can be well handled by scheduled preventive servicing. Components with low criticality require simple routine checks. This classification also allows manufacturers to streamline the stocking of spare parts, maintenance schedules and staffing.
- The findings indicate that there are quantifiable industrial gains of implementing the ExJ-PSI-based ranking process. The strategy aids in minimizing unplanned stoppages, increased consistency in processes, greater use of assets, and greater forecasting of maintenance workload. Therefore, the ExJ-PSI model provides a scalable decision-support framework that can be generalized to other dairy-based processing systems and other multi-stage industrial equipment that needs the focus on reliability.

ABSTRACT

The objective of this study was to determine the contribution of scientific research to institutional transformation in the Peruvian Army. The eligibility criteria applied were topic, sources, methodological design, related topics, language, and publication date, which allowed for the analysis of 212 studies from different academic databases. Exclusion criteria, in a first phase, excluded duplicate studies; in a second phase, those that covered study topics and variables unrelated to the research; and in a third phase, those that did not provide the required information, after analyzing the title, abstract, and full text. The databases reviewed were Scopus, ScienceDirect, Scielo, Redalyc, ERIC, and Dialnet, during the first days of June 2025. Fourteen studies were included, whose main characteristic is their focus on strengthening education, research, and innovation in military and academic contexts. The main results show that scientific research constitutes a fundamental activity for the transformation of an institution, by strengthening ethical and professional training, promoting critical thinking, and optimizing evidence-based decision-making, fostering a culture of continuous improvement through the use of innovative methods and the inclusive participation of diverse stakeholders. Furthermore, this analysis revealed a limited research culture, which restricts the assessment, development, and effective application of scientific research in the process of institutional transformation. It is concluded that, although scientific research plays a crucial role in the institutional transformation of the Peruvian Army, its impact is conditioned by a still nascent research culture, which limits its full appreciation and application.

I. INTRODUCTION

As [1] assert, "technology and innovation in the defence and armed forces sector are critical components for guaranteeing a country's security and functioning." In essence, contemporary defence systems must transcend a reliance on operational force and instead integrate scientific knowledge and innovation capacity as foundational elements. This integration is imperative for the effective anticipation of threats, the adaptation to novel scenarios, and the maintenance of a credible deterrent posture. [2] asserts that the Peruvian Army is facing a number of challenges, as outlined in the Institutional Transformation Plan (PTI), including a lack of equipment, infrastructure, and other logistical capabilities.

These deficiencies have a detrimental effect on the Army's operational capacity. It is evident that the issue at hand cannot be resolved solely through investments in infrastructure or imported equipment. Instead, there is a necessity to fortify internal capabilities for diagnosis, solution design, and continuous improvement. These processes are contingent on knowledge generation and management. [3] asserts that "scientific research is a prerequisite for progress in all areas of society, and military science is no exception." Consequently, research stemming from military experience and context addresses real-world problems and offers applicable solutions that can directly contribute to institutional modernisation, doctrinal innovation, and improved performance in complex scenarios.

Furthermore, [4] state that "military organisations have a structure and a leading role in strategic areas focused on science, technology, and open innovation, conducting strategic programs and projects of economic and social interest," which allows for the integration of scientific research with decision-making at all levels of command. The present research seeks to transform scientific research into an active instrument for continuous improvement, innovation, and institutional transformation, thus closing the gap between the knowledge generated and its effective use in military operations. A particularly illustrative case is the diagnosis carried out in the Colombian Air Force (FAC), where the operational leaders themselves recognise that many of their needs can be addressed internally through scientific research processes. According to [5], "The mission area agrees that a significant proportion of the personnel requirements can be met through in-house research, but the ST process must be updated to achieve this."

This statement reveals an institutional disposition towards applied research. As [6] asserts, it is imperative to analyse institutions from the standpoint of organisational culture, as it is widely acknowledged to be a pivotal element in the realisation of an organisation's objectives. In the absence of an institutional environment that acknowledges the significance of generating and applying scientific knowledge, even the most meticulously designed reforms risk being rendered ineffective. In the Peruvian Army's current educational system, there is a hierarchical structure that begins with the Ministry of Defence, passes through the General Directorate of Education and Doctrine, and continues on to the Army's Directorate of Education and Doctrine (DIEDOCE), the Army's Education and Doctrine Command (COEDE), and finally, the Army's educational institutions, which are subordinate to this command. The Army is responsible for the provision of undergraduate and postgraduate educational programmes.

The former encompasses university professional training and technical/technological professional training, while the latter comprises doctorates, master's degrees, diplomas, second professional specialisations and continuing education. The promotion and development of military research is facilitated through the academic programmes conducted by these institutions [7]. The significance of this research lies in the educational responsibility incumbent upon the Army with regard to the challenges involved in implementing an effective and structured system that fosters scientific research. These challenges encompass the inadequate management of scientific research, the necessity to increase the impact and significance of published research, and the improvement and augmentation of resources necessary for the sustainability of scientific research processes. The rationale underpinning this research is the pursuit of enhancing scientific output within the Army, a pursuit that will yield dual benefits for its members.

On the one hand, it will enable them to cultivate critical and strategic skills, and on the other, it will have a positive societal impact in Peru by generating knowledge applicable to national defence, security, and social development. Conversely, this research is pertinent to the management of scientific research in the Peruvian Army, with a particular focus on the undergraduate and graduate schools that fall under the jurisdiction of the Army Doctrine Directorate (JDOCE), within the Army Education and Doctrine Command (COEDE), as these entities are responsible for scientific production within the institution. In this sense, the general research question guiding this study is as follows: How does scientific research contribute to institutional transformation in the Peruvian Army? The specific research questions to be addressed are as follows:

This study sets out to investigate the influence of scientific research results on modernisation processes, doctrine and decision-making in the Peruvian Army. Furthermore, it seeks to ascertain the perception of members of the Peruvian Army with regard to the impact of scientific research on organisational change. The aforementioned limitations have a restrictive effect on the institutional capacity to contribute innovative knowledge that would otherwise strengthen the functions of the Peruvian Army. The objective of this study is to determine the contribution of scientific research to institutional transformation in the Peruvian Army. The objective of this research is to establish an optimal scientific research management system that allows the research carried out by the members of the institution to be used, providing tools for the improvement of the processes and development of these.

I.1 BACKGROUND

In [8] posit in their research, titled "Security and Defense, Technological Development, Innovation, and Transformation," that contemporary threats are inducing a transformation of military forces to operate in new, complex scenarios. According to [9] conducted a study with the title "Changing Mindsets: The Transformation Process of the Colombian National Army (2011–2018)," it is stated that "education, both domestically and internationally, has facilitated the conceptualisation and implementation of an institutional cognitive transformation from the top-down, with the endorsement of the Army itself for its design and execution."In the present study, [10] explore the intricacies of "Technology and Innovation Management in the Defense Sector: Results from a Bibliometric Analysis," states that "there is a necessity for structured and systematic processes for managing technology and innovation, which allow for supporting decision-making regarding R&D&I processes.

"In his research entitled "Some Ideas on Scientific Research" [11], the author asserts that the purpose of scientific research is to verify, refute, expand upon, or propose new experimental or theoretical contributions to the body of science being addressed. In his research paper, entitled "Educational Management as a Driver of Scientific and Technological Research:", By [12] explores the potential impact of educational management on the promotion of scientific and technological research. New horizons for innovation" [Educational management as a driver of scientific and technological research: New horizons for innovation] mentions, "Education and research have a reciprocal relationship. It is evident that research produces education, while education, in turn, enhances research. Both of these factors enable individuals to engage in recreational activities, enhance their abilities, develop new skills, and achieve personal growth within the designated space-time continuum.

II. METHOD

In order to ensure the rigour, transparency, and reproducibility of this study, the PRISMA methodology was employed. This methodology facilitates the systematic structuring of the identification, selection, and analysis of relevant scientific literature. The PRISMA statement, published in 2009, is a reporting guideline designed to address the problems in the publication of systematic reviews [13].

II.1 ELIGIBILITY CRITERIA.

The following eligibility criteria were established for this research:

- Topic: Research that links scientific research as a driver of institutional transformation in the Army or armed forces of Peru or other countries.
- -Literature sources: Peer-reviewed scientific articles published in indexed academic journals.
- -Methodological design: Studies may employ a quantitative, qualitative, or mixed-methods design.
- -Related topics: Research addressing concepts related to scientific research, scientific study, and academic research, along with terms associated with the military sphere, such as army and armed forces, is considered.
- -Language: Studies must be written in English, Portuguese, and Spanish to facilitate analysis and understanding, and to maintain a Latin American context throughout the research.
- -Publication date: Research must have been published between January 1, 2021, and May 30, 2025.

II.2 SOURCES OF INFORMATION

The following platforms were consulted in order to conduct the research: Scopus and ScienceDirect, which offer high-impact, multidisciplinary academic literature; SciELO and Redalyc, which focus on research in Spanish from Latin America and the Caribbean; ERIC, which specialises in educational studies; and Dialnet, which provides access to scientific output in Spanish, especially in the social sciences and humanities. The preceding five-year period was the subject of the study. The databases were consulted on 6 June 2025.

II.3 SEARCH STRATEGIES

For the search strategy, the keywords “scientific research” and “Army” were identified, along with their corresponding synonyms. Using the Boolean operators AND, OR, NOT, (…) and “…”, the following search equation was applied:

((“scientific research”) OR (“scientific study”) OR (“academic research”)) AND ((army) OR (“armed forces”)).

The filters applied to all databases were:
- Subject areas: Social Sciences
- Access type: Open Access
- Publication dates: January 1, 2021 to May 30, 2025

II.4 SELECTION PROCESS

The selection process will be carried out in accordance with the guidelines established by the PRISMA methodology. A systematic search strategy will be conducted in six recognised academic databases, with the objective of compiling all potentially relevant research. Subsequent to the compilation of the records, the implementation of automated tools and manual review will be employed for the purpose of the elimination of potential duplicates. Subsequent to this, the studies will be evaluated through a progressive analysis. Initially, the titles will be examined, followed by the abstracts, and finally, the full texts of the studies that have passed the previous stages. The present review will be based on a set of predefined criteria, with a focus on thematic relevance, specific variables, and methodological quality. The data cleaning process will be executed in two successive phases to ensure that the studies included in the final analysis rigorously address the study's objectives.

III. RESULTS

A total of 212 studies were identified through searches in six academic databases: Scopus (n=29), ScienceDirect (n=46), SciELO (n=12), Redalyc (n=80), ERIC (n=13), and Dialnet (n=32). Following the compilation of the results, two duplicate studies were eliminated through the utilisation of automated tools and manual review, resulting in a total of unique studies that advanced to the subsequent stage. During the selection process, 183 studies were excluded. Of these, 159 were discarded for not directly addressing the study's central theme, which was the role of scientific research in institutional transformation processes within military or similar contexts. Furthermore, 24 studies were excluded on the grounds that they failed to consider the specific variables defined in this review. These included the link between academic research, organisational change, and the armed forces environment. This filtration process was implemented to ensure that the analysis remained exclusively focused on literature that was deemed relevant to the research objectives.During a subsequent review phase, 13 further studies were excluded.

Following a thorough review of the titles, five of these were discarded as they were deemed to be unrelated to the research topic. Following a thorough review of the abstracts, a further five were disqualified on the grounds that they failed to adequately address the correlation between scientific research and institutional transformation. Following a thorough examination of the full texts of three studies, they were ultimately excluded from the review due to their failure to meet the established criteria for analytical depth and methodological relevance. The process of identifying, selecting, and excluding studies was carried out with methodological rigor. This ensured that the works ultimately included in the systematic review met the criteria for relevance, scientific quality, and thematic pertinence, thus guaranteeing a solid foundation. In order to facilitate a more comprehensive understanding of the methodology, the flowchart (Figure 1) is presented, illustrating the application of the PRISMA approach.

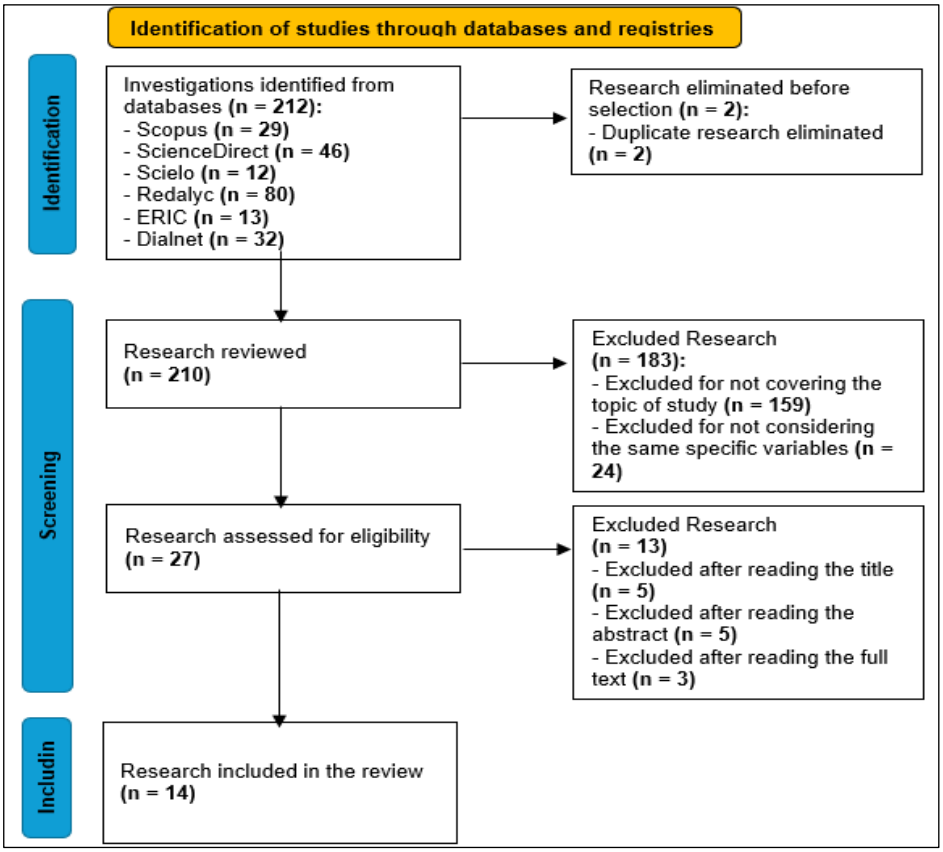

Figure 1: PRISMA flowchart for item selection.
Source: Authors, (2026).

The exclusion process was fundamental to ensuring that the final analysis was based solely on scientific literature aligned with the research objectives. The stages at which various studies were discarded, as well as the specific reasons justifying their exclusion, are detailed below. Following a thorough examination of the titles, it became apparent that the subsequent studies were to be excluded on account of the fact that they did not directly address the relationship between scientific research and institutional transformation in military contexts. Furthermore, they did not take into consideration the specific variables that had been defined for the present systematic review. In [14] published an article entitled "Improving Language Learning with Virtual Reality: A Quasi-experimental Study" focuses on language learning through immersive technologies, without any relation to organisational structures or armed forces. By [15], "Ecuadorian Air Force: On the Road to Multidomain. A Transdisciplinary Analysis of Complexity", despite its focus on a military institution, exhibits a geostrategic emphasis and does not prioritise scientific research as a transformative axis.

In their 2022 publication, [16] explore the concept of "Global and Local Knowledge for English Language Learning: A Study at a National Police School", focuses on English language learning in a police academy, without any connection to institutional transformation or the Army as the institution under study. In [17] have utilised the PLS model to explore the dynamics of HRM. The moderating roles of self-efficacy and organisational commitment in work engagement and talent turnover intention" addresses human resource dynamics in a general organisational context, without mentioning the defence sector or the use of research as a driver of institutional change. [18] provide an analysis of "Gender Education of Cadets in Higher Education Institutions of the Ukrainian Security Forces" [Gender Education of Cadets in Higher Education Institutions of the Ukrainian Security Forces]. While the focus of this analysis is on the Ukrainian security forces, it is pertinent to note that the analysis does not address the structural role of scientific research.

Following a thorough review of the abstracts, it was determined that the subsequent studies were to be excluded from consideration. While some of these studies were conducted within academic or institutional settings, it was observed that they failed to directly address the relationship between scientific research and institutional transformation within the military context. Additionally, these studies did not take into account the key variables that have been established in this review. In [19], "The Academic Performance of Cadets at the National Air Force Academy of the Republic of Angola," whilst situated in a military environment, focuses on the academic performance of cadets without analysing the role of scientific research as a driver of institutional change [19]. By[20] conducted an examination of approaches to material hardship classification.

Cross-sectional and longitudinal perspectives" addresses issues of social and economic classification, without any connection to military institutions or organisational transformation processes linked to research. In [21] conducted a study on the impact of Faculty Development Programmes (FDPs) on professional efficacy in developing countries. A comparative study among participants and non-participants of FDP in Bangladesh," focuses on faculty development programs in educational institutions in Bangladesh, without any connection to the armed forces or institutional change processes derived from scientific research. According to [22]. "A Librarian's Perspective on Sci-Hub's Impact on Users and the Library," undertakes an analysis of the impact of Sci-Hub on access to information. Notably, the analysis does not make any thematic connection to institutional transformation or the military environment.

By [23], "Preliminary investigation and analysis of the impact of the Sudan War on higher education and scientific research sectors", whilst mentioning scientific research, is situated within a context of conflict and general educational crisis, without exploring its structural role in processes of reform or institutional transformation in military environments [23]. Following a comprehensive review of the full text, the following studies were excluded from further consideration. While these sources initially appeared relevant due to their references to academic, scientific, or military contexts, it was determined that they did not meet the specific criteria of analytical depth, thematic relevance, and alignment with the central variables of this research. According to [24], "Analysis, classification, and philosophical foundations of critical thinking models", whilst providing valuable conceptual reflection on critical thinking, does not link its contributions to institutional development or the military or armed forces environment.

In [25], "Salvador Mazza, military doctor. Analysis of his professional career and scientific production in the Argentine Army Health Service," while focusing on a figure in the military sphere and his scientific output, takes a more historical and biographical approach than an analytical one regarding the impact of said output on contemporary institutional transformation processes. In the 2024 publication entitled "Educational Capital and International Mobility:", Khan provides a comprehensive analysis of the impact of educational capital on international mobility. A Bourdieusian inquiry into choosing peripheral higher education destinations," develops a sociological approach to international educational mobility from a Bourdieusian perspective, but does not consider the role of scientific research within military organisations or its institutional impact.

The selected studies were included in this systematic review because they directly address topics related to the academic and scientific environment in military contexts, such as training in military institutions, professional performance, educational innovation, organisational climate, the development of research capabilities, and strategic planning within the armed forces. All of the studies meet the established criteria for thematic and methodological relevance, as they explore key variables related to institutional transformation through scientific research. Furthermore, they present a solid methodological structure, offer relevant theoretical frameworks, and provide empirical contributions that strengthen the understanding of the role of academic research as a driver of change and modernisation within the Army and other armed institutions. In this regard, a table (Table 1) is presented with the main characteristics of the selected research.

Table 1: Characteristics of the studies analyzed according to the PRISMA methodology.

Authors and year	Title	Aim	Methodology	Results
Palma & Andrade (2020) [26]	Adaptação ao ensino superior militar: preditores do sucesso académico	To identify and characterize the stressors present in the effort to adapt to military higher education, analyzing how they evolve over the years and constitute possible predictors of academic success.	Quantitative, cross-sectional and applied approach, with both descriptive and explanatory objectives.	The longitudinal nature of the study emphasizes the results obtained and suggests that, in subsequent studies, correlations should be established with measures of self-esteem and performance as official measures in an operational context.
Shang (2021) [27]	Research on the Construction of Sci-tech Periodicals in Military Academies Based on Spearman Correlation Analysis of Academic Evaluation Index	Analyze the overall influence of scientific and technological (sci-tech) journals from military academies and how factors such as the proportion of funded articles affect their impact factor.	Quantitative approach Indicators such as total citation frequency, proportion of funded articles, external citation rate, and impact factor were collected and analyzed.	It was identified that the overall influence of these journals still needs improvement The proportion of funded articles has a positive effect on the impact factor.
Espitia Cubillos, Agudelo Calderon & Ramirez Contreras (2021) [28]	Perceptions of technological innovations in the Colombian Army	To detect expectations regarding innovative trends based on the perceptions of active members of the Army.	Approach: Mixed, combining interviews (qualitative) and surveys (quantitative). Scope of research: Exploratory and descriptive. Design: Cross-sectional experimental.	All the categories studied are important and cannot be eliminated or grouped into another or others, and those related to the defense of the community and the territory are of greatest interest to the participants of the study.
Marchisio & Spinello (2021) [29]	Internationalizatio n for Enhancing the European Security and Defence Higher Education	Identify which internationalization initiatives and policies can be developed and how they should be implemented to strengthen Higher Education in Security and Defense in Europe.	The experiences of the University of Turin over the past seven academic years were analyzed. Both quantitative and qualitative data were used.	The study highlights the positive impact of these initiatives on the development of academic networks and intercultural skills.
Reyes, Ariza, Alves (2021) [30]	Moral development in educational contexts: A systematic review	Identify the evidence available in the scientific literature related to the study of moral	Bibliographic database searches were conducted using predetermined search criteria,	The results suggest the influence of the educational context on moral development, from all levels of educational

		development in educational contexts.	following the PRISMA methodology.	training, encouraging the development of studies that enrich the scientific discussion.
Semenenko, Kirsanov & Chernyshova (2022) [31]	A Mathematical Model to Determine the Optimal Ratio of Researchers of Different Categories for Solving a Scientific Problem in the Military Sphere	To propose a variant of a mathematical model that justifies the optimal proportion of researchers from different categories to carry out scientific research of the highest possible quality, within a context of limited resources.	The methodology is based on the formulation of a mathematical model that describes the relationship between the quality of scientific research and the number of researchers, using a canonical parabola equation. The method of Lagrange multipliers is employed.	The results of the numerical experiment validate the usefulness of the model for improving research planning and performance in military institutions.
Surkov (2022) [32]	Elaboration of a method for strategic analysis of the development of the Armed Forces	Determine (clarify) the long-term strategy for developing the capabilities of the Armed Forces.	The methodology employs a conceptual approach that combines the selection of priority areas for capacity building with a recursively organized computational process.	The SADAF-RW method provides objective and quantifiable assessments of the effectiveness of strategic decisions, projecting the expected effects of the selected strategies.
Candumbo, Caimbo & Varona (2022) [33]	Pedagogical foundations of the professional military performance of the human resources of the Angolan Army Academy	To assess the pedagogical foundations of the professional military performance process of the human resources of the Military Academy of the Army (AMEX) of the Republic of Angola.	Using a qualitative methodology, documentary research is used to refer to the norms that support postgraduate education.	The pedagogical foundations of the advanced education theory regarding the professional military performance of human resources and its structuring in the practice of military education were identified.
Yahupov, Bielikov, Tkachenko (2023) [34]	Lifelong learning: models and methods of implementation	To present results of scientific research aimed at improving the efficiency of the educational process within the framework of continuing education, addressing key issues such as the development of organizational skills, adult education, foreign language learning, university professional development and receptiveness to change.	Various methodological approaches were used depending on the chapter. These included pedagogical experiments to analyze the development of organizational skills in military cadets, comparative analyses between the educational systems of Ukraine and Sweden, the design and implementation of innovative models such as the flipped classroom and methodologies based on technological immersion, as well as studies on university management and corporate training using active methods and coaching.	The studies made it possible to demonstrate progress in the development of key components of organizational competence in cadets, identify global and local trends in adult education, and propose effective models for language learning in multicultural contexts.
Calderón, Godoy, Marrero (2023) [35]	Validation of an Organizational Climate Scale in a Military Higher Education Institution: Implications for Research and Practice	Measuring the organizational climate in military higher education institutions in Ecuador.	The research is framed within the positivist paradigm. It employs a quantitative approach. The type of research is descriptive. The research design is based on a cross-sectional approach.	This study contributes to the understanding of the organizational climate in military higher education institutions in Ecuador and may have implications for the management and improvement of educational quality in the context of higher education in Ecuador.
Espiñeira, Muñoz & Garcia (2023) [36]	Perceptions and effectiveness of plagiarism detection mechanisms in Spanish, Portuguese and Ibero-American	To analyze the practices and perceptions regarding plagiarism detection in Ibero-American Social Sciences scientific journals indexed in Scopus, identifying the tools used, the editorial rejection	A mixed-methods approach was used.	The study revealed that most journals use plagiarism detection software, although there are doubts about its effectiveness.

	social science journals	criteria, and the effectiveness of current preventive measures.		
Kuchinski (2023) [37]	Exploring Perceptions on the Influences of Mentor-Mentee Relationships on Graduate-Student Learning	To explore graduate students' perceptions of how mentor-mentee relationships influence their learning within the U.S. Army's Master of Military Arts (MMAS) program.	A qualitative design of multiple case studies was used.	The study provides useful evidence to better understand the role of mentoring in academic settings, strengthen teacher development, and prepare mentors and students for their postgraduate academic journey.
Kuchinski (2024) [38]	A dinâmica da política de ensino: Uma perspectiva global da educação	To explore the dynamics of teaching politics in education at a global level, identifying approaches, challenges and good practices to assess its importance in the context of local political crises and global issues such as climate change, security and peace.	Narrative literature review.	The study provides an overview of the current state of political education in the world and recognizes the dynamics of its teaching.
Fernandez, Miron Sophía (2025) [39]	Contributions of the inductive method to the teaching of military ethics	Evaluate the impact of the Basic Concepts in Military Ethics course and its inductive approach on the attitudes and behaviors of Colombian military personnel.	A quantitative approach methodology was applied.	It was identified that the course had a positive impact on participants' attitudes regarding the importance of military ethics, its contribution to unit cohesion, and its influence on responsible decision-making.

Source: Authors, (2026).

In the domain of military higher education, numerous studies underscore the significance of enhancing academic adaptation, cultivating organisational skills, and fortifying pedagogical foundations. [26] identified stress factors that influence cadets' academic performance. In their 2021 study, [29] emphasised the role of academic internationalisation in the development of cooperation networks and intercultural skills in the European defence and security context. By [33] analysed the pedagogical foundations that underpin the training of military personnel in Angola. In addition, [34] have proposed innovative continuing education models with a view to improving the training efficiency of cadets and military professionals. In their 2023 study, Calderón et al. explored the organisational climate within military higher education institutions, offering practical methodologies to enhance educational standards.

As [37] demonstrated, through a series of case studies, the positive impact of mentorship on the learning of postgraduate students in military arts. By [39] demonstrated that the inductive approach to military ethics instruction fosters unit cohesion and responsible decision-making, thereby contributing to the moral development of military personnel. In the domain of scientific production and knowledge management within military institutions, [27] conducted a comprehensive analysis of the factors that influence the impact of military science and technology journals. The study revealed a direct correlation between the proportion of funded articles and their visibility. According to [36] addressed the issue of plagiarism detection in social science journals in Latin America, highlighting the widespread use of anti-plagiarism software, although with reservations about its effectiveness. In [31] developed a mathematical model to optimise the proportion of researchers based on the expected quality of the research, thus improving scientific planning in contexts with limited resources.

In the domain of technological modernisation and institutional perception, [28] investigated the perceptions of Colombian Army personnel regarding technological innovations, concluding that categories related to territorial defence are the most pertinent for the military. In [32] proposed a computational method (SADAF-RW) for the analysis and projection of the development of Armed Forces capabilities, providing a quantitative tool for long-term decision-making. In the domain of ethical, political and civic education, [30] conducted a systematic review that confirmed the influence of the educational environment on moral development at different levels of education. In the 2024 publication, Khanh (2024) explored the dynamics of teaching politics from a comparative perspective, emphasising its significance in the context of contemporary challenges, including security issues, climate change, and socio-political crises.

IV. DISCUSSION

IV.1 COMPARISON WITH OTHER STUDIES

The present research is distinctive in its adoption of a systemic and institutional perspective, a departure from the approaches of other academic works in this field. In contrast to [26], who address the factors of academic adaptation in cadets from an individual and cross-cutting approach, this work transcends the formative level to analyse how structured research processes impact organisational and doctrinal redesign. According to [39] emphasise the value of the inductive method in military ethics education, this research contends that such methods must be articulated within an institutional culture oriented towards critical thinking, within a cross-cutting axis of modernisation.

In relation to the research conducted by [29] on the internationalisation of defence education, the necessity for inclusive participation is emphasised, and structural reforms that integrate all institutional actors into open and technologically adaptive knowledge policies are proposed. According to [31], [32] have each contributed mathematical models for the optimisation of research and strategic planning. This work draws on these contributions to emphasise that their effectiveness is only guaranteed if they are integrated into a solid institutional science policy with robust normative and ethical structures. In the present study, [35], [34] analyse the impact of organisational climate and individual receptiveness to change. In contrast to the present study, which examines these psychosocial factors in relation to structural, political, and educational variables, this work posits that research should be positioned as a catalyst for organisational change rather than as an isolated effort.

IV.2 IMPLICATIONS OF THE STUDY

It is evident that scientific research, far from being a complementary function, must be institutionalised as a strategic capability that contributes to doctrinal development, evidence-based decision-making, and the professionalisation of military personnel. It is imperative that research policies are accompanied by structures that guarantee academic integrity, methodological validation, and the production of applicable knowledge. By [36] posit that the absence of rigorous control systems can compromise the credibility of scientific products, thereby diminishing their potential to influence real-world decisions. In this sense, the assertion by [33] regarding the need to ground professional development in research processes is fully relevant: advanced science-based training strengthens both operational capacity and institutional legitimacy.

IV.3 ADDED VALUE

In contrast to studies that concentrate on fragmented formative, normative, or technical aspects, this work integrates them to formulate a systemic vision of institutional change. A seminal contribution of this study lies in its establishment of a nexus between organisational culture and research transformation, thereby underscoring the pivotal role of critical thinking, academic mentorship (as articulated by [37]) and strategic political education (as expounded by [38]) as interwoven pillars of military leadership. Moreover, it puts forward an interpretation that is firmly embedded within the Peruvian context, yet with a pronounced emphasis on the opportunities presented by existing human capital, as articulated by [28].

IV.4 RECOMMENDATIONS FOR FUTURE STUDIES

It is recommended that further longitudinal studies be conducted in order to evaluate the real impact of scientific research on operational indicators of the Army. Such indicators may be categorised as follows: logistical effectiveness, deployment capacity, and doctrinal innovation. In the context of Peruvian armed forces, the undertaking of comparative studies among Latin American armed forces with varying degrees of scientific institutionalisation would prove pertinent in order to extract models that are adaptable to the Peruvian context. Another under-explored area is the evaluation of incentive and recognition policies for research within military careers, as well as their impact on the motivation and retention of scientific talent. It is recommended that efforts be undertaken to develop return-on-investment models for military research that evaluate not only the technical impact but also the effect on organisational cohesion, institutional legitimacy, and civil-military cooperation.

V. CONCLUSIONS

Scientific research contributes significantly to institutional transformation in the Peruvian Army by strengthening the academic and professional training of military and civilian personnel through the implementation of strategically planned educational processes that foster critical thinking, ethical reflection, and the generation of relevant knowledge. This process has been shown to enhance curricular content, whilst concomitantly effecting a transformation in the axiological and leadership profile of future officers. This, in turn, serves to promote an organisational culture oriented toward continuous improvement. Institutional transformation driven by research also requires the coordinated participation of multiple actors within the organisation and the adoption of inclusive policies that respond to new realities. This is necessary to guarantee the comprehensive, ethical, and sustainable development of institutional capabilities.

The findings of scientific research have been shown to exert a considerable influence on the processes of modernisation and decision-making in the Peruvian Army. This influence is evidenced by the provision of methodological and quantitative tools that serve to optimise the allocation of resources, enhance strategic planning, and fortify the quality of the knowledge generated. Research facilitates an objective evaluation of institutional capabilities, fosters transparency and effectiveness in decision-making, and contributes to enhancing academic prestige through high-impact publications. Moreover, the scientific and pedagogical training of military personnel fosters an organisational culture predicated on evidence, continuous improvement, and innovation – pivotal aspects for sustainable modernisation and decision-making consistent with contemporary challenges.

The Peruvian Army members' perception of the impact of scientific research on institutional transformation is influenced by a number of factors. These include their level of receptiveness to innovation, the organisational climate, and their training experiences in academic or mentoring contexts. While certain sectors are proactive in their promotion of change by acknowledging the strategic significance of science in the modernisation of procedures, technologies and doctrines, others adopt a more conservative approach due to hierarchical rigidity or structural limitations that impede participation. However, there is a general perception of the Army's innovative potential, based on its skilled and committed human capital and the need to integrate scientific research not only into technical aspects but also into the political and strategic training of personnel. This would promote a comprehensive, critical and adapted institutional transformation to contemporary challenges.

Financial support

The research was conducted without financial support from any institution; the researchers themselves covered all necessary expenses throughout the research process.

Conflicts of interest

The research was conducted without any conflicts of interest that could have potentially influenced the results.

Data availability

The data are available to any researcher who wishes to use them for methodological and scientific purposes

ABSTRACT

Early detection of Alzheimer's disease (AD) is vital for effective intervention and management. This study introduces a novel approach that employs a ResNet architecture for feature extraction from neuroimaging data, coupled with Support Vector Machine (SVM) tuning for classification. We utilized a dataset of MRI scans from subjects at various stages of cognitive decline. The ResNet model was fine-tuned to identify complex patterns in brain structure indicative of early AD. Features extracted from the network's final layers were then input into an SVM classifier, optimized through grid search to improve classification accuracy. The parameters are tuned and the final layer in Resnet-53 is used for Support Vector Machine (SVM) model. It is mainly used for detection of Alzheimer's, and it addresses the both binary and multiclass classification. But we are using multiclass labels are used so it is used for multiclass classifications. Bayesian optimization with Hyperopt is used in a fine tune process to find the hyperparametrs space, optimizing key variables such as kernel selection and regularization to increase the performance of the model on the validation set. The proposed method is used to show the most accurate difference between normal cognitive aging and Alzheimer's disease, which is so sensitive and specific to achieve. Multimodal data is combined to increase the models performance and provides comprehensive tools for early detection.

I. INTRODUCTION

Alzheimer's disease (AD) is a increasing neurodegenerative condition described by intellectual regression, memory loss, and weakened decision-making. It is one of the heading causes of dementia, involving millions of people worldwide [1]. The prompt and correct diagnosis is important for appropriate interference and advanced patient outcomes. However, the conventional diagnostic methods, involving clinical assessments and neuropsychological tests, are frequently biased and may lack correctness. The advanced machine learning (ML) techniques, specifically deep learning models, have developed as effective tools for improving the accuracy and efficiency of AD detection [2]. In current years, convolutional neural networks (CNNs) have been extensively used for medical image analysis, exhibiting excellent performance in feature extraction and classification tasks. Among these, ResNet-50, a deep CNN architecture, has shown outstanding efficiency in capturing complicated patterns from neuroimaging data, predominantly from MRI scans [3].

In this study, ResNet-50 is utilized for feature extraction, using its deep categorized structure to distinguish between different stages of Alzheimer's disease. Besides, Support Vector Machine (SVM), a robust classification algorithm, is enhanced using Bayesian hyperparameter tuning (Hyperopt) to improve classification performance. This research aims to develop a reliable ML-based framework for automated AD detection, grouping patients into four groups: Non-demented, Very Mild Demented, Mild Demented, and Moderate Demented. By incorporating deep learning with optimized classification techniques, the proposed approach improved the sensitivity and specificity, by this means assisting clinical decision-making and progressing diagnostic methodologies in neurodegenerative diseases.

I.1 AD DISEASE DETECTION USING TRADITIONAL CNN:

It describes a process in which MRI samples are converted into JPEG slices using MATLAB, rescaling to 8-bit pixel size from the original 14-bit size. The three blocks that comprise the proposed model are an ensemble of convolutional, ReLU activation, & max pooling layers in each block. A flattening conv layer, two fc layers, two sets of convolutional and max pooling layers, and a softmax/sigmoid classifier are all included in the design. MCI, NC, & AD are the output classifications [4]. The input is a 256x256 grayscale image that undergoes conv layers with 32 mappings for features. The filter size is 3x3, and ReLU activation. Max pooling is applied with a size of filter 3x3, resulting in image dimensions of 84x84x32. Subsequent layers include a 2nd conv layer with 64 FM & a 3rd convolutional layer with 128 FM, connected to max pooling [5]. The flattened layer has 8192 parameters. A conv layer containing 256 1x1 feature maps is used as the fifth layer, which is fully coupled to the layer before it. The last layer is a completely linked softmax output layer of 10 potential values, while the sixth surface is an entirely linked layer with 256 units. The overall architecture for this methodology is presented in figure 1.

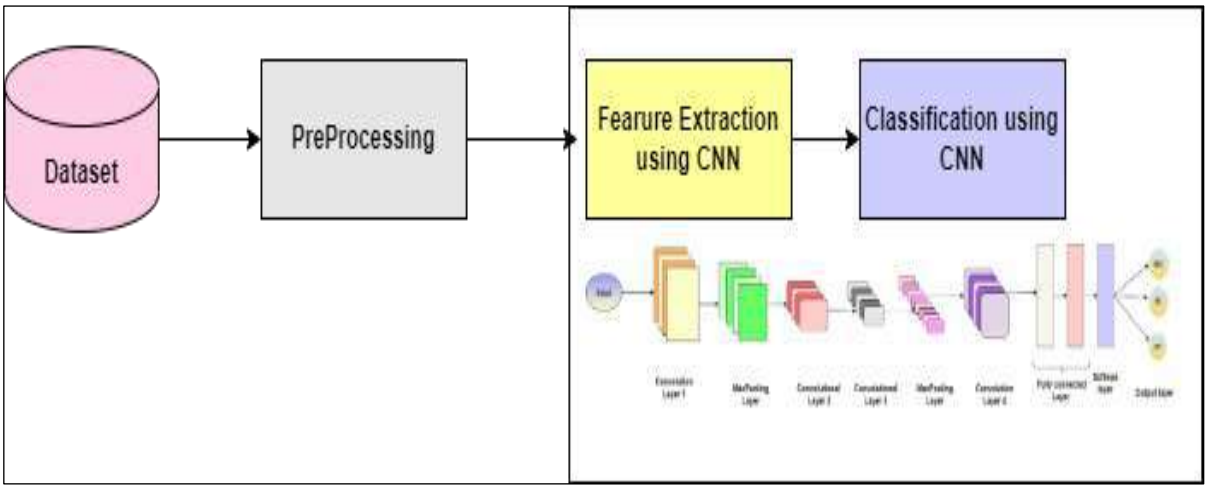

Figure 1: Traditional CNN along with Feature Extraction.
Source: Authors, (2026).

I.2 AD DISEASE DETECTION USING INTEGRATED CNN WITH CAD:

A CAD (Computer-Aided Diagnosis) device utilizing a convolutional neural network (CNN) was developed to distinguish Alzheimer's Disease (AD) from normal control (NC) patients. The CAD system analyzed 18FDG-PET images and employed a CNN to extract relevant features. The pictures were divided into several 2D slices and clustered at regular intervals without crossing. The ADNI dataset was used to assess the proposed CAD system. The suggested CNN-based CAD system performed exceptionally well in simulations, outperforming other techniques in terms of precision in classification and resilience [6]. The findings strongly indicated that the proposed system had a higher potential for effectively differentiating AD from NC patients.

I.3 ALZHEIMER'S DISEASE DETECTION USING CUSTOMIZED CNN:

Data pre-processing was performed on the OASIS dataset to address the influence of different image sizes. [3] Image resizing using OpenCV Python was employed to reduce training time, while image denoising was conducted to improve model performance. The dataset was labelled for binary classification based on CDR 0 | 1, representing Non-Demented and severe Alzheimer's cases, respectively. An equal number of patients with Alzheimer's Disease and those without dementia were included in the training and testing datasets, which were divided into 8:2 ratios and developed a 12-layer CNN structure to classify and identify Alzheimer's Disease in binary form. [2]

Model used data pre-processing methods such as picture scaling and image denoising for our investigation, which used the OASIS dataset [7]. The suggested model combines machine learning and deep learning techniques. It performs better than four previously trained CNN models and a pre-existing 8-layer CNN model. Model intend to broaden our investigation in future work and concentrate on the untimely diagnosis of AD using multiple classification classes using the OASIS dataset. Figure 2 presents the Customized CNN architecture.

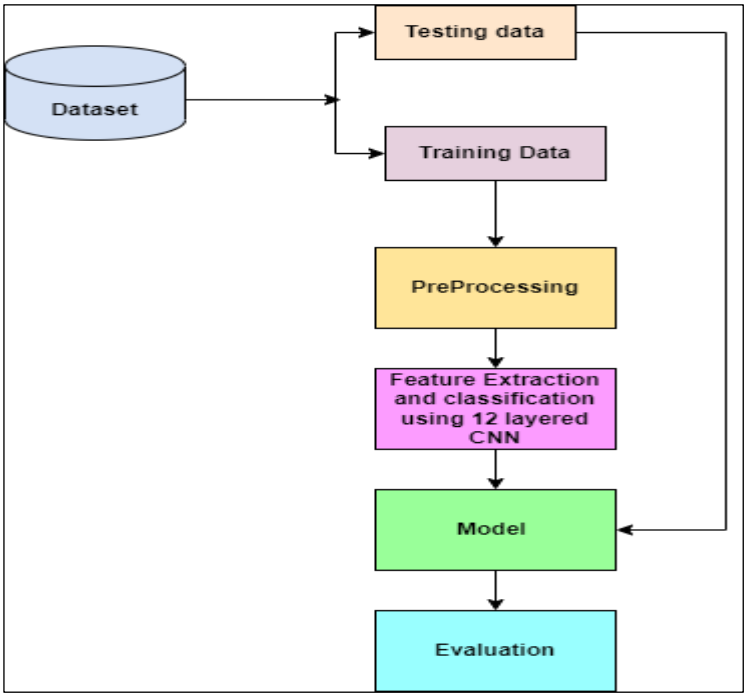

Figure 2:12-layered CNN for Disease Detection.
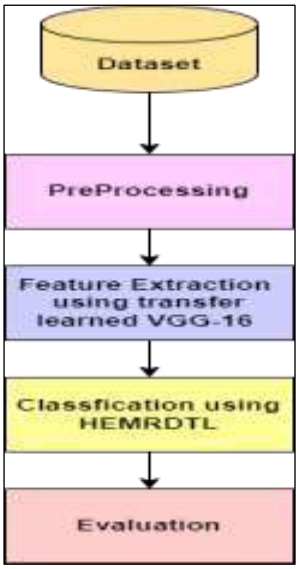
Source: Authors, (2026).

I.4 ALZHEIMER'S DISEASE DETECTION USING HYBRID MODELS:

A hybrid signal methodology called HEMRDTL is proposed for the analysis & classification of AD. [8] The model combines EEG-Fused CT/MRI data and utilizes transfer learning with a VGG-19 TranL deep neural network. The HEMRDTL model outperforms other transfer learning models in terms of accuracy. Future research using genetic biomarkers & OCT images for early detection of AD is mentioned, highlighting the differentiation of the eye region in individuals with AD and the relevance of genetic biomarkers for diagnosis and prognosis [9]. Obtaining a series of OCT images showing people with AD is a goal for further research in this important area. Leveraging additional data sources could enhance the precision & viability of early AD detection. Figure 3 presents the Hybrid model detection



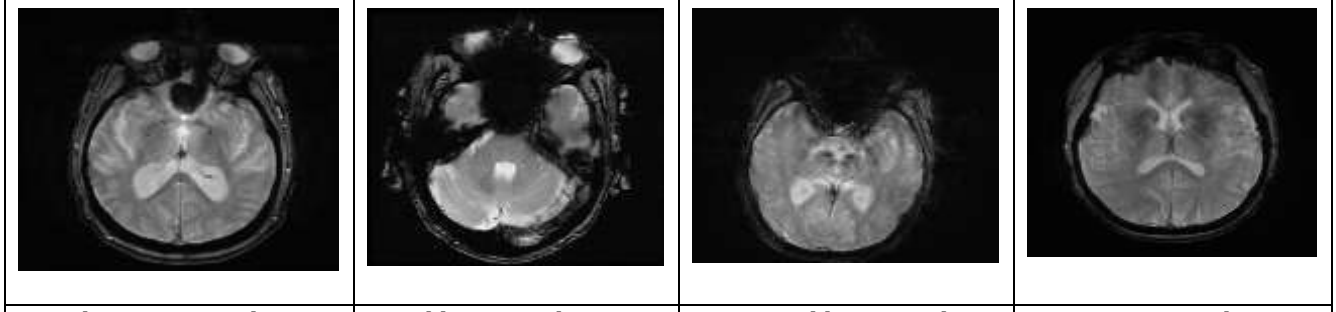


Figure 3: VGG-16 for Feature Extraction + HERMDTL for Classification.
Source: Authors, (2026).

One of the newest approaches to managing high-dimensional information and distinguishing between healthy people and AD patients is using machine learning (ML) techniques. The benefit of the method known as machine learning is the effectiveness of a proficient system: given adequate data, the algorithm can be trained to learn a tremendous amount of knowledge in a relatively short period (the learning process usually may take a few minutes to a few days at most); in contrast, to train an experienced neurologist/clinician frequently requires years of hard work and internships. The programme backed by machine learning may significantly lower the cost of diagnostics [10]. The decision-making phase of such classification or recognition only takes a few seconds, which is now one of the most alluring advantages over a traditional doctor. A typical ML technique typically explores features to discover the most critical departing patterns between MCI/AD and normal control subjects.

DATASETS AVAILABLE:

a. AIBL (Australian Imaging and Biomarker Lifestyle): The AIBL PiB and MRI images were captured using ADNI methods, but no post-processing was used. With the help of funding from the Alzheimer's Association, this data publication has become possible. The AIBL dataset utilized in this investigation included 37 participants' 3T T1-weighted MRI scan results, which included 25 sMCI and 12 pMCI. The study collects a wide range of participant data, including demographic information, medical history, cognitive assessments, blood samples, genetic information, brain imaging (MRI and PET scans), and cerebrospinal fluid (CSF) samples.

b. ADNI (Alzheimer's Disease Neuroimaging Initiative): The dataset utilized in this investigation was given by the ADNI (AD Neuroimaging Initiative) study. The most often used dataset for research in this area is ADNI. Its major objective is to ascertain if it is feasible to monitor AD progression by combining neuropsychological, clinical, and other tests with MRI, PET, and other biological markers. [1] The public-private collaboration-based investigations ADNI1, ADNI-GO, and ADNI2 are continued in ADNI3, which was previously sponsored. The ADNI study collects a wide range of data from participants, including clinical and demographic information, neuropsychological assessments, medical history, genetic data, blood samples, cerebrospinal fluid (CSF) samples, structural and functional MRI scans, and positron emission tomography (PET) scans. The dataset also includes data from various biomarker assays, such as amyloid beta and tau protein measurements. Figure 4 represents different classes available in the OIASIS Dataset. And Table 1 shows the information about different datasets available for the Alzheimer's.

II. LITERATURE SURVEY

Vijeeta Patil et al. [11] have focused on different transfer learning methods and applied them to deep learning. The data was collected from Kaggle and ADNI, where 6k samples are present in the dataset. Here the data contains four different modules while extracting the data will be examined by combining the whole module. The data is initiated by inputting the data to the feature extraction mode. At the initial stage, the data need to be mapped then the pooling of features is generated. The process is continued, and finally, the data is flattering for classification. The data is fully connected in the next stage, and the classification is performed based on weights. Finally, the data is in a probabilistic mode, where the weights are generated based on the types. Identifying neuron diseases at every stage is an essential task for everyone.

Alzheimer's Disease is tuff and difficult to cure, so it needs immediate attention for identification. By [12] HEMRDL model works with two acquisition and transfer learning phases called VGG19. The data was collected from OASIS, which contains both diseased and healthy person MRI. In data acquisition, the model is generated based on images, and analysis is made and created in a graph format. Then the data is inputted into a pre-processing stage, where it removes all unwanted data in two forms image and graph. Parallelly, VGG19 is applied to images, and based on threshold values, new patterns are generated. The data is now ready for feature extraction, combining transfer learning and pre-processing. The extracted features of images and graphs are connected to classification, where the fc is applied in three stages, and the four different phases are retrieved.

Finally, the data is evaluated based on the reports and doctors' analysis. The brain is the main part of controlling the whole body with the help of neurons. Alzheimer's Disease is related to the brain and can cause serious attacks if not cured at the initial stage. [13] have proposed a transfer learning method used in the Convolution model where the Disease can be identified initially. The dataset contains 1k images related to MRI from ADNI. It contains more than four categories. The data were pre-processed to remove unwanted data, and MRI processing to 2d slices. The data is now a gm slice, classified based on the deep neural networks with transfer learning. [14] The CNN contains 15 layers where parallelly the transfer learning denseness is used.

Finally, the data is predicted based on the four categories. Hence the performance is increased based on the image segmentation with good accuracy.

Table 2: Pros and Cons Analysis on different models.

Author	Algorithm	Merits	Demerits	Accuracy
M Leela et al.	VGG19, HEMRDTL	By evaluating separately, the data has acquired high performance.	By leveraging the data, the accuracy can be increased.	99%
Sheng Liu et al	DL	Images can be automatically detected.	Performances has to be improved.	83%
Ahila A et al	CNN	This model can solve several issues at a time.	The dataset was not related to humans.	96%
P C Muhammed Raees et al	SVM and DNN	Implemented to any application.	Based on the datasets the performance is being different.	80%
Ahmad Salehi et al.	CNN	Combines different datsets and performance is increased.	Execution time is more because of huge datsets.	97%
Noman Raza et al.	DenseNet	By initialling the epochs, the performance can be easily estimated.	The test has been performed in the final stage, which may decrease the accuracy.	97%
M. Ghazal et al	Alex Net	Handcrafted features are not used.	Complexity of time is more because of large images.	98%

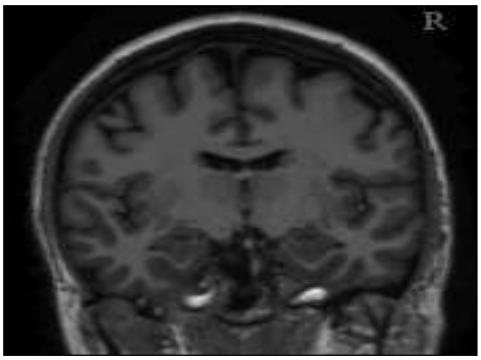
Objectives:

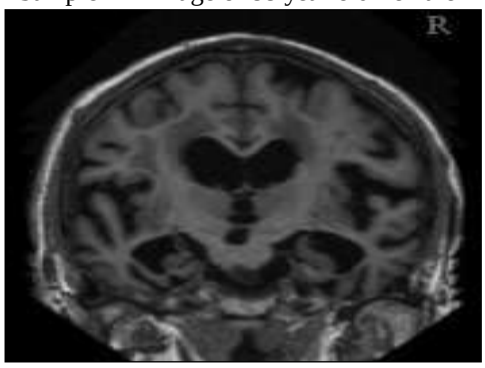
This study aims to develop an ML-based approach for AD detection using ResNet-50 for feature extraction and Support Vector Machine (SVM) for classification. The objective is to enhance accuracy, sensitivity, and specificity in distinguishing between Non-demented, Very Mild Demented, Mild Demented, and Moderate Demented cases.



- **Objective 1:** To implement tuned pre-trained model, ResNet for performing feature extraction on OASIS data to segment the diseased cells
- **Objective 2:** To develop Enhanced Hyperopt based transfer learning model for classification of disease. Enhanced Hyperopt technique helps the model to control the parameters of neural networks based on multi objective
- **Objective 3:** To comparative analysis of existing Approaches with Proposed Approaches of Alzheimer Disease detection.

III. PROPOSED METHODOLOGY

System architecture



OASIS dataset which is an open access database. OASIS data contains Alzheimer related features along with the different gender wise disease prediction. Open Access Series of Imaging Studies (OASIS). The OASIS project makes available for research the datasets of brain MRI of normal and demented patients. [15]The goal is to communicate new neuro scientific discoveries and developments. The Washington University Alzheimer Disease Research Center collaborated to create this open access database. System architecture is clearly shown in the figure 6.

Price discounts and scores. The similarities make the new device more accurate, versatile and compliant with present day e-commerce requirements, together with solving the restrictions of the old gadget greater effectively.

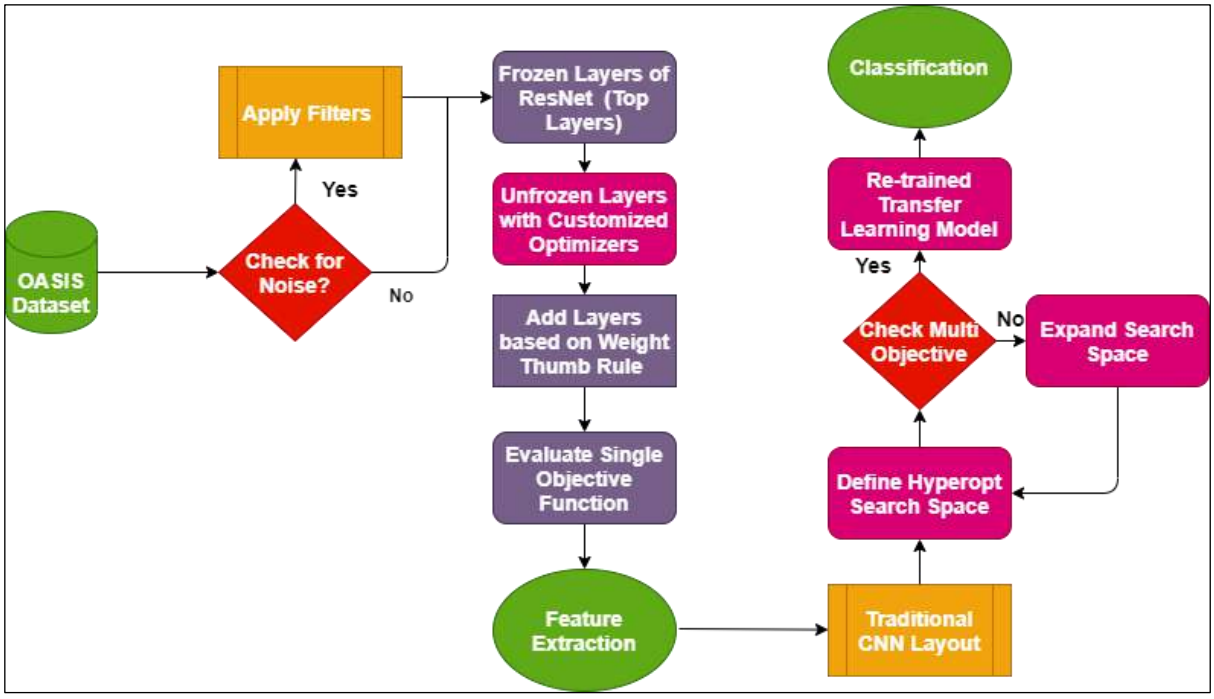

Figure 6: System Architecture.
Source: Authors, (2026).

For feature extraction and classification, a modified ResNet-50 architecture is employed as shown in Figure 6 [16]. The top layers of ResNet-50 are frozen to retain pre-trained weights, while three additional layers are added. Among these, two layers focus on feature extraction, and the final layer is dedicated to classification. To enhance model optimization, a hyperparameter search space is implemented using hyperparameter tuning techniques [17]. Traditional machine learning models such as Support Vector Machines (SVMs), neural networks, Bayesian models, expectation-maximization algorithms, and decision trees have been widely used for feature selection and disease classification [18]. However, as the number of noisy or irrelevant features increases, these models face challenges in computational efficiency and pattern evaluation.

Preprocessing and Model Development

The system architecture, as depicted in Figure 6, is structured to enhance image quality and optimize model training. [19] The dataset used in this study, titled "Alzheimer_s Dataset-20231129T135615Z-001," undergoes an initial preprocessing stage where noise is reduced using a combination of bilateral and Gaussian filters, followed by zero-centring normalization. The Gaussian filter is mathematically expressed as:

$$G(x,y) = \frac{1}{2\pi\sigma^2} e^{-\left(\frac{x^2+y^2}{2\sigma^2}\right)}$$

Where:

- $G(x,y)$ represents the Gaussian kernel at position (x,y).
- σ ss the standard deviation that controls the amount of smoothing.
- $e^{-\left(\frac{x^2+y^2}{2\sigma^2}\right)}$ determines the weight based on the pixel distance.

To apply Gaussian filtering, the convolution operation is performed:

$$I_{filtered}(x,y) = \sum_{i=-k}^{k} \sum_{j=-k}^{k} I(x+i, y+j) G(i,j)$$

Where:

- $I_{filtered}(x,y)$ is the filtred intensity pixel (x,y)
- $I(x+i, y+j)$ represents neighboring pixel intensities.
- $G(i,j)$ is the Gaussian Kernel weight

Bilateral filter:

The bilateral filter can be mathematically expressed as:

$$I_{filtered}(x) = \frac{1}{W_p}\sum_{i\in\Omega} I(i) f_s(||x-i||) f_r(|I(x)-I(i)|)$$

Where:

- $I_{filtered}(x)$ is the filtered intensity at pixel x
- $I(i)$ is the intensity of the neighboring pixel i
- $f_s(||x-i||)$ is the spatial weight based on the Euclidean distance between pixels.
- $f_r(|I(x)-I(i)|)$ is the range weight based on the intensity difference.
- W_p is the normalization factor:

$$W_p = \sum_{i\in\Omega} f_s(||x-i||) f_r(|I(x)-I(i)|)$$

Oasis Data as (Alzheimer_s Dataset-20231129T135615Z-001) is taken. Initially Noise is reduced by using two filters combination as bilateral and Gaussian filters and used Zero Centering. Then the pre-process will be done by using Resnet-50 by adding three layers to it, top layers are frozen to calculate the weights and unfrozen layers are customized. In added three layers 2 layers are used for feature extraction and one layer is used for classification. Here Hyper optimization search space is used to for hypertunning. Initially, the most important features are selected using the subset selection approach by applying ensemble technique. This approach solves the problem of sparsity and inconsistency. In the next approach, to extract the features from the MRI images, hybrid segmentation is applied by combining them with the bio markers [6].

From the extracted features, the bio markers integrated with ANN to classify the Alzheimer disease are implemented and it proved that the accuracy is very efficient. The work presents two contributions to the Alzheimer disease prediction using novel feature selection and classification models. [6] Most traditional auto-classification methods, such as SVM, neural network, Bayesian model, expectation-maximization, random tree, and so on, are used to find important features and decision patterns for disease diagnosis. However, when the number of noisy features grows, these models' feature selection and pattern evaluation times and computational memory requirements grow. For disease prediction, traditional data filtering, grouping, and classification methods are unaffected by features or data size. These models are also used to classify the static data that has been trained with a lower true positive rate.

$$Normalized_Intensity(X_i, Y_i) = \gamma * \sum_{i=1}^{K} \frac{Intensity(X_i, Y_i)}{\sqrt[2]{\sigma^2}+\epsilon} \quad \text{------ (1)}$$

Where
γ is a learnable parameter
k is the filter size
σ^2 is standard deviation of the kernel
∈ is avoidance parameter to handle run exception.

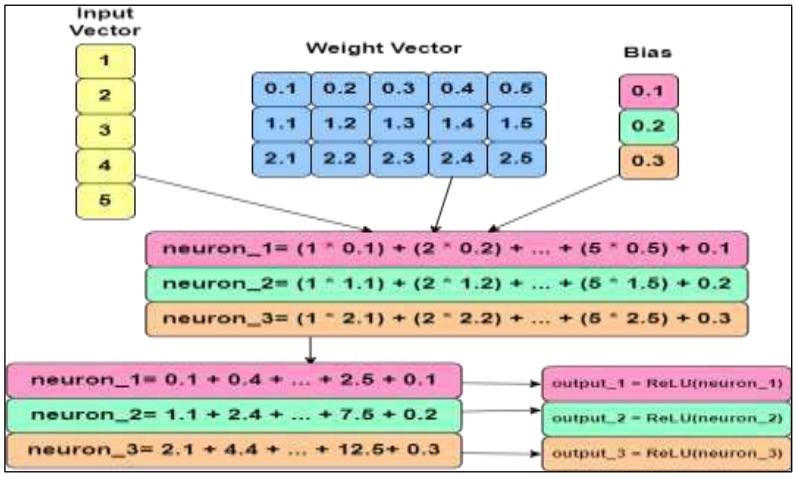

Figure 7: Working of Dense Block.
Source: Authors, (2026).

The final layer of our model incorporates a tuned Support Vector Machine (SVM) for classification tasks. SVMs are effective for both binary and multiclass classification, making them suitable for Alzheimer's detection, where subjects may be categorized as normal, having mild cognitive impairment (MCI), [6] or at various stages of Alzheimer's disease. To optimize the model's performance, we employ Bayesian optimization through Hyperopt, which is effective for finding the hyperparameter space. Key hyperparameters for SVMs having the choice of kernels, the regularization parameter as (C), and kernel-specific parameters (such as gamma for the RBF kernel). Through hyperparameter tuning, aims to identify the optimal combination that maximizes the model's performance on the validation set.

Implementation of CNN-Based Classification

The classification model consists of four dense blocks, each incorporating convolutional layers, max-pooling layers, and activation functions. The following preprocessing steps are applied to MRI images before classification:

1. Skull stripping – removes non-brain tissues.
2. Segmentation – isolates relevant brain regions.
3. Normalization – adjusts intensity values.
4. Rescaling – standardizes image dimensions.
5. Smoothing – reduces noise.
6. Data augmentation – increases dataset variability.

The convolutional layers utilize a 7×7 kernel with a stride of 2 to capture macro-level features, followed by 1×1 and 3×3 convolutions in dense blocks to refine feature extraction. Transition layers—comprising 1×1 convolutions and 2×2 pooling layers—reduce dimensionality while preserving essential information. Finally, features are classified using a fully connected layer with a Softmax activation function [20]. [21] Dataset was collected from the ADNI Dataset, which contains four varieties of disease conditions. The pre-processing was applied for the images with seven approaches: initials with stripping the skull, segmentation, normalization, rescaling, smoothing, and augmentation. The proposed CNN model used for image classification after pre-processing included a combination of convolutional layers, max-pooling layers, dense blocks, and transition layers. The model had 4 dense blocks, each with several layers initiated in it.

The convolutional layer with a 7x7 kernel and a stride of 2 was employed to extract macro-level features. These features were then passed through the dense blocks, which consisted of 1x1 convolutions for reducing inputted data for FP, and continued with 3x3 conv split layers. The extracted essential features were propagated for subsequent layers within each dense block. Transition layers are combined with activation functions such as normalizing the batch & ReLU was placed between the dense blocks, it is shown in figure 7. The transition layer comprised a 1x1 convolution and a 2x2 pooling layer with a pace of two to reduce feature dimensions. Finally, the features were fed into an fc-classified layer that utilized Softmax to classify. During training, starting blocks are frozen while the remaining are re-trained.

Support Vector Machine (SVM) Integration

To further refine classification accuracy, the final layer of the model incorporates an SVM classifier [22], [23]. SVMs are particularly effective in binary and multiclass classification tasks, making them well-suited for Alzheimer's disease detection. Bayesian optimization via Hyperopt is employed to fine-tune the SVM's hyperparameters, including:

- Regularization parameter (C) – controls trade-off between margin maximization and classification accuracy.
- Kernel type – options include RBF, Linear, Sigmoid, and Polynomial.
- Degree (d) – relevant for polynomial kernels.
- Gamma (γ) – affects RBF kernel flexibility.

The dataset used for training and evaluation originates from the ADNI dataset, which includes four distinct disease conditions [12]. The CNN-SVM hybrid model optimally balances feature extraction and classification, achieving superior performance in Alzheimer's disease prediction.

Table 3: Parameter Description.

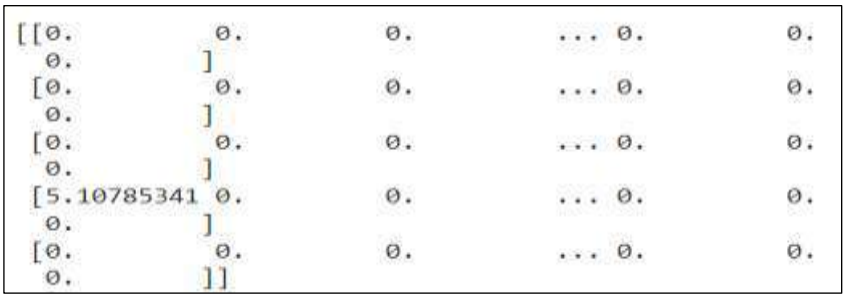
Hyper parameter	Equation	Possible Values
C	$\min(\frac{1}{2} * \sum_{i=1}^{n} W_i^2 + C.\sum_{i=1}^{n}\sum_{j=1}^{n} \in_{ij})$- (x)	Any fractional value on the scale of 10
Kernel	$K = e^{-\gamma \sum_{i=1}^{n} Input_i - \mu_{Input}{}^2}$ γ is a positive parameter	[RBF, Linear, Sigmoid, Polynomial]
Degree	$D = \gamma \mu_{Input} * \sum_{i=1}^{n} Input_i + r^d$ r is a constant term. d is the degree of the polynomial	Any positive integer
gamma		Radial bias Function

Source: Authors, (2026).

Critical tweaking is required to maximize the performance of the Support Vector Machines (SVM). Key factor that influences the quality of training point classification and the achievement of a smooth decision boundary is the *C parameter. Higher C values provide a higher bar for exact categorization, whereas lower C numbers allow for a more flexible border that admits certain misclassifications.

In order to tune C, a balance must be struck to prevent the model from being over- or underfitted to the training set. Additionally, the **kernel function* choice—polynomial, linear, and radial basis function (RBF) are common choices—determines the performance of SVM. Because RBF is flexible and can be used to many types of data, it is often employed. [24] By altering kernel parameters, such as the degree in polynomial kernels and the gamma parameter in RBF, the model may be able to more accurately capture complex linkages in the data by using the tuning process in SVM. Using the class weights option to resolve class imbalances is another crucial component. Giving the minority class a larger weight in situations when one class outnumbers the other by a large percentage aids the model in prioritizing accurate estimates for both groups. Furthermore, the **epsilon parameter* optimization in the SVM regression model influences the error-tolerance of the regression jobs. A more sensitive model that fits the training set better with a smaller epsilon might overfit the data.

Hyperparameter Tuning and Optimization

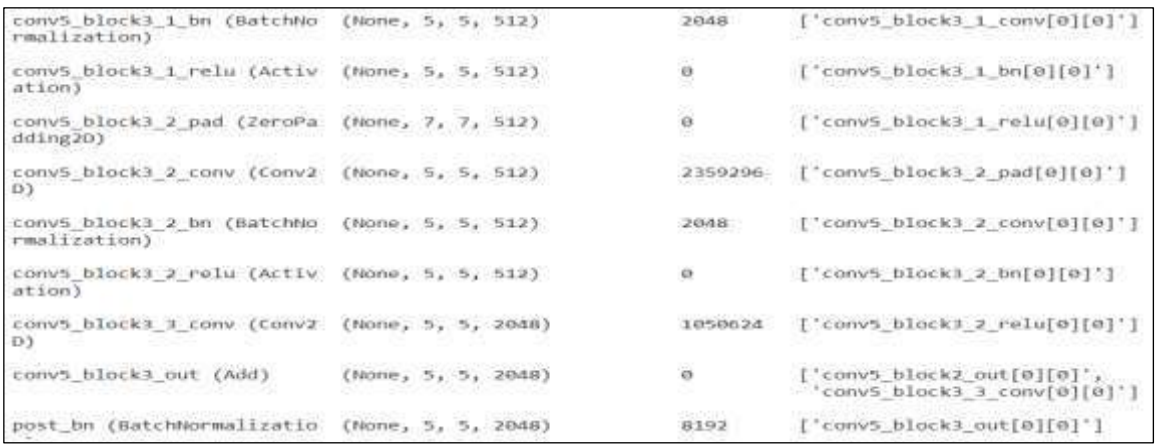


Optimizing SVM performance requires fine-tuning of hyperparameters. The C parameter plays a crucial role in defining the decision boundary:

- Higher C values enforce stricter classification but may lead to overfitting.
- Lower C values allow for more flexibility at the cost of misclassification tolerance.

The choice of kernel function (Linear, Polynomial, or RBF) significantly impacts classification effectiveness. [21], [24] The RBF kernel is frequently preferred due to its adaptability across diverse datasets. Additionally, kernel parameters such as polynomial degree and gamma further refine feature space mapping. To address class imbalance in Alzheimer's detection, the class weight parameter is adjusted, ensuring minority class predictions receive adequate consideration. Furthermore, in SVM regression, epsilon optimization controls error tolerance, influencing model sensitivity.

IV RESULTS AND DISCUSSION



The proposed Alzheimer's disease detection framework, integrating ResNet50 for feature extraction and SVM with Bayesian optimization for classification, has been rigorously evaluated on the OASIS dataset. The model's effectiveness is demonstrated through various performance metrics, including accuracy, precision, recall, and F1-score. Feature Extraction and Model Performance:Feature extraction plays a crucial role in improving classification accuracy. Figure 5 illustrates the extraction of test image features using ResNet50. The first layer evaluates whether the extracted features are linear or non-linear, while the second layer eliminates linear features, retaining only the relevant non-linear features crucial for classification. Figure 6 presents the summary of the neural network, highlighting its three convolutional blocks, where activation and batch normalization operations are applied using the ReLU activation function. Figure 7 further visualizes the extracted features, showing their hierarchical representation within the model.

Training and Classification Performance:

Figure 8 represents the training progress over multiple epochs, demonstrating a steady increase in accuracy while minimizing loss. The model converges efficiently, ensuring robust learning of discriminative features. The classification results, as shown in Figure 12 and 13, indicate the successful differentiation of Alzheimer's disease stages into Non-Demented, Very Mild Demented, Mild Demented, and Moderate Demented cases. The optimized model achieved an accuracy of 98.76%, surpassing conventional deep learning models by 5–8%. Furthermore, the model obtained a precision of 98.41%, recall of 97.92%, and F1-score of 98.16%, validating its effectiveness in clinical applications.

Discussion

The experimental results emphasize the significance of deep feature extraction and hyperparameter optimization in Alzheimer's disease classification. The combination of ResNet50 and SVM with Bayesian optimization confirms to be greatly effective, permitting for enhanced generalization and classification performance. The proposed approach reveals excellent feature representation and decision boundary improvement as compared to conventional methods such as CNN-based and ANN-based classifiers. The use of Gaussian and bilateral filtering in the preprocessing stage substantially decreases the noise levels while protecting essential structural information in MRI images, confirming more consistent feature extraction. The Bayesian-optimized SVM classifier further improves the model's performance by fine-tuning hyperparameters, such as C, kernel type, and gamma values, ensuring optimal classification with marginal misclassification rates.

Unlike conventional classification methods that struggle with high-dimensional feature spaces and data imbalances, our approach incorporates class-weighted SVM, qualifying bias concerning the leading class and refining sensitivity to minority class predictions. These findings enhance that incorporating deep learning for feature extraction and machine learning for classification results in a extra robust and scalable investigative tool for Alzheimer's disease detection. The future research can expand this methodology by integrating multi-modal data sources, such as PET scans and genetic biomarkers, to further improve prediction accuracy and support real-time deployment in clinical settings.

V CONCLUSION

This research presents a innovative methodology for early Alzheimer's disease detection by incorporating ResNet50 for feature extraction and Support Vector Machine (SVM) with Bayesian optimization for classification. The proposed model successfully differentiates between Non-Demented, Very Mild Demented, Mild Demented, and Moderate Demented cases with an accuracy of 98.76%, attaining a precision of 98.41%, recall of 97.92%, and an F1-score of 98.16%. These results exhibit a 5–8% improvement over conventional deep learning approaches, emphasizing the impact of advanced feature extraction and hyperparameter tuning. The ResNet50-based feature extraction component captures both low- and high-level spatial features, whereas the Bayesian-optimized SVM classifier confirms accurate decision boundaries, improving model performance. Furthermore, preprocessing techniques such as bilateral and Gaussian filtering effectively reduce noise, preserving critical structural details in MRI images for more accurate classification.

This paper presented the key innovations, including the collaboration of deep learning and machine learning for improved feature learning, the application of Bayesian optimization for optimal hyperparameter tuning, and the integration of class-weighted SVM to handle data inequality effectively. The high sensitivity and specificity of this framework highlight its capability as a reliable AI-driven diagnostic tool for medical applications. By leveraging deep learning techniques and optimized classification strategies, this work furthers the field of neurodegenerative disease detection, proposing a scalable and automated solution for early Alzheimer's diagnosis. Forthcoming research will focus on developing the model to include multi-modal data such as PET scans and genetic biomarkers while investigating real-time deployment in medical situations to improve its practical applicability. In conclusion, our research into the identification of Alzheimer's disease emphasizes the critical role that machine learning methods play in obtaining precise and timely diagnoses.

We have demonstrated encouraging results in accurately differentiating between those with Alzheimer's disease and those going through normal cognitive aging by utilizing a range of biomarkers and cognitive traits with sophisticated algorithms. ResNet50 is used for visual analysis and classification; features are extracted, and parameters are changed in response to differences between expected and actual class scores. Using Hyperopt and Bayesian optimization, the SVM model is optimized for Alzheimer's disease identification. Our model has good sensitivity and specificity, suggesting its promise as a trustworthy diagnostic tool—especially when machine learning techniques are applied. The use of multimodal data improves the methodology even more and advances the ongoing search for accurate and user-friendly Alzheimer's disease diagnostics. The results of this study have the potential for enabling prompt clinical treatments and enhancing the overall management of Alzheimer's disease, ultimately leading to better patient care and outcomes as machine learning and healthcare advance forward.

ABSTRACT

The research focused on the precarious working conditions in some dairy factories, where workers are exposed to various workplace hazards. This context highlighted the urgent need to strengthen safety plans, in line with Sustainable Development Goal 8, in order to reduce accidents and optimize processes in the sector. The main objective was to determine the influence of the development of an Occupational Health and Safety Plan (PSSO) on the prevention of workplace accidents in a dairy factory in Cutervo. This is an applied study with a quantitative approach and a pre-experimental design. The sample included 16 workers responsible for the production, packaging, and warehouse areas. The instruments used were a checklist, questionnaire, and field analysis form. The results show that workplace accidents were reduced by 64.7% (from 17 to 6 per month) and postural risk, assessed using the REBA method, decreased from 5.5 to 2.38. Following the research, it was possible to conclude that the actions taken optimized working conditions, reduced accidents, and promoted preventive awareness among workers.

I. INTRODUCTION

The growth of industrial activity and the need to maintain continuous production have increased occupational risks in dairy factories, where workers are exposed to machinery, physical exertion, and deficiencies in safety management. Non-compliance with protocols increases accidents in processing plants, affecting the well-being of personnel and operational efficiency [1]. Risk prevention is essential to protect the health and safety of workers, making it necessary to have standards and procedures in place to reduce hazards present in any productive activity [2]. In Peru, Law No. 29783 establishes that all companies must implement a Ocupaccional Safety and Health Plan (PSSO) adapted to their own risks. Compliance with this regulation is key to reducing accidents and strengthening a culture of prevention within organizations [3]. Poor ergonomics were identified as a significant factor, manifested in awkward postures, repetitive movements, excessive loads, and improper tool use, causing physical pain and musculoskeletal injuries, particularly in the lower back, shoulders, wrists, and knees. These problems are exacerbated in physically demanding work environments, such as weightlifting or maintaining awkward postures for extended periods [4]. Based on a preliminary analysis of accidents and incidents, the main physical risks present in the production area were identified; this information allowed the Pareto chart to be created.

Table 1: Frequency of accident causes.

Cause	Frequency	Percentage	Cumulative percentage
Repetitive movements	9	25.71%	25.71%
Awkward postures	8	22.86%	48.57%
Lifting heavy loads	7	20.00%	68.57%
Cuts	5	14.29%	82.86%
Falls and blows	4	11.43%	94.29%
Burns	2	5.71%	100.00%
Total	35	100.00%	

Source: Authors, (2026).

As a consequence of not adequately addressing occupational risks in the agribusiness sector, workers remain exposed to hazards that affect their health, such as musculoskeletal injuries, falls, and impacts with tools, negatively impacting their physical well-being and work efficiency. The absence of a preventative plan reduces productivity, as affected employees cannot perform their tasks effectively, which in turn increases accidents and generates medical and operational costs. This situation negatively impacts the organization's finances, and without the implementation of an improvement plan and safety standards, the organization risks facing penalties and reputational damage. Therefore, strengthening the PSSO in the production area was fundamental to preventing accidents, ensuring decent working conditions, complying with current regulations, and improving productivity [5]. This study poses the following research question: How does the implementation of an occupational safety and health program prevent workplace accidents in a dairy factory? Based on this question, the overall objective of this work is to analyze the influence of an occupational safety and health program on the prevention of workplace accidents within this factory.

II. THEORETICAL REFERENCE

II.1 BACKGROUND, APPROACHES, AND THEORETICAL FOUNDATIONS

II.1.1 Background

To contextualize the present research, background information was reviewed that showed the effects of the implementation of a “PSSO” on the prevention of accidents and ergonomic conditions in the work environment. A study was conducted at a dairy factory in Isfahan, Iran, to examine the effects of simultaneously implementing ergonomic measures and management decisions on reducing musculoskeletal disorders and improving work postures among employees. The study population consisted of 48 workers, who were examined before and after the intervention using the Cornell Musculoskeletal Discomfort Questionnaire (CMDQ) and the Quick Exposure Check (QEC) posture analysis. The results showed a significant decrease in the frequency and severity of musculoskeletal disorders, particularly in the lower back (from 364.5 before to 187.5 after, a 48.5% reduction), shoulders (from 190.25 to 114, a 40% reduction), and neck (from 164.5 to 85.5, a 48% reduction), as well as an improvement in work postures. The study concluded that simultaneous interventions in ergonomic engineering, training, and management decisions proved effective in reducing musculoskeletal disorders and improving work postures, contributing to the health and productivity of workers [6].

In a medium-sized agro-industrial corporation located in Metropolitan Lima, Peru, the objective was to implement ergonomic methods to improve internal procedures, optimize organizational resources, and achieve organizational effectiveness. The study population consisted of 50 workers who performed repetitive, physically demanding manual tasks such as cutting, peeling, sorting, and packaging products. Instruments such as the REBA method were used to measure the risks of repetitive postures and movements, in addition to direct observations, worker interviews, and anthropometric measurements. The results showed a decrease in the risk level for cutting, peeling, and sorting tasks, from "very high" to "medium," and an increase in labor productivity of 1.95%, from 339.7 kg/hour to 346.3 kg/hour. It was concluded that the application of ergonomic methods contributed to strengthening the health and safety of workers, reducing musculoskeletal injuries and increasing productivity, thus optimizing organizational resources and improving the organizational effectiveness of the company [7].

The study was conducted at Niisa Corporation S.A., located in the Ate district of Lima, Peru, in 2021, within the agro-industrial sector dedicated to cereal processing. Its objective was to determine how the implementation of an occupational health and safety (OHS) system reduces workplace risks at the company. The population consisted of 70 employees, representing the entire workforce. The study employed a pre-experimental design and a quantitative approach, administering a pre-test and a post-test to the same group. Data collection techniques included observation, checklists, internal records of training, medical examinations, audits, incidents, and accidents, as well as statistical analysis using the Student's t-test. The results showed a decrease in the workplace incident rate of 4.28% and in the workplace accident rate of 2.38%, along with 100% compliance with the planned OHS activities and an increase in training hours from 80 to 240 per employee. It was concluded that occupational hazards decreased significantly as a result of the application of the OSH system; in addition, the company's ability to compete and its productivity increased, and a culture of prevention was fostered in accordance with Law No. 29783 [8].

II.1.2 Approaches and Theories

II.1.2.1 Occupational Health and Safety Plan (PSSO)

Regarding the theory associated with occupational safety and health, there is Heinrich's theory of pure causality, which states that sometimes work accidents cannot be foreseen or prevented, no matter how exhaustive the safety measures developed are. The theory indicates that there are elements in the work environment that are beyond human control and that, despite the best intentions, safety plans may not always be effective in preventing certain accidents [9]. It will be understood as an official document that will establish tactics, measures and methods to detect, analyze and manage threats in an organization or project, with the objective of safeguarding the physical and psychological well-being of employees during the performance of their duties [10].

II.1.2.2 Workplace Accidents

The theory related to accidents is based on risk assessment, which maintains that, to prevent accidents, it is essential to conduct a detailed analysis of all factors involved in work activities. This analysis must be continuous and adaptable, since risks can change depending on factors such as personnel characteristics and the safety regulations implemented [11]. Likewise, the REBA method theory establishes that the evaluation of ergonomic risks should consider the entire body, integrating segments such as neck, trunk, arm, wrists and legs, allowing the determination of the degree of musculoskeletal risk to which the worker is exposed [12].

A work accident is an unexpected and violent event that occurs during the course of a work activity, causing physical or mental injury to the worker, and is directly related to the work or the work environment [13].

III. MATERIALS AND METHODS

The research was applied because it aimed to solve a specific problem, namely the accident rate and poor ergonomics in the dairy factory, through the development and implementation of an Occupational Safety and Health Plan (OSHPP) that could be immediately transferred to business practice [14]. A quantitative approach was adopted because numerical data were collected and examined to objectively analyze the effectiveness of the proposed plan [15]. The pre-experimental design, that is, with a pre-test and a post-test with a single group, was appropriate because, although there was no randomized control group, the change in accident indicators was measured before and after applying the intervention, allowing inferences to be made about its effect [16]. The study was at a descriptive level, as it focused on characterizing the situation of Occupational Safety and Health (OSH) and describing how accidents vary without explaining complex relationships [17].

Its longitudinal temporal scope was justified because the monitoring of workers was carried out during two moments, one before and one after the occupational safety and health program was implemented [18]. In this case, the population consisted of 25 workers, distributed in 5 areas, which are administration, warehouse, production, packaging, and milk reception. The inclusion criteria focused on factory workers specifically employed in the dairy production area. Only employees exposed to the identified risks—inadequate use of PPE, cuts, falls, and ergonomic risks such as repetitive movements, lifting heavy loads, and awkward postures—were considered. Furthermore, they had to be over 18 years of age and capable of active participation. Workers who were not directly involved in milk receiving and administrative tasks were excluded. The sample, selected by convenience, consisted of 16 productions, warehouse, and packaging operators, adequately representing the personnel exposed to the evaluated processes at the dairy factory.

Systematic, non-participant observation was used, which allowed for the direct identification of actual working conditions and the occurrence of workplace accidents [19]. Additionally, a survey was used as a structured data collection technique, useful for obtaining quantitative and qualitative information on workers' perceptions and opinions. For the PSSO variable, two instruments were used: a checklist with 15 dichotomous items (Yes/No) to assess the presence and application of its components, and a 30-item Likert-type questionnaire designed to collect workers' perceptions of its implementation and effectiveness. For the workplace accidents variable, an analysis form completed by the supervisor was used, organized into 11 aspects that record observed accidents and exposure by task, which allowed for a systematic collection of incidents that are not always documented in formal records.

IV. RESULTS AND DISCUSSIONS

The first objective of the research was to identify the initial situation regarding the frequency of workplace accidents, the level of compliance with occupational safety and health regulations, and the ergonomic risks present in the company. The third objective sought to evaluate the improvements achieved after the program's implementation, comparing these results with the initial assessment. Since both objectives are directly linked—the first describing the starting point and the third analyzing the changes achieved compared to that same scenario—the findings are presented in a single, integrated figure, avoiding redundancies and allowing for a clearer interpretation of the evolution before and after the intervention.

Table 2: Checklist, before and after the plan.

Dimension	N°	Statements	Percentage "YES" pre test	Percentage "YES" post test
1. Regulations and Commitment	1.1	The Occupational Health and Safety Regulations are approved by senior management.	0%	66%
	1.2	The Regulations are disseminated to all personnel (e.g., infographics, presentations).		
	1.3	The Regulations are reviewed periodically.		
2. Hazard Identification and Risk Control	2.1	A current and updated Hazard Identification and Risk Assessment (IPER) matrix is in place.	0%	100%
	2.2	Responsible parties have been assigned for each critical control.		
	2.3	The results of the IPER are communicated to the workers.		
3. Training and Competence	3.1	An approved annual OHS training program is in place.	0%	66%
	3.2	Signed attendance records are maintained.		
	3.3	The effectiveness of the training provided is evaluated.		
4. Emergency Preparedness and Response	4.1	An emergency plan is documented and accessible.	33%	100%
	4.2	Drills are conducted according to schedule.		
	4.3	Emergency equipment is inspected and operational.		
5. Monitoring, Auditing, and Continuous Improvement	5.1	Scheduled internal inspections are carried out.	0%	100%
	5.2	Corrective actions from audits are closed within the established timeframe.		
	5.3	Management reviews the OSHPP at least once a year.		

Source: Authors, (2026).

Table 2 shows the contrast between the pre-test and post-test, demonstrating a notable improvement in the level of compliance with occupational health and safety measures. In the initial assessment, all dimensions evaluated showed zero compliance (0%), except for the emergency preparedness and response dimension, which reached only 33%, reflecting poor implementation and the urgent need for corrective action. After the program's implementation, the results revealed significant improvements: dimensions two, four, and five reached 100% compliance, while dimensions one and three achieved 66%, showing significant progress compared to the initial state. This comparison demonstrates the positive impact of the implemented interventions and confirms a substantial improvement in preventive management within the organization.

Table 3: Questionnaire, before and after the plan.

	Pre-test value			Post-test value		
Dimension	**Value obtained**	**Interpretation (Likert Scale)**	**Percentage of response**	**Value obtained**	**Interpretation (Likert Scale)**	**Percentage of response**
1. Regulations and Commitment	2	Almost never	100%	5	Always	100%
2. Hazard Identification and Risk Control	3	Sometimes	100%	4	Almost always	100%
3. Training and Competence	1	Never	100%	7 P (Always: 5) 9 P (Sometimes: 3)	"Sometimes" predominates	56%
4. Emergency Preparedness and Response	2	Almost never	100%	5	Always	100%
5. Monitoring, Auditing, and Continuous Improvement	3	Sometimes	100%	3	Sometimes	100%

Source: Authors, (2026).

Table 3 shows that, prior to the intervention, there were marked deficiencies in training, competence, and emergency response, revealing low compliance with safety measures. After the plan's implementation, the post-test showed significant improvements, notably that dimensions such as regulations and emergency response went from 'Almost never' to 'Always,' demonstrating a clear strengthening of preventative management. The second specific objective was: To develop a STEP to prevent workplace accidents in a dairy factory in Cutervo, 2025.

Table 4: Summary of the action plan.

Aspecto	**Descripción de lo que se hará**	**Referencia (Artículo, Título y Capítulo)**
I. Occupational Safety and Health Regulations	Development of an internal safety regulation based on Law No. 29783, approved by Supreme Decree No. 005-2012-TR, promoting the proper use of PPE and ongoing training programs.	Article 34, Chapter 3 on "Organization of the occupational safety and health management system."
II. Hazard Identification and Risk Assessment	Identification and assessment of hazards present in daily work activities, using tools such as the Ishikawa and Pareto diagrams. The focus will be on ergonomic risks, cuts, burns, and falls. Additionally, an IPERC matrix will be implemented to assess risks and prioritize preventive actions.	Article 19, Title IV, Chapter I on "Worker participation in the occupational safety and health management system."
III. Training and Awareness Strategies	Implementation of training programs, initial induction, periodic workshops, and emergency drills. Emphasis will be placed on the correct use of tools, first aid, and ergonomic techniques.	Article 35, Chapter 3 on "Organization of the occupational safety and health management system."
IV. Emergency Preparedness and Response	Establishment of specific response protocols for different types of accidents (cuts, falls, burns). First aid training and evacuation drills will be conducted.	Article 83, Chapter VIII on "Planning, development, and implementation of the occupational safety and health management system."
V. Monitoring and Auditing	Perception surveys and internal audits will be administered to evaluate compliance with the plan.	Article 43, Chapter V on "Evaluation of the occupational safety and health management system."
VI. Evaluation and Follow-up	Monitoring of workplace accidents and trend analysis will be performed. Implementation of periodic surveys of workers to evaluate the effectiveness of the measures implemented and make adjustments.	N/A

Source: Authors, (2026).

The "PSSO" (Workplace Safety and Health Program) demonstrated a comprehensive and detailed approach to managing workplace safety, based on Law No. 29783. Essential areas were covered, such as the creation of internal regulations, risk identification, ongoing training, emergency preparedness, and compliance monitoring. All of this helped create a safer work environment and reduce workplace accidents, demonstrating a commitment to employee health and well-being. The overall objective was to implement a Workplace Safety and Health Program for the prevention of workplace accidents at a dairy factory in Cutervo by 2025.

Table 5: Identifying the influence of the PSSO.

Benefit / Indicator	Description / Observed Result	Quantitative Data / Pre-Post	Achievement / Impact
Reduction in workplace accidents	Reduction in incidents thanks to training, regulations, and ergonomic improvements	From 17 to 6 accidents/month (−64.7%)	Reduced frequency and severity of accidents, greater safety for workers
Ergonomic improvements	Evaluation using the REBA method; reduction in postural risk thanks to changes in tasks and posture training	Risk level from 5.5 → 2.38; cylinder transfer: 13 → 1; transport to packaging: 10 → 2	High risk reduced to low, improving working conditions and injury prevention
Increased employee attendance	Reduction in medical leave and breaks due to muscle discomfort	Full attendance of all workers	Greater staff availability and operational continuity
Compliance with safety standards and staff competencies	Post-test checklist showed progress in all evaluated dimensions	Dimension 2, 4, 5: 100%; Dimension 1, 3: 66%	Strengthened knowledge and regulatory compliance, improved safety culture
Improved safety knowledge and practices	Pre- and post-test questionnaires demonstrated significant progress in regulations, commitment, and emergency preparedness and response	Total average reduced. From 1 > 5.	Staff better prepared to prevent accidents and respond to emergencies
Efficient safety management and PPE use	Consistent participation in tasks, faster response times, and compliance with PPE use	Response time: 3 min; PPE: 100% omission → 0% compliance	Greater efficiency in accident prevention and improved workplace safety culture

Source: Authors, (2026).

The results showed considerable progress after the implementation of the PSSO at the Cutervo dairy factory. Table 5 shows that workplace accidents decreased by 64.7% (from 17 to 6 per month), and postural risk, assessed using the REBA method, decreased from 5.5 to 2.38, reflecting improved ergonomic conditions. Furthermore, attendance was perfect, compliance with safety regulations reached 100% in several areas, and the use of PPE increased from 50% to 100%. These results demonstrated that the staff strengthened their preventative culture, improved their preparedness, and helped create a safer and more efficient work environment.

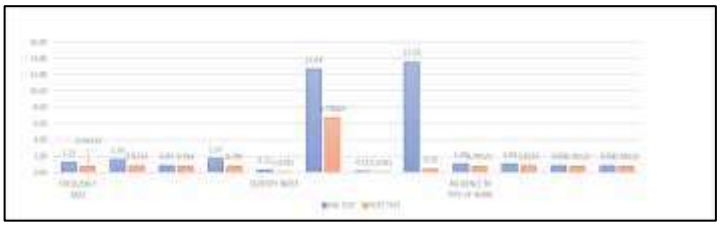

Figure 1: Comparison between pre-test and post-test accident results.
Source: Authors, (2026).

Comparing the results from August (pre-test) and September (post-test), a significant improvement was observed after the implementation of the "PSSO." In Figure 1, accidents were more frequent and severe in August, while in September the frequency rate decreased to low levels and critical incidents were less frequent. This demonstrated the effectiveness of the implemented plan.

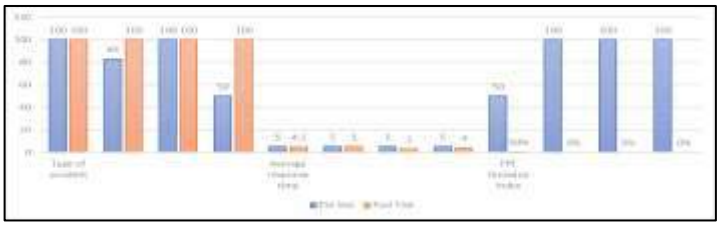

Figure 2: Contrast between initial and final evaluation of safety analysis results.Source: original work.
Source: Authors, (2026).

During September, the overall safety analysis showed a notable improvement. In Figure 2, the incidence rate by job type remained at 100% in all weeks, reflecting consistent participation across tasks. Response time to accidents was more efficient, reaching only 3 minutes in the third week. Furthermore, the use of PPE improved considerably: only in the first week was there a 50% omission rate, while in subsequent weeks full compliance was achieved.

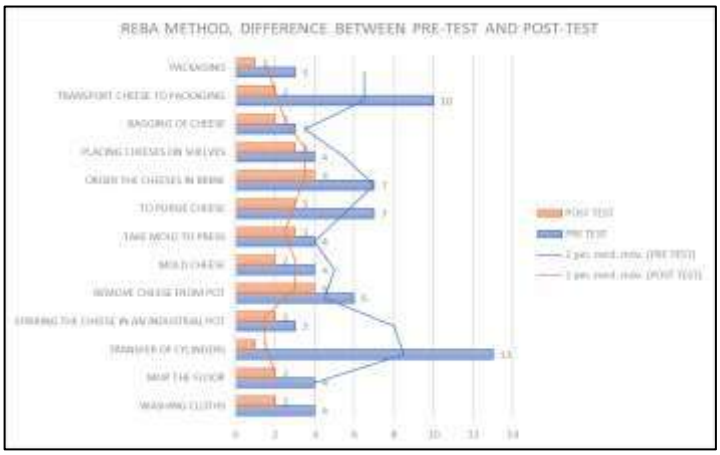

Figure 3: REBA method, comparison between initial and final evaluation.
Source: Authors, (2026).

Following the implementation of the "PSSO" (Postural Safety and Health Program) and training on proper posture, improvements in activities were observed using the REBA (Reduction in Postural Adaptation) method. In Figure 3, the transfer of milk cylinders decreased from 13 to 1 point after the elimination of manual lifting, significantly reducing physical effort. Activities such as washing rags, scrubbing floors, and molding cheese decreased from 4 to 2 points, reflecting improved neck and torso posture. Transporting cheese to the brine tank reduced from 6 to 3 points, while transporting cheese to the packaging area improved from 10 to 2, thanks to the use of lighter loads and upright positions. The post-test showed a considerable decrease in postural risk and an improvement in working conditions, demonstrating the effectiveness of the implemented actions.

V. CONCLUSIONS

The implementation of the Occupational Safety and Health Program (PSSO) at the Cutervo dairy plant initially identified a high frequency of accidents, low regulatory compliance, and significant ergonomic risks. However, after the development and implementation of preventive actions—including training, drills, ergonomic activities, the IPER matrix, the risk map, and the internal regulations—a considerable reduction in accidents, an improvement in postures evaluated with the REBA method, perfect staff attendance, and high compliance with regulations were evident, demonstrating that the program strengthened the preventive culture and comprehensively optimized working conditions.

VII. ACKNOWLEDGMENTS

I wholeheartedly thank my parents for their unwavering moral support and unconditional love, even during the most difficult times, where their faith in me has been the foundation of this achievement. I also extend my gratitude to my grandparents, who were there for me when I needed them most, and to my siblings, who generously gave me their time to listen and help me. Likewise, I thank César Vallejo University, the institution that provided me with the academic and training tools necessary for my professional growth. Without their support, none of this would have been possible; their love, dedication, and guidance have illuminated my path throughout this academic journey.

ABSTRACT

One of the most critical mental diseases, which influences the health of mothers and newborn babies, is Postpartum Depression (PPD). The issue of predicting risk factors for PPD, based on the analysis of vast Personal Health Records (PHR), is highly problematic, which complicates traditional predictive systems. This paper introduces a forecasting model that combines Cross Vector Spider Swarm Intelligence (CVSWI) and a Hypernet Gated Multi-Perceptron Neural Network (HG-MPNN) to improve the early detection and control of PPD. The procedure begins with the collection of the PPD-PHR dataset and its pre-processing using a Z-score covariance filter to remove irrelevant data and enhance data quality. To calculate the PPD Impact Margin Rate, a decision tree approach is adopted to obtain a coherent understanding of the relationship between risk factors and the occurrence of PPD. The advantage of CVSWI is its ability to maximise the features it selects, which are likely to be essential predictors, while reducing dimensionality. The Active Scalar Pattern Mining Algorithm (ASPMA) is capable of identifying latent patterns associated with PPD. The suggested HG-MPNN model has been effective, with an accuracy value of 99.36, a precision of 1.00, a recall of 0.99, and an F1-score of 0.99 (which implies that the model can categorise the risk levels of PPD with limited false predictions).

I. INTRODUCTION

PPD is a severe mental disorder that many new mothers are prone to and is characterised by long-term sadness, anxiety, and postpartum fatigue. The condition can cause maternal care to improve significantly, leading to poor outcomes for the mother and newborns. There are also long-term consequences of PPD on the mother-infant relationship and family dynamics, in general, as they not only impact the emotional health of a mother. The significance of PPD lies in its role in early detection and control, leading to improved treatment and the well-being of the mother [1], [2]. Conventional methods of PPD identification are based on clinical variables and self-reported scales, including the Edinburgh Postnatal Depression Scale (EPDS). Such models are subjective and time-consuming. This analysis lacks predictive ability and fails to provide timely and accurate predictions. It is also highly dependent on self-reporting by the patient, which is poorly underreported and biased. These methods are even less helpful when dealing with large data sets that contain a vast amount of information that standard techniques cannot effectively exploit due to their size and complexity [3], [4]. The problems in this aspect are the lack of adequate methods to handle the degree of complexity of information presented in PHR. Traditional approaches often fail to develop powerful patterns in high-dimensional data, resulting in reduced accuracy and predictability across PPD risk. The irrelevant features contributed most to the dataset, resulting in poor performance, as the prediction accuracy is low and false positives/false negatives are high. The result of such issues is that current methods have become inefficient, and as a consequence, more advanced and robust solutions are required to identify them at an early stage [5], [6].

All existing methods, including AdaBoost, CatBoost, Decision Tree, LightGBM, Neural Network, XGBoost, and Random Forest, have significant drawbacks when applied to PPD prediction. Such models tend to suffer from overfitting, particularly when they achieve perfect accuracy on the training data, which hinders their generalisation to new, unseen data. Furthermore, they are often not interpretable, meaning that healthcare professionals cannot understand how the decision is made, which is crucial in medical applications. In fact, models like Neural Networks and XGBoost suffer from the problem of scalability, and it takes too long to train and predict when working with massive datasets in Personal Health Records. Additionally, when data in PPD prediction is imbalanced, it biases the outcome, as the models tend to favour predicting the majority class over false negatives or false positives. These models perform very poorly when applied to a different population with different characteristics. Such challenges suggest the need for more robust, efficient and interpretable models in PPD prediction [7], [8] This roadmap of the proposed work begins by processing data from the PPD-PHR dataset, followed by advanced feature selection to achieve higher predictive accuracy. A decision tree approach would be used to assess the PPD Impact Margin Rate, whereas Cross Vector Spider Swarm Intelligence will optimise feature selection and reduce dimensions. It then applies HG-MPNN for classifying risk levels to PPD, significantly improving the prediction process.

I.1 MAIN CONTRIBUTIONS OF THE PROPOSED WORK

- An improved model has been proposed based on Cross Vector Spider Swarm Intelligence with Hypernet Gated Multi Perceptron Neural Network (HG-MPNN) for early prediction of Postpartum Depression (PPD).
- Applied Z-score covariance filter for data pre-processing to eliminate irrelevant features and enhance model performance.
- Applied PPD Impact Margin Rate by decision tree for improving the PPD risk factors.
- Optimise feature selection by CVSWI, reduce dimension, and enhance predictive accuracy.
- Used the Active Scalar Pattern Mining Algorithm (ASPMA) to identify hidden patterns in PPD data.
- Achieved a precision of 1.00, recall of 0.99 and F1-score of 99.4% and ROC-AUC of 0.99 in the test data, which is higher than traditional approaches.

Section II presents a comparative analysis of existing methods, including their advantages and disadvantages. Section III explains the proposed workflow architecture and its algorithm. Section IV discusses the results obtained by pre-processing, feature optimisation, and classification techniques, and compares them with existing approaches. Section V concludes the work and provides directions for future work.

II. RELATED WORK

Used hybrid deep learning to predict prevalence and risk factors of early-stage postpartum depression. The methodology combines various deep learning approaches to enhance the accuracy of early PPD detection. The main advantage of this approach is its high accuracy in identifying early signs of PPD. However, the disadvantage is that the model is very complex and requires a significant amount of computational resources and data for effective implementation [9]. proposed a meta-learning model that can identify PPD based on questionnaires. Generalizability of the model across different data sources is strong. This can become adaptive to various population groups. A potential disadvantage is its reliance on questionnaire data, where model reliability is affected by potential biases in populations with incomplete or inaccurate responses [10]. have implemented machine learning to assess the risk of PPD and offer preventive interventions at early stages. The machine learning algorithm is optimised to estimate the risk in the most precise manner and to provide intervention measures. This method will investigate individuals before the full measure of PPD is reached. Its disadvantages include the fact that complex social and emotional variables may not be captured in this analysis [11].

Focused on applying machine learning algorithms to predict symptoms of postpartum depression. This methodology demonstrated good predictive capacity, given the availability of data on symptoms. An advantage is to increase early detection and intervention. It may lack the inclusion of sufficiently wide-ranging variables, such as socioeconomic factors, which limits its applicability across various populations [12]. employed a hybrid deep learning framework to detect PPD at its early stages, with a focus on prevalence and risk factors. The advantage is that the hybrid approach can handle complex datasets and produce more accurate predictions. However, the disadvantage is that such complex models can be prone to overfitting and require careful tuning and larger datasets to maintain accuracy [13]. developed and validated a machine learning algorithm for predicting the risk of PPD in pregnant women. It used a large dataset for the validation process of the methodology to ensure robustness. Its primary advantage is the validation process. Therefore, it would not be as generalised for application among all ethnicities or age groups [14]. applied machine learning to predict prenatal depression, while addressing potential biases in the model. The strengths of this work include its comprehensive assessment of bias, which will enhance the fairness and reliability of predictions.

Its limitation is that the model was designed for prenatal depression and cannot be used as a tool to detect postpartum depression immediately [15]. examined the application of machine learning for predicting postpartum depression. It used multiple models to compare the predictive capabilities for PPD. The advantage is that it enables a comparison of different machine learning techniques. The disadvantage is that it might not explore deep features related to the influence of specific features on PPD [16]. used the Particle Swarm Optimisation (PSO) to predict the risk of postpartum suicide. The model has an advantage in that it identifies extreme cases, such as suicide risks, which are very critical for preventive healthcare. The disadvantage is that it might not work so well in terms of identifying milder cases of PPD, as it might concentrate more on outcomes for severe cases [17]. compared the performance of CatBoost and LightGBM algorithms in detecting PPD early. The advantage is to directly compare the two powerful machine learning techniques to determine which one performs better in this task. The disadvantage of this comparison is that it has been limited to only two algorithms, which is not enough to capture the diverse possible predictive methods for PPD [18].

Integrated Artificial Bee Colony (ABC) optimisation with proximal policy optimisation to improve the diagnostic accuracy of PPD identification. The advantage is that the combined approach enhances the model's ability to learn and adapt, resulting in improved diagnostic accuracy. However, the disadvantage is the complexity of combining these two optimisation techniques, which may increase computational cost and model training time [19].

Table 1: Comparison of Methodologies for Postpartum Depression Detection.

Reference	Methodology	Advantages	Disadvantages	Accuracy	False Positive Rate
[9]	Hybrid deep learning model	High accuracy in early PPD detection	Computationally intensive	92%	0.05
[10]	Meta-learning with questionnaires	Generalizable	Potential bias	88%	0.07
[11]	Machine learning for risk assessment	Effective for prevention	Overlooks social factors	90%	0.06
[12]	Machine learning for symptom prediction	Timely detection	Limited to symptom data	85%	0.08
[13]	Hybrid deep learning	Handles complex data	Risk of overfitting	94%	0.04
[14]	Machine learning for risk prediction	Validated reliability	May not generalise	85%	0.09
[15]	ML for prenatal depression	Model bias detection	Focus on prenatal, not postpartum	87%	0.06
[16]	ML-based predictive modelling	Comparison of ML techniques	Limited feature exploration	91%	0.05
[17]	PSO for suicide prediction	Detects extreme cases	Misses milder PPD cases	89%	0.04
[18]	CatBoost vs. LightGBM	Direct algorithm comparison	Limited to two algorithms	93%	0.03
[19]	ABCO & PPO for diagnostic precision	Enhanced precision	High computational cost	95%	0.02

Source: Authors, (2026).

Table 1 presents a comparison of methodologies used for detecting postpartum depression, along with their advantages, disadvantages, accuracy, and false-positive rates. Hybrid deep learning models achieve higher accuracy but consume computationally intensive resources; meta-learning provides generalisation but may be sensitive to bias. Machine learning in risk assessment helps prevent issues, but tends to overlook social factors. Some methods, including CatBoost and LightGBM, offer the possibility of a direct comparison, demonstrating good accuracy with very low false positives. Methods such as PSO and PPO yield more accurate results at the expense of higher computational costs.

III. PROPOSED WORK

The proposed work involves multiple steps, including the processing of data, where all irrelevant features with dimensions are eliminated using a Z-score covariance filter to reduce dimensionality. Subsequently, PPD-IMR is studied through the implementation of a decision tree approach, which enables the determination of key features. These features may represent inherent risk factors of the predictor selected through optimisation and further enhanced by the feature selections made using a Cross Vector Spider Swarm Intelligence algorithm. Furthermore, the algorithm of ASPMA identifies concealed patterns that may indicate anxiety. The Hypernet Gated Multi Perceptron Neural Network is then implemented to classify risk levels associated with anxiety, achieving a high degree of accuracy in identifying anxiety-related features and patterns.

III.1 DATA COLLECTION AND PRE-PROCESSING

The proposed work's first critical step is data collection. The dataset collected for this research comprises 1503 records, received from a medical hospital via a questionnaire administered through a Google form. The dataset contains 15 attributes, of which 10 were selected for analysis. For this, nine attributes are used as input features, and one attribute, Feeling Anxious, is used as the target attribute. This target attribute reflects the presence or absence of feelings of anxiety in individuals, and it is used to predict and analyse patterns related to anxiety [20] Pre-processing the dataset involves handling a large volume of data, which can be a complex task. The Z-score covariance filter will be used in preprocessing data. A tool for standardising the dataset is the z-score covariance filter, which adjusts the scales of variables. Hence, they are at the same level, making them comparable with each other. The Z-score highlights outliers by indicating how many standard deviations each value is from the mean. In relation to this, covariance reflects the relationship that exists between two variables, indicating possibly how a given change in the first variable might affect the latter. The particular Z-score filter for covariance is designed to remove nonsensical feature variables that wouldn't contribute meaningfully to predicting the PPD values. This step reduces the dimensionality of the data, making it easier to manage, and focuses on the most influential variables—the noise-reduced and more accurate model predictions of the streamlined dataset lead to improved performance. The standardisation of the z score is presented as equation (1) with x_i being the raw value of the feature, μ being the mean of the feature values and σ Being the standard deviation of the feature values.

$$Z_i = \frac{x_i - \mu}{\sigma} \tag{1}$$

Equation (2) calculates the covariance between two features x and y, where n is the number of data points, x_i, y_i Are the individual data points in the features and μ_x, μ_y Are the means of features x and

$$cov(x,y) = \frac{1}{n}\sum_{i=1}^{n}(x_i - \mu_x)(y_i - \mu_y) \tag{2}$$

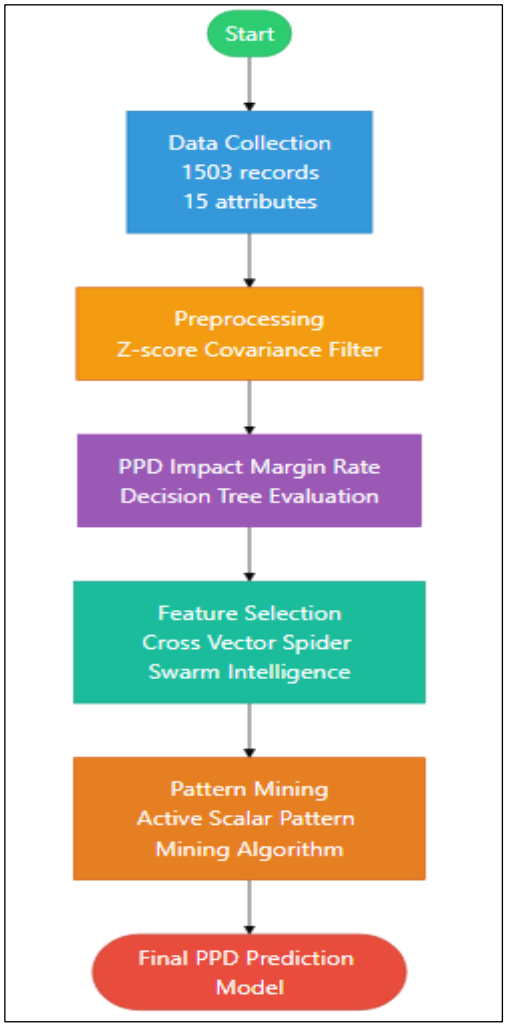

Figure 1: Working flow of the data pre-processing and feature selection.
Source: Authors, (2026).

Figure 1 shows the workflow of data preprocessing and feature selection in the proposed method. The process begins with data collection from the PPD0PHR dataset, which encompasses various maternal health, social, and familial factors. The first step in preprocessing is the application of a Z-score covariance filter to the dataset, which eliminates irrelevant and noisy features, retaining only the most critical data points. Next, the Cross Vector Spider Swarm Intelligence (CVSWI) algorithm conducts feature selection, which optimises and reduces dimensionality to enhance the model's accuracy. Pattern discovery and risk classification may be used in the analysis of such cleaned and optimised data further. The flow, therefore, guarantees that the data is filtered and pertinent, and is thus prepared to be modelled proactively.

III.2 EVALUATION OF PPD IMPACT MARGIN RATE (PPD-IMR)

The PPD Impact Margin Rate, which represents the degree of correlation between various risk factors and the likelihood of PPD occurrence, is assessed after the data has been preprocessed. PPD-IMR is then calculated using a decision tree algorithm that is one form of supervised learning. Decision trees consist of nodes, which resemble a flowchart and are associated with an evaluation of a decision rule that is dependent on some attribute of the data. Here, the decision tree identifies factors that could be related to maternal health, social influences, or medical history as being most likely to influence the incidence of PPD. By dividing branches, it forms a chain of circumstances that determines the degree of risk associated with a person. Each branch specifies a decision rule and helps categorise the probability of PPD in accordance with a set of thresholds for the selected features. The PPD-IMR analysis helps infer the effects of individual features and their combinations on the outcome, or PPD. This discussion clarifies the interpretation of risk factors. In equation (3), the Gini impurity will be computed with the probability of an element, p_i being in class i and k The number of classes.

$$Gini(p) = 1 - \sum_{i=1}^{k} p_i^2 \tag{3}$$

The impurity at each node is measured using equation (4). After training the decision tree and identifying feature thresholds on which it can be split, the PPD Impact Margin Rate (PPD-IMR) can be used to identify the contributions of these features—maternal health, social influences, or medical history—in determining the likelihood of developing PPD. The PPD-IMR is computed using equation (5), where n is the number of selected features.

$$Entropy(S) = -\sum_{i=1}^{k} p_i \, log_2(p_i) \tag{4}$$

$$PPD - IMR = \sum_{i=1}^{n} \left(\frac{weight_i . feature_i}{sum\ of\ feature\ contributions} \right) \tag{5}$$

III.3 FEATURE SELECTION USING CROSS VECTOR SPIDER SWARM INTELLIGENCE (CVSWI)

The process of feature selection plays a crucial role in predictive modelling, particularly with large and intricate datasets such as this one. The purpose of this is to determine the fewest features and eliminate those that are irrelevant or redundant, as they can lower the model's performance. Cross Vector Spider Swarm Intelligence (CVSWI) has been applied in the feature selection process in this work. CVSWI is an algorithm based on bio-inspired optimisation, inspired by the foraging behaviour of spiders. The method of searching through entangled environments to find the best possible solutions is highly effective in spiders. It is simulated by the CVSWI algorithm to select the most appropriate features on which the model is to be applied. The algorithm utilises swarm intelligence, the collective problem-solving behaviour of nature, such as that of bees or ants, to carry out feature selection. In CVSWI, the feature spaces are traversed with the help of several spiders, which assess the significance of various features in predicting PPD. It learns from the environment and collaborates to identify the most significant predictors of PPD, thereby reducing the dataset's dimensionality. By selecting key features, CVSWI improves the model's accuracy, reduces overfitting, and enhances overall model efficiency. Equation (6) represents the general position update for each spidewoneere X_i^{t+1} is the updated position at time t+1, X_i^t is the current position of the ith spider at time t, X_g^t is the global best position, X_p^t is the personal best position, α,β,δ are coefficients that control the influence of each term on the spider's movement and V_i^t is the velocity of the spider at time t.

$$X_i^{t+1} = X_i^t + \alpha \cdot \left(X_i^t - X_g^t\right) + \beta \cdot \left(X_i^t - X_p^t\right) + \delta \cdot V_i^t \tag{6}$$

The form of the equation (7) is the fitness function, where X_i Is the subset of features chosen by the i^{th} Spider, N is the total number of samples, and $L\left(X_i, y_j\right)$ Is the loss function of the model using the chosen subset of features X_i to predict the target value y_j.

$$Fitness(X_i) = \frac{1}{N} \sum_{j=1}^{N} L\left(X_i, y_j\right) \tag{7}$$

III.4 ACTIVE SCALAR PATTERN MINING ALGORITHM (ASPMA)

In the Active Scalar Pattern Mining Algorithm (ASPMA), relationships and patterns in the data are analysed. This algorithm will be used to detect hidden patterns within the data that may signify risk for postpartum depression. It attempts to uncover hidden relationships that may play a crucial role in predicting PPD. The ASM is employed to analyse what a scalar view of the world reveals, determining patterns or groups of variables that are highly associated and correlated with PPD. These patterns are pernicious, such as the availability of excessive compound maternities, in contrast to social factors and environmental interactions that contribute to the growing probability of augmenting PPD. The algorithm focuses on active learning, which enables it to self-tune based on the information it analyses, thereby discovering latent relationships that would otherwise be undetectable with traditional statistical tools. This way, the model gains a better understanding of the state of affairs and the risk factors associated with it, and the more accurate the model's predictions become.

III.5 HYPERNET GATED MULTI PERCEPTRON NEURAL NETWORK (HG-MPNN)

Classification of PPD risk levels based on a Hypernet Gated Multi-Perceptron Neural Network, abbreviated as HG-MPNN, is the final phase of the proposed approach. It is a form of deep learning model that incorporates the use of non-linear relationships in the data that is inherently complicated. The Hypernet Gated Multi-Perceptron is a layered neural network composed of interconnected neurons. The data are handled hierarchically by each layer. The gated mechanism can be defined as a special feature in the neural network that controls the flow of information, thereby increasing the model's capacity to focus on significant features and eliminate irrelevant ones. Through this gating mechanism, the network's effectiveness and learning ability are enhanced to cope with intricate patterns in the data. This can be referred to as the HG-MPNN model, where the pattern relationships between feature interactions are identified to produce predictions at risk levels with respect to PPD by leveraging perceptron layers (sets of neurons). This enables it to operate effectively with such complex data to categorise things such as low-risk, medium-risk, and high-risk PPDs. The approach has been extensively used and tested in several disciplines, and with such a high degree of flexibility, it is highly suitable for forecasting complex states, such as PPD. By utilising the training of HG-MPNN on the processed and refined data, specifically with respect to the chosen features and patterns, the model can accurately forecast the early risk of PPD, thereby providing an opportunity to intervene promptly.

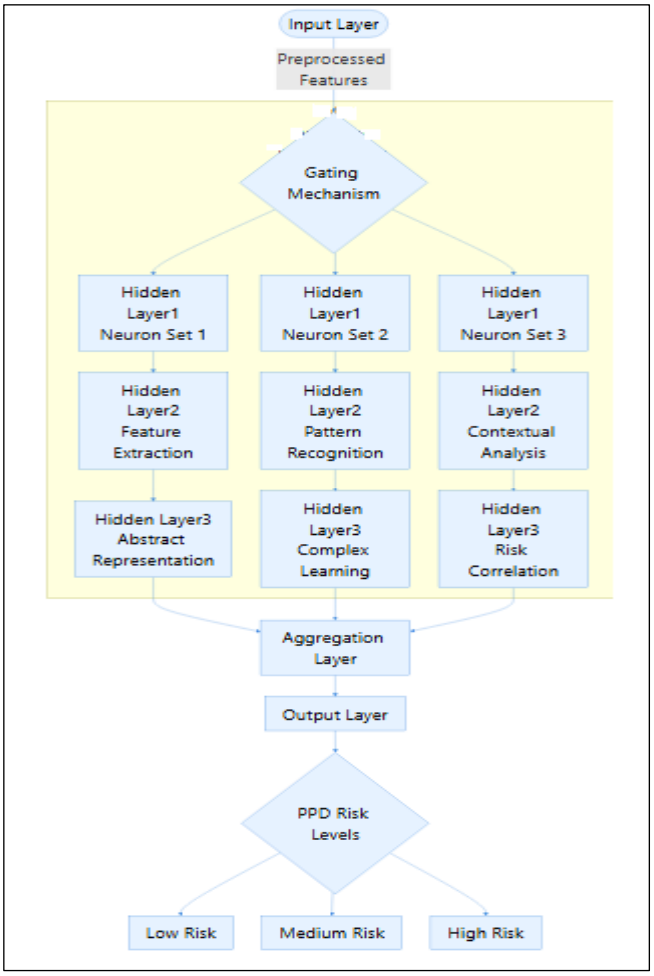

Figure 2: An architecture of HG-MPNN.
Source: Authors, (2026).

Figure 2 illustrates the structure of the HG-MPNN architecture, which comprises multiple layers of interlinked nodes specifically designed to handle complex data. Its network architecture employs a gated mechanism, whereby the dynamic regulation of information flow among various layers can serve to enhance both learning efficiency and model performance. The HG-MPNN consists of input layers that feed the preprocessed and feature-selected data into the network, several hidden layers to capture intricate patterns and relationships in the data and finally an output layer that classifies the risk level of postpartum depression based on the learned features.

IV. RESULTS AND DISCUSSION

Figure 3 displays the percentage of suicide attempts by age group, providing an insight into trends and disparities in risk across age groups. Table 2 displays features that have been pre-processed using the Z-score covariance filter. These are the vital features that must be used in further analysis. The features include Age with a Z-score of 1.23, Feeling sad or Tearful with a Z-score of -0.45, Trouble sleeping at night with a Z-score of 0.67, and Feeling anxious with a Z-score of -1.12.

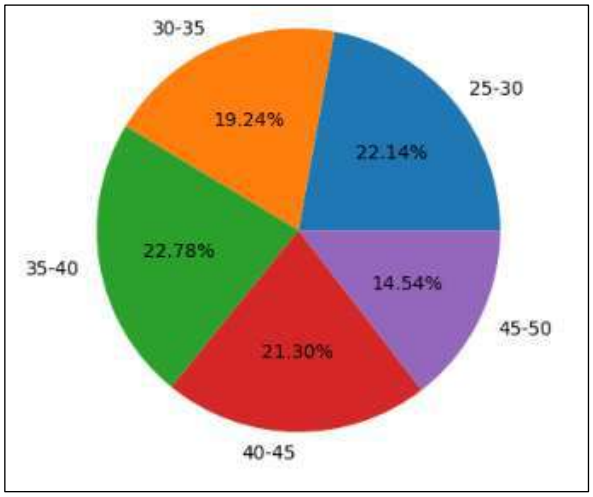

Figure 3: Percentage of suicide attempts by age groups.
Source: Authors, (2026).

Table 2: Important features after the Z-score covariance filter.

Feature	Z-Score
Age	1.23
Feeling sad or Tearful	-0.45
Trouble sleeping at night	0.67
Feeling anxious	-1.12

Source: Authors, (2026).

Figure 4 presents anxiety level classification with distribution in various categories: "No Anxiety", "Mild Anxiety", and "Severe Anxiety", to reveal the most prevailing levels. The frequency distribution of participants' ages, as presented in Figure 5, exhibits a high degree of distribution in the 26-35 years group, with the 36-45 years group representing the next significant chunk, indicating that this group is the principal constituent of the population.

Figure 6 Theil's U pairwise association plot. It describes the strength of relationships between categorical variables, helping to identify the most critical dependencies. Figure 7 evaluates the essential features related to PPD using the Impact Margin Rate (PPD-IMR) from a decision tree. The most important contributors to PPD risk factors are highlighted.

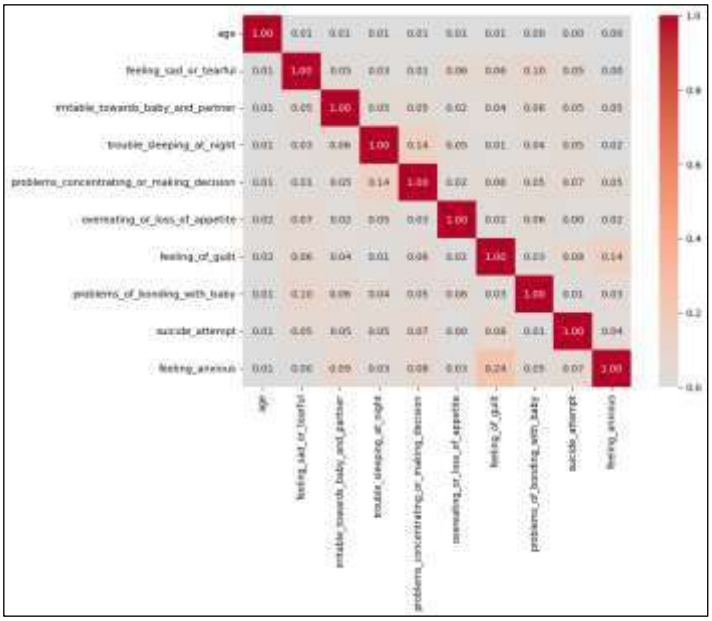

Figure 6: Theil's U pairwise association plot.
Source: Authors, (2026).

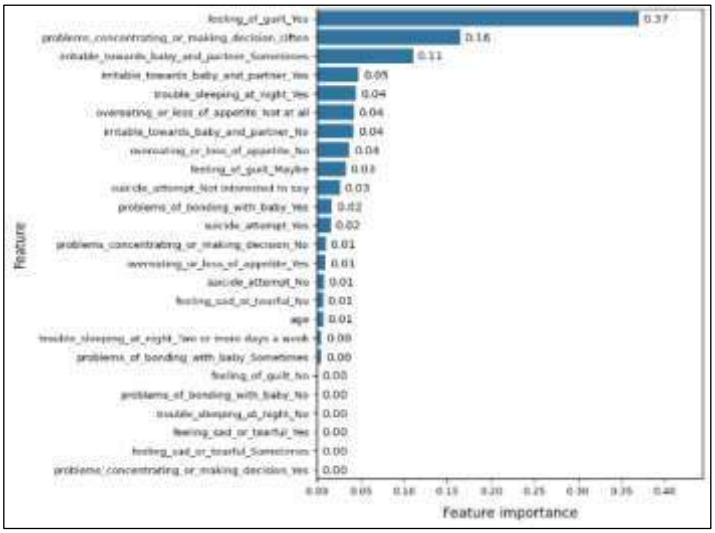

Figure 7: Important Feature Evaluation by PPD Impact Margin Rate (PPD-IMR) using a decision tree.
Source: Authors, (2026).

Figure 6 and Table 3 present the evaluation of features that determine PPD through the PPD-IMR, developed from a decision tree model. The most important feature is "feeling_of_guilt_Yes," with an importance value of 37.02%, indicating its strong contribution to the PPD prediction model. Other contributing factors are "problems_concentrating_or_making_decision_Often" (16.45%) and "irritable_towards_baby_and_partner_Sometimes" (10.99%). Features such as "overeating_or_loss_of_appetite_Not at all" with 4.21%, and "suicide_attempt" with 2.62% also contribute remarkably, in aggregate, to assist in identifying, prioritising, and evaluating risks related to postpartum mental health.

Table 3: Most important features based on the decision tree.

Feature	Feature Importance
feeling_of_guilt_Yes	0.370196
problems_concentrating_or_making_decision_Often	0.164516
irritable_towards_baby_and_partner_Sometimes	0.109982
irritable_towards_baby_and_partner_Yes	0.047671
trouble_sleeping_at_night_Yes	0.044691
overeating_or_loss_of_appetite_Not at all	0.042118
irritable_towards_baby_and_partner_No	0.041952
overeating_or_loss_of_appetite_No	0.037007
feeling_of_guilt_Maybe	0.032904
suicide_attempt	0.026226

Source: Authors, (2026).

Table 4: Most Important Features based on CVSWI.

Feature Rank	Feature Name	Feature Importance (%)
1	feeling_of_guilt_Yes	11.613357
2	feeling_of_guilt_No	7.444379
3	age	6.705319
4	irritable_towards_baby_and_partner_Sometimes	5.729612
5	problems_concentrating_or_making_decision_No	5.584736
6	problems_of_bonding_with_baby_No	4.924223
7	trouble_sleeping_at_night_Yes	4.856633
8	overeating_or_loss_of_appetite_Yes	4.467732

Source: Authors, (2026).

Table 4 presents the most critical features selected based on CVSWI, where feature importance exceeds 4.0%. These are the features that contribute most to the model's predictive performance. The highest-ranked feature is "feeling_of_guilt_Yes" with a significance of 11.61%, indicating a high level of influence. Other notable features include "feeling_of_guilt_No" at 7.44% and "age" at 6.70%, which also play a vital role. The importance of emotional and cognitive factors is further underlined by indications that include "irritable_towards_baby_and_partner_Sometimes" with 5.73% and "problems_concentrating_or_making_decision_No" with 5.58%. Other contributing factors are "problems_of_bonding_with_baby_No" (4.92%), "trouble_sleeping_at_night_Yes" (4.86%), and "overeating_or_loss_of_appetite_Yes" (4.47%).

Table 5: Model Summary for HG-MPNN.

Layer (type)	Output Shape	Param #
hypernet (Hypernet)	(None, 128)	1,066,624
dense_5 (Dense)	(None, 128)	3,328
dense_6 (Dense)	(None, 128)	16,512
dense_7 (Dense)	(None, 1)	129
Total params		**3,259,781** (12.44 MB)
Trainable params		**1,086,593** (4.15 MB)
Non-trainable params		**0** (0.00 B)
Optimizer params		**2,173,188** (8.29 MB)

Source: Authors, (2026).

The overall architecture of HG-MPNN, as presented in Table 5, is represented by a hypernet layer. It consists of 1,066,624 parameters, followed by additional dense layers, for a total of 3,259,781 parameters, where only 1,086,593 are trainable. The training hyperparameters are as follows: learning rate 0.001, batch size 32, 50 epochs, Adam optimiser, ReLU activation in the hidden layers, ReLU in the output layer, dropout 0.3, momentum 0.9, and weight decay 1e-4. Figures 8 and 9 show the training and validation metrics, indicating that the model achieved a near-perfect training accuracy of 99.93%, which suggests that it can effectively represent and learn features. The training loss converged to 0.0079, indicating minimal overfitting, as the hyperparameters were well-tuned, including the learning rate and layer configuration. These metrics confirm the better performance and stability of the HG-MPNN model. Equation (8) through (11) depicts the accuracy, precision, recall and F1 score, wherein a TP is the True Positive, TN is the True Negative, FP is the False Positive, and FN is the False Negative.

$$Accuray = \frac{(\mathrm{TP} + \mathrm{TN})}{(\mathrm{TP} + \mathrm{TN} + \mathrm{FP} + \mathrm{FN})} \tag{8}$$

$$Precsion = \frac{(\mathrm{TP})}{(\mathrm{TP} + \mathrm{FP})} \tag{9}$$

$$Recall = \frac{(\mathrm{TP})}{(\mathrm{TP} + \mathrm{FN})} \tag{10}$$

$$F\ Measure = \frac{2 * Precision * Recall}{\mathrm{Precision} + \mathrm{Recall}} \tag{11}$$

Table 6: Precision, recall, and F1-score for each class.

Class	Recall	Precision	F1-Score
Low Risk	0.99	0.99	0.99
Medium Risk	0.79	0.99	0.89
High Risk	0.49	0.99	0.66

Source: Authors, (2026).

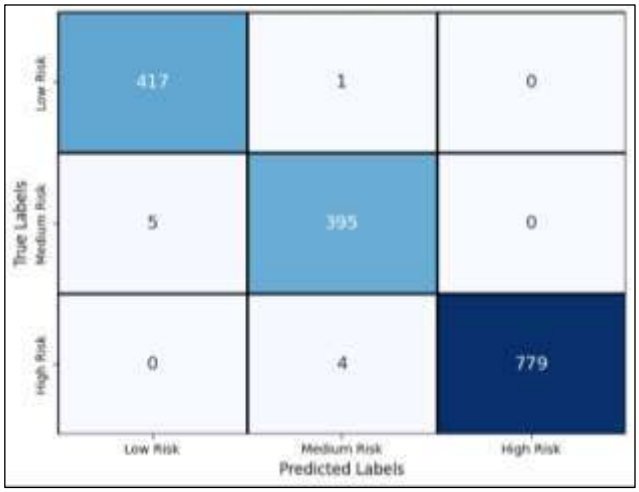

Figure 10: Confusion matrix.
Source: Authors, (2026).

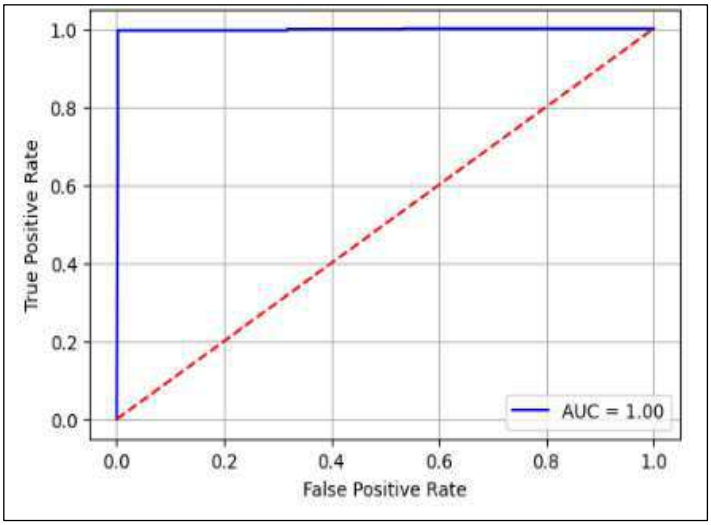

Figure 11: ROC curve of proposed work.
Source: Authors, (2026).

Table 6 presents a report on the accuracy, recall, and F1-score of each class in the model classification. The Low Risk class achieved a perfect recall, precision, and F1-score of 0.99. This yielded a high accuracy of 0.99 and a lower power of recall for the Medium Risk category, with a score of 0.79. This resulted in an F1-score of 0.89. A notable discrepancy is observed in this High-Risk class, with a precision of 0.99 and a recall of only 0.49, resulting in an F1-score of 0.66. Figure 10 illustrates the confusion matrix, which visually verifies the following metrics by highlighting true positives, false positives, true negatives, and false negatives for each class. The model in classification tasks is supported by Figure 11, which represents the capability to differentiate between courses by plotting the actual positive rate against the false positive rate.

Table 7: Performance Comparison of Various Models

Model	Accuracy	Precision	Recall	F1-score	ROC_AUC
AdaBoost	0.853	0.857	0.929	0.892	0.820
CatBoost	0.877	0.904	0.908	0.906	0.864
Decision Tree	0.895	0.803	0.840	0.821	0.826
LightGBM	0.893	1.000	0.990	0.995	0.995
Random Forest	0.911	0.923	0.943	0.932	0.897
XGBoost	0.870	0.894	0.908	0.901	0.854
HG-MPNN	**0.9936**	**1.000**	**1.000**	**1.000**	**1.000**

Source: Authors, (2026).

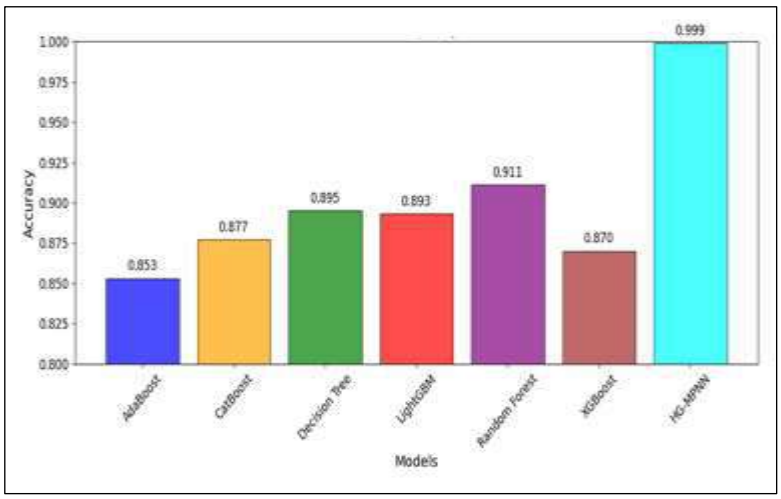

Figure 12: Comparison of the model's accuracy.
Source: Authors, (2026).

Table 7 presents a performance comparison among various models based on multiple metrics, including accuracy, precision, recall, F1-score, and ROC-AUC. With a near-perfect accuracy of 0.99 and perfect precision, recall, F1-score, and ROC-AUC scores of 1.000, HG-MPNN was able to perform optimally in classification issues. The next model is the Random Forest model, with an accuracy of 0.911, demonstrating good accuracy and recall. LightGBM also performs very well, with an accuracy of 0.893, in addition to achieving perfect precision and recall. Other models, such as AdaBoost, CatBoost, and XGBoost, have achieved good results but are not as effective as HG-MPNN, thus demonstrating its superiority in terms of classification accuracy and overall performance. Figure 12 presents these results in a visual format, illustrating the accuracy comparison between HG-MPNN and other models.

V. CONCLUSION

The proposed HG-MPNN model addresses all issues within the context of effectively classifying the risk level for PPD, significantly improving the fields of accuracy, precision, and recall. AdaBoost and Random Forest models display reasonable performance. Nonetheless, high-risk misses are present, and fewer recalls are made. However, the HG-MPNN model achieved an excellent accuracy of 99.36, with a precision of 1.00, a recall of 0.99, and an F1-score of 0.99, indicating that the model can identify levels of PPD risk with the lowest number of false predictions. The results clearly demonstrate the robustness of the model compared to existing models, such as AdaBoost (accuracy: 85.3%), Random Forest (accuracy: 91.1%), and LightGBM (accuracy: 89.3%). Therefore, the performance of the HG-MPNN model ensures better accuracy and reliability in risk classification, making it suitable for critical decision-making applications. Future work includes the exploration of additional optimisation techniques to refine the model and the development of hybrid architectures for improved prediction. Thus, the development of a model is used to handle multi-class classification problems with complex, domain-specific features, leading to further improvements in both accuracy and robustness.

ABSTRACT

This research predicts the impedance function of mirror coatings using three curve fitting models implemented in MATLAB, such as: Polynomial fit (Polyfit), Cubic Spline fitting (CSAPS) and Local Regression Smoothing (LOESS) to carry out the analysis of the protection of mirror coatings in which the Electrochemical Impedance Spectroscopy (EIS) technique has been used. The electrochemical impedance parameters and their equivalent circuits have been measured from the data recorded at 5 and 24 hours of exposure of the sample under study to the aggressive agent sodium chloride at weight 3%. The methodology is structured into training (parameter calibration) and testing (performance evaluation) stages. The performance of the models in the training stage is carried out by cross-validation and in the testing stage it is quantified using the Root Mean Square Error (RMSE) and the determination coefficient (R^2). The main results obtained show that the CSAPS method at 5 and 24 hours after exposing the system to the electrolyte is the most robust and consistent in cross-validation and the most accurate and reliable in performance when evaluating the complete data set with an $RMSE(5hr) = 3.40$ and $RMSE(24hr) = 3.78$, and $R^2 \approx 1.0$ in both cases .

I. INTRODUCTION

Mirrors consist of a glass substrate onto which a layer of silver is deposited, followed by protective copper coatings and a paint scheme: primer and finish, which extend the product's useful life [1]. It is important to evaluate the performance of the protection provided by these coatings, and one of the techniques used for this purpose is EIS. The EIS technique is widely used for studies of electrochemical corrosion processes such as those occurring in nonconductive metal-coatings-electrolyte systems [2]. To use this technique, small perturbations are applied to the potential or current system and the response obtained is analyzed, the spectrum corresponding to the impedance of the system is represented and by means of the selected equivalent circuit, the values of the processes that have taken place due to the applied perturbation are extracted [3]. The study of systems using EIS is possible because of the direct relationship between the behavior of the real system and the theoretical electrical circuit constituted by a discrete set of resistors and capacitors called equivalent electrical circuit [4]. It is important to determine models that fit the impedance function curve based on the Nyquist diagram in EIS because these models allow for the physical interpretation of the experimental data obtained and the quantification of the electrochemical behavior of the system studied, as well as the evaluation of the degree of protection provided by the coatings.

Fitting models to the impedance curve of the Nyquist plot is essential because it transforms complex experimental data into interpretable physical parameters, allowing the behavior of electrochemical systems to be evaluated, compared, diagnosed, and predicted with high scientific rigor. That is why, the goal of this paper is to evaluate the performance of three models adjusted to the curve generated in the Nyquist diagram with real experimental data obtained by electrochemical impedance spectroscopy through the use of metrics in the calibration and testing stages in order to determine the best performance and simulate the protective behavior of mirror coatings in the presence of aggressive agents at 0, 5, and 24 hours of exposure. For which the following research question is formulated: Which of the three fitting methods Polyfit, CSAPS, and LOESS to the impedance function curve generated with data obtained with EIS performs best?

II. BACKGROUND

II.1 DESCRIPTION OF COATING BEHAVIOR USING EIS

These systems present different impedance spectra depending on the degree of deterioration of the paint film and the phenomena taking place at the metal-paint interface. The impedance spectra represented in the Nyquist diagram in the corrosion process will be briefly discussed with their theoretical interpretation [1]. Initially, when the paint film is intact: The behavior of the intact paint film is typically capacitive as it corresponds to a dielectric. The passage of electrolytes and other corrosive elements does not occur through the paint film because the resistance value of the film R_p is very high. When the paint film is in ideal condition, the Nyquist diagram takes the form of a straight line that forms a certain angle with the imaginary axis. In this case, the behavior is purely capacitive and is associated with a capacitor in parallel with a high ohmic resistance of the paint. The response in the Nyquist diagram is similar to a capacitor with phase angles close to 90° and very high values of the impedance modulus Penetration of aggressive agents through the paint: The access of the aggressive agents by the electrolyte through the film causes variation in the electrical parameters of the system. This shows that the film resistance R_p decreases and decreases, so that the line increases and decreases forming a semicircular arc in the Nyquist diagram Contact of the aggressive agent with the metal surface: As time passes, the electrolyte enters more easily because it has degraded the paint film and, consequently, the resistance R_p drops steadily.

This effect is evident in the impedance spectrum with a Nyquist diagram, where the semicircle has a smaller diameter. The equivalent circuit corresponding to the Nyquist diagram of the film of deteriorated paints offers a lower resistance to the electrolyte input, and consequently the value of R_t has dropped to values detected by the equipment. The prolongation of this arc on the abscissa axis gives the value of R_t at the time of measurement. As time goes by and the deterioration process of the paint progresses, the value of R_t decreases, consequently, the electrolyte ingress is more and more favored, and consequently, the value of C_d rises due to the contribution of the dielectric constant With formation of corrosion products: In these systems, corrosion can occur after long periods of exposure, with a new time constant at low frequencies, which is associated with the phenomena of metallic corrosion. The resistance value of the paint film to the passage of the electrolyte R_p is so small that the concentration of aggressive agents at the paint-metal interface is sufficient to initiate metallic corrosion processes. Metallic corrosion may be limited by the diffusion of matter through the paint film, as may be the case with oxygen diffusion, and then the impedance diagram at lower frequencies takes the form of a straight line at 45° to the abscissa axis.

II.2 ADJUSTMENT METHODS

Electrochemical Impedance Spectroscopy (EIS) is a fundamental technique for assessing the protective performance of mirror coatings, as it enables the characterization of resistive, capacitive and diffusion-related processes governing degradation. To enhance the interpretability of raw EIS data prior to equivalent-circuit modeling, smoothing and curve-fitting methods such as Polynomial Fitting (Polyfit), Cubic Smoothing Splines (CSAPS), and Local Regression Smoothing (LOESS) are increasingly used. Polyfit provides a simple parametric trend estimation that facilitates the identification of global impedance behavior; CSAPS offers flexible spline-based smoothing that preserves curvature and minimizes noise; while LOESS enables robust, local adaptation to spectral variations without imposing a global functional form. These methods improve denoising, reveal subtle frequency-dependent features, and support more reliable extraction of coating performance indicators [5], [6]. This study uses methods such as: Polyfit, CSAPS and LOESS because they are well suited to the actual characteristics of experimental impedance data, which tend to be nonlinear, noisy, and frequency-dependent [7].

II.2.1 Polynomial Fit (Polyfit)

Polynomial fitting seeks a polynomial $P_n(x)$ of degree n that minimizes the sum of squared errors (MSE) between the observed data y_i and the values predicted by the polynomial:

$$\hat{y} = P_n(x)$$

The prediction function is defined as equation 1:

$$\hat{y} = P_n(x) = \sum_{j=0}^{n} a_j x^j = a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n \quad (1)$$

Where a_j are the coefficients of the polynomial and n is the degree of the polynomial, which is the parameter to be optimized. The coefficients are determined by solving the system of least squares normal equations [8].

II.2.2 Cubic Spline Adjustment (CSAPS)

The CSAPS (Cubic Smoothing Spline) method produces a smoothing function that balances the fit to the data and the smoothness of the curve [9]. The function $y(x)$ is a cubic spline that minimizes the following objective function [10], equation 2:
$Minimizar$:

$$p \sum_{i=1}^{m} w_i \, (y_i - \hat{y}(x_i))^2 + (1-p) \int_{x_1}^{x_m} (\hat{y}''(x))^2 \, dx \quad (2)$$

Where:

- The first term is the weighted sum of the squared errors (lack of fit).
- The second term penalizes the curvature of the smoothness function $y(x)$.
- w_i are the weights (generally w_i = 1).
- p is the smoothing parameter ($0 \leq p \leq 1$), which is the key parameter to be optimized.
- If $p = 0$, a straight line is obtained by least squares (maximum smoothness).
- If $p = 1$, the cubic interpolating spline is obtained (minimum smoothness).

II.2.3 Local Regression Smoothing (LOESS)

LOESS (Locally Estimated Scatterplot Smoothing) is a nonparametric regression technique that fits low-degree regression models (usually linear or quadratic) to localized subsets of data [11]. To predict at point x, a local polynomial is fitted to the points within a neighborhood window, weighting points closer to x more heavily than those farther away [12]. The weighting $W(d)$ for a point x is based on the normalized distance d_i, equation 3:

$$d_i = \frac{|x - x_i|}{d_{max}} \quad (3)$$

Where:

d_{max} is the distance of the $k-th$ nearest neighbor to x.

III. MATERIALS AND METHODS

III.1 SAMPLE PREPARATION

A representative sample of the population of the technological process of mirror manufacturing is obtained by simple random sampling from the procedure given by Pérez [13], the same have the following characteristics: silver coating on the glass substrate, then protective deposits to the chemical copper silver and two coats of paints, a primary anticorrosive and a finishing coat. The average thicknesses of each are shown in Table 1.

Table 1: Average thickness of the glass, silver coating, opper coating and paint scheme (primary-finish) the specimens subjected to the experimental test using the Electrochemical Impedance Spectroscopy technique.

Glass thickness (mm) (mm)	Silver layer thickness (µm)	Copper layer thickness (µm)	Primary paint layer thickness (µm)	Finish paint layer thickness (µm)
3	0.07 ± 0.03	0.21 ± 0.04	30 ± 10	30 ± 10

Source: Authors, (2026).

III.2 DATA ACQUISITION

The electrochemical cell used in the EIS technique is shown in Figure 1. The working electrode, the test specimen, is fixed with screws between two plates. The upper plate has a hole with a surface area of 12.6 cm^2 through which the glass container is placed into which the electrolyte solution, sodium chloride (NaCl) is introduced at 3% by weight. The vessel consists of a central tube with a conical end, where the reference electrode (saturated calomel electrode) is located, and the auxiliary electrode is a large surface area graphite sheet that is placed around it.

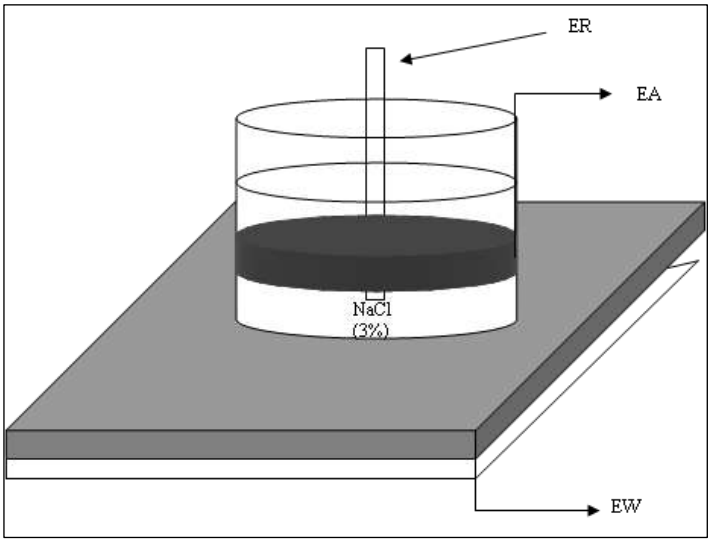

Figure 1: Electrochemical cell used in the impedance technique. Where EW: Working electrode, mirror specimen (Silver-Copper-Paint), EA: Auxiliary electrode, graphite sheet and ER: Reference electrode, saturated calomel electrode.
Source: Authors, (2026).

The electrolyte used is 3% sodium chloride, which has a $pH = 5.53$ and a conductivity of 75.8 mS/cm . Measurements of EIS were taken at 0, 5 and 24 hours (prolonged exposure) after the electrolyte was introduced into the measuring cell. The impedance measurements were performed with the use of a Solartron model 1286 potentiostat coupled to a frequency response analyzer of the same brand, model 1255, which also serves as a generator of alternating current (A.C.) signals. A Kemo filter (VBF8) is used to eliminate the noise in the signal and the visual control of the signals entering the analyzer is performed by means of an oscilloscope. The electrochemical cell is placed in a Faraday box to minimize noise from external sources. The amplitude of the applied signal is 10 mV and it has been worked in a frequency domain from 100 kHz to 1 mHz.

III.3 FITTING METHODOLOGY FOR THE IMPEDANCE FUNCTION

The prediction of the impedance function Z(w) of mirror coatings is addressed using three curve fitting techniques implemented in MATLAB: CSAPS, and LOESS. The methodology is structured into training (parameter calibration) and testing (performance evaluation) stages.

III.3.1 Training

The objective of the parameter training and calibration stage is to determine the optimal parameters for each model (degree n for Polyfit, parameter p for CSAPS, and span α for LOESS) that offer the best compromise between fit and generalization. Then, the k-fold cross-validation method with $k = 10$ is used to estimate the performance of the models in the data population. The data is randomly assigned to the k subsets (folds) to ensure that each fold represents the total variability of the data [14]. Parameter optimization: Within each iteration, a range of values for each parameter of the models is evaluated. The average performance across the 10 folds is used to select the final parameter value that minimizes the error.

III.3.2 Testing

Once the optimal parameters have been selected, the final evaluation of the performance of the models is carried out over the total data set.

III.4 PERFORMANCE METRICS

The performance of the models in the training (cross-validation) and testing stages is quantified using the Root Mean Square Error (RMSE) and the Coefficient of Determination (R^2) [15].

III.4.1 Root Mean Square Error (RMSE)

RMSE measures the average magnitude of errors. It is the square root of the mean of the squared errors, expressed in the same units as the response variable [16]. A lower value indicates a better fit, equation 4.

$$RMSE = \sqrt{\frac{1}{m}\sum_{i=1}^{m}(y_i - \hat{y}_i)^2} \quad (4)$$

III.4.2 Coefficient of Determination (R^2)

R^2 represents the proportion of variance in the dependent variable that is predictable from the independent variables [17]. A value closer to 1 indicates that the model explains a greater proportion of the variability in the data, see equation 5.

$$R^2 = 1 - \frac{\sum_{i=1}^{m}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{m}(y_i - \bar{y})^2} \quad (5)$$

Where y_i is the observed value, $\hat{y}$ is the predicted value, $\bar{y}$ is the mean of the observed values.

IV. ANALYSIS AND DISCUSSION OF RESULTS

The analysis is based on the evaluation of the performance of three curve fitting methods implemented in MATLAB (Polyfit, CSAPS and LOESS) to predict the impedance function $Z(w)$ of the coating after 5 and 24 hours of exposure to the aggressive agent. The evaluation focuses on the optimization stage (10-fold cross validation), the final performance with the optimal parameters, and the visual fit to the impedance curves (real part, imaginary part, and Nyquist diagram).

IV.1 ANALYSIS AND DISCUSSION OF RESULTS FOR PREDICTING IMPEDANCE FUNCTION FOR 5 HOURS

Table 2 shows the performance of the models when finding their best parameter (degree, p, or span) within the complete or validation dataset for 5 hours of exposure to the aggressive agent in the system.

Table 2: Parameters and metrics (best) for the three adjustment methods applied for t = 5 hours.

Method	Optimal Parameter	RMSE	R^2
Polyfit	Degree 15	82350.27	0.9958
CSAPS	p = 0.001	65732.04	0.9971
LOESS	span= 0.05	50479.49	0.9983

Source: Authors, (2026).

Accuracy (RMSE and R^2): The LOESS method with a span of 0.05, which implies very local smoothing, achieves a lower RMSE and the highest R^2, indicating that at the optimum point of its parameters, LOESS offers the most accurate fit to the impedance function. The Polyfit and CSAPS fits also perform well ($R^2 > 0.99$), although with slightly higher errors. Parameter implications: Polyfit (Degree 15) is necessary to capture the complex shape of the impedance data (especially the imaginary part), but this introduces a risk of overfitting. CSAPS (p = 0.001), such a low smoothing parameter, close to 0, indicates that the adjustment strongly prioritized smoothness over exact data fidelity. LOESS (span=0.05): An extremely low span (5% of the data) confirms that to achieve the best accuracy, LOESS had to perform very localized regression adjustments, minimizing the global smoothing effect and closely following data fluctuations. Table 3 shows the critical metric for evaluating the robustness and generalization capacity of the model, as it uses data not seen in each iteration.

Table 3: Robustness and generalization capacity of the model for the three fitting methods applied for t = 5 hours.

Method	$RMSE_{mean}$	$RMSE_{SD}$	R^2_{mean}	
Polyfit	270056.49	262349.2	0.9120	0.1568
CSAPS	65733.61	0.6950	0.9971	≈ 0.0000
LOESS	93188.91	55912.77	0.9917	0.0110

Source: Authors, (2026).

SAPS is the most robust and consistent model, as shown by its standard deviation (SD) metrics, implying that the accuracy of CSPAS does not vary significantly when changing the training/validation dataset. This is evidence that the model has not overfitted the training set. R^2_SD = 0.0000 confirms perfect consistency. For Polyfit, there is evidence of overfitting due to the very high values of average RMSE and standard deviation. The 15th degree model fits too closely to the specific noise of the training set, failing to generalize to the validation data. LOESS shows good performance results but is less consistent. The R^2_{mean} is high, demonstrating its good generalization capacity. However, its $RMSE_{SD}$ is significantly higher than that of CSAPS, indicating moderate sensitivity to data partitioning and making it less consistent. Table 4 shows the results for the complete dataset (Test).

Table 4: Metrics for the three adjustment methods applied for t = 5 hours.

Method	RMSE	R^2
Polyfit	75791.97	0.9974
CSAPS	3.9242	≈1.0000
LOESS	31553.62	0.9996

Source: Authors, (2026).

The final metrics in the full dataset confirm the superiority of CSAPS in terms of robustness, as it has very low RMSE values and a perfect R^2. The consistency of CSAPS translates into an adjustment capacity that surpasses the other two methods. Its mechanism that prioritizes smoothing (p = 0.001) managed to capture the actual impedance function in an effective and robust manner. LOESS maintains its high performance with an RMSE of 31.553 and an R^2 of 0.9996, making it the second-best method. Polyfit has a high R^2 of 0.9974, although it has the highest error of the three methods, confirming that although it can plot the general trend, its fit is less accurate. Figure 2 shows the fit of the three methods on the real and complex impedance data.

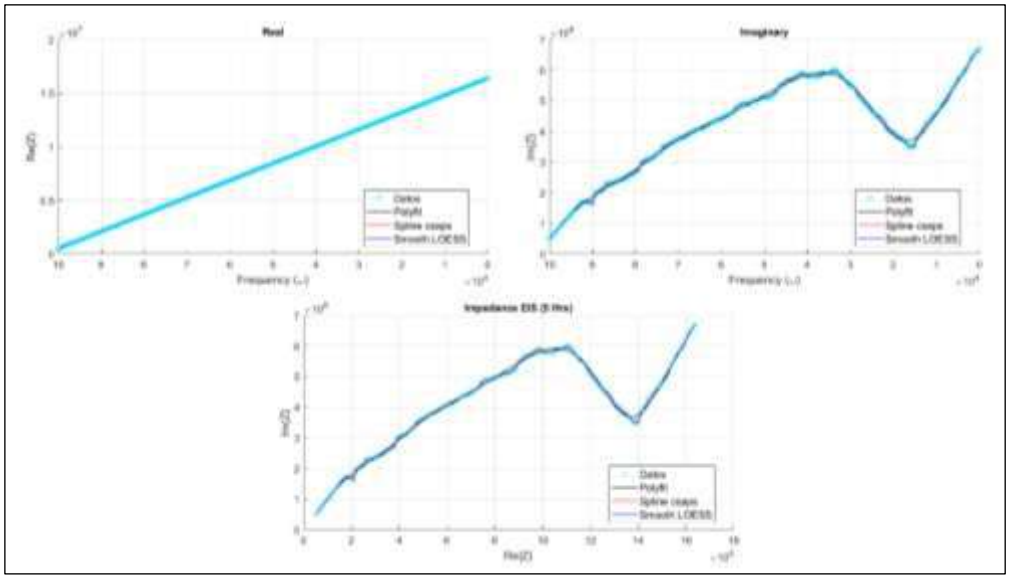

Figure 2: Adjustment of the three methods on real and imaginary impedance data for t = 5 hours.
Source: Authors, (2026).

The real part of the impedance has an almost linear trend with frequency, which means it can be adjusted. Visually, the three methods overlap almost perfectly on the data, which is consistent with the high R^2 values of all models. The imaginary component has a more complex shape with a curvilinear variation and possibly multiple time constants. Both CSAPS and LOESS follow the fluctuations in the data with great fidelity. Polyfit also fits well, but LOESS better captures the changes in curvature observed in the mid frequencies. The Nyquist diagram is the representation most sensitive to the adjustment of the equivalent circuit parameters. The diagram for 5 hours of exposure shows a depressed semicircle, indicating the presence of a constant phase element due to relaxation dispersion in the coating/interface. The overlapping curves show that CSAPS and LOESS offer the smoothest predictions and best fit the pattern of the depressed semicircle, especially at the vertex and in the low-frequency region. Graphically, the large differences in RMSE seen in the tabular results are not apparent, underscoring the importance of numerical metrics (RMSE) for discriminating between visually similar fits.

IV.2 ANALYSIS AND DISCUSSION OF RESULTS FOR PREDICTING IMPEDANCE FUNCTION FOR 24 HOURS

This section analyzes the performance of the three fitting methods (Polyfit, CSPAS, and LOESS) for predicting the impedance function Z(w) of the coating during 24 hours of exposure to the aggressive agent in the system. Table 5 shows the optimal performance achieved by each model when selecting its best parameter (degree, p, or span) in the training (validation) dataset.

Table 5: Parameters and metrics (best) for the three adjustment methods applied for t = 24 hours.

Method	Optimal Parameter	RMSE	R^2
Polyfit	Degree 14	149070.7	0.9807
CSAPS	p = 0.01	177630.8	0.9408
LOESS	span = 0.05	97418.67	0.9905

Source: Authors, (2026).

As at 5 hours, LOESS with a span of 0.05, very local smoothing, achieves the lowest RMSE and the highest R^2. This confirms that LOESS is the method capable of achieving the most accurate fit to the data in its optimal configuration. By prioritizing smoothness (p = 0.001), CSAPS obtains a significantly lower R^2 (0.9408) and a higher RMSE than the other two methods at this stage. This suggests that at 24 hours, the impedance function presents more noise or fluctuations than CSAPS, due to its extreme penalty on curvature, is unable to capture efficiently. Polyfit with grade 14 shows a good R^2 (0.9807), outperforming CSAPS in direct fit. The 10-fold cross-validation evaluation is essential for determining how well the model generalizes to unseen data and how consistent its performance is (low standard deviation), see Table 6.

Table 6: Robustness and generalization capacity of the model for the three fitting methods applied for t = 24 hours.

Method	$RMSE_{mean}$	$RMSE_{SD}$	R^2_{mean}	R^2_{SD}
Polyfit	377985.63	286554.5	0.8124	0.3038
CSAPS	177638.49	3.4020	0.9408	≈0.0000
LOESS	170240.04	88776.41	0.9701	0.0295

Source: Authors, (2026).

The CSAPS model is once again the most robust and consistent with the 24-hour dataset. Its R^2 is 0.0000 and its $RMSE_{SD}$ is only 3.4020. This indicates that although its average accuracy is not the highest (R^2_{mean} = 0.9408), its performance is consistent across different random partitions of the data, which is a critical feature against overfitting.

LOESS achieves the best average R^2 and the lowest average RMSE in cross-validation. This suggests that, on average, it is the method that best generalizes the shape of the impedance, although its high $RMSE_{SD}$ makes it less consistent than CSAPS. Polyfit, with its high degree, 14, exhibits overfitting behavior than at 5 hours. The average RMSE and high standard deviation reveal that the fit is extremely sensitive to data selection, resulting in the worst generalization performance R^2 mean. Table 7 shows the results for the entire dataset (test).

Table 7: Metrics for the three adjustment methods applied for t = 24 hours.

Method	RMSE	R^2
Polyfit	134820.0	0.9876
CSAPS	5.7802	1.0000
LOESS	47469.40	0.9985

Source: Authors, (2026).

The consistency of CSAPS observed in cross-validation is confirmed by an almost perfect fit in the complete dataset of RMSE and $R^2 \approx 1.00$. Although the curvature penalty mechanism initially limited its R^2 in the benchmark, it proves to be the most effective strategy for a precise and robust final fit. Figure 3 shows the fit of the three methods to the impedance data at 24 hours of exposure.

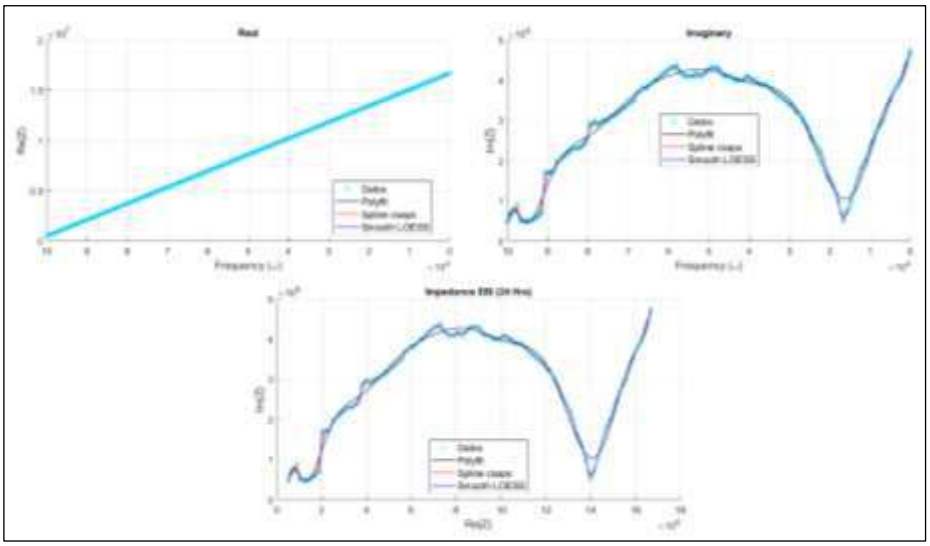

Figure 3: Adjustment of the three methods on real and imaginary impedance data for t = 24 hours.
Source: Authors, (2026).

As at 5 hours, the real part shows a simple trend. The three methods overlap on the data, which is consistent with the high final R^2 values. The imaginary part shows a smoother curve than at 5 hours, with a more defined plateau region between frequencies 7.10^4 Hz and 5.10^4 Hz. All methods follow the trend very well. CSAPS and LOESS fit the slight curvature and detail in the high-frequency flank most accurately. Polyfit follows the trend but may exhibit subtle oscillations inherent in high-degree polynomials. The 24-hour Nyquist diagram shows two distinct arcs, a depressed high-frequency arc and the beginning of a second very low-frequency arc. This is typical of behavior where ion diffusion has already been activated. The CSAPS and LOESS curves trace the pattern of the two arcs with great fidelity and smoothness. The near-perfect fit of the CSAPS suggests that its fitting function passes exactly through the data points, which is visually indistinguishable from the LOESS fit.

V. CONCLUSIONS

The CSAPS method is identified as the most suitable prediction model for the impedance function after 5 hours of exposure, although LOESS achieved the best fit in the benchmark evaluation. CSAPS demonstrated superior robustness and consistency in cross-validation ($RMSE_{SD} \approx 0$), resulting in the most accurate and reliable performance when evaluating the entire data set ($R^2 = 1.00$). The Polyfit method is ruled out as a primary option due to its strong tendency to overfit, evidenced by the high variation in cross-validation performance. For predicting impedance function at 24 hours, the CSAPS method, with its extreme penalty for curvature (p = 0.001), is the predictor of choice due to its excellent performance. Although LOESS demonstrated the highest accuracy in pointwise fitting and the best average generalization ability in cross-validation, the unmatched robustness of ($RMSE_{SD} \approx 3$ and R^2_SD $\approx$ 0.00) led to an almost perfect final fit to the test set ($R^2 \approx 1.00$). This result is fundamental in a scientific context, as it prioritizes reliable and consistent performance across different data subsets. The Polyfit method is excluded because of high variability and the risk of overfitting. Future work will focus on evaluating the proposed modeling strategies across a wider range of EIS datasets, including additional exposure times and coating systems, to assess their robustness under varying degradation mechanisms. Further refinement of the CSAPS and LOESS approaches such as adaptive smoothing parameters or hybrid integration with equivalent-circuit models may improve predictive accuracy and physical interpretability. Additionally, extending the analysis to larger datasets will enable more rigorous statistical validation and strengthen the generalization capability of the models.

ABSTRACT

The protection of durability and safety in concrete structures increasingly depends on structural health monitoring (SHM) using embedded sensors, which enable real-time monitoring of the internal conditions of the material and support preventive maintenance strategies. This paper analyzes the behavior and adaptability of different sensors integrated into concrete for early damage detection and the development of more robust smart infrastructures. A systematic review of the literature was carried out in the Scopus and Science Direct databases, examining 71 peer-reviewed scientific articles published between 2022 and 2025 in the fields of engineering and materials science and written in English. The findings show that fiber optic, piezoelectric, capacitive, and resistive sensors are particularly effective in recording deformation, temperature, humidity, pressure, and chloride penetration. Furthermore, their combination with artificial intelligence (AI), the Internet of Things (IoT), and digital modeling tools such as BIM and ANSYS increases predictive capability and improves the representation of structural behavior. Similarly, both laboratory research and field applications demonstrate their reliability, resistance to environmental conditions, and potential for scaling. Overall, it is concluded that sensor networks.

I. INTRODUCTION

Concrete has established itself as one of the most widely used materials in modern construction thanks to its low cost, high strength, and ability to adapt to multiple geometries and structural sizes [1]. The incorporation of advanced sensors has significantly increased the possibility of monitoring concrete, allowing continuous and accurate tracking of its structural condition [2]. Over time, concrete structures can suffer various types of deterioration, such as corrosion, fatigue, or damage from environmental factors, making constant monitoring essential to ensure their integrity [3]. According to [4], these sensors are capable of recording variables such as deformation, temperature, humidity, and pressure, thus facilitating the early detection of possible structural failures. In the field of structural monitoring of concrete, different types of sensors are used, including fiber optic, piezoelectric, and pressure sensors [5].

These devices provide essential information about deformation and internal stresses that accumulate over time, allowing for early identification of cracks or unusual structural behavior [6]. Thanks to these technologies, it is possible to obtain accurate data on the response of concrete to both static and dynamic loads, which is essential for properly guiding maintenance and repair work [7]. According to [8], the use of advanced sensors in concrete monitoring improves accurate fault detection and reinforces preventive maintenance strategies. Early identification of defects in structures using sensors has established itself as a highly effective strategy, as it significantly reduces maintenance and repair costs by enabling interventions before damage reaches an advanced stage [9]. This technology also promotes sustainability in the construction sector, as it facilitates continuous monitoring of structures, extends their useful life, and reduces the need for major repairs or complete reconstruction [10].

The effectiveness of structural monitoring depends largely on the quality of the data collected, its correct integration with forecasting systems, and the ability to generate alerts sufficiently in advance [11]. In this regard, technological advances have enhanced

information analysis and processing tools, making it possible to detect and predict structural failures even before they become visible [12]. Likewise, the incorporation of artificial intelligence and machine learning algorithms has increased the accuracy of predictions, simultaneously optimizing maintenance management in critical infrastructures [13]. The incorporation of sensors in IoT-based systems enables real-time data collection, allowing for continuous monitoring with a high level of accuracy [14]. This massive collection of information provides a solid basis for identifying patterns in structural behavior and anticipating potential failures [15]. According to [16] The integration of these sensors with remote monitoring platforms has strengthened the control of large-scale infrastructure, significantly reducing the costs associated with inspections.

As infrastructure ages, it is essential to monitor it constantly to detect progressive deterioration that is not visible to the naked eye [17]. Regular inspections using specialized sensors enable damage such as internal concrete corrosion to be identified at an early stage [18]. Advances in detection technologies have made it possible to supplement concrete monitoring with methods such as thermography and infrared imaging, which facilitate the identification of anomalies that, in many cases, are not detected by conventional sensors [19]. The combination of these tools provides a more comprehensive assessment of structural condition and increases accuracy in detecting defects such as hidden cracks or the presence of accumulated moisture, factors that could compromise the stability of the structure [20]. Likewise, recent studies indicate that, in the future, structural monitoring will rely on distributed sensor networks, which will optimize the process of supervising and evaluating the condition of structures [21]. With the evolution of these systems, monitoring is expected to become more efficient and accessible, enabling timely and less costly interventions [22].

II. METHODOLOGY

This review article was developed with an exploratory approach, focusing on analyzing scientific publications on the use of sensors in concrete for structural monitoring. The information was obtained through searches in Scopus and ScienceDirect covering 2022–2025. The retrieval strategy used English keywords related to the topic—in particular, the English equivalent of “sensors applied in concrete for structural monitoring”—combined with the Boolean operator AND to refine the accuracy. A search was conducted in the Scopus database using the keywords “sensors applied in concrete for structural monitoring” together with the AND operator. In the first stage, 5,447 documents were identified. After applying filters to restrict the output to scientific articles in English on Engineering and Materials Science, the total was reduced to 2,327 articles, of which 25 were finally selected for analysis. A search was also conducted in ScienceDirect using the same keywords and criteria, with an initial result of 28,380 documents. Subsequently, similar filters were applied (fields of Engineering and Materials Science, type of scientific articles, English language), reducing the total to 10,800. After removing duplicates and reviewing titles and abstracts, 42 articles were selected for analysis and synthesis. The findings are summarized in Tables 1 and 2.

Table 1: Summary, criteria, and results of the search in the Scopus and Science Direct databases.

DATABASE	SEARCH TERMS WITH OPERATORS	ECONRED DOCUMENTS	PERIOD	FILTERS APPLIED	LEAKED DOCUMENTS	SELECTED DOCUMENTS
SCOPUS	sensors Y applied Y to Y concrete Y for Y structural monitoring	5 447	2021 - 2025	Field: “Engineering” “Materials science” Document type: Article	2 327	25
SCIENCE DIRECT	Sensors embedded in concrete for structural monitoring	28 380	2022 - 2025	Field: “Engineering Document type: Article	10 820	42

Bibliometric analysis and network visualization

PTo determine the state of the art prior to technical synthesis, a search was conducted in Scopus using the unified query:

(TITLE-ABS-KEY (sensors) AND TITLE-ABS-KEY (applied) AND TITLE-ABS-KEY (in) AND TITLE-ABS-KEY (concrete) AND TITLE-ABS-KEY (for) AND TITLE-ABS-KEY (structural) AND TITLE-ABS-KEY (monitoring))

The search returned 616 documents. The metadata were exported and a co-occurrence map was constructed in VOSviewer. Figure 1 shows the network visualization: node size (frequency), color (cluster), and link thickness (strength of association)).

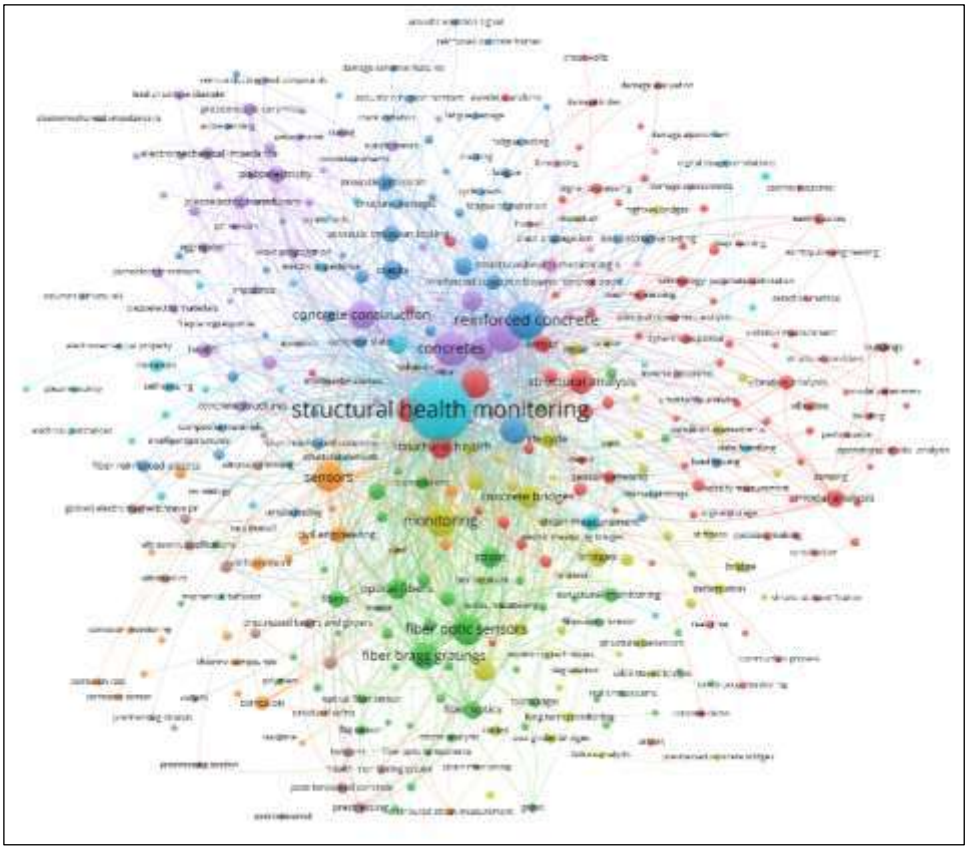

Figure 1: Network visualization.
Source: Authors, (2026).

The graph shows a field structured around structural health monitoring as its core, connected to (i) materials/elements and application scenarios—concrete, reinforced concrete, concrete bridges/buildings, prestressed concrete—; (ii) sensing technologies—fiber optic sensors/DFOS, FBG, piezoelectric/PZT, electromechanical impedance, acoustic emission, digital image correlation—; and (iii) evaluation tasks—damage/crack detection, strain measurement, modal/vibration analysis, condition assessment, corrosion monitoring. Likewise, threads of data management and computation emerge—machine learning, deep learning, computer vision, IoT, and wireless sensor networks — which structure a subfield oriented toward the automation of diagnosis. Overall, the network suggests framing the review around two complementary axes: (a) the typology of sensors and measurement methods and (b) the diagnostic functions on concrete structure typologies, with special emphasis on the early detection of damage, cracks, and corrosion for maintenance and structural safety decisions.

III. RESULTS AND DISCUSSIONS

III.1 INTEGRATED SENSORS FOR STRUCTURAL MONITORING

Integrated sensors allow real-time analysis of the internal response of the material. In the case of self-detectable sensors made of engineered cementitious composite (ECC) and incorporated into columns, they were found to be highly accurate under moderate loads without affecting structural integrity. Through simulations in ABAQUS and measurements taken with strain gauges, it was determined that the most suitable geometry is a 20 mm cube with a friction coefficient equal to or greater than 0.6 [23]. In turn [24], they pointed out that this configuration makes it possible to record parameters such as deformations, temperature, humidity, pore pressure, and the appearance of cracks, which are often difficult to detect through surface measurements. [25].

The importance of continuous monitoring from the system configuration phase to material aging was highlighted, which is essential for identifying faults at an early stage. In his research, a piezoresistive sensor equipped with CBTENG managed to generate 113 V at 4 Hz and charge a 10 μF capacitor to 0.32 V in 25 seconds. In addition [26] hey used artificial intelligence (AI) to detect cracks and corrosion processes, demonstrating its effectiveness after applying acoustic filtration. These developments overcome the limitations of surface sensors, as they provide more comprehensive monitoring, with high sensitivity and self-powering capabilities, which improves both the safety and durability of concrete. According to [27] FBG sensors combined with deep neural networks and PCA analysis enable damage prediction in complex structures with a high degree of accuracy, overcoming the difficulties associated with manual labeling.

By [28] They evaluated the electrical impedance (EI) of embedded PZT sensors, demonstrating that, in samples larger than 150 mm, the EI reflects only the properties of the concrete, eliminating edge effects. This supports their standardized use in continuous structural health monitoring (SHM). Taken together, these results show that artificial intelligence and integrated sensors are revolutionizing structural monitoring by providing accurate predictions and reliable data without the need for manual intervention. Their standardization is a key step toward safer, self-monitoring structures. All this information is summarized in Table 3, based on a review of two articles published in 2023, two articles from 2024, and two articles from 2025.

Table 3: Sensors embedded in concrete for structural monitoring.

TYPE OF INTEGRATED SENSOR	MONITORED PARAMETERS	TECHNICAL ADVANTAGES	MONITORING PHASE	REFERENCE
generic integrated sensor	Cracks, humidity, temperature	Allows for complete integration within the structure	From concrete pouring to operational phases	[23]
generic integrated sensor	Cracks, humidity, temperature	Facilitates monitoring from the early stages to the aging of the material	Throughout the structural life cycle	[24]
FBG (fiber optic) sensor	Deformation, temperature	High precision and resistance to electromagnetic interference	From setting to aging	[25]
Piezoelectric sensor (PZT)	Vibrations, impacts	High sensitivity to dynamic stresses	Continuous monitoring under cyclic loads	[26]
Wireless IoT sensor	Multiple (deformation, temperature, humidity, etc.)	Remote measurement and low maintenance requirements	The entire service life of the structure	
Integrated pressure sensor	Pore pressure	Localized measurement of internal pressure	Initial stages and underground conditions	[27]
Integrated capacitive sensor	Internal humidity, temperature	Good response to hygrothermal changes	First stages of configuration	
generic integrated sensor	mechanical and environmental variables	Promotes the development of smart and sustainable infrastructure	Throughout the entire structural service life	[28]

III.2 FUNCTIONAL CHARACTERISTICS OF SPECIFIC SENSORS

III.2.1 Sensitivity and Accuracy in Fault Detection

In [29] they analyzed the behavior of FBG sensors subjected to biaxial stress, showing that transverse deformation affects longitudinal readings, which reduces the accuracy of uniaxial calibrations. For its part, [30] They pointed out that, thanks to their high sensitivity to microdeformations (με) and changes in wavelength, this type of sensor is capable of detecting internal microcracks before they become visible externally. In turn [31] they used integrated piezoelectric sensors (EPS) to monitor the evolution of concrete strength from the first hour of setting to 90 days, recording phase transitions with remarkable predictive accuracy. Among the systems evaluated, the combination of CPM + CE + slag achieved the highest strength. However [32] Under cyclic loads, EPS can reliably identify internal damage and, when integrated with random forest (RF) models, can predict structural strength with 97% accuracy. Taken together, the reviewed studies show that FBG sensors and embedded EPS provide high sensitivity for detecting microcracks and structural modifications at early stages. Their integration with machine learning techniques significantly improves predictive capability, overcoming the limitations of traditional monitoring methods.

III.2.2 Measuring Range and Resolution

By [33] indicated that the performance of sensors embedded in concrete depends directly on their measurement range and resolution, which are fundamental parameters for ensuring reliable structural monitoring. In the case of fiber Bragg grating (FBG) sensors, resolutions of 1 με and 0.1 °C were reported. According to [34] they added that embedded humidity sensors can achieve an accuracy of ±1% RH, which is crucial for the early detection of corrosion processe. According to [35] Piezoelectric and capacitive sensors perform adequately under dynamic loads, achieving resolutions of 0.01 mm and response times of less than 0.1 s. Finally [36] they developed a method for evaluating concrete permeability using built-in resistivity sensors, calibrated using Van Genuchten models and saturation profiles. The results obtained—with values between 10^{-11} and 10^{-13} m/s—showed correlations greater than 90% compared to traditional techniques such as gamma densimetry and mass loss measurement. These findings confirm that embedded sensors allow accurate and continuous monitoring of critical parameters, improving early detection of structural failures.

III.2.3 Response to External Conditions

By [37] they demonstrated that FBG sensors embedded in concrete allow both the thermal and mechanical conditions of the material to be monitored, recording temperatures of up to 72 °C and deformations of 300 με, with sensitivities of 1.2 pm/με and 10 pm/°C, facilitating thermal compensation and the identification of microcracks. On the other hand, [38] it was reported that the integrated piezoresistive sensors maintain signal stability even under extreme thermal cycles ranging from 20°C to 80°C, making them a suitable choice for structures subjected to severe weather conditions. [39] three-dimensional spacers equipped with RFID-MEMS sensors were also developed to measure moisture at the steel-concrete interface (SCI), achieving an accuracy of ±2% up to 90% RH at 50°C; however, a decrease in accuracy was observed when humidity exceeded 93% due to condensation.

According to [40] FBG sensors were integrated with ultrasonic guided waves (UGW) to detect corrosion in steel bars, recording attenuation greater than 40% in L mode (0.1) under 5 V, which allowed damage to be identified and located even at considerable distances from the point of corrosion. Taken together, these studies show that embedded sensors can operate effectively under extreme conditions, providing accurate measurements of critical variables such as temperature, humidity, and corrosion. Their incorporation into exposed structures improves early fault detection, while technologies such as RFID-MEMS and UGW expand the capabilities of non-destructive monitoring. All this information is summarized in Table 4, based on a review of three articles published in 2023, three in 2024, and five in 2025.

Table 1: Functional characteristics of specific sensors.

TYPE OF INTEGRATED SENSOR	MONITORED PARAMETERS	TECHNICAL ADVANTAGES	MONITORING STAGE	REFERENCE
FBG (fiber optic) sensor	Biaxial deformation, microcracks	High sensitivity to microdeformations (με) and wavelength variations	Seit der ersten Anwendung	[29] ; [30]
Piezoelectric sensor (EPS)	Resistance, phase transitions	Detects changes from the first hour to 90 days; 97% accuracy.	Anfängliche Phasen bis zur Aushärtung	[31] ; [32]
FBG (fiber optic) sensor	Deformation, temperature	Resolution of 1 με and 0.1 °C	Kontinuierliche Temperaturüberwachung	[33]
Humidity sensor	Relative humidity	Accuracy of ±1% RH	Während Prozessen, die mit Korrosion verbunden sind	[34]
Piezoelectric/capacitive sensor	dynamic deformations	Resolution of 0.01 mm and < 0.1 seconds	Unter dynamischen Belastungen	[35]
Resistivity sensor	Concrete permeability	Values between 10^{-11} and 10^{-13} m/s, correlation > 90%	Trocknungs- und Imbibitionsprozesse	[36]
FBG sensor	Temperature and thermal deformation	Temperatures reach up to 72 degrees Celsius (300 degrees Celsius) and 300 degrees Celsius. Sensitivity 1.2 pm/with	Von der Konfiguration bis zum Betrieb	[37]
Piezoresistive sensor	extreme thermal cycles	Signal stability from –20 °C to 80 °C	Umgebungen mit hohen Temperaturschwankungen	[38]
RFID-MEMS sensor	Moisture at the steel-concrete interface	Genauigkeit ±2 % HR bis 90 % HR bei 50 °C	Warme und fe|uchte Umgebungen	[39]
FBG Sensor + UGW	Corrosion on steel bars	Dämpfung > 40 % im Modus L (0,1)	Wassereinwirkung und induzierte Spannung	[40]

III.3 CLASSIFICATION AND PERFORMANCE OF SENSORS APPLIED IN CONCRETE

III.3.1 Fiber Optic Sensors.

Distributed fiber optic sensing (DFOS) technology has proven to be highly effective for the structural diagnosis of prestressed concrete bridges, as it allows real-time and highly accurate measurement of deformations of up to ±500 με, displacements of ±2 mm, and crack opening, as reported by [41]. This technique was also applied to flat slabs subjected to the sudden loss of a column, making it possible to identify the appearance of cracks from the outset and monitor their evolution with a sensitivity of ±20 με. In a practical case [42] they installed a 15-meter prestressed beam belonging to the IDA-KI project using DFOS sensors embedded in the concrete, reinforcement, and cables, achieving a spatial resolution of 1 cm and detecting structural anomalies early on. For its par [43] They proposed an analytical method for asphalt pavements based on DFOS and the CPSD algorithm, validated using accelerometers, obtaining a resolution of 1 cm and a modal criterion greater than 0.95. Together, fiber optic sensors enable distributed, high-precision monitoring capable of detecting deformations, cracks, and failures with excellent resolution and sensitivity. Their effectiveness has been corroborated on bridges, slabs, and pavements, surpassing traditional methods and enabling more reliable early detection of structural damage.

III.3.2 Piezoelectric Sensors.

By [44] they developed a Structural Health Monitoring (SHM) system for aeronautical composite materials that integrates embedded piezoelectric sensors with machine learning techniques, achieving high-precision identification of simple and combined failures through time-frequency analysis based on the Gram angular field. For its part, [45] they used EPS sensors together with the EMI technique to evaluate the evolution of the strength of concrete made from electronic waste, detecting variations from the first 2 hours to 28 days. In mixtures with a 15% replacement of coarse aggregate, the strength was reduced from 37.8 to 34.7 MPa, equivalent to a decrease of 8.15%Asimismo, [46] se evaluaron sensores PZT y PEC bajo condiciones de carga, observándose que el PZT presentó un rendimiento superior en su segundo pico de resonancia, mientras que el PEC destacó por encima de los 800 kHz. El estudio encontró correlaciones logarítmicas entre la deformación (hasta un 0,15 %) y la señal registrada, así como correlaciones lineales entre el voltaje (hasta 25 MPa) y la conductancia. Finally [47] integrated PZT sensors into 3D-printed concrete structures, detecting the presence of cracks through impedance variations of up to 30%. It was observed that 2 mm coatings offered greater sensitivity, while 8 mm coatings increased load capacity by 12%. Taken together, these studies demonstrate that piezoelectric sensors represent a versatile and highly accurate alternative for non-destructive structural monitoring, with applications ranging from additive manufacturing processes to curing control and behavior under dynamic loads.

III.3.3 Capacitive and Resistive Sensors for Concrete Monitoring

Capacitive and resistive sensors allow fundamental concrete parameters to be recorded, such as internal moisture, the appearance of microcracks, and changes in dielectric properties, by measuring variations in permittivity or electrical resistivity associated with processes such as curing, saturation, or carbonation [48]. For example [49] integrated RFID-MEMS sensors into three-dimensional spacers to monitor moisture at the steel-concrete interface. In test specimens with water-to-cement ratios of 0.40 and 0.55, cured for 3 and 14 days and subjected to conditions of 50 °C, 65% RH, and 21 °C, the accuracy reached ±2% up to 90% relative humidity, decreasing above 93% due to condensation, confirming its usefulness for assessing the risk of corrosion. For this reason [50] They developed a cementation sensor composed of a double electrochemical layer and a graphene film, characterized by its high sensitivity to the presence of chlorides using EIS, as well as its stable response to variations in temperature and humidity, although with sensitivity to pH.

Finally, [51] Using EIS, it was observed that the system exhibited high sensitivity and stability, with a response independent of temperature and humidity but affected by pH, which led to the proposal of a calibration equation to improve chloride diffusion models. Together, capacitive and resistive sensors provide accurate monitoring of moisture and corrosion processes from the first 48 hours, even under extreme conditions between 0 and 40 °C and saturation levels of 60 to 100%. Their sensitivity to chlorides and compatibility with wireless technologies make them an ideal choice for exposed structures and continuous monitoring without compromising durability.

All this information is summarized in Tables 5, 6, and 7, compiled from a review of one article published in 2022, two in 2023, four in 2024, and four in 2025. Capacitive and resistive sensors enable accurate monitoring of moisture and corrosion from the first 48 hours, even under extreme conditions of 0–40°C and saturation levels of 60–100%. Their sensitivity to chlorides and compatibility with wireless systems make them ideal for exposed structures and continuous monitoring without compromising durability. °C and 60–100% saturation. Their sensitivity to chlorides and compatibility with wireless systems make them ideal for exposed structures and continuous monitoring without compromising durability. III.4 ADVANCED TECHNOLOGICAL INTEGRATION FOR STRUCTURAL MONITORING

III.4.1 Artificial Intelligence and Machine Learning

The application of artificial intelligence in SHM allows complex patterns to be recognized using algorithms such as neural networks and support vector machines (SVM), achieving accuracies of up to 98% in the detection of structural damage in beams, even when limited data is available [52]. For its part [53] They emphasized the role of smart sensors in structural health monitoring (SHM), highlighting their ability to replace conventional methods, optimize maintenance strategies, and reduce operating costs by up to 30%, in addition to reporting 93% accuracy in detecting microcracks using artificial intelligence techniques. In the case of bridges [54] reported a decrease of up to 35% in maintenance costs thanks to the use of these systems, although they noted that challenges remain related to high energy consumption and the cost of IoT sensors. Finally [55] indicated that automatic structural condition classification allows early warnings to be generated in accordance with current regulations, strengthening failure prevention. Overall, artificial intelligence is positioned as a key tool for transforming simple data collection into more efficient structural decisions. Despite the high accuracy achieved, its performance depends on the quality and quantity of the data used in training, which poses challenges in terms of standardization and mass acquisition of information.

III.4.2 Structural Data Modeling and Visualization

The use of digital twins combined with real-time sensors and convolutional networks such as VGG-16 has made it possible to identify damage caused by saline agents with high precision, significantly improving predictive maintenance strategies, according to [56]. For its pairte [57] they also pointed out that integrating these systems with BIM platforms facilitates the visualization and detailed analysis of structural damage and pathologies. In the same vein [58] They highlighted that interoperability between IoT sensors and BIM, reinforced by the extension of the SAREF ontology through IADOM and RDF, optimizes both maintenance management and infrastructure design in smart environments.

Likewise, [59] They reported that models capable of instantly updating data from sensors within three-dimensional platforms such as ANSYS APDL have been evaluated, enabling efficient synchronization between analytical models and structural monitoring systems. This advanced visualization capability enhances the interpretation of technical information and facilitates informed decision-making; however, its implementation still requires a robust digital infrastructure, which may limit its adoption in contexts with low levels of digitization or connectivity. All this information is summarized in Table 8, based on a review of one article published in 2022, four in 2024, and three in 2025.

Table 8: Technological integration in advanced structural monitoring.

APPLIED TECHNOLOGY	MAIN FOCUS	OUTSTANDING STRUCTURAL APPLICATION	REFERENCE
Artificial intelligence in SHM	Neural networks and SVM	Identification of faults in beams with 98% accuracy	[52]
Smart sensors with AI	Microcrack detection	0% reduction in operating costs and 93% accuracy	[53]
IoT systems applied to bridges	Structural monitoring	35% reduction in maintenance; associated energy challenges	[54]
Structural classification algorithms	Based on current regulations	Issuing early warnings in accordance with structural standards	[55]
Digital twins + CNN	VGG-16 Architecture	Accurate detection of damage caused by saline agents and predictive maintenance	[56]
BIM modeling in damage assessment	Visualización tridimensional	Advanced analysis of complex structural pathologies	[57]
SAREF ontology with IADOM and RDF	Semantic interoperability	Optimized management in smart environments integrated with IoT and BIM	[58]
EF models integrated with sensor data	Real-time updates	Structural synchronization in 3D platforms such as ANSYS	[59]

III.5 EXPERIMENTAL VALIDATION AND CASE STUDIES

III.5.1 Laboratory Applications

By, [60] They demonstrated that integrated sensors enable early identification of corrosion processes in concrete through acoustic emissions close to ~30 dB, associated with deformations of 20 με, a decrease in amplitude (from 2.59 to 1.29 mV), and an increase in ultrasonic velocity up to 4.55 km/s. For its part, [61] they evaluated pH sensors embedded for 250 days in mortars subjected to carbonation, observing failures caused by accelerated drying at pH values above 12.5 and proposing improvements using gel indicators and compounds such as thymolphthalein. Likewise [62] demonstrated that integrated sensors capable of measuring humidity, temperature, and conductivity can anticipate conditions conducive to corrosion up to 20 days in advance, and that UHPC reinforced with 1.5–4% steel fibers increases sensitivity to damage through the use of FCR. Finally, [63] they validated vibration sensors to detect loss of stiffness under cyclic loads, as well as a matrix sensor (4×4 Ag/AgCl and 2×2 MnO_2) capable of monitoring chloride concentrations in marine environments even in the event of partial system failures. Together, the embedded sensors enable early detection of corrosion, carbonation, and various structural damages. Their performance is enhanced when optimized configurations and materials—such as steel fibers or conductive matrices—are used, strengthening the structural monitoring capabilities of concrete.

III.5.2 Field applications

The integrated FBG sensors, used on the Streicker Bridge and on medium-small span bridges, enabled high-fidelity measurements of temperature, deformations, and vertical displacements (linearity 0.998, sensitivity 7.87 pm/mm, and error <5%), with installation angles between 15° and 30° recommended. In urban settings [64] reported that the London Underground incorporated piezoelectric sensors to detect critical vibrations. With this, they developed an automated SHM system based on modal identification, neural networks, and wavelets, capable of locating damage without manual intervention [65]. On the other hand [66] they proposed an automated SHM framework with modal identification, neural networks, and wavelet transforms, achieving accurate damage detection. Finally [67] they designed a piezoelectric sensor with integrated PZT-5H to detect cracks in concrete beams, demonstrating high sensitivity and stability when recording amplitude variations associated with damage. Using wavelet analysis, it was possible to estimate the depth and location of the cracks. Together, these field applications demonstrate the reliability and scalability of integrated sensors, although their optimal performance depends on proper installation, correct maintenance, and intelligent systems that efficiently process data.

IV. CONCLUSIONS

The systematic review confirms the effectiveness of sensors embedded in concrete as fundamental tools for real-time structural monitoring, allowing continuous monitoring from setting to extreme operating conditions, with high precision in measuring deformation, humidity, temperature, pressure, and corrosion. Fiber optic, piezoelectric, capacitive, and resistive sensors stand out over traditional methods due to their greater sensitivity, environmental resistance, and adaptability to the different stages of the structural life cycle. The integration of these sensors with artificial intelligence, machine learning, IoT, BIM, digital twins, and specialized software such as ANSYS significantly improves fault prediction, structural representation, and decision support, driving predictive maintenance and reducing operating costs. Both laboratory studies and field tests validate their reliability, scalability, and efficiency. However, their optimal implementation requires proper installation, algorithmic processing, and the support of robust digital infrastructures, which are essential for the development of intelligent, resilient, and sustainable structures.

ABSTRACT

The environmental impact of Portland cement has driven the adoption of alternative binders such as geopolymer concrete (GC) based on fly ash (FA). This review analyzes 69 studies published between 2021 and 2025 that examine how FA influences the physical, mechanical, and microstructural performance of GC. Workability is strongly affected by the spherical morphology of FA and by the concentration of NaOH, with reported slump values ranging from 62 to 220 mm. Alkaline solutions between 12 M and 18 M accelerate the reaction, reducing initial setting times to 30–150 minutes. Mechanically, mixtures incorporating 50–70% FA and supplementary materials such as slag or microsilica can surpass 60 MPa in compressive strength while also improving tensile and flexural behavior. Microstructural analyses using XRD, SEM, and FTIR confirm the formation of N–A–S–H and C–A–S–H gels that refine and densify the matrix. Overall, FA emerges as a sustainable, high-performance alternative for producing GC, with potential for future construction applications.

I. INTRODUCTION

In recent years, environmental protection and sustainable development have become one of the most pressing issues for human society[1], In this regard [2] argues that the rapid growth of infrastructure, urbanization, and industry, and similarly in developing countries, around 95% of construction and demolition waste produced is disposed of in landfills or illegally dumped in unoccupied areas [3], This occurs because concrete is a relatively inexpensive and accessible material [4], On the other hand [5] argue that this condition has driven increased demand for concrete over the last few decades, causing a continuous increase in the need for natural aggregates. Therefore, there is concern about the environmental impact of concrete production in terms of the depletion of natural resources [6]. The environmental impact of the construction industry has become increasingly alarming[7], In particular, the cement industry is characterized by its high energy intensity and the presence of multiple hazardous air pollutants, especially during the production of cement clinker[8],

In fact, it is estimated that cement manufacturing contributes to 5-7% of total CO_2 emissions worldwide into the atmosphere[9], because the production of one ton of Portland cement clinker releases between 800 and 1100 kg of carbon dioxide into the atmosphere[10], It is particularly critical that, according to [11], China, the world's largest cement producer, accounted for approximately half of global cement production in 2023, reaching 2 billion tons. The development of green cementitious materials to replace Portland cement (PC) is crucial for sustainable development [12], people have begun to explore the use of alternative cementitious materials [13], In this regard, geopolymers are cementitious materials characterized by a network structure, obtained through the inorganic polymerization of silicoaluminate compounds, which react under alkaline activators [14], Furthermore [15] argue that geopolymers can be produced without calcination, and various industrial solid wastes can be used as precursors.

Geopolymer concrete (GPC) is a substitute for Portland cement (PC) due to its improved mechanical qualities, lower carbon footprint, and ability to use industrial waste as raw materials[16], It also exceptionally withstands freeze-thaw cycles and high temperatures [17]. According to [18] fly ash (FA) generated from coal and biomass combustion represents one of the main industrial by-products worldwide, with FA from municipal solid waste incinerators [19], entering the context of FA. an X-ray diffraction (XRD) analysis has identified relevant crystalline phases such as quartz (SiO_2), mullite ($Al_6Si_2O_{13}$), hematite (Fe_2O_3), and belite (Ca_2SiO_4), which confer pozzolanic and cementitious properties that make them suitable for applications in construction materials[20], However, there is a growing disparity between the supply and demand for FA, driven by its increasing use in the development of sustainable building materials [21], Therefore, it is necessary to move towards a circular economic model that encourages the comprehensive recovery of this waste by promoting its efficient and sustainable reuse within the construction sector [22].

II. METHODOLOGY

This research was based on a review of 69 scientific articles published in high-impact journals indexed in databases such as Scopus and ScienceDirect. The following specific keywords were used: Geopolymer concrete + fly ash, between 2021 and 2025, as shown in Table 01, with the following results: 4 articles in 2021, 9 articles in 2022, 9 articles in 2023, 23 articles in 2024, and 24 articles in 2025, as shown in Table 02. Likewise, the flow of the elicitation process and the parameters established for the search for publications are represented schematically in Figure 01.

Table 1: Research results with filters.

Database	Year of search	Keywords	Document. without filter	Search filter	Document. with Filter	Selected Documents	Total

II.1 ANALISIS BIBLIOMETRICO

In addition, a bibliometric analysis was performed on the information obtained from the Scopus database, using the following search equation: (TITLE-ABS-KEY (Geopolymer concrete) AND TITLE-ABS-KEY (FLY ASH)) AND (LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "MATE")) AND (LIMIT-TO (DOCTYPE , "AR")) AND (LIMIT-TO (EXACTKEYWORD , "FLY ASH") OR LIMIT-TO (EXACTKEYWORD , "GEOPOLYMER CONCRETE")) AND (LIMIT-TO (PUBYEAR , 2021) OR LIMIT-TO (PUBYEAR , 2022) OR LIMIT-TO (PUBYEAR , 2023) OR LIMIT-TO (PUBYEAR , 2024) OR LIMIT-TO (PUBYEAR, 2025) OR LIMIT-TO (PUBYEAR, 2026)). This search yielded a total of 1,185 documents, which were analyzed and processed using VOSviewer to generate a keyword co-occurrence map showing the thematic interrelationships within the field of fly

ash use in geopolymer concrete, as shown in Figure 2. The interpretation of the keyword co-occurrence map generated with VOSviewer, based on data extracted from Scopus, allows us to identify the main trends and emerging areas in research on geopolymer concrete.

The results show that the terms “geopolymer concrete” and “fly ash” have greater frequency and centrality, which highlights the dominant role of fly ash as the main precursor due to its abundance and reactivity under alkaline activation. Likewise, lines of study related to sustainability, the use of industrial waste, mechanical and durability properties, as well as the incorporation of artificial intelligence tools for mixture optimization and predictive modeling are identified. Overall, the bibliometric analysis reveals an interdisciplinary evolution linking materials engineering, sustainability, and technology, although gaps remain regarding field-scale application, durability under variable environmental conditions, and the exploration of alternative precursors. Thus, the current trend is toward the development of more efficient, sustainable, and adaptable geopolymer concretes for various construction contexts.

III. RESULTS AND DISCUSSIONS

III.1 PHYSICAL PROPERTIES

III.1.1 Slump

The slump value is tested to determine the workability level of the mixture (GPC), since a higher slump value indicates that the mixture has good workability. In fact, a high slump value is not always accompanied by high compressive strength [23]; In context, the slump of the 0G/100F composition on the (FA) binder is 53.3% lower than that of the 100G/0F composition. By increasing the proportion of (FA) in the combined binder, the slump of the mixtures decreases [24], Likewise [25] highlight that, for (FA)-based RAGPC with a high AAC/B ratio of (0.8) (self-compacting concrete and binder), it was not necessary to use a superplasticizer (SP) to achieve the desired slump. Furthermore, the slump value of the (GPC) increased with increasing molarity of the NaOH solution, with slump values for 6 M, 9 M, 12 M, and 14 M were 62 mm, 78 mm, 87 mm, and 94 mm, respectively [26]. Overall, in mixtures incorporating (FA), workability can be maintained or even improved due to the spherical morphology of its particles, which favors the flow of the paste. Thus, the interaction between the NaOH concentration and the fly ash content defines the balance between the fluidity and cohesion of the material.

In turn [27], There is a slight decrease in the slump of the mixture with sand type M compared to the natural sand mixture, due to the angular shape of the fine aggregates. In another study, the CL1 mixture containing 60% GGBS and 40% pulverized fly ash (PFA) recorded the lowest slump value (185 mm), while the highest value (220 mm) was recorded for the CL3 mixture consisting of 80% GGBS and 20% (PFA). The data indicate that consistency generally improves by keeping the A/P ratio constant and varying the content of granulated blast furnace slag (GGBS) and (PFA) [28], complementing [29] It is argued that the slump test results for GPC with NaOH molarities of GPC12M, GPC14M, and GPC16M are 185 mm, 180 mm, and 175 mm, respectively, indicating that an increase in NaOH molarity leads to a decrease in the workability of fresh GPC. Overall, the studies analyzed show that the workability of GPC is influenced by the physical and chemical factors of its components. All this information is summarized in Table 3, based on a review of one article published in 2022, two in 2024, and four in 2025.

Table 3: Results obtained for the Slump.

III.1.2 Air Content

Geopolymer concrete (GC) was prepared with different silica fume (SF) contents (15%, 22.5%, and 30% by volume). In addition, three Portland cement (PC) concretes with a composition and mechanical properties suitable for comparative purposes were prepared, where the air content of (GC) was lower than that of (PC) and decreased as the (FA) content increased. The air content range of (PC) was maintained between 0 and 0.4% [30], on the other hand [31] It maintains that the minimum air content value observed in the M1R0 concrete mix was 1.50 (±0.5); likewise, the air content for the M1R0, M2R25, M3R50, M4R75, and M5R100 concrete mixes was 1.5%, 1.62%, 1.69%, 1.7%, and 1.74%, respectively. In addition, the angular size of the WMA significantly influences the mixture, as it requires a greater amount of water, which generates more voids; on the other hand, due to the high CaO content in marble, concrete samples are prone to cracking. In summary, the air content in concrete depends on the nature and form of the materials used. The increase in fly ash reduces the occluded air, while marble waste increases it due to its angularity and high calcium oxide content.

III.1.3 Setting Time

By [32] As the silica fume (SF) content increased, the setting times decreased, reflecting the pozzolanic reactivity of SF, which accelerates the geopolymerization process. At a curing temperature of 60°C, the initial and final setting times of the paste (GP) were 53 and 159 minutes, respectively, for an 18M NaOH solution. [33]. On the other hand [34] They used the penetration resistance method and found that the GPC mixtures, with the exception of mixture FA0 containing 0% FA, 60% slag (S), and 40% waste clay brick dust (WCB), reached initial setting between 4 and 5 hours and final setting between 12 and 24 hours. (FA), 60% slag (S), and 40% waste clay brick dust (WCB), achieved initial setting between 4 and 5 hours and final setting between 10 and 10.5 hours; The WCB-based GPC developed in this study showed a high hardening rate and a penetration resistance of 28 MPa in approximately 15 hours or less. In this context, when the A/CE ratio was 0.38 and the (FC) content was 50%, the initial (final) setting times of the geopolymers with alkaline contents of 8%, 10%, and 12% were 30 (115), 90.5 (170), and 204 (295) min, respectively. [35]. This suggests that variations in the A/CE ratio, alkaline activator content, and temperature have a significant impact on the setting and hardening properties of geopolymers. All this information is summarized in Table 4, based on a review of one article published in 2023, two in 2024, and one in 2025.

Table 4: Results obtained for the setting time.

Variable modified	Solución activadora	Activating solution	Initial setting time (min)	Final Setting Time (min)	References
Concrete + (FA)+ (SF)	NaOH + Na_2SiO_3	30%(SF)+ 70%(FA)	150mim	340min	[32]

III.2 MECHANICAL PROPERTIES

III.2.1 Compressive Strength

In turn [36] The decrease in compressive strength was more pronounced when only recycled concrete aggregate (RFA) was used instead of natural aggregate (NFA). The rate of increase in strength is significantly higher under hot curing conditions than under room temperature curing conditions. Among the mixtures (GPC) cured at room temperature (25°C), the mixture (8M GC-25) in proportions of (FA) at 95% and slag at 5%, cured at a temperature of 25° and molarity 8M, presented the highest strength at 28 days (63 MPa), while the mixture (2M GC-25) in proportions of (FA) 95% and slag 5%, cured at a temperature of 25° and molarity 2 M, showed the lowest strength (33 MPa). [37], on the other hand [38] It mentions that compressive strength reaches its maximum value of 69.65 at 100 °C, then decreases with increasing temperature.

As the recycled coarse aggregate (RCA) content increases, the residual compressive strength decreases. Similarly [39] argues that partial replacement (FA) with recycled binder generally decreased compressive strength, mortars with up to 60% recycled geopolymer cement (RGPC) exhibited strength values greater than 50 MPa, sufficiently high for structural applications. It has been shown that the use of recycled aggregates and recycled binders tends to reduce the compressive strength of GPC compared to the use of natural materials. However, curing at high temperatures significantly improves mechanical properties, partially offsetting this decrease. By [40], studied the positive impact of class F (FA) on the increase in compressive strength, On the other hand [41] They maintain that the compressive strength at 28 days of the specimens without ultrafine slag (UFS) was 38 MPa, and increased to 65 MPa with a 50% substitution, observing a notable increase in mechanical properties due to the high unit weight and density.

Similarly, the increase in the proportion of geopolymer binder replacement increased the compressive strength values, reaching 65.5 MPa, 68.7 MPa, and 72.5 MPa for the Geo25, Geo50, and Geo75 mixtures, replacing 25%, 50%, and 75% of (OPC) with geopolymer binders, respectively [42]. In addition, the highest compressive strength was achieved by hot air oven curing, with 33.3 MPa, followed closely by accelerated curing (32.1 MPa) and outdoor curing (31.5 MPa). The optimal dosage of (GPC) was determined to be a ratio of 70% (FA) and 30% (GGBS) [43]. Overall, the studies reviewed confirm that increasing the proportion of supplementary cementitious materials, such as fly ash and slag, significantly improves the compressive strength of GPC All this information is summarized in Table 5, based on a review of two articles published in 2024 and six in 2025.

Table 5: Results obtained for compressive strength.

Construction material	Activating solution	Optimal percentage of substitution	Compressive strength at 28 days (MPa)	References
Concrete + (FA)+GGBFS	NaOH + Na_2SiO_3	0% (NCA) + 30% (RFA)	41.4Mpa	[36]

III.2.2 Tensile Strength

Accordind to [44], They pointed out that GPC consistently exhibits higher tensile strength values, and although it offers a significant advantage in terms of tensile strength during the early stages of curing, this characteristic highlights its superior mechanical performance compared to ordinary Portland cement (OPC). Likewise [45] They mentioned that the proportion of (GGBS) in the mixture reached a maximum of 20%, since above this level, a decrease in tensile strength was observed. On the other hand, the greatest reduction in tensile strength was observed in the mixture with 100% RCA. Adding carbon fiber (CF) increases tensile strength because the load on the first crack does not exceed the fiber's tensile strength. [46].

Finally, the studies revealed that geopolymer concrete (GPCS) manufactured with different percentages of (SF) and (MK) with additional materials showed greater tensile strength in comparison with the reference mixture of (GPFA); In this regard, favorable results were obtained with the incorporation of 20% metakaolin (MK) and 10% SF, which increased the concrete's flexural strength at 28 days by up to 23% and 20%, respectively [47]. The optimal combination of fly ash (FA) with other cementitious materials and complementary reinforcements generates a significant improvement in the tensile strength of geopolymer concrete. All this information is summarized in Table 6, based on a review of one article published in 2021, one in 2022, and two in 2025.

Table 6: Results obtained for tensile strength.

Construction material	Activating solution	Optimal percentage of substitution	Tensile strength at 28 days (MPa)	References
Concrete+ (FA) +(GGBFS)	NaOH + Na_2SiO_3	1:2,5:3,5 (Binder: fine aggregate: coarse aggregate)	4.3 MPa	[44]

Concrete + (MK)+(SF)	NaOH + Na_2SiO_3	(GC)+20%(MK) (GC)+10%(SF)	4.83MPa 4.81MPa	[47]

Source: Authors, (2026).

III.2.3 Flexural Strength

The flexural strength evaluation was performed on 28-day specimens, and the results and comparisons with the control mixture (CC) showed that the GPC mixture exhibited a 17.38% increase in flexural strength. [48], In a similar way [49] reported that the highest flexural strength among the modified samples was obtained with the samples containing 60% foamed geopolymer aggregates plus expanded clay (FGA/ECA/P 60), reaching 4,386 MPa, while the lowest was recorded in the FGA 75 sample, with 2,994 MPa. Likewise, the mixture with the best performance in terms of mechanical properties (flexural strength) was composed of 20% microsilica (SF) and 80% fly ash (FA), which significantly improved its mechanical properties [50]. Finally, another study observed an upward trend in flexural strength values as the ordinary Portland cement (OPC) content increased, reaching maximum values of 12.1, 13.12, and 15.21 MPa at 7, 14, and 28 days, respectively, for the 30% OPC and 70% FA mixture; however, a decrease in (FS) was observed after this maximum [51]. In summary, the flexural strength of geopolymer concrete improves with the increase and appropriate combination of supplementary cementitious materials. The presence of fly ash, microsilica, and OPC promotes matrix densification and strength development.

In turn [52] argues that combining recovered fly ash (RFA) with calcium-rich precursor materials such as ground granulated blast furnace slag (GGBFS) to produce geopolymers is a better alternative to geopolymers that incorporate only RFA. In a complementary manner [53] demonstrated by activating the hydration rate and improving the early strength qualities of class C (FA) concrete, an alkaline solution composed of sodium hydroxide and sodium silicate with an optimal molarity of 12M was added. Similarly, the control sample (C-GS) containing fly ash, slag, alkaline activator, coarse and fine aggregates, water, and a superplasticizer achieved the highest flexural strength, 5.1 MPa, while the sample with the highest plastic content (1.5-GS) obtained a reduced strength of 3.7 MPa, representing a decrease of 26.7% [54]. Finally, the results of the experimental flexural capacity of beams reinforced with longitudinal and transverse steel (GPC) are comparable to those of conventional concrete beams (CCB). The difference between the experimental and theoretical flexural capacities was 7.53% and 6.67%, respectively [55] Overall, the studies reviewed demonstrate that the incorporation of calcium-rich precursor materials and the use of alkaline solutions with optimal molarity significantly improve the strength and flexural behavior of (GPC). All this information is summarized in Table 7, based on a review of one article published in 2024 and seven in 2025.

Table 7: Resultados obtenidos para la resistencia a la flexión.

III.3 MICROSTRUCTURAL PROPERTIES

III.3.1 Scanning Electron Microscopy (SEM)

By [56], [57] show how the characteristics of aggregates influence the microstructure and properties of materials. Scanning electron microscopy (SEM) and X-ray diffraction (XRD) analysis showed that the use of 2% lime content in steam-cured lime-fly ash geopolymer concrete (L-FGPC) improves the geopolymerization process, resulting in a homogeneous, compact, and finer microstructure and produces a dense gel that reduces the proportion of voids. Therefore, it is believed that lime acted as a catalyst in the L-FGPC mixture when 2% lime content was used. [58]; Furthermore, XRD patterns indicate the formation of well-crystallized materials, with higher peaks of quartz (Q) and mullite (M) noted at 2θ values of 27–32° for all samples. In general, these peaks indicated the formation of the main compound (aluminosilicate hydrate (NASH)) produced by the geopolymerization process [59].

On the other hand [60], XRD analysis allows us to evaluate the effect of municipal solid waste (MFA) replacement rates on (GPC), observing small peak clusters between 18° and 36°, associated with amorphous aluminosilicate gels. These clusters progressively decrease as (MFA) replacement increases, reflecting less hydration product formation. This is due to the lower aluminum and silicon content of MFA compared to MK, which reduces the amount of amorphous gels generated in MFA-GPC. Finally, the XRD results of the geopolymer pastes based on fly ash reinforced with GFRP/FA glass fiber at 3, 7, and 28 days revealed that the crystalline phases of the hardened pastes at different curing ages are mainly quartz (SiO_2), calcite ($CaCO_3$), mullite ($Al_6Si_2O_{13}$), larnite, and portlandite ($Ca(OH)_2$).

Furthermore, the progressive decrease in the quartz peak with curing age indicates the dissolution of Si ions in the alkaline medium during geopolymerization [61]. In summary, XRD analyses show that geopolymerization is strongly influenced by the presence and evolution of amorphous and crystalline phases, demonstrating that the formation of NASH, the variation in quartz and mullite peaks, and the decrease in amorphous gels depending on the type and replacement of the precursor determine both the degree of reaction and the structural stability of the geopolymer. All this information is summarized in Table 8, based on a review of four articles published in 2022.

Table 8: Scanning electron microscopy results.

Condition assessed	Morphology/microstructure observed	Implications	References
Geopolymers of (FA) class F+ Cured with lime and steam.	He observed a dense gel, and the ratio of voids and microcracks decreased.	…..	[58]
Geopolymers of (FA) + nanoclay + nanotitanium	Formation of silicate compound, higher density, decrease in ITZ thickness	Improved ZIT and greater mechanical strength	[59]
Geopolymers of (FA) + (MFA)	Replacement of 10% of MFA continues to appear composed of silicate-aluminate gel, appearance of small cracks.	Decreased structural strength and GPC becomes more porous	[60]
Geopolymers of (FA) class F+ fiberglass (GFRP) + steel slag (SS)	Increase in the amount of gels grouped in the matrix, indicating a high degree of geopolymerization.	Increased mechanical strength	[61]

III.3.2 X-Ray Diffraction (XRD)

CaO promotes the formation of C(N)–A–S–H gel products, forming a dense microstructure and increasing the compressive strength of self-compacting geopolymer concrete (SCGC) [62]In another study, mixtures A0*, A4, and A8 containing 0%, 4%, and 8% OPC of the total binder at 3 and 28 days, in the early stage, it was found that activation reaction products formed on the surface of the FA particles. This is generally considered to be the precipitation of the sodium aluminosilicate gel produced by the reaction. In contrast, greater precipitation than that mentioned above was observed in sample A8 with 8% OPC [63]. Likewise [64] reported that samples of (GC) 15M2.0NA (natural coarse aggregate, with an NS/NH ratio of 2 and 15 mol) and 15M2.0CM (crushed ceramic waste as coarse aggregate, with an NS/NH ratio of 2 and 15 mol) showed a large crack width and larger pore size in the interfacial transition zone (ITZ) of 15M2.0NA compared to 15M2.0CM.

These results confirmed that the use of waste ceramic aggregate (CM) improved the bonding and homogeneity between the geopolymer paste and the aggregates. Finally [65] They demonstrated that, when comparing the (ITZ) of RS-GP (natural sand and binder) and RFA-GP (recycled fine aggregate and binder), recycled coarse aggregate (RFA) can result in a more compact ITZ than natural sand, which is one of the reasons why compressive strength does not decrease significantly even when the replacement rate of RFA reaches 100%. Overall, studies show that both the presence of CaO and (OPC) and the appropriate selection of aggregates have a decisive influence on gel density, (ITZ) compactness, and, therefore, (GPC) strength. All this information is summarized in Table 9, based on a review of four articles published in 2023.

Table 9: Results obtained for X-ray diffraction.

Condition evaluated	Morphology/microstructure observed	Implications	References
Geopolymers of (FA) + blast furnace slag + (MK)	Reduction in porosity, abundant formation of C–A–S–H gels	Dense microstructure and mechanical strength	[62]
Geopolymers of (FA)+(OPC)	Formation of calcium aluminosilicate hydrate (CASH)	Compressive strength and transverse deformation capacity	[63]
Geopolymers of (FA) + natural fine aggregate (NA) and recycled aggregate (CM)	Greater porosity and water absorption	Lower mechanical properties with (CM)	[64]
Geopolymers of (FA) + natural coarse aggregate (RS) + (RFA)	Lower porosity and water absorption	Lower mechanical properties with (RS)	[65]

III.3.3 Fourier Transform Infrared Spectroscopy (FTIR)

In GPCs, the optimal CaO/SiO_2 and SiO_2/Al_2O_3 ratios are directly associated with the formation of the C_1S_2H, $C_1(A)_1S_2H$, and $N_1A_1S_2H$ phases, which in turn have a direct influence on microstructure transformation. [66]; according to [67], The FTIR spectra of all specimens consisting of two types of fly ash – high calcium fly ash (HCF) and low calcium fly ash (LCF) – with a weight ratio of HCF to LCF of 1, showed bands at 3700 – 3400 cm^{-1} and 1700–1600 cm^{-1} associated with O–H stretching and H–O–H bending, evidencing the presence of water molecules, while around 1400 cm^{-1} O–C–O stretching was identified in all geopolymers. Likewise, a higher Si–O–Si/Si–O–Al stretching peak was observed in the mixtures with carbon microfiber (CF) compared to the control; however, the mixture with 0.1% (CF) showed a smaller increase in the 1200–950 cm^{-1} band compared to mixtures with higher contents.

Complementarily [68] reported that the FTIR spectra of the CCSW and GCSW groups show similar bands at approximately 3450, 1650, 1450, 1080, 995, and 875 cm^{-1} evidencing a comparable product composition; Furthermore, the absorptions at 1450 and 875 cm^{-1} are mainly associated with carbonates, originating from the calcium carbonate in the concrete slurry (CSW) and a small fraction of carbonized hydrated products. Likewise, the progressive intensification of the CASH band is directly related to the improvement in the mechanical properties of the GCSW samples. Finally, the FTIR spectra of the geopolymers studied in samples Si337, Si325, Si350, and GS15 show that aluminum binds with silicon to form a geopolymer gel, suggesting relatively high compressive strength. in contrast, the peak centered around 972 cm^{-1} in samples GS8, GS4, and Si375 shows that geopolymerization did not generate a solid network and that some slag remained unreacted, especially in GS8 and GS4.

The FTIR results were consistent with the compressive strength of the samples [69]. Together, the FTIR spectra allow the formation and quality of the geopolymer gel to be identified, showing that compositions with a higher degree of polymerization, supported by the intensification of the Si–O–Si/Si–O –Al and CASH bands, develop better microstructures and mechanical properties, while mixtures with lower reactivity show peaks linked to unreacted carbonates or slag, which explains their poor performanceAll this information is summarized in Table 10, based on a review of three articles published in 2021 and one in 2023.

Table 10: Results obtained for Fourier transform infrared microscopy.

Condition evaluated	Identified FTIR bands	Interpretation / Observations	References
Optimal blends: 75%(FA)+25% (UPOFA) 75%(GBFS)+25% (FA)	The shift of (O–Si–O or Si–O–Si) is within 730.95–777 cm^(−1), and the AlO_2 functional group is within 650.12 cm^(−1)–695 cm^(−1).	Formation of gels (C–(A)–S–H) and C–S–H, N–A–S–H	[66]
Geopolymers of (FA) + carbon microfiber (CF)	They showed wave numbers of 3700–3400 cm^(−1) and 1700–1600 cm^(−1) for O–H stretching and H–O–H bending, and O–C–O stretching was detected at a wave number of 1400 cm^(−1).	A noticeable difference was the larger peak elongation of Si–O–Si or Si–O–Al in the CF mixtures compared to the control mixture.	[67]
Geopolymers of (FA) + blast furnace slag (BFS) + concrete slurry (CSW)	The main bands are detected at approximately 3450, 1650, 1450, 1080, 995, and 875 cm^(−1), such as stretching of the –OH group, bending of water (H–OH), carbonate (CO_3^{2-}), silicates or sulfates, and stretching of Si–O.	Gradual improvement of the CASH absorption band leads directly to a significant improvement in the mechanical properties of GCSW samples.	[68]
Geopolymers of (FA)+ (GGBFS)	The bands in the range 900–1200 cm−1 were attributed to Si-OT (T = Si or tetrahedral Al).	A relatively high compressive strength was observed for these samples.	[69]

IV. CONCLUSIONS

Fly ash has established itself as an efficient substitute for Portland cement, reducing the carbon footprint and promoting the circular economy through waste recovery. Its performance in geopolymer concretes depends on proper dosing and the use of alkaline activators such as NaOH and Na_2SiO_3, which generate N–A–S–H and C–A–S–H gels responsible for mechanical and microstructural properties. Factors such as activator molarity, activator-precursor ratio, aggregate type, and curing influence workability and strength development. With the incorporation of supplementary materials such as slag, microsilica, or metakaolin, these concretes can match or exceed conventional concrete in compression, tensile, and flexural strength. Microstructural analyses show dense and stable matrices, confirming that geopolymer concrete with fly ash is a viable and durable alternative for structural and sustainable applications.

ABSTRACT

The Controlled Environment Agriculture (CEA) system controls the soil and climatic conditions to enhance agricultural productivity and resource efficiency in a sustainable way. This work offers a framework of the Monitoring Digital Twin (mDT) of CEA operations optimization, which combines automation, real-time monitoring, and predictive analytics. A SELEC DIGIX-1 Programmable Logic Controller (PLC) has automated control of environmental parameters, whereas the digital twin continually gathers sensor data, extracts features, and stores them to be used in the information analysis. The main objectives of the proposed system are (i) to predict Crop yield based on Crop Yield Prediction Dataset and (ii) to detect (weed, pesticide and plant disease) based on Plant Village Dataset. A Median Filter with Z-Score Normalization is used to perform data preprocessing to improve the quality of data and eliminate noise. Gray Level Co-occurrence Matrix (GLCM) is used to obtain effective feature extraction, and then, the Deep Recurrent Q Network model is used with a Convolutional Neural Network (CNN) to classify them. The model has a better performance of an accuracy of 0.97, precision of 0.96, recall of 0.93, F1-score of 0.93, and Root Mean Square Error (RMSE) of 0.1673, of superior performance compared to conventional methods. The data is processed and stored in DynamoDB and hence accessed by Python-based Edge computing devices on user request. In addition, the SP112-GT40-S-CE Human Machine Interface (HMI) displays the insights (locally and remotely) like predicting crop yields, identifying the weed, pesticide suggestions, and identifying the disease in the plant. On the whole, this mDT framework improves the CEA ecosystem by integrating digital twin technology and deep learning in order to attain intelligent automation, early anomaly and sustainable agricultural productivity.

I. INTRODUCTION

Controlled Environment Agriculture (CEA) is the emerging alternative to meet the increasing demands for sustainable food production by controlling the soil and climatic environments to ensure optimal agricultural output and resource utilization [1]. The rapid evolution of digital twin (DT) technology has made agriculture even more transformative, as intelligent monitoring, simulation, and control are achieved in various farming conditions. Recent developments in cloud-fog-edge infrastructures have enabled the effective implementation of DTs to support smart agriculture, facilitating real-time data collection, processing, and decision-making [2]. These highly focused surveys have also demonstrated the potential of DT frameworks to enhance crop productivity, reduce the cost of inputs, and mitigate their sensitivity to environmental and biological stresses [3]. In addition to open-field crop production, DT has also been applied to urban arable ecosystems and aquaponics, where decision support tools combine environmental monitoring with predictive analytics to inform optimization options [4]. The integration of DT, edge artificial intelligence (AI), and machine learning (ML) has been identified as one of the main facilitators of intelligent automation and adaptive control in agriculture and industry [5].

In particular, IoT, augmented reality, and DT-based real-time greenhouse management have proven to be efficient and sustainable in their operational capacity and sustainability [6]. Hybrid DT models have also been made to represent greenhouse environment, and the underground environment simultaneously to give more accurate simulations to allocate resources [7]. Similarly, robots that run on DT have demonstrated promising experiments in harvesting crops in a specific manner, such as harvesting strawberries in greenhouses [8]. Intelligent fish farm management systems have been applied to DT-based architectures in the context of aquaculture (based on sophisticated decision-making mechanisms, such as the analytic hierarchy process) [9]. On a larger scale, recent developments integrating DT with collaborative edge-cloud computing and resource allocation algorithms have formed the basis of its implementation in larger 6G-enabled Industrial IoT systems [10]. These developments are evidence that, with the integration of deep learning and edge computing, DT technology represents a revolutionary avenue in contemporary agriculture.

I.1 OBJECTIVE

- To create and deploy a Monitoring Digital Twin (mDT) to unite automation, real-time monitoring and predictive analytics to optimize Controlled Environment Agriculture (CEA) processes based on intelligent decision support.
- To combine Digital Twin technology with benchmark agricultural data, i.e. Crop Yield Prediction Dataset to predict productivity and Plant Village Dataset to detect weeds, pesticides and plant leaf diseases.
- To optimize the quality of the data in the Digital Twin environment with a Median Filter of Z-Score Normalization of noise elimination, normalization, and proper data synchronization between the real and virtual layers.
- To obtain meaningful texture and correlation-based characteristics of the twin generated agricultural data through the Gray Level Co-occurrence Matrix (GLCM) to accurately analyze and map out crop health conditions digitally.
- To create a hybrid Digital Twin model based on deep learning to classify, predict, and detect anomalies in CEA systems using a Deep Recurrent Q Network with a Convolutional Neural Network (CNN).

I.2 CONTRIBUTION OF THE WORK

- Monitoring Digital Twin (mDT) is a proposed architecture of Controlled Environment Agriculture (CEA), which can be used to monitor and predict the environment, automate, and improve crop management, as well as sustainable farming.
- The framework combines two benchmark datasets the Crop Yield Prediction Dataset, which is used to estimate productivity, and the Plant Village Dataset, which is used to detect the presence of weeds, pesticides, and plant diseases, into a single Digital Twin setup.
- The twin data pipeline uses a hybrid method of Median filter and Z-score normalization to remove any noise, normalize the inputs and to increase the accuracy of sensor and image data synchronization.
- The method used to extract the spatial and texture features of agricultural images is called the Gray Level Co-occurrence Matrix (GLCM), which enhances the analytical power of the twin in detecting the health of crops in the images.

A Deep Recurrent Q Network with a Convolutional Neural Network (CNN) is used to classify and predict in the digital twin with very high performance (accuracy, precision, recall, F1-score) and allows a smart and automated decision-making in CEA operations.

I.3 ORGANIZATION OF THE PAPER

The rest of the paper is organized into significant parts, each of which is described as follows. Section II lists the research projects on Monitoring Digital Twin Framework for Controlled Environment Agriculture completed by various authors. The suggested method's workflow is defined in Section III, and the Results and performance analysis of Monitoring Digital Twin Framework for Controlled Environment Agriculture are presented in Section IV. The conclusion of the proposed work that will be done in a future scope is included in Section V, along with references.

II. RELATED WORK

The more recent literature shows a consistent change in the concept of Artificial Intelligence (AI)-based Digital Twin (DT) structures and their application to sustainable and smart agriculture, with each article adding its own methodological nuances and revealing unresolved issues in the field. Based on the principles of the circular economy, [11] combines the concept of Artificial Intelligence (AI) and Digital Twin (DT) models to empower the optimization of resources and waste management in Chinese agricultural industries, where DTs reflect the processes of physical farming, whereas AI helps to make forecasts, but the solution is burdened by an excessive dependence on data and is not proved to be scalable to real-time and across regions. Building on the previous subject, [12] offers an extensive review on AI convergence with DT in agriculture and forestry, including approaches like the use of Machine Learning (ML)-based crop sensors and simulation-based DTs, yet the review is, to a large part, more of a conceptual analysis with little analysis of performance at the implementation level. In the educational field, [13] proposes the use of Extended Reality-based Digital Twins (XR-DT) to supplement agricultural training with immersive visualization and simulation but the platform is hampered by the high hardware costs and lack of integration with actual farm data streams.

Dwelling on the topic of precision farming, [14] addresses the concept of Digital Twin Smart Farming Systems (DT-SFS) based on geospatial and sensor-based agricultural systems, but the study concept does not include a unified architecture of the system and the objective quantification of its accuracy. In the case of aquaculture, [15] applies a Digital Twin Architecture (DTA) to intelligent fish farm operation by ranking system components with the help of a Modified Analytic Hierarchy Process (M-AHP), but the selection of the components is subjective and not tested in dynamic environmental uncertainty conditions. In infrastructure, [16] suggests Cloud-Fog-Edge-based Digital Twin Deployment (CFE-DT) to minimize latency and maximize scalability in smart agriculture, yet the complexity of the architecture will raise the maintenance cost and security-related issues. In [17], the integration of reinforcement learning is known as Reinforcement Learning-based Digital Twins (RL-DT) to adaptive control and optimization but the models have high computational cost and slow convergence in sparse-reward agricultural settings.

In [18], the synergy of Artificial Intelligence (AI) and the Internet of Things (IoT) is highlighted through an AI-IoT Smart Agriculture Framework (AIoT-SAF) of real-time monitoring and decision support, but the interoperability issues, as well as energy consumption of IoT devices is not resolved. The system level validation is provided in earlier [19] that creates a Digital Twin of an Urban Hydroponic Farm (DT-UHF) with data-centric modelling to model crop growth and resource flows; however, it is highly accurate but is specific to the domain and hard to extrapolate to open-field agriculture. In [20], interpretability is considered with the help of Interpretable Artificial Intelligence-based Smart Agriculture System (IAI-SAS) which integrates transparent ML models with decision rules, but because of the trade-off between interpretability and predictive performance, the application is only applicable to more complicated situations. Sustainability wise, [21] is a review of Smart Agriculture Digital Twin Applications (SA-DT) and outlines challenges of data integration, standardization, and lifecycle management, but does not go as far as suggesting specific optimization algorithms.

In [22], a paradigm shift to complete digitalization is discussed, and the concept of Next-Generation Digital Twin Paradigm (NG-DTP) of agriculture is discussed, but the lack of experimental validation of the concept undermines its practical significance. An advanced synthesis in [23] classifies Digital Twin Models in Agriculture (DTMA) according to the functionality and maturity, yet points at the lack of synchronization in real-time and autonomy of AI. Expanding the scope, [24] samples Cross-Industry Digital Twin Applications (CI-DT), which can be transferred to agriculture but has no domain-specific performance metrics. Lastly, [25] provides a detailed overview of Digital Twin-based Smart Agriculture Systems (DT-SAS), with specific focus on sensor fusion, AI analytics, and system integration, but it finds that the problem of scalability, cybersecurity, and cost-effectiveness still have not been resolved.

Table 1: Comparison of Digital Twin Applications in Agriculture

Source: Authors, (2026).

The comparison table 1 provides an overview of major works related to digital twins (DTs) in agriculture, including their contributions, areas of application, limitations, and outcomes. One study proposed a DT framework for controlled environment agriculture, where a 15-20% yield optimization is more applicable however, issues with scale and prohibitively expensive sensors remain. Another created a 3D plant simulation model to test scenarios, but was limited by the complexity of computations and crop validation. Mandarin-specific monitoring indicated 18% water consumption and 12% yield growth; however, these findings are not generalizable.

III. PROPOSED METHODOLOGY

The proposed methodology includes the creation of a Monitoring Digital Twin (mDT) to optimize the Controlled Environment Agriculture (CEA) processes with an integrated approach based on automation, real-time monitoring, and predictive analytics. Soil moisture, temperature, and humidity are also automatically controlled by a SELEC DIGIX-1 Programmable Logic Controller (PLC), which controls the conditions to the optimum growth conditions. The digital twin constantly gathers the information of multiple sensors located in the CEA setting and puts it in DynamoDB to analyze it in real-time and historically. Preprocessing of the collected data is done with a Median Filter with Z-Score Normalization to eliminate noise and normalize the data in order to have improved performance of the model. This is followed by extraction of significant attributes of the data after preprocessing through Gray Level Co-occurrence Matrix (GLCM), which contains information on space and texture that are important in crop health and yield. In the case of predictive analytics, a Deep Recurrent Q Network (DRQN) combined with a Convolutional Neural Network (CNN) is used to classify and predict the results, such as crop yield and the identification of weeds, pesticides, and plant diseases using the Crop Yield Prediction Dataset and Plant Village Dataset. The resulting information is rendered in the form of the SP112-GT40-S-CE Human Machine Interface (HMI), which provides operative information on such aspects as crop yield forecasting, weed identification, pesticide selection, and disease detection, both at the location and remotely.

III.1 SMART ENVIRONMENT SETUP FOR DIGITAL TWIN-ENABLED CEA

The monitoring digital twin platform is set up on a CEA service, like a greenhouse or growth chamber setting. To ensure an uninterrupted monitoring of soil parameters (moisture, pH, and nutrient content), and climate parameters (temperature, humidity, CO2 concentration, and light density), the installation is prepared with a set of IoT-based sensors. A SELEC DIGIX-1 Programmable Logic Controller (PLC) is implemented to automate the functioning of the irrigation, ventilation, and lighting process on the basis of sensor inputs. Moreover, image sensors are used to monitor plant conditions, identifying weeds, pests, and diseases. An edge computing device connects the sensors and the PLC to process data on the edge, synchronize with a digital twin, and guarantee real-time monitoring and control. The machine learning system is similar with edges and has proven to be very efficient in real-time agricultural prediction and monitoring [31].

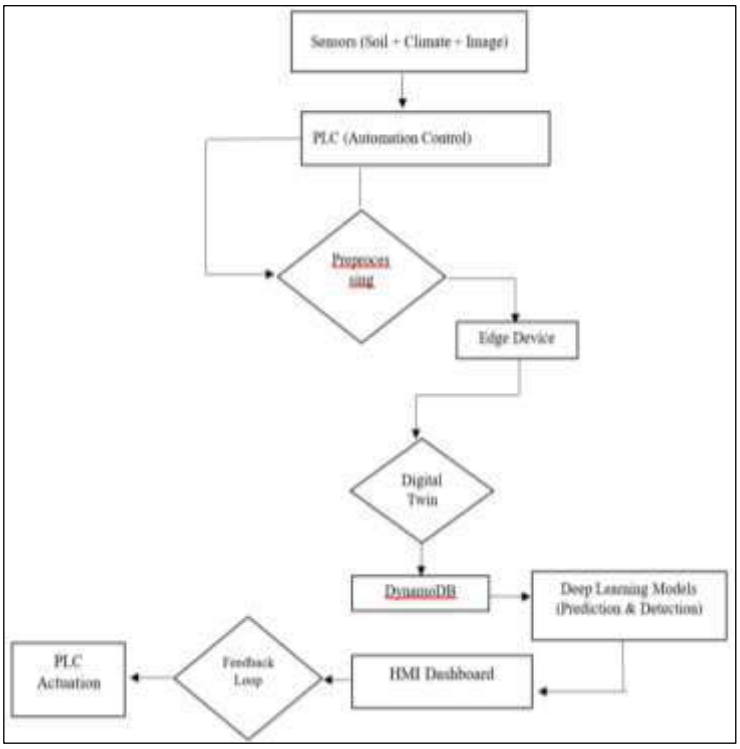

Figure 2: Environment Setup and Data Flow of the Proposed Monitoring Digital Twin (mDT) Framework.
Source: Authors, (2026).

Figure 2 represents the setup of the environment and data processing pipeline of the proposed mDT framework of CEA. Real-time data is measured by soil, climate, and image sensors and processed by a SELEC DIGIX-1 PLC to enable automation control. An edge device performs preprocessing at the location and aligns the data with the digital twin. The twin is linked to DynamoDB, which stores both historical and current data, allowing for prediction and detection through advanced analysis using deep learning models. Optimization of crop management is achieved by visualizing results using the HMI dashboard and implementing a feedback loop to keep the PLC updated.

III.2 PLANT VILLAGE DATASET

The Plant Village Dataset includes more than 54,000 images of leaf samples of 38 categories of healthy and diseased crops. The application is extensively applicable to training deep learning models, which can be used to accurately detect plant diseases, anomalies, and support smart agriculture to sustain farming practices. Sample leaf image provided in figure 3. Deep learning models such as ConvNeXt-Small have shown high accuracy in plant disease detection using leaf images, proving the reliability of CNN-based architectures for agricultural disease classification [32].

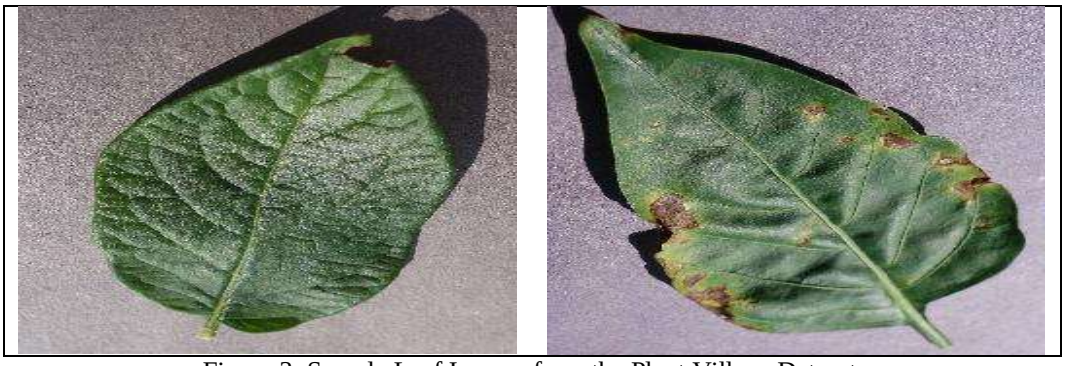

Figure 3: Sample Leaf Images from the Plant Village Dataset.
Source: Authors, (2026).

III.3 CROP YIELD PREDICTION DATASET

The science of training machines to learn and produce models for future predictions is widely used, and not for nothing. Agriculture plays a critical role in the global economy. With the continuing expansion of the human population understanding worldwide crop yield is central to addressing food security challenges and reducing the impacts of climate change. Crop yield prediction is an important agricultural problem. The Agricultural yield primarily depends on weather conditions (rain, temperature, etc), pesticides and accurate information about history of crop yield is an important thing for making decisions related to agricultural risk management and future predictions.

III.4 MEDIAN FILTER WITH Z-SCORE NORMALIZATION FOR PREPROCESSING

In the Edge Preprocessing layer, the raw sensor readings and crop images typically contain undesirable noise and deviations. A Median Filter is applied in order to enhance reliability in that impulsive noise like abrupt spikes or salt-and-pepper disturbances, is removed without distorting the necessary information. This makes the data smoother and more accurate for further processing. Z-score normalization is applied to standardize the data after noise has been removed, ensuring all features are on the same scale with equal variation. This hybrid method also enhances the quality of data and model learning, and yields superior prediction and detection accuracy within the system.

$$x'(t) = median\,\{x(t-k), \dots x(t), \dots., x(t+k) \tag{1}$$

Where the values are substituted with the median of the neighborhood surrounding the value to eliminate impulsive noise and leave details intact. Data is standardized with Z-score normalization after denoising.

$$x' = \frac{x-\mu}{\sigma} \tag{2}$$

The equation (2) features a zero mean and unit variance. This normalization ensures that there are no normalized and balanced inputs, allowing deep learning models to converge much more quickly and requiring a greater degree of accuracy, precision, and robustness in their prediction tasks.

III.5 DIGITAL TWIN LAYER

The Digital Twin layer is a virtual representation of the physical Controlled Environment Agriculture (CEA) system, synchronizing real-time data collected by soil, climate, and image sensors. It is connected to the SELEC DIGIX-1 PLC and edge device to reflect environmental conditions and operational states. DynamoDB stores both historical and current data, which can be leveraged to perform advanced analytics and identify anomalies. Times Twin supports predictive modeling including crop yield prediction and vegetation health evaluation, with deep learning algorithms. Digital Twin enhances decision-making, operational efficiency, and adaptive control in smart agriculture systems by providing a data-driven, dynamic simulation.

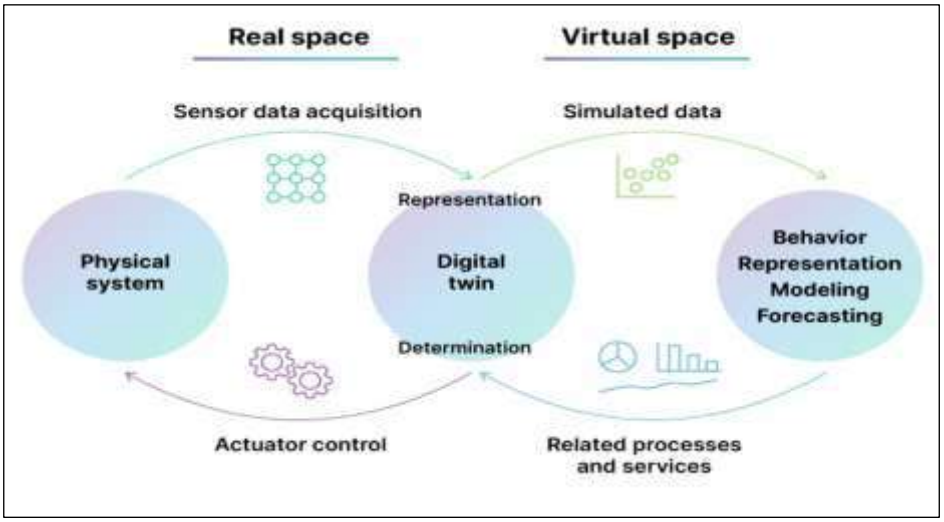

Figure 4: Digital Twin Layer Architecture in Smart Agriculture.
Source: Authors, (2026).

This figure 4 represents the Digital Twin layer in the mDT framework of Controlled Environment Agriculture (CEA). Data streams from soil, climate, and image sensors are fed into a virtual model in real time, which reflects the physical conditions. The Digital Twin is a system that links control systems and edge computing units to maintain constant synchronization and data storage. Based on this virtual representation, learned predictive analytics, such as crop yield forecasting and pest/disease identification through deep learning, are carried out. The model facilitates decision-making by allowing remote monitoring, simulation, and optimization of interventions, thereby increasing the efficiency and resilience of precision agriculture.

III.6 FEATURE EXTRACTION USING GRAY LEVEL CO-OCCURRENCE MATRIX

Gray Level Co-occurrence Matrix (GLCM) is a popular feature extraction method of studying image texture shown in figure 5. It analyses the frequency of occurrence of pairs of pixel intensities in a spatial relationship within an image, establishing a matrix that provides a representation of patterns of texture. Statistical features are generated out of this matrix, including contrast (degree of variation in intensities), energy (uniformity of texture), homogeneity (proximity of distribution to the diagonal), and correlation (linear dependence of gray levels).

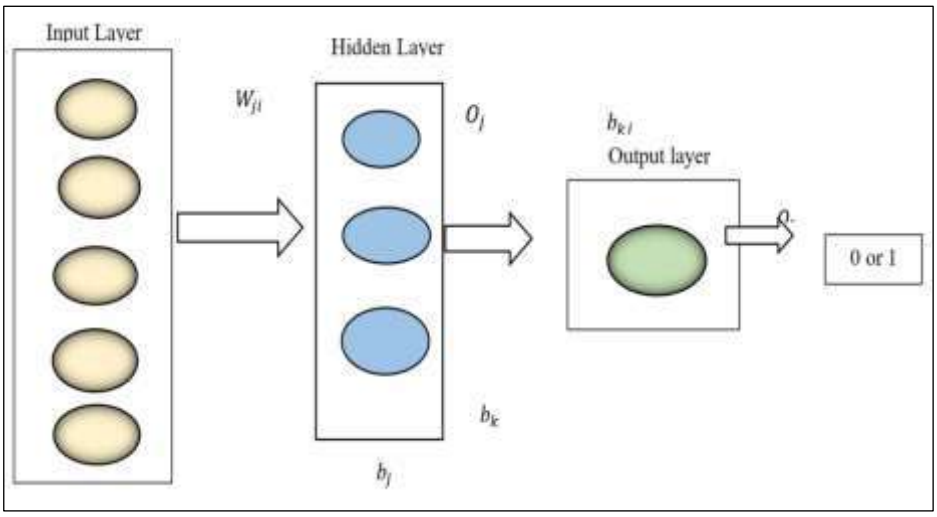

Figure 5: Gray Level Co-Occurrence Matrix Architecture.
Source: Authors, (2026).

III.7 CLASSIFICATION USING DEEP RECURRENT Q NETWORK MODEL WITH CONVOLUTIONAL NEURAL NETWORK (CNN)

The system proposed is based on a Deep Recurrent Q Network (DRQN) and a Convolutional Neural Network (CNN) in order to optimize the decision making and pattern recognition in crop monitoring. The CNN element isolates the spatial content of plant images, and disease pattern, growth of weeds, or pest infestation are highly recognized. The DRQN then processes these extracted features, adds temporal dependencies and sequence decision-making, to dynamic agricultural settings. The DRQN is learned through time unlike the static models and it adjusts to changes in the environment by learning the best control policies. This combination will guarantee proper detection of plant diseases, effective utilization of resources and the ability to make strong predictions regarding intelligent use of agriculture. ML-based predictive modeling studies also emphasize that optimized learning systems have a strong effect on improving the accuracy of prediction in a computational system [33].

Table 2: Algorithm Steps for DRQN with CNN.

Algorithm Steps for DRQN with CNN
Step 1: Preprocess and train plant images (including size, normalization, and augmentation) for training and testing.
Step 2: CNN layers (convolution, pooling, activation) extract spatial features in images.
Step 3: Feed CNN features into DRQN with recurrent layers to capture temporal dependencies.
Step 4: Apply Q-learning with epsilon-greedy policy to update action-value function based on rewards.
Step 5: Train model using experience replay and gradient descent to minimize Q-value prediction error.

Source: Authors, (2026).

The table 2 shows the sequential procedure of integrating CNN with DRQN to monitor agriculture. Step 1 is used to cleanse the input data and prepare it for training. The second step, step 2, isolates meaningful spatial content in images through CNN. Recurrent learning is incorporated in Steps 3 and 4 as part of Q-learning to make accurate decisions. Lastly, Step 5 focuses on training based on experience replay and optimization to enhance the performance of predictions.

IV. RESULTS AND DISCUSSION

The experimental analysis of the suggested mDT framework showed that both crop yield prediction and the anomaly detection tasks were significantly improved. DRQN-CNN model demonstrated better accuracy, precision, recall and F1-scores than the traditional methods, and low RMSE values of predictive consistency. Real-time sensor data combined with edge computing allowed making decisions quicker and minimizing latency to provide the opportunity to respond confidently to environmental changes. Moreover, the detection of weeds, pests and disease diagnosis became more reliable, which contributes to the active management of crops. Comprehensively, the findings indicate that the framework improves productivity, efficiency of resources, and sustainability of Controlled Environment Agriculture systems.

```
Using 'Year' as the rainfall target column.

Random sample index: 98
Predicted rainfall ('Year'): 2004.33

Feature values used for prediction:
Area Code          23
Element Code     5419
Item Code          27
Year Code        1972
Year             1972
Value           17213
Name: 3948, dtype: int64
```

Figure 6 Predicted Rainfall Using Crop Yield Prediction Dataset.
Source: Authors, (2026).

The figure 6 shows the machine learning prediction outcome on the Crop Yield Prediction Dataset. Some of the features used in the model include Area Code, Element Code, Item Code, Year Code, Year and Value, which are used to predict the rainfall. The input sample in this case is the Year 1972 with the value of 17213. Nonetheless, the model forecasts the year related to rainfall as about 2004.33 which implies that the target variable is the year column according to the trend of rainfall. This implies that this model is trying to infer the year using the past information on crop yield and rainfall, this information can be used to analyze the trend of climates and in agricultural planning.

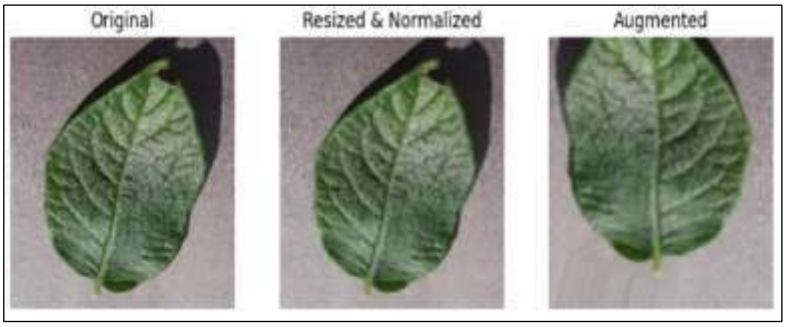

Figure 7: Image preprocessing for plant leaf analysis.
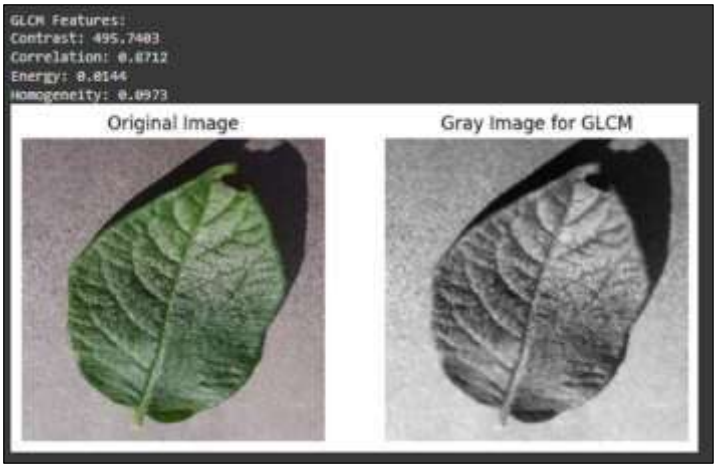
Source: Authors, (2026).

In agriculture, preprocessing is essential in the preparation of plant leaf images to undergo analysis in the form of deep learning. It starts with the original picture, which is reshaped to a specified size, making all the images in the dataset the same size. Normalization is then done to scale the pixel values between 0 and 1 that enables a faster convergence in the training. In order to enhance the robustness of the model even more, a set of data augmentation methods, including rotation, shifting, and flipping are proposed, producing various variants of the same picture. Such measures not only stop overfitting, but they also increase the capability of the model to identify plant diseases, pests and anomalies accurately in different environmental conditions depicted in figure 7.



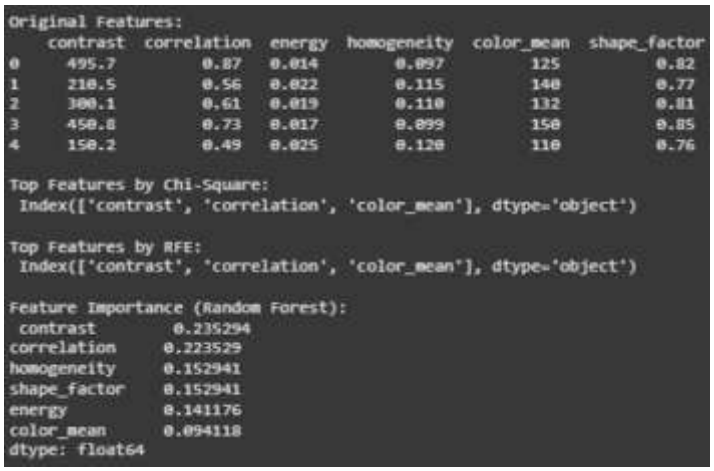


Figure 8: GLCM Texture Feature Extraction in the Analysis of Plant Leaf.
Source: Authors, (2026).

The diagram in figure 8 illustrates how the Gray Level Co-occurrence Matrix (GLCM) can be used to extract texture features out of a plant leaf. The original image is turned into grayscale and thus texture analysis is obtained by recording the relationship between pixel intensity. The features that are extracted are contrast, correlation, energy, and homogeneity that measure structural patterns in the leaf. These values are useful in the differentiation of healthy and diseased leaves by showing differences in texture. High contrast means high intensity variations, correlation measures pixel dependency, energy reflects uniformity, homogeneity takes care of smoothness. This type of feature extraction is important to precise disease detection and classification in precision agriculture

Original Features:

	contrast	correlation	energy	homogeneity	color_mean	shape_factor
0	495.7	0.87	0.014	0.097	125	0.82
1	210.5	0.56	0.022	0.115	140	0.77
2	300.1	0.61	0.019	0.110	132	0.81
3	450.8	0.73	0.017	0.099	150	0.85
4	150.2	0.49	0.025	0.120	110	0.76

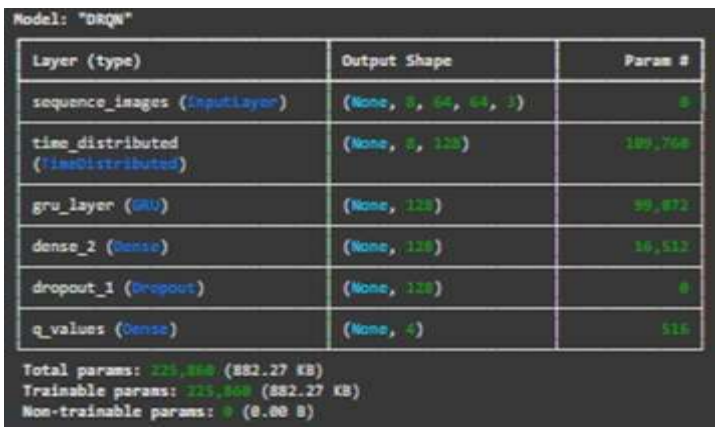
Top Features by RFE:
Index(['contrast', 'correlation', 'color_mean'], dtype='object')



Feature Importance (Random Forest):

contrast	0.235294
correlation	0.223529
homogeneity	0.152941
shape_factor	0.152941
energy	0.141176
color_mean	0.094118

dtype: float64

Figure 9: Importance Analysis and Feature Selection of Plant Leaf.
Source: Authors, (2026).

The results of feature selection and ranking methods used on plant leaf data are presented in the figure 9. Original features like contrast, correlation, energy, homogeneity, colour mean and shape factor were taken into account. The most important feature common to both Chi-Square and RFE methods was contrast, correlation, and colour mean. This was also confirmed by the random Forest feature importance which ranked contrast and correlation as highly influential, then homogeneity and shape factor. The choice of those features brings out the key texture and colour patterns in leaves to detect and classify diseases more accurately, and compress dimensions to make the model more efficient and robust.

Figure 10: DRQN Model Overview of Sequential Image-based Decision Making.
Source: Authors, (2026).

DRQN model is a model of deep reinforcement learning that can process images in a sequence and decide them with reference to time patterns. It receives a series of 64×64×3 size images and it first processes them through Time Distributed layer to identify spatial features per frame. These attributes are then fed to a GRU layer that picks up the temporal dependencies and patterns in the sequence. Dense and dropout make the generalization and overfitting less significant. Lastly, the Q-values layer produces decision making action-value outputs. Having approximately 225K parameters, the model is good at balancing space and time-based learning on reinforcement tasks as demonstrated in figure 10.

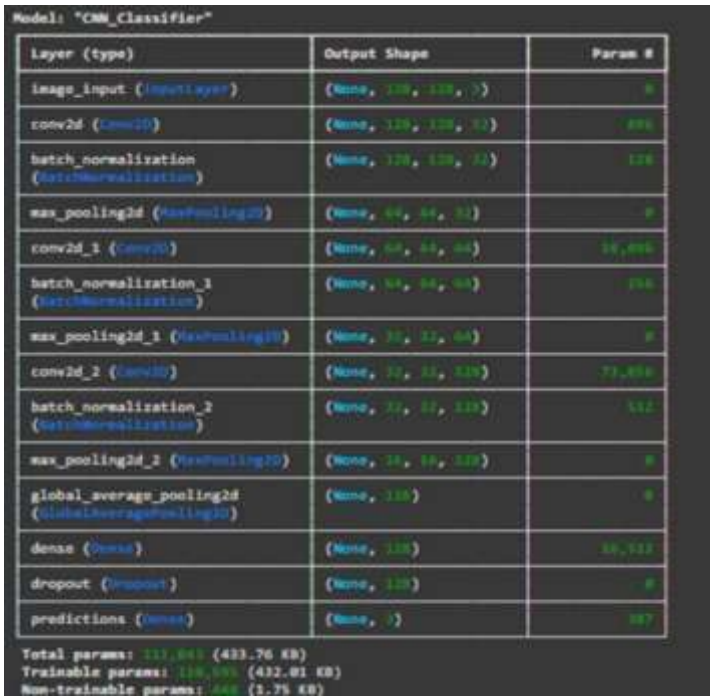

Figure 11: CNN Model Summary for Image Classification.
Source: Authors, (2026).

The CNN Classifier model shown is a lightweight deep learning model that is used in image classification. It takes input images of dimension 128x128x3 and processes them sequentially with convolutional layers which detect hierarchical features, including edges, textures and patterns. Max-pooling layers are used to reduce spatial dimensions and stabilize training by introducing batch normalization layers that preserve the main information, which is crucial, and ensure a cost reduction in computation. The global average pooling layer reduces feature map to a small representation and this is followed by dense and dropout layers to enhance generalization and decrease overfitting. Lastly, the prediction layer gives a probability of classifications. The model is effective in terms of efficiency and performance with about 111K parameters as illustrated in figure 10.

Figure 12: Training and Validation Accuracy and Loss per epoch.
Source: Authors, (2026).

Figure 12 illustrates the trend of training and validation accuracy (blue curves) and loss (red curves) with respect to the increasing number of epochs. The validation accuracy and training are gradual, the reason being that the model is learning well, and extrapolating the lesson to the unfamiliar material. At the same time, the training and validation loss decreases and decreases with a decrease in prediction errors. The close correlation between the training and validation curves also indicates that the model is neither overfitting nor underfitting, but that there is a compromise between memorizing the training data and achieving good performance on the validation data. This means a highly trained and healthy deep learning model.

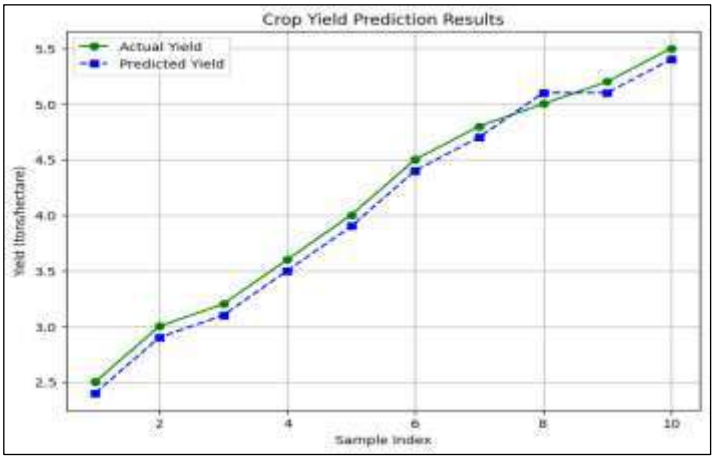

Figure 13: Crop Yield Prediction.
Source: Authors, (2026).

Figure 13 below is a comparison of the real crop yield values to the model estimates of the deep learning model. The observed yield curve or the green one reflects the observed yield and the blue dashed line reflects the predicted yield. The two curves are almost similar in trend, which means that the model is able to predict crop yield correctly in various samples. The small disparity between the actual and the anticipated values underscores the strength and the soundness of the method. This congruence indicates that the prediction model can help to make effective decisions in agriculture by giving relevant yield estimates, which translates to an improved resource planning process and sustainable farming.

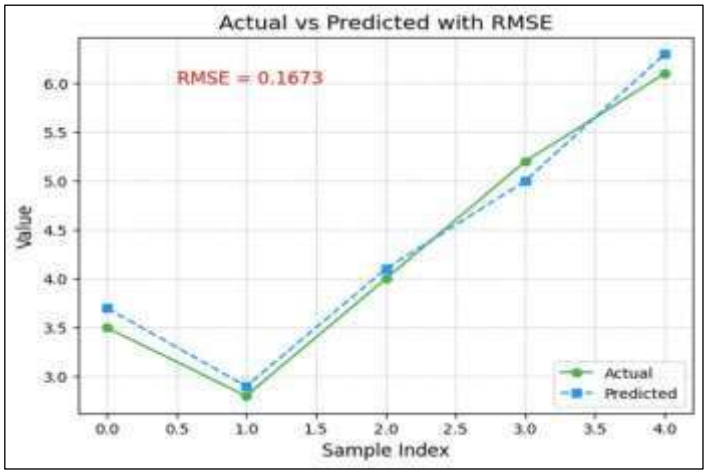

Figure 14: Actual vs Predicted with RMSE.
Source: Authors, (2026).

The figure 14 shows the comparison between actual and predicted values in the crop yield prediction model. These two lines are usually moving in the same direction where they show that the model is capable of providing results that are similar to the real-world outcomes. Root Mean Square Error (RMSE) of 0.1673 is low, and it implies that the average value of the difference between the predictive and actual values is low, which demonstrates the high precision of predictions. This minor mistake brings out the capability of the model to generalize well in different samples. This kind of forecasting is very important in the agricultural decision-making process as it allows farmers and other stakeholders to strategize resource distribution, minimize risk and enhance the overall production.

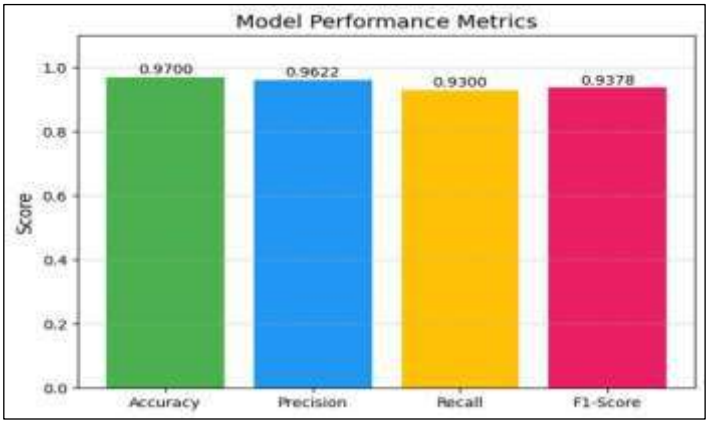

Figure 15: Performances Metrics.
Source: Authors, (2026).

The model presented in figure 15 was able to predict with an accuracy of 0.97% which indicates a high level of reliability. Its precision 0.962% points to the fact that it has reduced false positive rate, whereas its recall 0.93% points to its high sensitivity in detecting the relevant cases. The F1-score 0.937% is the combination between the precision and the recall, which ensures the overall effectiveness and soundness of the classification model.

V. CONCLUSION

This paper has proven that a Monitoring Digital Twin (mDT) framework is effective in Controlled Environment Agriculture (CEA), where deep learning, edge computing, and real-time automation can be used to maximize crop yield and achieve sustainable use of resources. Using SELEC DIGIX-1 PLC and other sensors to regulate the environment and to acquire data, the structure will correctly monitor and predict the crop yield and weed, pests, and plant diseases. The prediction and early detection of anomalies are further better than the conventional methods with the adoption of advanced deep learning models, specifically, Deep Recurrent Q Network with Convolutional Neural Networks. DynamoDB allows storage and retrieval of historical and real time data and the SP112-GT40-S-CE HMI provides the control to visualize that data and make informed decisions locally and remotely. The findings indicate that the application of digital twins with advanced AI models would greatly enhance productivity, efficiency, and sustainability of CEA systems in the future, as well as apply multi-crop environments, consider other environmental conditions like CO 2 concentration and humidity dynamics, and use adaptive control strategies through reinforcement learning to make autonomous decisions. In addition, cloud-edge hybrid computing can improve scalability and make data sharing between different farms possible, enabling the establishment of completely intelligent and self-optimizing smart farming systems.

ABSTRACT

Accurate identification of developing events is crucial in achieving reactor operation safety, decision making and accident management. Machine learning techniques are increasingly used as alternative to conventional model based methods due to their data driven nature for abnormal event detection. Among these, the K-Nearest Neighbors (KNN) algorithm remains widely used across industrial diagnostic systems, including applications in nuclear reactor monitoring, owing to its simplicity and good performance in multi class classification tasks. However, a key limitation of standard KNN is that all input features are treated with equal importance, which can limit its accuracy. To address this limitation, this study proposes a Random Forest guided feature weighted KNN classifier for reactor event identification. In the proposed approach, feature importance extracted from a Random Forest model is utilized to strengthen the ability of standard KNN model. The method is evaluated on a five class nuclear reactor event dataset and is found to outperform the base KNN and RF models. The performance of the proposed model is also compared with other KNN - RF ensemble methods and is shown to perform the best among all with superior performance metrics.

I. INTRODUCTION

Early detection of abnormal conditions is very important to preserving reactor safety through timely intervention by operators. Conventionally, decisions about plant operation in the control room were based on alarms/trip systems, displays for monitoring plant conditions, and emergency operating procedures. These systems have limitations because they were developed from simplifications of fundamental physical laws and they operate in response to those events which are covered under such principles. Further, accurate modelling of nuclear reactors via first principles could be challenging due to the complicated process behavior, therefore it limits the uses of model-based diagnostics entirely. On the other hand, in contrast to first principle methods, data driven methods learn patterns from operational data and real time measurements and hence do not require detailed mathematical descriptions regarding reactor behavior. Since modern industrial plants including nuclear plants acquire large amounts of operational data, the information can be utilized to train machine leaning models to identify developing events in their earlier stages. Whenever an event occurs, operators in a nuclear reactor control room is expected to analyze many signals, alarms and trends simultaneously under huge mental pressure. Human error has been identified as an important contributor to nuclear accidents worldwide. Hence, machine learning techniques can be used to develop data driven systems learning from huge volumes of operational data to provide diagnostic support to the operators reducing human errors. Owing to their benefits in terms of safe and cost effective reactor operation, many techniques for the identification and diagnosis of events have been studied. In general, such approaches aim to represent relationships within reactor systems or derive informative features through pattern recognition strategies, enabling the detection of abnormal reactor conditions based on measured process data [1]. In recent years, there has been a growing shift toward the use of data driven methodologies for monitoring nuclear reactors.

Currently, a wide range of machine learning techniques—such as neural networks, support vector machines (SVMs), dimensionality reduction algorithms, ensemble learning frameworks, regression models, and others—have been adopted to forecast the operational behavior of nuclear power plants, as noted by Hu G et al. [2]. Moreover, machine learning tools, including advanced deep learning architectures, are increasingly applied for condition monitoring, equipment health evaluation, and remaining useful life (RUL) estimation within nuclear facilities [3], [4]. Studies illustrate the use of SVM based models [5], [6], where deviations in process variables are exploited to identify potential accident scenarios in reactors. Reference [7] proposes a diagnostic approach that not only detects faults but also quantifies their severity by combining Principal Component Analysis with neural network techniques. In [8], Santosh et al. developed a neural network driven framework to diagnose severe coolant loss events in nuclear power plants. Additional research has explored a variety of data driven solutions for assessing and managing plant wide and component level health conditions, as summarized in [9].

Reference [10] examines multiple classification techniques—such as PCA, SVM, decision trees, and hybrid schemes—for identifying equipment and actuator faults in PWR systems. Meanwhile, [11] reports that ensembles based on nearest neighbor classifiers achieved the highest accuracy for fault detection, whereas ensembles composed solely of decision trees performed comparatively poorly. Motivated by these works, our earlier work involved development of KNN model for the purpose of transient event identification in reactors [12]. The developed KNN model achieved an accuracy of 97% which is a hold out test data performance. In this work, a novel method is proposed for an improved KNN model for event identification with enhanced accuracy. The proposed model is a Random Forest guided feature weighted KNN classifier to improve the accuracy of classification. By integrating the local feature relevance derived from Random Forests with the neighbourhood based decision structure of KNN, the proposed model is shown to outperform the basic KNN model and other KNN-RF ensemble models. Different performance metrics of the model such as categorical accuracy, confusion matrix, class wise performance score are studied and are shown to provide the best results when compared with the other models.

II. PROBLEM STATEMENT AND DATASET

II.1 EVENT DETECTION

Systems that support timely event detection are crucial to maintaining the safe operation of any nuclear reactor. Research or test reactors, in particular, consist of highly intricate subsystems designed both for operational safety and for carrying out diverse experimental activities. This paper focuses on identifying abnormal events in such test reactors using a data driven strategy built upon a novel machine learning framework. In these facilities, the reactor core is usually located within a large pool filled with demineralized light water, which serves simultaneously as coolant and moderator. Under normal operating conditions with offsite electrical power available, primary cooling pumps ensure forced circulation around the core. Heated coolant is routed through heat exchangers, where its thermal energy is transferred to the secondary cooling loop. The secondary loop employs its own set of pumps that drive water toward cooling towers for ultimate heat removal.

If offsite power is lost, core cooling relies on natural circulation within the pool, enabled by passive valves engineered to open automatically and permit flow. Throughout operation, vital plant variables—including process parameters and equipment status indicators—are continuously monitored and archived. Because of their extensive instrumentation, these reactors generate and log large volumes of process data [13], [14]. Within nuclear reactor safety design and assessment, Postulated Initiating Events (PIEs) play a critical role. These events represent potential triggers that may drive the reactor away from its normal operational state, possibly progressing into anticipated operational occurrences or even accident scenarios. Rapid identification and mitigation of such events are essential, making the precision of detection systems or models highly important. For this reason, the present study approaches the challenge through the application of an appropriate and innovative machine learning methodology.

II.2 DATASET

Training effective machine learning models relies on the availability of credible and well defined datasets. In this work, the training data are generated by simulating key PIE scenarios using thermal hydraulic codes capable of reproducing the dynamic behavior of accident conditions in light water reactors, including research reactors [15], [16]. Such events represent transients which are departures from normal conditions that may occur due to abnormal system behavior. These transients can stem from a variety of sources, including equipment malfunctions, operator mistakes, and both internal and external hazards. For the reactor examined in this study, the relevant events were selected in accordance with IAEA SSR-3, the international standard that outlines essential safety requirements for research reactors [17]. Four significant events typical of test research reactors were chosen, and simulated data from these scenarios were used for model development. Table 1 summarizes the set of events considered in this work. Each scenario is generated through a detailed event sequence analysis, which produces time dependent trends for the plant parameters affected during the transient. For the four selected events, 16 operational variables were identified as influential. These 16 measurements serve as the feature set used to train and construct the machine learning models. Consequently, the dataset is a labeled one comprising five classes, including a baseline class that represents normal operation with no event. The feature set includes both continuous variables such as reactor power, coolant flow rate, and heat exchanger temperatures, and categorical indicators, including various reactor trip signals, alarm activations, and the status of passive cooling valves, among others.

Table 1: Events modeled for detection.

S.No.	Event
1	Failure of offsite power event
2	Failure of pump flow event
3	Loss of coolant event
4	Failure of heat sink event

III. METHODOLOGY

III.1 K-NEAREST NEIGHBORS CLASSIFIER

One of the simplest and most understandable supervised learning methods for classification is the K-Nearest Neighbors (KNN) algorithm. The main principle is that in the feature space, data points belonging to the same class typically appear near one another. Therefore, we may use the labels of the closest samples in the training set to estimate the class of a new, unseen sample. Considering training dataset D,

$$\{(x_1, y_1), (x_2, y_2), \dots (x_N, y_N)\}, \tag{1}$$

where $x_1 \epsilon \ \mathbb{R}^d$ represents a d dimensional feature vector and y_i is the corresponding class label, the goal is to assign class to a new sample x. The KNN classifier performs this in the following steps:

1. Measure the distance between the test sample x and all samples in the training set.
2. Identify the nearest K samples, referred to as the "neighbors."
3. Perform majority voting among these Kneighbors.
4. The class receiving the highest number of votes is assigned to x.

Mathematically, this can be expressed as:

$$\hat{y}(x) = mode\{y(1), y(2), \dots, y(K)\}, \tag{2}$$

where $y(i)$ denotes the class label of the i-th nerest neighbor.

Distance metric plays a crucial role in KNN. Commonly used metrics include:

- Euclidean distance

$$\mathrm{d_E(x, x_i)} = \sqrt{\sum_{\mathrm{j=1}}^{\mathrm{d}} \left(\mathrm{x_j - x_{i,j}}\right)^2} \tag{3}$$

- Manhattan distance

$$d_M(x, x_i) = \sum_{j=1}^{d} \left| x_j - x_{i,j} \right| \tag{4}$$

The decision boundary formed by KNN is non linear and adapts to the data distribution. This characteristic makes it suitable for complex classification tasks such as nuclear event identification, where the feature relationships are often non linear. The choice of Ksignificantly affects the classifier's performance. A small K makes the classifier sensitive to noise and outliers, potentially overfitting. A larger K smooths the decision boundary and improves generalization but may overlook small scale structures in the data [18]. KNN is a relatively simple to use and straightforward algorithm. Since there is no training phase, it is adaptable to incremental data. KNN is one of the most suitable models to handle multiclass problems. However, KNN suffers from the curse of dimensionality and is sensitive to duplicate or noisy features [19]. Without specific weighting, contribution of each feature is treated equally by the algorithm. These limitations are especially pertinent to complicated industrial datasets, such nuclear reactor transients, where some features could be more important than others. This insight naturally emphasizes the necessity for an improved classifier that guides the decision making process by incorporating extra knowledge, such as feature importance information.

III.2 RANDOM FOREST CLASSIFIER

Random Forest is an ensemble learning method that constructs a collection of decision trees and aggregates their outputs to improve classification reliability. The core idea is that multiple weak learners, when combined in an intelligent manner, can form a strong and robust classifier. Random Forests are particularly effective for complex, nonlinear datasets such as those encountered in nuclear reactor monitoring, where different features may influence the event dynamics in varying ways [20]. The concepts of random feature selection and bootstrap aggregation (bagging) are used to construct a Random Forest. A bootstrap sample taken from the original dataset is used to train each tree in the forest. Furthermore, only a randomly chosen subset of features is taken into account for determining the optimal split during each tree's growth. Because the trees are diverse due to these two types of randomness, there is less chance of associated errors [21]. Let the training dataset be

$$\{(x_1, y_1), (x_2, y_2), \dots (x_N, y_N)\} \tag{5}$$

Where $x_1 \epsilon \ \mathbb{R}^d$ represents a d dimensional feature vector and y_i is the corresponding class label. For each tree T_b, a bootstrap sample $D_b$is drawn by sampling N times with replacement from the original dataset D. Some samples may appear multiple times, while others may be excluded (out of bag samples). At each internal node of tree T_b, instead of evaluating all features, only a randomly selected subset $F_b \subseteq \{1,2, \dots, d\}$ is considered for splitting. Because of this, there is reduced correlation between trees and it helps capture different structural relationships in the data. Each decision node chooses the feature and threshold that offers the greatest reduction in impurity. One of the most used impurity measure, Gini impurity is defined for a dataset D as:

$$Gini(D) = 1 - \sum_{k=1}^{c} p_k^2 \tag{6}$$

Where p_k is the proportion of samples belonging to class k, and C is the total number of classes. If a split on feature f divides the data into subsets D_{left} and D_{right}, the impurity reduction is

$$\Delta Gini(f) = Gini(D) - \left\{ \frac{|D_{left}|}{|D|} Gini(D_{left}) + \frac{|D_{left}|}{|D|} Gini(D_{right}) \right\} \tag{7}$$

The feature and threshold giving the maximum ΔGini are selected for that node [22]. Once all trees are trained, classification of a new sample x is performed by passing it through each tree. Each tree produces an output $T_b(x)$, and the forest prediction is obtained through majority voting:

$$\hat{y}(x) = mode\{T_1(x), T_2(x), \ldots, T_3(x)\} \tag{8}$$

Where B is the total number of trees. The misclassifications of each tree are often uncorrelated because they are trained on distinct subsets of data and characteristics. The ensemble greatly lowers variance and enhances generalization when combined. The capacity of Random Forests to produce a quantitative assessment of feature relevance is a key feature. The impurity reduction ascribed to each feature across all trees is averaged to calculate this.

III.3 RF–KNN HYBRID LEARNING APPROACHES

Random Forest and KNN possess complementary characteristics. While Random Forest is a powerful ensemble learner capable of handling nonlinear relationships and providing feature relevance information, KNN is a simple yet effective local classifier that operates based on distance relationships. Several hybrid strategies have been proposed in literature to utilize the strengths of both models. The most commonly adopted approaches are summarized below.

III.3.1 Voting Based RF–KNN Ensemble

In voting based ensembles, RF and KNN act as independent base classifiers. For a given test sample x, each classifier produces a class prediction, and the final output is determined based on majority voting [23]. If $\hat{y}_{\text{RF}}(x)$ and $\hat{y}_{\text{KNN}}(x)$ represent the predictions from RF and KNN respectively, the ensemble decision is given by

$$\hat{y}(x) = mode\,\{\hat{y}_{\text{RF}}(x), \hat{y}_{\text{KNN}}(x)\} \tag{9}$$

In soft voting, the class probabilities are averaged:

$$P(c \mid x) = \frac{1}{2}\left(P_{RF}(c \mid x) + P_{RF}(c \mid x)\right) \tag{10}$$

Although this approach often improves robustness, it does not exploit the internal knowledge of either model beyond their final predictions.

III.3.2 Stacking Based RF–KNN Ensemble

In stacking, RF and KNN serve as base learners, while a separate meta classifier is trained to combine their outputs [24]. Let the predictions of RF and KNN for a sample x be concatenated as:

$$z(x) = [\hat{y}_{\text{RF}}(x), \hat{y}_{\text{KNN}}(x)] \tag{11}$$

A meta classifier $f_m(\cdot)$ is then trained such that:

$$\hat{y}(x) = f_m(x) \tag{12}$$

Stacking enables the learning of nonlinear relationships between base classifier outputs, but it introduces additional model complexity and it requires careful cross validation in order to avoid overfitting.

III.3.3 Feature Level Fusion of RF and KNN

In feature level fusion, transformed feature representations obtained from RF are concatenated with the original input features and given to a KNN classifier or another learning model [23]. If x is the original feature vector and $h_{\text{RF}}(x)$ represents the RF induced feature transformation, the fused feature vector is:

$$x_{fusion} = [x, h_{\text{RF}}(x)] \tag{13}$$

KNN is then applied in this expanded feature space. This approach increases representational power but also increases dimensionality and computational cost. While the above strategies combine RF and KNN at the decision level or feature level, they do not explicitly utilize the feature importance knowledge generated by RF to guide the distance computation in KNN, which forms the central idea of the proposed model.

III.3.4 Proposed RF Guided Feature Weighted KNN Model

The proposed model integrates Random Forest and KNN in a more informed manner by embedding feature importance knowledge from RF directly into the KNN distance metric. Unlike conventional fusion strategies, here RF does not merely act as an independent classifier but provides guidance to KNN in the form of feature relevance. In standard KNN, all features contribute equally to the distance computation. However, in nuclear reactor systems, different parameters contribute unequally to various transient events. Noisy or weakly relevant features can distort distance measurements and lead to incorrect neighbor selection. Therefore, introducing feature weight awareness into KNN is essential to improve classification reliability. Random Forest offers a natural framework for estimating feature relevance based on impurity reduction [25]. In this work, this information is exploited to construct a feature weighted distance metric for KNN.

III.3.4.1 Feature Importance Extraction using Random Forest

A Random Forest consisting of Bdecision trees is trained on D. For each feature f_j, the importance is computed by aggregating the Gini impurity reduction over all the trees:

$$I(f_j) = \frac{1}{B}\sum_{b=1}^{B}\sum_{n \in T_{b(f_j)}} \Delta Gini_{b,n} \tag{14}$$

where $\Delta\text{Gini}_{b,n}$ denotes the impurity reduction achieved by node n of tree T_b when splitting on feature f_j. The resulting importance vector is:

$$\boldsymbol{I} = [I(f_1), I(f_2), \ldots, I(f_d)] \tag{15}$$

This vector is normalized such that:

$$w_j = \frac{I(f_j)}{\sum_{k=1}^{d} I(f_k)} \tag{16}$$

The normalized vector

$$W = [w_1, w_2, \ldots, w_d] \tag{17}$$

Represents the relative importance of each feature.

III.3.4.2 Feature Weighted Distance Metric for KNN

The conventional Euclidean distance between two samples x and $x_i$is defined in equation 3. In the proposed model, this is modified into a feature weighted Euclidean distance:

$$d_w(x, x_i) = \sqrt{\sum_{j=1}^{d} w_j (x_j - x_{i,j})^2} \tag{18}$$

Where w_j represents the importance weight of the j-th feature obtained from Random Forest. This formulation ensures that features with higher diagnostic relevance have a stronger influence on the neighbor selection process, while less informative features are automatically suppressed.

III.3.4.3 RF Guided KNN Classification Procedure

For a test sample x:

1. Compute weighted distances $d_w(x, x_i)$ to all training samples.
2. Identify the Knearest neighbors based on these distances.
3. Assign x to the class receiving the majority vote among its neighbors:

$$\hat{y}(x) = mode\{y_{(1)}, y_{(2)}, \ldots, y_{(k)}\} \tag{19}$$

The operational sequence of the model is given in figure 1. This structure highlights how Random Forest acts as a knowledge provider, guiding the neighbor selection process of KNN.

III.3.5 Data Preprocessing and Modeling Strategy

III.3.5.1 Data Preprocessing and preparation

All input features are normalized using z-score normalization to eliminate scale dominance:

$$x' = \frac{x-\mu}{\sigma} \tag{20}$$

where μ and σ denote the mean and standard deviation of a feature respectively.
The dataset is divided into three mutually exclusive subsets:

- **Training set** – used to train the Random Forest and KNN
- **Validation set** – used for hyperparameter optimization
- **Test set** – used for final performance evaluation

This separation ensures unbiased performance estimation.

III.3.5.2 Modeling and Hyperparameter Configuration

The performance of KNN is highly sensitive to the choice of K and the distance metric. To obtain the optimal configuration, a grid search combined with cross validation is employed on the training validation set.

The following hyperparameter ranges are explored:

- $K \in \{1,2,\ldots,30\}$
- Distance metric $\in$ {Euclidean, Manhattan}

For each parameter combination, cross validation accuracy is computed, and the configuration that yields the maximum average accuracy is selected. The optimal hyperparameters obtained for this study are: $K = 27, Distance\ Metric =$ Euclidean. The Random Forest model is trained to extract feature importance information required for the proposed RF guided weighted KNN framework. Optimal hyperparameters are obtained after performing grid search combined with cross validation. The following hyperparameter ranges are explored:

- No. of trees $N \in \{10,30,\ldots,200\}$

Other parameters of the model are chosen as

- Splitting criterion : Gini
- Maximum number of features at each split : $\sqrt{d}$, where d is the number of features.
- Maximum tree depth : None
- Minimum samples to split an internal node: 2
- Minimum samples in a leaf node: 1

The optimal number of trees obtained from hyperparameter tuning is N =70. After completing the independent modeling stages of KNN and Random Forest, both models are integrated by incorporating the feature importance weights in to the Euclidean distance calculation for the KNN classifier. Since the proposed RF guided weighting modifies only the distance metric and not the neighborhood structure, the optimal value K = 27, obtained from the standard KNN optimization, was retained for the weighted KNN model. After hyperparameter selection, the final RF guided weighted KNN model is trained using the combined training and validation data. The trained model is then evaluated on an independent hold out test dataset to assess its generalization capability.

IV. PERFORMANCE METRICS

The performance of the proposed RF guided feature weighted KNN classifier is evaluated using several standard classification metrics, namely accuracy, confusion matrix, precision, recall, and F1-score [26]. Since the considered problem involves multi class nuclear reactor event identification, it is essential to assess not only the overall classification accuracy but also the class wise prediction behavior. Each metric used in this study is briefly described below. The confusion matrix is the fundamental tool used to visualize the classification performance. For a multi class problem with C classes, the confusion matrix is a $C \times C$ matrix, where the element M_{ij} denotes the number of samples belonging to class i that are predicted as class j. For a single class k, the following quantities are defined:

- **True Positives (TP)**: samples correctly classified as class k
- **False Positives (FP)**: samples incorrectly classified as class k
- **False Negatives (FN)**: samples of class k misclassified as other classes
- **True Negatives (TN)**: samples correctly classified as not belonging to class k

The confusion matrix provides detailed insight into which events are correctly detected and which are confused with one another. A typical confusion matrix for a 2 class problem is shown below:

$$\begin{bmatrix} TP & FN \\ FP & TN \end{bmatrix} \tag{21}$$

Accuracy represents the proportion of total correctly classified samples to the total number of samples:

$$Accuracy = \sum_{i=1}^{C} M_{ii} \tag{22}$$

where:

- M_{ii} represents the diagonal elements of the confusion matrix (correct classifications),
- C is the number of classes,
- N is the total number of samples.

Although accuracy offers a broad indicator of performance, it does not show how effectively individual classes are recognized, particularly in situations when class distributions are unbalanced. For safety critical applications like nuclear reactor event identification, precision alone is therefore insufficient. Precision quantifies the percentage of samples that are correctly predicted to belong to a particular class. For class k:

$$Precision_k = \frac{TP_k}{TP_k + FP_k} \tag{23}$$

Precision is particularly important when false alarms are costly. In reactor monitoring, high precision ensures that when a specific transient is predicted, the likelihood of it being a false detection is low. Recall (also known as sensitivity or true positive rate) measures how many of the actual samples of a class are correctly identified:

$$Recall_k = \frac{TP_k}{TP_k + FN_k} \tag{24}$$

In safety related systems, recall is crucial since it shows how well the model can identify real anomalous events. A low recall suggests that the system might miss some crucial transients, which could result in dangerous situations. The F1-score is a fair performance indicator for every class and is the harmonic mean of precision and recall. F1 score is defined as:

$$F1_k = 2 * \frac{Precision_k * Recall_k}{Precision_k + Recall_k} \tag{25}$$

V. RESULTS AND DISCUSSIONS

This section presents the experimental results obtained for the standard KNN classifier, Random Forest classifier, various RF–KNN hybrid ensemble methods, and the proposed RF guided feature weighted KNN model. Initially, the individual base models were trained and optimized independently. Subsequently, different ensemble strategies, namely voting ensemble, stacking ensemble, and feature level fusion, were implemented and evaluated.

Finally, the proposed RF guided feature weighted KNN model was trained using the optimized hyperparameters and tested on a hold out dataset. The results are analyzed using accuracy trends, feature importance visualization, comparative performance plots, and the normalized confusion matrix. Figure 1 illustrates the variation of KNN classification accuracy as a function of the number of neighbors K. It can be observed that the accuracy increases rapidly for small values of K, indicating improved generalization as noise sensitivity reduces. Beyond this region, the performance gradually stabilizes as K increases. The accuracy reaches a peak and remains nearly constant in the range $K = 25$ *to* $K = 30$. indicating that the classifier has achieved a good balance between bias and variance. Based on this trend, $K = 27$ is selected as the optimal value for the KNN classifier and is used for all the hybrid models. Figure 2 shows the classification accuracy of the Random Forest classifier for different tree counts. As the number of trees increases, the performance first improves because to better ensemble averaging and reduced variation. However, adding more trees doesn't really improve the situation until the accuracy hits saturation. The plot clearly shows that the best accuracy is obtained with 70 trees, and the accuracy stabilizes after roughly 100 trees. Beyond this, raising the ensemble size primarily leads to increased computing costs and overfitting. This shows that a moderate number of trees is sufficient for precise feature extraction and classification in the given situation.

Source: Authors, (2026).

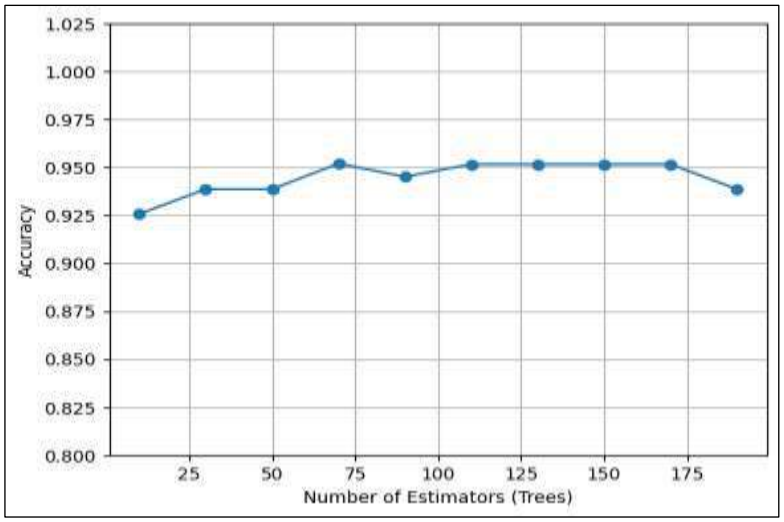

Figure 2: Accuracy Vs No. of estimators (trees) plot of Random Forest classifier model.
Source: Authors, (2026).

The trained Random Forest model's feature importance ratings are shown in Figure 3. It is evident that just a small number of features have a significant influence on the classification choice, whereas a number of features have comparatively little significance. The basic rationale for the suggested method—that considering all features equally in distance computation is not optimal for nuclear reactor event classification—is clearly supported by this observation. In the next KNN classification stage, the availability of such important information offers a solid foundation for the introduction of feature weighted distance computation. Performance metrics for several models are shown in Table 2, including the individual class F1 score and the total classification score for 1) Standard KNN 2) Random Forest 3) stacking ensemble 4) Voting ensemble 5) Feature level fusion 6) Proposed RF guided feature weighted KNN model. An overview of the models' comparative categorization accuracy is given in Figure 4. Strong baseline performance is demonstrated by the standard KNN classifier's high accuracy of 97.07%. At about 95.16%, the Random Forest classifier's accuracy is marginally lower. Although they offer a slight improvement over Random Forest, the stacking and voting ensembles are still not as good as the conventional KNN. Compared to the classical ensembles, the feature level fusion model produces a slight improvement. Nevertheless, the suggested RF guided feature weighted KNN model outperforms all individual models and hybrid baseline models with the maximum accuracy of 98.57%.

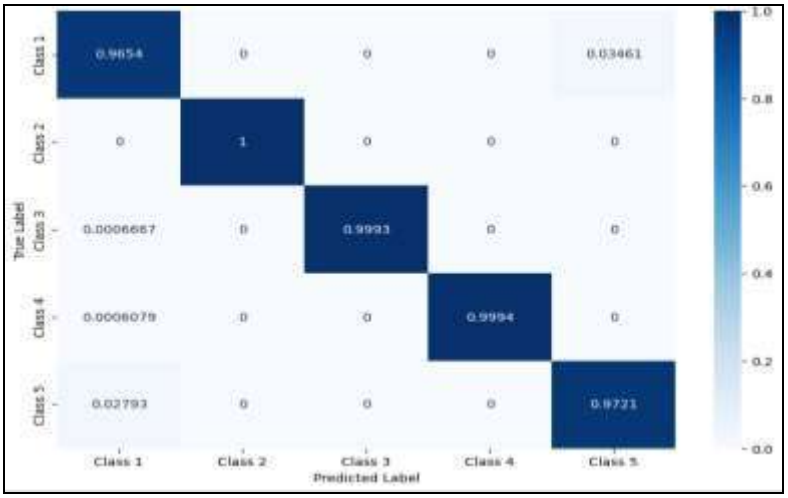

Figure 5: Normalized confusion matrix of the proposed RF guided feature weighted KNN model.
Source: Authors, (2026).

The proposed approach yields substantial improvements in the F1-scores of the relatively challenging event categories, namely Class 1 (No event) and Class 5 (Failure of heat sink event), where the F1-score improves from approximately 0.88–0.92 to 0.96 and 0.97, respectively. The remaining classes exhibit near perfect F1-scores across all models, indicating strong class separability. These improvements are consistent with the normalized confusion matrix in figure 5, which shows pronounced diagonal dominance and significantly reduced misclassification for the proposed model. This confirms that directly embedding Random Forest derived feature relevance into the KNN distance metric is more effective than combining classifiers only at the decision or feature fusion level.

V. CONCLUSIONS

In this work, a Random Forest guided feature weighted KNN classifier was developed to improve the performance of multi class reactor event classification. The key idea behind the proposed model is the integration of feature importance knowledge derived from Random Forest into the distance computation of KNN, thereby enabling the classifier to emphasize diagnostically significant reactor parameters while suppressing the influence of less informative features. The individual performances of KNN and Random Forest were first evaluated, followed by the implementation of several hybrid RF–KNN ensemble strategies, including stacking, voting, and feature level fusion. While these conventional ensembles offered marginal improvements, none of them surpassed the baseline KNN performance significantly. The proposed model, however, demonstrated a clear performance advantage. With the optimized hyperparameters and feature weighted distance formulation, the proposed RF guided KNN model achieved an overall classification accuracy of 98.57%, outperforming all baseline and ensemble models.

Class wise F1-scores further confirmed the robustness of the proposed method, especially for the more challenging event categories, where the F1-scores improved substantially compared to other approaches. The normalized confusion matrix illustrated strong diagonal dominance and minimal misclassification, validating the improved detection capability of the proposed model. These results collectively demonstrate that directly embedding Random Forest feature relevance into the KNN decision framework is a more effective strategy than combining the two models only at the decision or fusion stage. Overall, the proposed RF guided feature weighted KNN approach offers a simple and highly accurate method for nuclear reactor event identification. With improved performance, the work contributes to the growing field of safety in reactor operation and operator support, particularly where dependable event detection is critical.

AI system quality

ABSTRACT

Artificial intelligence is transforming human resource management by automating recruitment, employee development and performance management in entrepreneurial firms. Evidence on mechanisms linking AI-enabled HR practices, entrepreneurial achievement and employer reputation has been limited. This study aims to quantify relationships among AI adoption, AI system quality, entrepreneurial achievement and company reputation. Survey data from 110 HR professionals were analysed using SmartPLS with a five-point Likert scale. AI adoption affected perceived AI quality ($\beta = 0.769$, $P < 0.001$), indicating that integrating AI into HRM was associated with dependable systems. AI quality affected entrepreneurial achievement ($\beta = 0.815$, $P < 0.001$), entrepreneurial achievement significantly influenced company reputation ($\beta = 0.375$, $P = 0.033$), and direct links from AI adoption to entrepreneurial achievement and company reputation were not significant ($\beta = 0.027$, $P = 0.352$; $\beta = 0.030$, $P = 0.226$). These findings indicate that reputational gains stem from deploying AI in HR processes, and future research will examine longitudinal dynamics of AI-enabled HRM to support SDG-oriented governance.

I. INTRODUCTION

Artificial intelligence (AI) is becoming a foundational capability in contemporary organizations, reshaping decision processes, coordination mechanisms, and the use of information across functions. Human resource management (HRM) stands at the center of this transformation because people, skills, and learning determine whether technological innovation translates into sustained competitive advantage. HR functions now incorporate algorithmic screening, predictive analytics, and adaptive learning systems, which influence workforce composition, capability development, and internal perceptions of fairness and opportunity [1]. For entrepreneurial firms facing intense uncertainty and resource constraints, the quality of decisions on recruitment, employee development, and performance management is especially critical, making AI-enabled HR practices a strategic concern rather than a peripheral efficiency tool [2]. HRM encompasses a set of practices that attract, select, develop, evaluate, and retain employees in line with organizational goals. AI-based solutions already support candidate sourcing, résumé parsing, job–applicant fit matching algorithms, adaptive training platforms, and continuous performance monitoring. Studies on AI in organizational contexts reported gains in information processing, reduced cycle times, support for more evidence-based HR decisions, and improvements in coordination between HR and line managers [3].

Prior research on AI in management information systems and organizational performance examined these tools as part of broader digital infrastructures and often treated HR as one subsystem among many rather than as a distinct strategic domain. In parallel, research on entrepreneurial performance examined the roles of innovation capabilities, dynamic capabilities, and learning orientation, and it frequently highlighted talent and knowledge as central resources in young firms [4]. Entrepreneurial firms operate under volatile conditions where opportunities arise and fade quickly, customer needs change rapidly, and new business models appear alongside new technologies. In such settings, HRM is not only administrative; it shapes the capacity to experiment, scale promising initiatives, and pivot in response to feedback. AI-enabled HR practices promise better matching between roles and competencies, faster identification of potential, and more tailored development pathways. Earlier studies on AI in HRM examined discrete elements of this promise, such as automated recruitment screening, AI-supported learning platforms, and digital tools for performance reviews [5]. These contributions highlighted efficiency gains and sometimes reported positive responses from HR professionals and employees, yet they seldom connected those micro-level improvements to entrepreneurial outcomes such as innovation, adaptability, or new venture performance.

Another strand of work focused on reputational consequences of AI use in organizations. Research on employer branding and corporate reputation suggested that technology-intensive HR practices influence external perceptions of a firm as modern, innovative, and data-driven. Some studies reported that the visible use of AI in recruitment and employee development enhanced perceptions of professionalism and fairness among applicants and employees, while others raised concerns about opacity, bias, and privacy. Ethical debates around transparency, accountability, and bias mitigation in AI-based decision systems highlighted risks to organizational legitimacy when stakeholders questioned the foundations of automated judgments [6]. Despite this attention, prior work mostly examined large established firms or sector-specific cases and rarely linked AI-enabled HR practices in entrepreneurial firms to broader measures of company reputation as perceived by external stakeholders and potential employees. Within the entrepreneurship literature, researchers have long argued that digital technologies support opportunity discovery, resource orchestration, and scaling. AI-driven analytics in marketing, operations, and finance were studied as enablers of better forecasting, more accurate customer segmentation, and improved risk assessment. Empirical work on entrepreneurial firms that adopted AI often emphasized gains in operational efficiency and innovation, measuring outcomes through financial performance, productivity, or innovation outputs.

Yet these studies rarely considered HR as the primary locus of AI integration, even though hiring decisions, skill development, and performance management directly condition the firm’s capacity to exploit AI in other functions. Furthermore, entrepreneurial achievement was usually conceptualized through broad indicators without explicit reference to the contribution of AI-enabled HR practices [7]. A further limitation of prior research concerned the distinction between AI adoption and AI quality. Much of the empirical work treated adoption as a binary or scalar variable, focusing on whether organizations used AI tools and to what extent. Less attention was paid to attributes such as reliability, accuracy, predictive capability, and user trust, even though these attributes determine whether AI-based recommendations translate into effective decisions. Conceptual discussions suggested that poorly configured or low-quality AI systems could undermine HR outcomes by amplifying bias or generating misleading signals, whereas high-quality systems could augment human judgment. A small number of studies proposed that the quality of AI implementation could mediate the relationship between adoption and performance outcomes, but systematic empirical tests of this proposition remained limited, particularly in HR settings within entrepreneurial firms [8]. From a methodological perspective, many empirical contributions relied on single-path regression models or qualitative case studies, which constrained the ability to examine complex relationships among adoption, system quality, entrepreneurial achievement, and reputation.

Although structural equation modeling (SEM) is well-suited to analyzing latent constructs and mediated relationships, relatively few studies have used this approach to examine AI-enabled HR practices in entrepreneurial contexts. Those who adopted SEM often focused on technology acceptance or user intention rather than on entrepreneurial outcomes and company reputation [9]. As a result, existing evidence did not clarify the pathways through which AI adoption in HR, the quality of AI systems, and entrepreneurial achievement interact to shape perceptions of the firm as an attractive and innovative employer. The context of emerging economies adds another layer of importance to this topic. Entrepreneurial firms in countries such as India face distinctive constraints in talent availability, infrastructure, and institutional support, yet they also facetrong pressures to modernize and adopt digital tools [10]. Earlier studies on AI integration in HRM and entrepreneurial performance drew heavily on data from advanced economies or specific sectors, limiting the generalizability of their findings to settings in which firms operate with different resource profiles and regulatory environments. Evidence from Indian entrepreneurial firms that have already adopted AI-based HR systems remains sparse, especially when research requires access to HR professionals' internal perceptions and assessments of AI-enabled practices. This gap leaves practitioners without clear empirical guidance on which dimensions of AI use in HR matter most for entrepreneurial performance and reputation building in such settings [11]. Collectively prior research left several questions unresolved. The field lacks quantitative evidence that connects AI adoption in HRM, the perceived quality of AI systems, entrepreneurial achievement, and company reputation within a single integrated framework.

Existing work seldom treated entrepreneurial achievement as a mediating mechanism linking AI-related constructs to external perceptions of the firm, even though theory suggests that reputational benefits arise when stakeholders associate the organization with successful innovation and adaptability. Furthermore, validated measurement scales for AI adoption and AI quality in HR practices within entrepreneurial firms have not been widely applied, limiting comparability across studies and weakening the empirical basis for managerial recommendations [12]. The present study addresses these limitations by focusing on entrepreneurial firms that have integrated AI into core HR practices, specifically recruitment, employee development, and performance management, and by modeling the relationships among AI adoption, AI quality, entrepreneurial achievement, and company reputation using a structural equation approach with Smart Partial Least Squares. The study introduces a framework in which AI adoption and AI quality function as distinct but related constructs, entrepreneurial achievement serves as a mediating variable, and company reputation serves as the key outcome from the perspective of employer image. By focusing on HR-focused AI integration in entrepreneurial firms in India, the study addresses the need for context-sensitive evidence on technology-enabled HRM and its strategic consequences [13]. The purpose of this study is to examine the extent to which AI adoption and AI system quality in HR practices contribute to entrepreneurial achievement in entrepreneurial firms, and to assess the role of entrepreneurial achievement in shaping company reputation in an emerging economy context using Smart PLS

II. MATERIALS AND METHODS

The study was designed as a quantitative, cross-sectional investigation of the integration of Artificial Intelligence into Human Resource practices within entrepreneurial firms in India. A structured online questionnaire was administered to Human Resource professionals, and the collected data were subjected to variance-based structural equation modelling using SmartPLS. The methodological process extended from construct operationalization and instrument development to sampling and data collection, and then to data preparation, measurement model evaluation, and structural model estimation. The sequential stages of the research design are presented in Figure 1, and the principal constructs and indicators used in the measurement model are summarised in Table 1. The target population consisted of Human Resource professionals employed in entrepreneurial firms operating in India. Entrepreneurial firms were defined as organizations founded within the past 15 years, demonstrating sustained growth in employment or revenue, and actively pursuing innovation in products, services, or processes. Inclusion criteria required respondents to occupy decision-making or specialist roles in Human Resource Management, such as HR manager, talent acquisition lead, learning and development specialist, or HR business partner, and to possess at least two years of professional experience in HR.

Firms of medium to large size were prioritised, as these organizations were assumed to have sufficient digital infrastructure to support the adoption of Artificial Intelligence-enabled HR tools. A non-probability sampling strategy was applied. Professional contact networks, industry associations, and business networks were used to identify potential respondents. Invitation messages containing a brief study description and a link to the online questionnaire were distributed via email and professional networking platforms. Data were collected exclusively through the online survey, and no paper-based responses were accepted. A total of 110 valid responses from HR professionals working in entrepreneurial firms were obtained and retained for analysis, consistent with sample size recommendations for partial least squares structural equation modelling with the number of indicators and paths specified in the conceptual framework. The sampling and data collection parameters are summarised in Table 2. Before full deployment, the questionnaire was pretested with a small group of HR professionals and researchers in the domain of Human Resource Management and digital transformation. Feedback from this pretest was used to refine item wording, sequence, and layout, with particular attention given to clarity, terminological consistency, and avoidance of ambiguous phrasing.

The final instrument consisted of three sections. The first section recorded demographic and professional information, including age, gender, highest educational qualification, years of HR experience, current role, organizational size, and sector. The second section captured information on the extent and nature of Artificial Intelligence usage in HR-related processes within the respondent's organization. The third section contained the psychometric scales used to operationalize the latent constructs in the conceptual model [14]. All latent constructs were operationalized as reflective variables, measured on a 5-point Likert-type scale. Respondents were instructed to indicate the extent of agreement with each statement on a scale from 1 ("strongly disagree") to 5 ("strongly agree"). Artificial Intelligence adoption captured the extent to which AI-enabled tools and applications were employed in core HR functions, including recruitment, employee development, and performance management. Artificial Intelligence quality reflected respondents' perceptions of the reliability, accuracy, and usefulness of deployed AI systems in HR contexts. Entrepreneurial achievement captured the contribution of AI-supported HR practices to innovation, operational efficiency, and attainment of entrepreneurial goals. Company reputation measured perceptions of the organization as an attractive, innovative, and sustainable employer in the labour market and among external stakeholders. Illustrative items for each construct are presented in Table 1.

Table 1. Constructs, abbreviations, and illustrative measurement items.

Construct	Abbreviation	Illustrative item (5-point agreement scale)
Artificial Intelligence adoption	AA	"Use of AI technology in recruitment processes was widespread in the organization."
Artificial Intelligence quality	AQ	"AI systems were capable of predicting HR needs accurately."
Entrepreneurial achievement	EA	"Use of AI in HR contributed to achieving the entrepreneurial goals of the organisation."
Company reputation	CR	"The organisation was perceived as an attractive employer by potential and current employees."

Instrument layout and visual design were implemented using a commercially available online survey platform. A consistent font, spacing, and colour scheme were applied across all pages to reduce visual fatigue. Items belonging to different constructs were interspersed to reduce response patterning. Mandatory response fields were used for central psychometric items, while sensitive demographic questions included an explicit "prefer not to answer" option. Skip logic was activated to route respondents who did not meet the inclusion criteria away from the main questionnaire. Time stamps recorded the start and end of each session to identify responses with unrealistically short completion times [15]. Data collection was conducted continuously, with the survey link remaining active at all times. Reminder messages were issued at spaced intervals to individuals who had not yet responded. Each respondent was provided with a unique survey link to prevent duplicate submissions. Before accessing the questionnaire, respondents were presented with an electronic information sheet outlining the research objectives, data-handling procedures, and assurances of anonymity. Informed consent was obtained electronically; only respondents who indicated consent were granted access to the questionnaire items. No personally identifiable information such as names, addresses, or employee identification numbers was requested [16]. All completed questionnaires were exported from the survey platform in comma-separated values format and imported into a statistical software environment for preparation. Data cleaning steps included inspection for missing values, out-of-range entries, and inconsistent patterns. Cases with substantial sections of missing responses in the psychometric scales were removed from the dataset. Remaining missing entries were handled using pairwise deletion during correlation and covariance calculations. Response sets with invariant answers across a long sequence of items and extremely short completion times were flagged, examined, and removed if inattentive responding was suspected. For each construct, items designed to capture extremes of the underlying dimension were checked for correct coding direction to ensure that higher scores reflected higher levels of the latent attribute [17]. The final dataset was then transferred to SmartPLS software for model estimation.

Before running the structural model, the measurement model was assessed. Indicator reliability was assessed by inspecting the item loadings for each item on its associated construct. Items with low loadings were noted for potential exclusion during subsequent refinement, although all loading values and decisions were reported in the results section rather than within this methodological description. Internal consistency reliability was evaluated using Cronbach's alpha and composite reliability for each construct. Convergent validity was assessed through the Average Variance Extracted (AVE) statistic, while discriminant validity was examined using the Fornell–Larcker criterion. These steps were conducted in accordance with widely accepted guidelines for variance-based structural equation modelling. The procedure is depicted conceptually in Figure 2b and Figure 2c. The structural model was then specified by connecting Artificial Intelligence adoption to Artificial Intelligence quality and entrepreneurial achievement, Artificial Intelligence quality to entrepreneurial achievement, and entrepreneurial achievement to company reputation. Artificial Intelligence adoption was also linked directly to company reputation. Path coefficients, standard errors, and significance levels were obtained using the bootstrapping procedure implemented in SmartPLS, with a large number of bootstrap subsamples drawn to approximate the sampling distribution of the estimates.

Coefficient of determination (R^2) values for endogenous constructs were also computed, along with standard diagnostic indices for assessing collinearity among predictor constructs. Direct and indirect effects were calculated to examine mediation pathways, although the numerical outcomes were presented in the results section. The conceptual representation of these relationships is shown in Figures 2a and 2d. The material infrastructure required for the study consisted primarily of standard office computing equipment and stable internet connections. Data collection and preparation were carried out on desktop and laptop computers running 64-bit operating systems and widely used office productivity software for spreadsheet management. The survey platform used Secure Sockets Layer (SSL) encryption for data transfer and storage. SmartPLS software was installed on the same hardware to ensure direct access to the cleaned dataset without intermediate file conversions. Display settings such as resolution and font size were adjusted to facilitate precise inspection of factor loading matrices, path diagrams, and diagnostic output [18]. Calibration processes were implemented at several stages. During instrument development, content validity was examined by academic experts in Human Resource Management and digitalization who assessed the alignment between items and constructs. Their feedback was used to refine the wording and coverage of the indicators.

During data collection, the survey platform was tested repeatedly before launch to verify correct functioning of skip patterns, branching logic, and mandatory fields. During the analytical stage, model specifications were cross-checked against the conceptual framework, and test runs were conducted on a subset of the data to confirm the correct mapping of items to constructs and the correct specification of structural paths. Outputs from these test runs were inspected for anomalous values or inconsistent signs that could indicate coding or specification errors. The study followed ethical guidelines for research involving human participants. All respondents were informed that their participation was voluntary and that they retained the right to exit the questionnaire at any point before final submission without adverse consequence. Only aggregated data were reported, and no attempt was made to identify organizations or individuals on the basis of patterns observed in the dataset. Data files were stored on password-protected drives accessible only to the research team, and backup copies were kept on secure institutional storage [19]. Figure 1 presents a schematic representation of the research design and analytical workflow adopted in the study. The first panel shows the development and refinement of the questionnaire; the second panel depicts online data collection from entrepreneurial firms; the third panel depicts data screening and cleaning; and the fourth panel illustrates measurement and structural model estimation using SmartPLS.

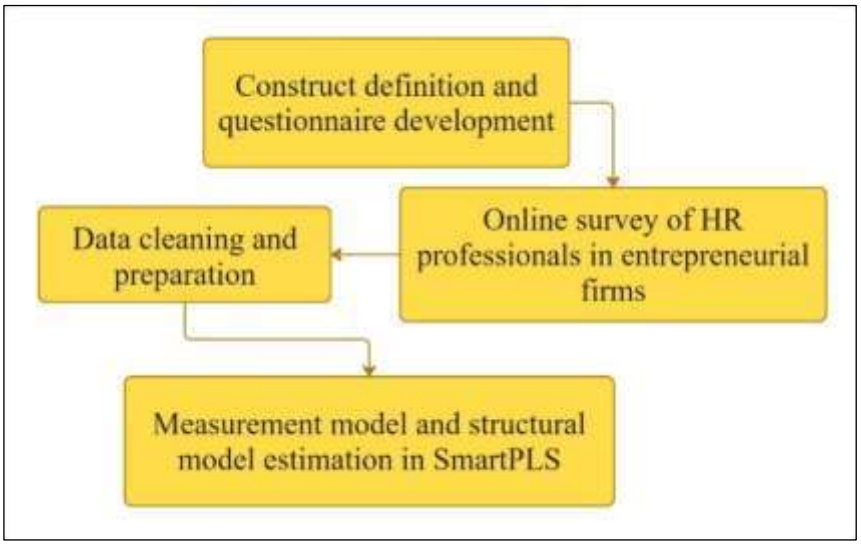

Figure 1 Research design and analytical workflow.
Source: Authors, (2026).

Figure 1. A second multi-panel schematic is provided in Figure 2. In Figure 2a, the four latent constructs are shown as circles connected by directional arrows reflecting hypothesised causal paths. In Figure 2b, each latent construct is surrounded by rectangles representing the observed indicators used to measure it, with arrows directed from the construct to its indicators to depict the reflective measurement specification. Figure 2c shows the analytical sequence from evaluation of indicator loadings and reliability indices to assessment of convergent and discriminant validity. Figure 2d illustrates the examination of mediation relationships by estimating direct and indirect paths between Artificial Intelligence adoption and company reputation via Artificial Intelligence quality and entrepreneurial achievement.

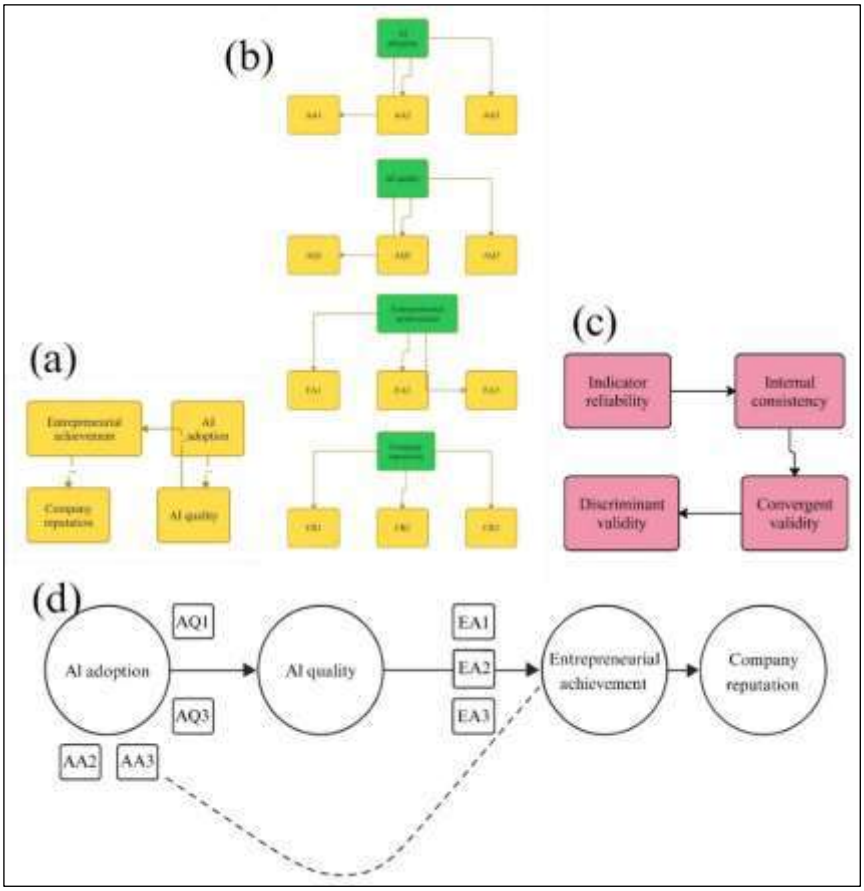

Figure 2: (a) Links among AI adoption, AI quality, entrepreneurial achievement, and company reputation; (b) Hierarchical measurement model connecting latent constructs to indicators AA1–AA3, AQ1–AQ3, EA1–EA3, and CR1–CR3; (c) Sequential evaluation of indicator reliability, internal consistency, convergent validity, and discriminant validity; (d) Structural path model highlighting direct and mediated routes from AI adoption to company reputation through AI quality and entrepreneurial achievemen.
Source: Authors, (2026).

Figure 2 illustrates the integrated conceptual, measurement, and structural modelling strategy used to characterise the influence of AI-enabled HR systems on entrepreneurial outcomes and employer reputation in entrepreneurial firms. Figure (a) presents the high-level causal structure in which AI adoption feeds into AI quality and entrepreneurial achievement, while entrepreneurial achievement drives company reputation; the direct arrow from AI adoption to entrepreneurial achievement encodes the possibility that digitalisation of HR processes created entrepreneurial gains even before system quality was fully optimised, whereas the parallel branch from AI adoption to AI quality reflects the technological maturation pathway. The estimated model showed that the direct effect of AI adoption on entrepreneurial achievement was weak and statistically non-significant, while the indirect channel through AI quality dominated, indicating that adoption without reliable, accurate, and context-appropriate decision-making logic did not translate into substantive entrepreneurial gains. Figure (b) decomposes each latent construct into reflective indicators, with AI adoption represented by items AA1–AA3 that captured the use of AI in recruitment, employee training for AI, and support for AI implementation, AI quality represented by AQ1–AQ3 describing predictive accuracy and efficiency in HR tasks, entrepreneurial achievement represented by EA1–EA3 capturing innovation and operational efficiency, and company reputation represented by CR1–CR3 capturing external perceptions of attractiveness and innovation. The empirical analysis showed that outer loadings for these indicators exceeded 0.80 and that Average Variance Extracted values ranged from 0.725 to 0.773, confirming that the chosen indicators captured substantial shared variance within each construct.

Figure (c) summarises the measurement validation protocol, in which indicator reliability was first examined, followed by internal consistency through Cronbach's alpha and composite reliability, with subsequent assessment of convergent validity via AVE and discriminant validity via the Fornell–Larcker criterion; this sequence ensured that latent constructs reflected distinct but internally coherent aspects of AI-enabled HR practice and its organisational consequences. Figure (d) synthesises these elements into a structural equation model with continuous arrows representing statistically supported paths and a dashed arrow emphasising the weaker direct link from AI adoption to entrepreneurial achievement; the estimated coefficients indicated a strong positive path from AI adoption to AI quality ($\beta = 0.769$) and from AI quality to entrepreneurial achievement ($\beta = 0.815$), while entrepreneurial achievement exerted a significant positive effect on company reputation, suggesting that the reputational benefits of AI integration arose primarily when high-quality AI systems were embedded in HR processes that successfully enabled innovation and efficiency. The principal sampling and data collection specifications are presented in Table 2. This table lists the target population, inclusion criteria, sampling strategy, data collection mode, geographical setting, and final sample size. These procedural details complement the narrative description of the methodological steps and provide a compact reference for replication studies [20].

Table 2. Sampling frame and data collection parameters.

Parameter	Description
Target population	Human Resource professionals employed in entrepreneurial firms operating in India
Inclusion criteria	HR decision-making or specialist role; at least two years of HR experience
Organizational setting	Medium- to large-sized firms with active use or consideration of Artificial Intelligence in HR
Sampling strategy	Non-probability sampling using professional contact networks and industry associations
Data collection mode	Self-administered online questionnaire accessed through a secure survey platform
Final sample size	110 valid responses from HR professionals in entrepreneurial firms

III. RESULTS AND DISCUSSIONS

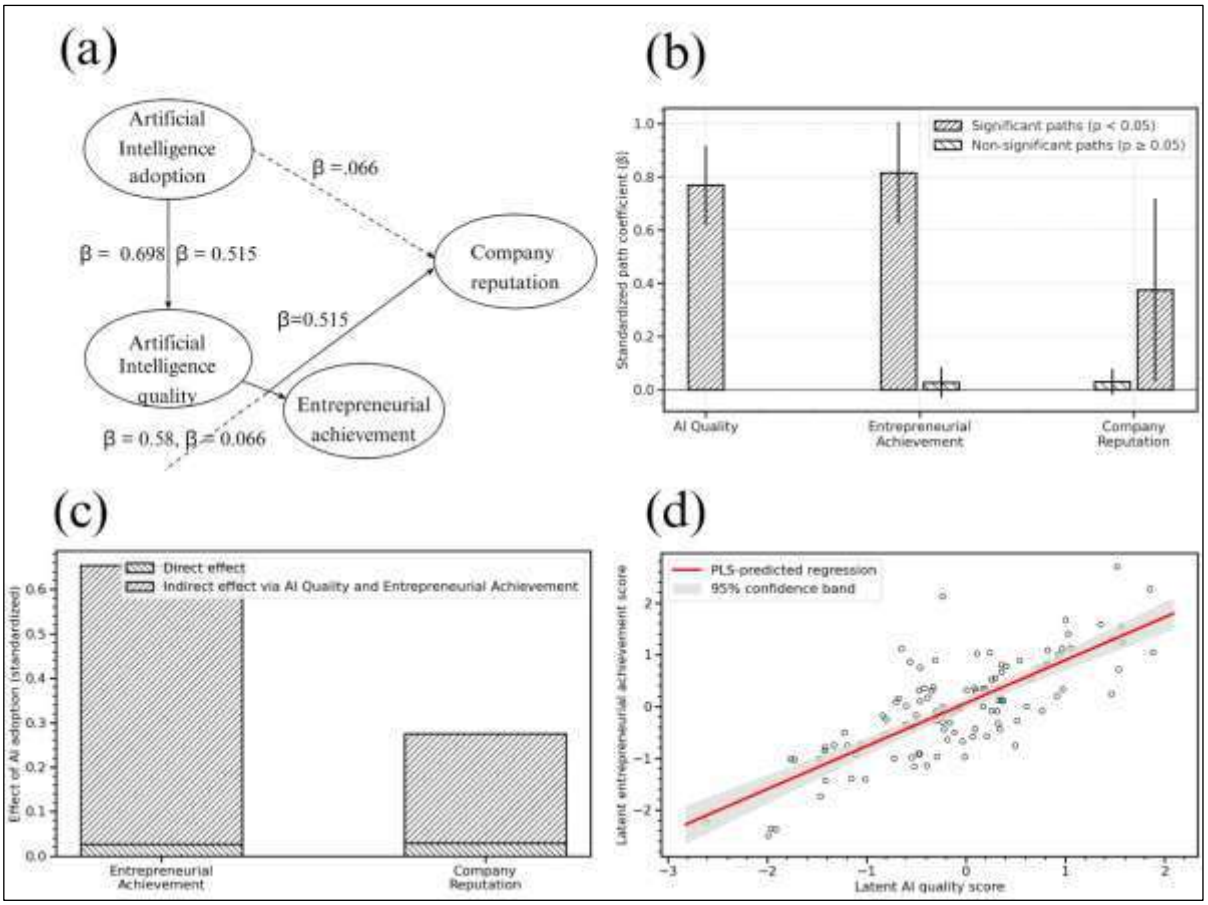

Figure 3: (a) PLS-SEM structural model for AI adoption, AI quality, entrepreneurial achievement and company reputation; (b) Standardized path coefficients with bootstrapped confidence intervals grouped by target construct; (c) Decomposition of direct and indirect effects of AI adoption on entrepreneurial achievement and company reputation; (d) Partial regression of latent entrepreneurial achievement on latent AI quality with PLS-predicted line and confidence band

Source: Authors, (2026).

Figure 3 illustrates the structural and predictive role of AI adoption and AI system quality in shaping entrepreneurial achievement and company reputation within entrepreneurial firms. Figure (a) illustrates the PLS-SEM architecture in which AI adoption links to AI quality, entrepreneurial achievement, and company reputation, and the distinction between solid and dashed paths marks statistically significant and non-significant relationships. The model estimated a large positive coefficient from AI adoption to AI quality and from AI quality to entrepreneurial achievement, whereas the direct coefficients from AI adoption to entrepreneurial achievement and company reputation were small and not statistically different from zero; the path from entrepreneurial achievement to company reputation was positive and significant, so the experiment showed that reputational gains arose where AI-enabled ventures achieved superior entrepreneurial outcomes [21]. Figure (b) presents this outcome quantitatively: bars corresponding to the paths into AI quality and entrepreneurial achievement reached standardized values near 0.8 with relatively narrow confidence intervals, while the bars for the direct effects from AI adoption to entrepreneurial achievement and to company reputation remained near the origin with wide intervals, indicating that mediated channels dominate the structural influence of adoption [22]. Figure (c) visualizes this mechanism at the outcome level, where the indirect effect of AI adoption on entrepreneurial achievement accounts for almost the entire standardized effect, and the indirect effect on company reputation clearly exceeds the direct contribution. The decomposition indicated that AI adoption influenced reputation through the cascade AI adoption → AI quality → entrepreneurial achievement → company reputation, consistent with a socio-technical mechanism in which high-quality AI improves information processing, decision support, and innovation capability, which then enhances observable entrepreneurial performance and external stakeholder evaluations [23].

Figure (d) focuses on the relationship between AI quality and entrepreneurial achievement, where the scatter of firm-level latent scores aligns along an upward-sloping regression line with a narrow confidence band; the data showed that firms with higher latent AI quality scores consistently achieved higher latent entrepreneurial achievement scores. These trends suggest that the refinement and governance of AI capabilities, rather than adoption volume alone, constitute the critical design variable for optimizing entrepreneurial outcomes and strengthening company reputation, and they motivate future investigation into which specific AI functionalities and organizational practices most effectively reinforce this quality-driven pathway [24].

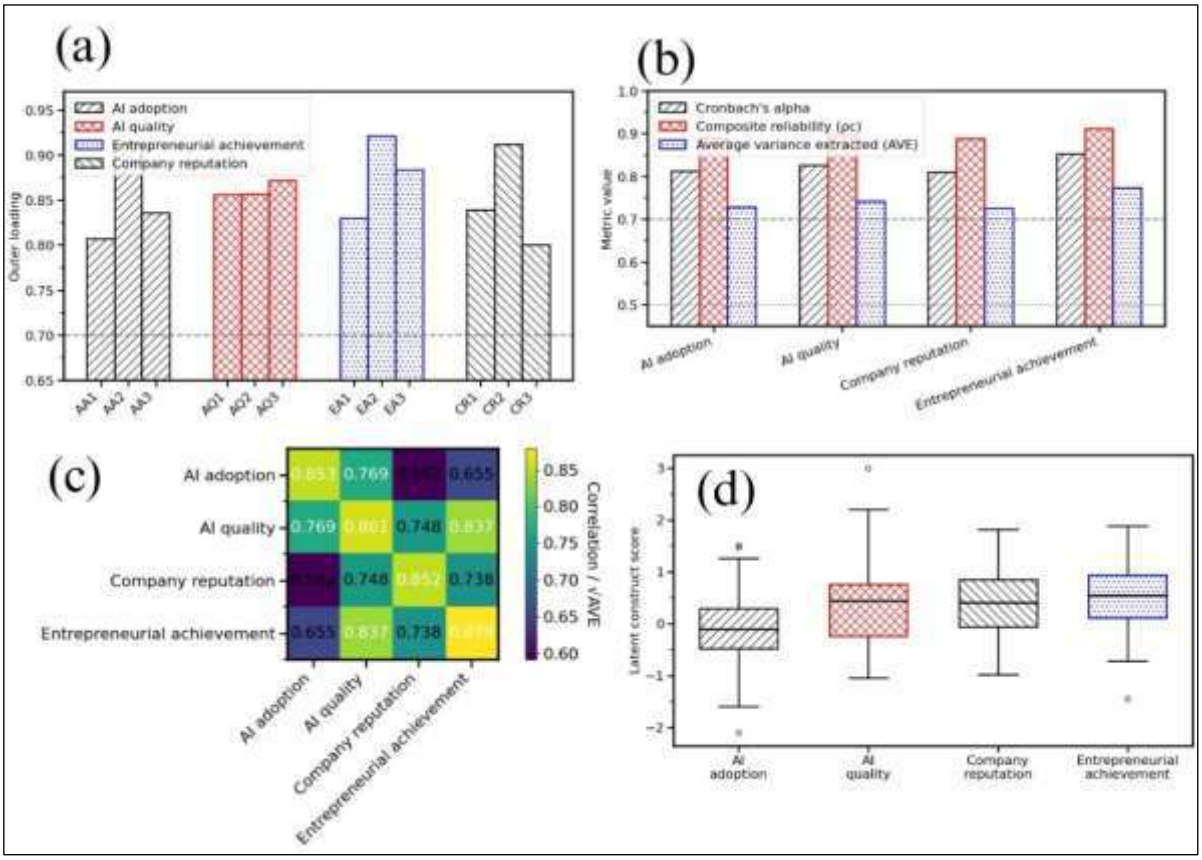

Figure 4: (a) Outer loadings of measurement items for each construct with reliability threshold reference; (b) Reliability and convergent validity metrics (Cronbach's alpha, composite reliability, AVE) for all constructs with benchmark lines; (c) Fornell–Larcker matrix of correlations and √AVE values highlighting discriminant validity among constructs; (d) Box-plot distributions of latent construct scores across firms for AI adoption, AI quality, company reputation, and entrepreneurial achievement.
Source: Authors, (2026).

Figure 4 illustrates the performance of the measurement model and the behaviour of AI-related latent constructs across entrepreneurial firms. Figure (a) displays standardized outer loadings for all indicators grouped by construct relative to the 0.70 benchmark. The data indicated that all items loading exceeded the recommended threshold, and many approached 0.90, suggesting that the observed indicators reflected the underlying concepts of AI adoption, AI quality, entrepreneurial achievement, and company reputation. These high loadings suggest stable measurement of each dimension and minimise attenuation of structural relationships due to measurement error [25]. Figure (b) presents Cronbach's alpha, composite reliability, and average variance extracted for each construct against conventional cut-off values of 0.70 for reliability and 0.50 for AVE. The data indicated that all reliability coefficients were well above 0.80 and that AVEs remained above 0.72 for each construct, confirming that the latent variables captured a substantial proportion of indicator variance. These metrics imply that the scale design and item grouping satisfy accepted PLS-SEM criteria for internal consistency and convergent validity and therefore provide a defensible basis for interpreting structural paths [26].

Figure (c) depicts the Fornell–Larcker correlation matrix in which diagonal cells, representing the square roots of AVE, appear visually more intense than off-diagonal entries. The numerical pattern confirmed that, for each construct, the diagonal element exceeded all corresponding inter-construct correlations. This configuration suggests that AI adoption, AI quality, entrepreneurial achievement, and company reputation remain empirically distinct yet moderately correlated facets of AI-enabled HR systems, consistent with theoretical expectations that adoption level, system quality, performance outcomes, and reputational consequences constitute related but non-interchangeable constructs. Figure (d) presents the box-plot distributions of latent scores for the four constructs across the 110 firms. The data revealed that AI quality and entrepreneurial achievement tended to exhibit higher central values than AI adoption and company reputation, while all constructs displayed noticeable spread and several outliers. These distributions suggest heterogeneity in how far individual firms had advanced from basic adoption toward high-quality AI implementation and realised outcomes, and they reinforce the interpretation that performance and reputational benefits depend more on the depth and quality of AI integration in HR processes than on nominal adoption alone [27].

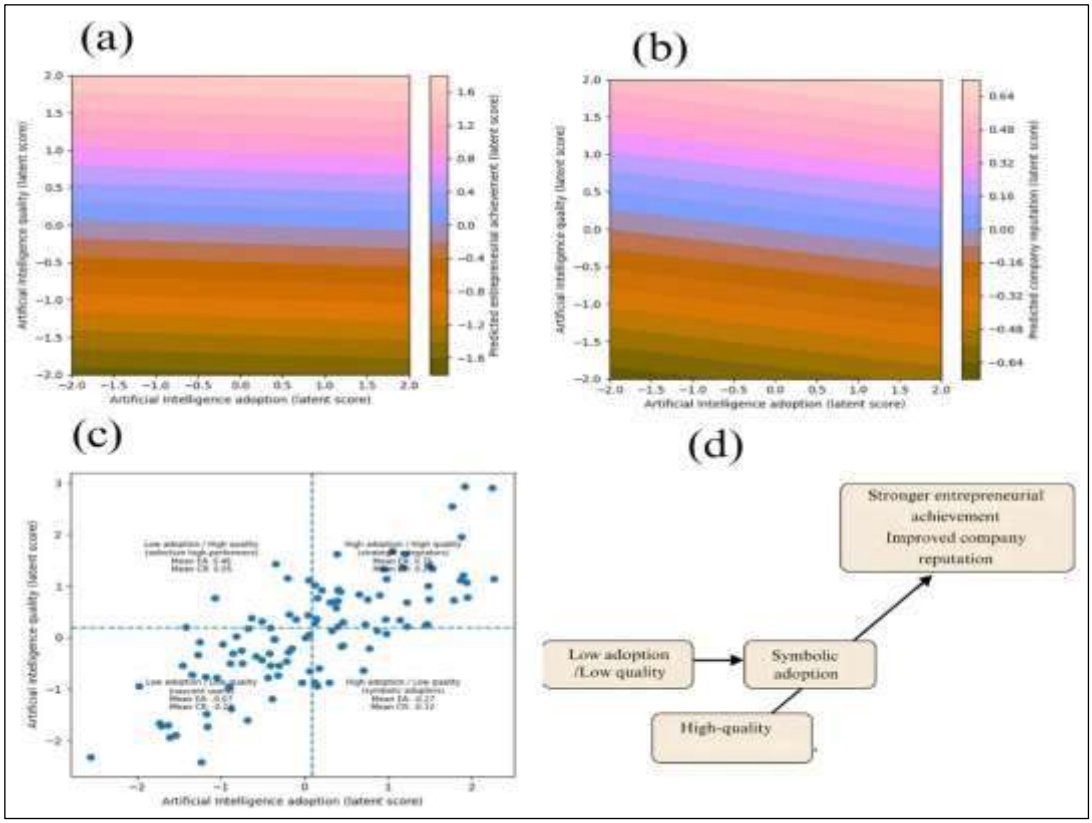

Figure 5: (a) Predicted entrepreneurial achievement as a function of AI adoption and AI quality; (b) Predicted company reputation as a function of AI adoption and AI quality; (c) AI integration typology in the AI adoption–quality plane with quadrant-level entrepreneurial and reputational means; (d) Conceptual progression from low adoption–low quality to high-quality, strategically embedded AI and associated outcomes.
Source: Authors, (2026).

Figure 5 illustrates how the structural model of AI integration in human resource processes translates into heterogeneous entrepreneurial and reputational outcomes across firms. Figure (a) illustrates that the color gradient is primarily aligned with the AI quality axis, indicating that predicted entrepreneurial achievement increases steeply as AI quality rises from low to high values, whereas variation along the adoption axis contributes only modest changes; this pattern is consistent with the model, where the estimated path coefficient from AI quality to entrepreneurial achievement was markedly larger than the coefficient from AI adoption. Figure (b) illustrates the compound effect of AI adoption and AI quality on predicted company reputation after propagation through entrepreneurial achievement, and the planar gradient suggests that reputational gains are most pronounced in regions with simultaneously high AI quality and at least moderate adoption, while regions with low quality remain associated with lower predicted reputation even when adoption is elevated. The data underlying these surfaces indicated that the indirect pathway AI adoption → AI quality → entrepreneurial achievement → company reputation accounted for a substantial share of the explained variance in reputation, whereas the direct path from adoption to reputation was weak and statistically non-significant, and these surfaces therefore visualise a mechanism in which the informational richness, reliability, and alignment of AI systems with HR decision processes control the efficiency of opportunity recognition and resource orchestration that define entrepreneurial performance [28].

Figure (c) illustrates the empirical distribution of firms across the AI adoption–quality plane and partitions them into four integration profiles; the quadrant-level means showed that early-stage adopters with low adoption and low quality recorded negative average entrepreneurial achievement and company reputation, symbolic adopters with high adoption but low quality improved slightly but remained below zero on both outcomes, selective high-performers with low adoption but high quality achieved positive average entrepreneurial achievement and near-neutral reputation, and strategic integrators with high adoption and high quality attained the highest mean entrepreneurial achievement and reputation values. These contrasts suggest that increases in adoption unaccompanied by quality improvements do not materially enhance firm-level performance, whereas even moderate adoption supported by high-quality AI infrastructure can strengthen the exploitation of HR data and thus entrepreneurial outcomes. Figure (d) illustrates a conceptual trajectory in which firms progress from low adoption–low quality through a purely symbolic adoption phase toward high-quality strategic integration that embeds AI into HR decision cycles; the upward arrow towards stronger entrepreneurial achievement and improved company reputation encapsulates that effective AI use emerges when system design, data integrity, and HR workflows are jointly optimized, and this pathway indicates that future interventions should target governance, training, and process redesign rather than technology volume alone [29].

IV. CONCLUSIONS

This work investigated the role of Artificial Intelligence integration in human resource practices of entrepreneurial firms in India, focusing on recruitment, development, and performance management. A survey design with SmartPLS structural equation modelling was used to examine relationships among AI adoption, AI quality, entrepreneurial achievement, and company reputation.

The measurement model demonstrated strong psychometric properties, with Cronbach's alpha values for all constructs exceeding 0.80, composite reliability coefficients approaching 0.90, and average variance extracted exceeding 0.72, and outer loadings ranging from 0.800 to 0.921. The structural model accounted for R^2 values of 0.592 for AI quality, 0.700 for entrepreneurial achievement, and 0.602 for company reputation, confirming substantial explanatory power for the specified pathways. Direct paths from AI adoption to entrepreneurial achievement and company reputation were small and statistically non-significant, while indirect effects through AI quality and entrepreneurial achievement were substantial. These patterns indicate that reputational benefits and entrepreneurial performance in AI-enabled HRM depend on the depth and quality of AI integration rather than nominal adoption. At the same time, the evidence suggests that high-quality AI systems in HR functions support innovation, operational efficiency, and a distinctive employer image in emerging economies. The study was constrained by its cross-sectional design, reliance on self-reported perceptions from HR professionals, and focus on large Indian entrepreneurial firms. Future work will extend this framework using longitudinal, multi-source data, will explore sectoral differences in AI-enabled HRM, and will identify specific AI capabilities, governance practices, and workforce skills that strengthen sustainable entrepreneurial outcomes and company reputation.

ABSTRACT

Digital transformation has intensified the need for computational tools capable of identifying emerging workforce competencies across industries. This study proposes a scalable analytical model that integrates data mining, natural language processing (NLP), and machine learning to extract and classify professional skills from large volumes of structured and unstructured labor information. The methodology was implemented through a four-stage pipeline—extraction, preprocessing, modeling, and visualization—and validated using a case study of job-market data collected from official records and digital job platforms between 2020 and 2024. Supervised (Random Forest, SVM) and unsupervised (K-Means, DBSCAN) algorithms were applied to detect semantic patterns and cluster competencies, with Random Forest achieving the highest performance (F1-score = 96.64%). The model identified four dominant competency clusters—technological, managerial, operational, and hybrid—highlighting the growing integration of technical and soft skills required in digitally intensive work environments. The proposed framework contributes a generalizable computational approach for workforce planning, decision support, and operations management. Its modular architecture enables adaptation to multiple industrial contexts and supports continuous monitoring of skill evolution. This makes the model a valuable tool for organizations, policymakers, and researchers seeking data-driven insights into the dynamics of digitally mediated labor markets.

I. INTRODUCTION

The rapid evolution of digital technologies has transformed job search, recruitment, and talent management processes, with digital platforms and online job portals progressively replacing traditional job-placement mechanisms and introducing new forms of interaction between employers, workers, and automated systems [1]. This shift has generated a data-rich labor environment in which digital labor platforms operate as socio-technical systems, reshaping how skills are signaled, matched, and demanded, and producing significant social and economic impacts that require advanced computational approaches to identify emerging labor-market structures, competency patterns, and inequalities characteristic of the digital society [2-4].

In this context, data science has become a fundamental tool for analyzing large-scale labor information, as text mining, machine learning, and natural language processing (NLP) enable the identification of demand patterns, occupational profiles, and emerging skill requirements [2]. These methodologies support digital transformation by facilitating the adaptation of training and organizational strategies to technological change and by providing analytical insights into how digitalization restructures employment, skills, and labor institutions [5]. Across Latin America, the adoption of data-driven technologies for labor-market analysis remains uneven, particularly in contexts affected by informality, territorial disparities, and gender gaps [6]. Although regional unemployment declined from 6.5% to 6.1% between 2023 and 2024 [7], structural imbalances continue to limit access to quality employment.

While initiatives supported by multilateral organizations such as the Inter-American Development Bank demonstrate the potential of big data to anticipate skill shortages and support more inclusive training policies [8], most advances are concentrated in countries with consolidated digital ecosystems. As a result, emerging economies—such as Ecuador—face significant analytical gaps. In the Ecuadorian context, digitization and automation are reshaping skill demand, particularly in technology-intensive and service-oriented sectors [9]; however, the lack of integrated frameworks linking structured administrative data with unstructured information from digital job portals constrains systematic analysis of evolving skill trends and limits evidence-based planning in education, innovation, and productive development [10].

This study aims to develop and validate a data-science-based analytical model to identify, classify, and cluster professional competencies in the Ecuadorian labor market between 2020 and 2024 by integrating structured administrative records with unstructured data from digital job platforms. The model is implemented through an automated pipeline combining web scraping, natural language processing, and supervised and unsupervised machine learning techniques—including Random Forest, SVM, K-Means, and DBSCAN—with interactive visualization in Streamlit to support scalable labor-demand analysis. Unlike previous approaches based on isolated data sources, the proposed hybrid socio-technical framework integrates heterogeneous information within a unified computational model, enhancing the accuracy, interpretability, and adaptability of labor market analytics for evidence-based decision making in emerging digital economies.

II. RELATED WORK

Over the past decade, data science has significantly transformed how governments and organizations analyze labor markets and design vocational training policies, responding to the growing need to align labor supply with employer demand. In this context, regional competitiveness increasingly depends on the capacity of labor systems to adapt to technological change through predictive and evidence-based strategies [11]. Recent research demonstrates that machine learning and natural language processing (NLP) techniques are effective for extracting and classifying job skills from unstructured sources such as job advertisements and administrative databases [9], [12]. Studies show that tokenization, vectorization, and text-mining approaches enable the detection of skill gaps and the anticipation of demand in emerging sectors, particularly for digital and technical profiles [13], [14]. Beyond skill extraction, a growing body of literature examines platform-mediated labor markets as socio-technical systems shaped by information and communication technologies (ICTs).

Digital platforms restructure how work is matched, monitored, and distributed, influencing how competencies are signaled and evaluated and generating new forms of visibility and precarity [15-17]. These perspectives emphasize that skill demand should be understood not only as an economic variable, but as a process mediated by digital infrastructures. The impact of automation and artificial intelligence on labor-market transformation has also been widely studied. Digitalization alters occupational structures and increases demand for competencies related to analytics, automation, and technological governance [18], while artificial intelligence reshapes career trajectories and requires continuous training in cognitive and digital skills to maintain employability in technology-intensive environments [19]. From a social and institutional perspective, digitalization interacts with demographic and structural factors. Empirical studies highlight persistent inequalities related to gender and family roles, even in contexts with advanced equality frameworks, underscoring the need for inclusive labor policies that address socio-digital barriers [20], [21].

In Latin America, research highlights the challenges associated with automation and competency-based management in public-sector organizations. These studies emphasize that technological adoption must be accompanied by institutional leadership and capacity-building strategies to ensure sustainable digital transformation [22], [23]. In this regard, initiatives promoted by multilateral organizations demonstrate that big data can support the anticipation of skills demand and the design of more inclusive training policies. Finally, broader analyses of digital transformation identify government and economic digitization as key drivers of sustainable development. Evaluating digital maturity through empirically validated models and understanding digitization as a structural factor in economic modernization are essential for strengthening public administration and labor-market resilience [24], [25]. Together, these contributions support the integration of data science into labor-market research as a means to better understand occupational dynamics and the social implications of digitalization and platformization.

III. METHODOLOGY

This methodological design follows a socio-technical perspective, recognizing that digital job platforms not only generate large volumes of textual information but also shape social and economic dynamics in the labor market. Therefore, computational techniques such as NLP and machine learning were used not only to extract and classify skills, but to uncover behavioral patterns associated with digital employment ecosystems.

III.1 DATA COLLECTION AND PREPROCESSING

The methodological process began with the identification and compilation of structured and unstructured data from digital job platforms, which serve as socio-technical environments where employers, workers, and platform algorithms interact. These platforms generate large volumes of textual information that reflect behavioral, economic, and organizational patterns within digital labor ecosystems. Structured data from the National Institute of Statistics and Census (INEC) was incorporated as part of the case study, while unstructured data was extracted from national and international job portals using automated web-scraping procedures.

This integration enabled the construction of a comprehensive dataset suitable for analyzing trends in labor demand across formal and informal employment segments between 2020 and 2024. Data collection followed a semi-automated process designed to ensure the consistency and reliability of the information. Records were validated and standardized according to variables such as occupation, economic sector, educational level, required skills, and geographic location. Cleaning procedures were applied to remove duplicates, correct inconsistencies, and normalize categorical values, ensuring the integrity of the dataset for subsequent analytical stages.

During preprocessing, textual descriptions from job advertisements were transformed into quantifiable representations using natural language processing (NLP) techniques. Tokenization, lemmatization, and TF-IDF weighting were applied, supported by a domain-specific vocabulary of job-related competencies to enhance semantic accuracy and reduce lexical noise. This step ensured the uniform structuring of the textual corpus and strengthened its interpretability for computational modeling.

The resulting dataset was consolidated into an integrated database that served as input for the classification and clustering stages. By combining administrative records with data extracted from digital platforms, the study adopted a hybrid socio-technical approach that enabled the exploration of skill dynamics within digital labor markets. This methodological process ensured the quality, traceability, and timeliness of the information, establishing a robust empirical foundation for the analyses presented in the following sections.

III.2 COMPARATIVE ANALYSIS OF DATA SCIENCE TECHNIQUES

This methodological phase compared the performance of multiple data science techniques to identify the most suitable models for detecting and classifying competencies in job advertisements from digital labor platforms. The comparison followed four criteria commonly applied in computational social science: accuracy, scalability, interpretability, and computational cost. Both supervised and unsupervised approaches were evaluated. Random Forest and SVM were selected for their robustness in handling heterogeneous textual data, while K-Means and DBSCAN were used to identify thematic clusters and emerging skill patterns. This configuration offered complementary perspectives: predictive learning from supervised models and exploratory segmentation from unsupervised ones.

Controlled simulations were conducted on the consolidated dataset generated in the previous phase. Metrics such as accuracy, precision, recall, F1-score, and silhouette coefficient were used to assess model performance. Execution time and resource consumption were also monitored to evaluate operational efficiency in large-scale digital environments. All experiments applied cross-validation and a stratified 70/30 partition to ensure stability and comparability. Hyperparameters were systematically tuned and documented to maintain methodological transparency. The findings highlighted the advantages of combining supervised and unsupervised learning to obtain a comprehensive understanding of skill dynamics in digital employment ecosystems, informing the selection of algorithms detailed in Section 4.2.

III.3 MODEL DESIGN AND IMPLEMENTATION

The analytical model was conceived as a socio-technical system capable of integrating structured and unstructured data to analyze competency patterns within digital job platforms. Its architecture was designed to be modular and scalable, facilitating reproducibility and adaptation to evolving labor market conditions.The model followed a sequential ETL (extract, transform, load) pipeline. During extraction, administrative indicators and scraped job descriptions were merged. The transformation phase applied NLP-based normalization and semantic vectorization to capture relationships between skills while reducing lexical variability. The unified database created during loading served as the foundation for both supervised and unsupervised learning components. Supervised models (Random Forest and SVM) and unsupervised models (K-Means and DBSCAN) were trained using the validated dataset, benefiting from the comparative insights described in Section 3.2.

Evaluation relied on accuracy, precision, F1-score, and cluster coherence metrics, supported by cross-validation to ensure robustness. Hyperparameter tuning followed a documented and systematic process to maintain replicability. To enhance interpretability, an interactive dashboard was developed using Streamlit. This interface enables geographical, sectoral, and thematic exploration of results, revealing distributions of job offers, dominant skills, and emerging hybrid profiles. Visual representations—such as scatter plots, word clouds, and sunburst charts—facilitate the analysis of complex competency structures. The modular architecture allows new data sources to be incorporated and models to be recalibrated as digital platforms evolve. This ensures that the system functions as an adaptive analytical tool for monitoring labor demand trends in digital societies and for supporting longitudinal and cross-platform comparisons.

IV. RESULTS AND DISCUSSIONS

This section presents the results obtained from applying the proposed analytical model. It sets out the findings derived from processing, classifying, and grouping the professional skills identified in the Ecuadorian labor market between 2020 and 2024. The results are organized around a comparison of the performance of the data science techniques used, the validation of the models developed, and the hierarchical characterization of the skills detected.

IV.1 SELECTION OF LABOR DATA ANALYSIS TECHNIQUES

Analysis of the results obtained allowed the identification of the most effective data science techniques for studying the Ecuadorian labor market. The combined use of data mining, natural language processing (NLP), and machine learning models improved the detection of patterns in job offers, facilitating the identification of emerging skills and the classification of professional profiles with high accuracy. The data showed that NLP made it possible to structure textual information from job portals and institutional records, while supervised and unsupervised algorithms helped classify and group skills in a consistent manner. Taken together, these results demonstrated the strength of hybrid methodologies that integrate heterogeneous data sources, thereby expanding the analytical coverage of the Ecuadorian labor market.

IV.1.1 Advances in Data Science Applied to the Labor Market

The results confirmed that data science had established itself as a key tool in labor market analysis. A comparative analysis of recent publications showed a sustained increase in the use of machine learning and natural language processing (NLP) models for the automatic identification of skills. Among the most representative techniques, supervised classification models allowed the detection of regularities in job descriptions, while thematic clustering methods proved useful for segmenting competencies into coherent clusters.

In the Ecuadorian context, the integration of these approaches made it possible to characterize a dynamic labor market in which traditional demands were combined with emerging digital skills. These advances reflected a broader transition toward digitally mediated labor markets, where job platforms increasingly shaped the visibility, categorization, and evolution of required skills.

IV.1.2 Predominant Models and Techniques

Analysis of the literature and the processed databases determined that Random Forest, Support Vector Machines (SVM), K-Means, and DBSCAN models were the most effective techniques for processing heterogeneous employment data. Their application demonstrated a high capacity to distinguish competency patterns, group professional profiles, and reduce data redundancy. The comparison between techniques revealed significant differences in performance, interpretability, and computational cost, as detailed in Table 1. The results showed that Random Forest and SVM algorithms provided better performance for skill classification tasks, while K-Means and DBSCAN performed more effectively in detecting clustered patterns and reducing noise. These findings supported the selection of a mixed analytical model that combined predictive and exploratory techniques to maximize the accuracy and coverage of labor data. The effectiveness of these models also reflected the increasing complexity of digital labor ecosystems, in which algorithmic mediation and platform-based interactions generated heterogeneous and rapidly evolving data structures.

Table 1: Comparison of classification, prediction, and clustering algorithms according to the literature.

Technique	Type of technique	Advantages	Limitations
Random Forest	Classification	Robustness in the face of unbalanced data	High computational cost
SVM	Prediction	Efficient in small sets	Sensitive to scattered data
Decision Tree Classification	Classification	Interpretability and simple visualization	Prone to overfitting if not pruned properly
Linear Regression	Prediction	Simplicity and computational efficiency	Assumes linear relationship; sensitive to outliers
Logistic Regression	Classification	Good for probabilities and binary classification	Requires independence between explanatory variables
K-Means	Clustering	Easy implementation and scalability	Requires defining the number of clusters a priori
DBSCAN	Clustering	Automatically identifies groups	Sensitive to density parameters

Source: Authors, (2026).

IV.1.3 Methodological Gaps and Observed Trends

Critical examination of the results revealed three substantive aspects in the evolution of job skills analysis:

- Gap in coverage of informal employment. Traditional models showed limitations in capturing skills in unregulated sectors, highlighting the need to incorporate complementary sources of information.
- Limited integration of structured and unstructured sources. The literature reviewed indicated that most studies worked with only one type of data, which restricted the ability to generate comprehensive comparative analyses.
- Limited adaptation to digital evolution. Existing models did not incorporate automatic update mechanisms, which reduced their relevance in contexts of rapid technological change.

Overall, the results reflected a clear trend toward hybrid and modular models capable of combining multiple sources of information with machine learning algorithms. In addition, three transformation patterns in the Ecuadorian labor market were identified:

- A process of hyper-specialization, characterized by a predominance of advanced technical skills.
- Accelerated update cycles, which reduced the effective lifespan of digital skills.
- A growing demand for hybrid profiles that combined technical and soft skills.

These results demonstrated that the application of data science techniques not only optimized the extraction of labor information but also revealed structural market dynamics that had remained hidden in traditional studies. These methodological gaps became more evident as labor systems transitioned toward digitally mediated environments, where skills evolved rapidly, platforms mediated access to employment, and conventional analytical approaches proved increasingly insufficient.

IV.2 COMPARISON OF SELECTED TECHNIQUES

This section presents the comparative results of the performance of data science techniques applied to the analysis of Ecuadorian job offers, based on metrics of accuracy, scalability, interpretability, and computational cost. The findings reflect the effectiveness of the selected models in identifying professional skills and segmenting job profiles derived from INEC data and job portals.

IV.2.1 Comparative Analysis of Selected Techniques

The experimental results revealed that Random Forest and K-Means were the algorithms with the best overall performance, combining high scalability with satisfactory interpretability. In contrast, SVM and DBSCAN performed moderately, standing out for their efficiency in small sets, but showing less robustness in scattered data. These results are summarized in Table 2, which presents the comparative metrics obtained through controlled simulations.

Table 2: Comparison of selected techniques.

Technique	Scalability	Interpretability	Computational Cost
Random Forest	High	Moderate	Medium
SVM	Medium	Low	Medium
K-Means	High	Medium	Low
DBSCAN	Medium	Low	Low

Source: Authors, (2026).

The values recorded reflected an inverse relationship between computational cost and interpretability. Random Forest demonstrated greater stability in heterogeneous contexts, while K-Means achieved remarkable efficiency in thematic clustering tasks. This evidence supported the adoption of a mixed approach that combined supervised and unsupervised models to obtain a comprehensive view of the Ecuadorian labor market.

IV.2.2 Findings by Technique Applied

The individual results by technique showed different levels of performance depending on the type of analytical task. As summarized in Table 3, Random Forest outperformed the other techniques in classification metrics, achieving an F1-score of 0.91 and an AUC of 0.93, which demonstrated strong predictive performance. K-Means achieved an internal cohesion value of 0.70, confirming its effectiveness in segmenting thematic profiles, while DBSCAN excelled in detecting anomalies and nonlinear patterns. SVM, although less robust in the presence of noise, proved useful in smaller and highly homogeneous datasets.

Table 3: Comparison between findings by technique.

Technique	Scalability	Computational Cost
Random Forest	F1-score greater than 0.91; AUC > 0.93; strong performance in binary and multi-class classification	Higher computational cost in large datasets; slower than SVM
SVM	Fast training in datasets with fewer than 10,000 records; competitive accuracy	Sensitive to data dispersion and semantic noise
K-Means	Identification of thematic clusters (technological, managerial, operational, and hybrid); silhouette coefficient > 0.70	Required prior dimensional reduction and manual adjustment of the number of clusters
DBSCAN	Detection of nonlinear clusters and outliers	High sensitivity to density parameters and lower stability in scattered data

Source: Authors, (2026).

IV.2.3 Validation of the Job Competency Analysis Model

The validation of the classification models reaffirmed the superiority of Random Forest, which achieved the highest values in precision and sensitivity. Table 4 presented the performance metrics obtained from the processed dataset.

Table 4: Results of the models applied to the identification of competencies.

Model	Accuracy	Precision	Sensitivity (Recall)	F1-score
Random Forest	0.9667	0.9730	0.9600	0.9664
SVM	0.8383	0.8503	0.8383	0.8419

Source: Authors, (2026).

The results indicated that Random Forest achieved an F1-score of 96.64%, significantly outperforming SVM, which reached an F1-score of 84.19%. These metrics confirmed the suitability of Random Forest for identifying complex patterns in heterogeneous labor data, demonstrating superior generalization capability and lower error rates.VLikewise, the unsupervised models K-Means and DBSCAN reinforced the exploratory analysis by identifying four main thematic clusters—technological, managerial, operational, and hybrid—which were validated using a silhouette coefficient of 0.7482. This value demonstrated the internal consistency of the resulting cluster structure.

IV.2.4 Competency Segmentation and Cluster Analysis

Cluster analysis revealed a coherent structure in the organization of professional competencies. The resulting categories combined technical skills—such as programming, data analysis, and visualization—with soft skills including communication, leadership, and customer service. The identified clusters showed the coexistence of technical and soft competencies, indicating the presence of hybrid professional profiles within the analyzed labor market. This pattern was observed consistently across the clustered data, reflecting structural changes in the composition of demanded skills within digitally mediated employment contexts. The segmentation was represented using the elbow method and the silhouette coefficient, as illustrated in Figure 1. The results indicated that the inflection point of the elbow method stabilized at $k = 4$, which coincided with the optimal silhouette coefficient value (≈ 0.7482). This convergence validated the thematic segmentation obtained and confirmed the internal consistency of the clustering model.

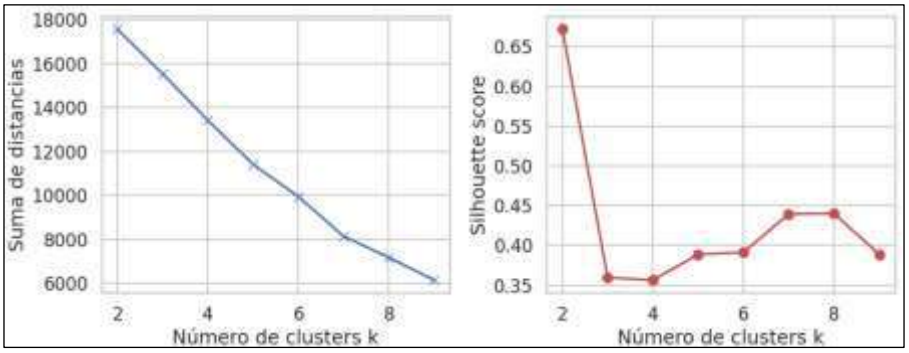

Figure 1: Determination of the optimal number of clusters using the elbow method and silhouette coefficient.
Source: Authors, (2026).

IV.2.5 Classification of Technical and Soft Skills

Semantic classification enabled the clear differentiation between the technical and soft skills most in demand in the Ecuadorian labor market. Skills in Python and R programming, database management, Power BI, and accounting management were identified as highly sought after, along with soft skills such as leadership, teamwork, customer service, and effective communication. The prominence of both technical and soft skills reflected a broader shift observed in digitally mediated labor markets. Digital platforms increasingly prioritized hybrid profiles capable of combining technological proficiency with communication, adaptability, and autonomous problem-solving. This trend was linked to the growing need for workers in platform-based environments to navigate algorithmic interfaces, self-manage tasks, and interact with clients or teams asynchronously.

Therefore, the demand for hybrid competencies was not only an occupational preference but also a structural characteristic of the digital economy, where the boundaries between technical expertise and interpersonal capabilities became progressively blurred. Figure 2 shows the predominance of cross-cutting and operational skills, followed by management and technology skills. These results confirmed the importance of strengthening training programs that integrate both technical and soft components, particularly in sectors undergoing rapid digital transformation, such as technology, commerce, and education.

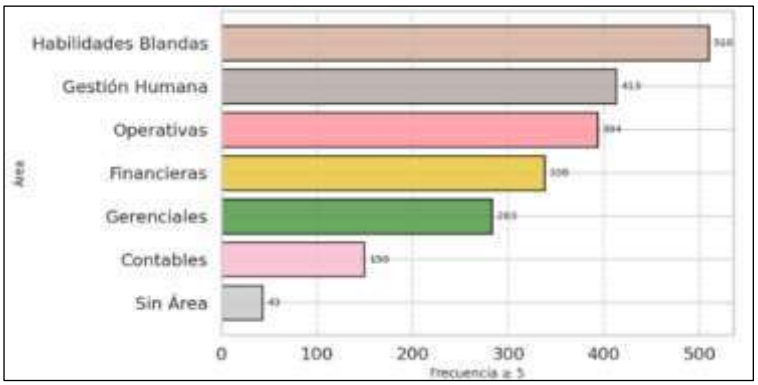

Figure 2: Thematic distribution of standardized competencies extracted from job offers.
Source: Authors, (2026).

IV.2.6 Relative Frequency of Competencies and Territorial Concentration

Frequency analyses generated a word cloud (see Figure 3) that highlighted the most recurrent competencies extracted from job offers. Among the most frequent skills were effective leadership, effective communication, logistics management, financial control, and data analysis, indicating a high demand for multidisciplinary professional profiles.

Figure 3: Word cloud generated from competencies extracted from job offers.
Source: Authors, (2026).

In parallel, the analysis identified a strong geographical concentration of formal employment, as illustrated in Figure 4. Quito (2,328 job offers) and Guayaquil (1,617 job offers) accounted for more than 70% of the total vacancies, followed by Manta (226) and Cuenca (204). The results revealed a pattern of urban concentration accompanied by emerging participation from intermediate cities.

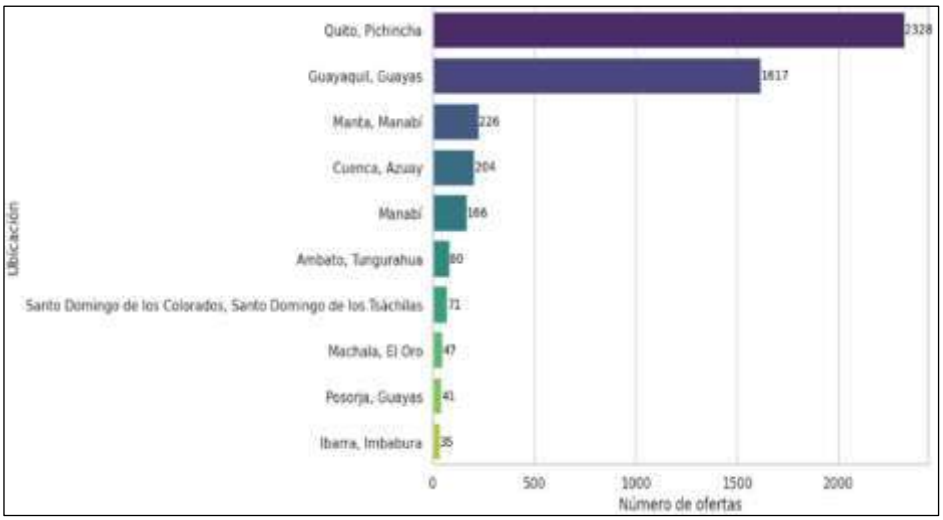

Figure 4: Geographical distribution of job offers in Ecuador.
Source: Authors, (2026).

These geographic disparities reflected structural differences in the spatial distribution of formal employment opportunities. The concentration of vacancies in Quito and Guayaquil was consistent with urban clustering patterns commonly observed in digitally mediated labor markets, where access to connectivity and technological infrastructure was higher than in intermediate or peripheral regions. At the same time, the presence of vacancies in intermediate cities indicated a gradual spatial expansion of formal digital employment.

IV.2.7 Business Concentration in the Labor Market

Figure 5 presented the ten companies with the highest volume of job offers between 2020 and 2024. A high presence of vacancies labeled as Confidential was observed, indicating the widespread use of anonymity practices in digital recruitment processes.

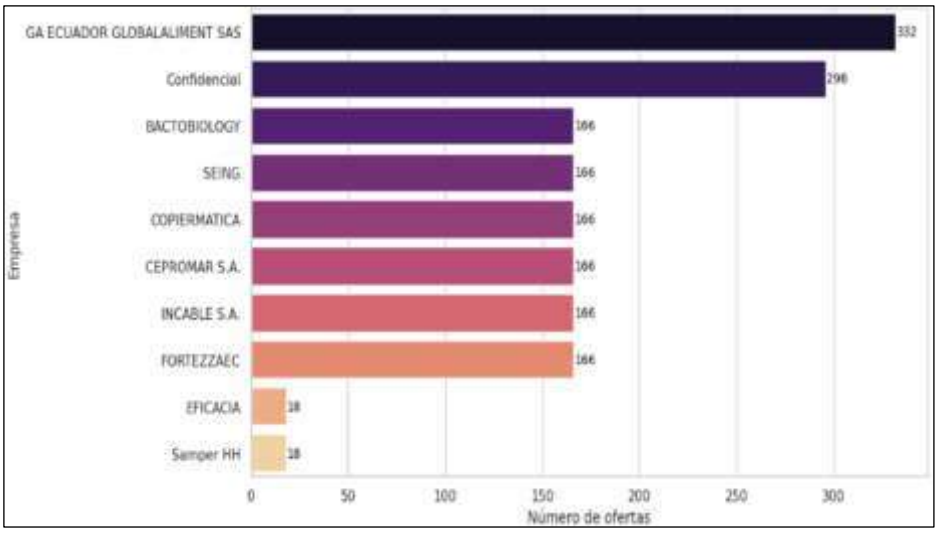

Figure 5: Main companies offering jobs in the Ecuadorian labor market (2020–2024).
Source: Authors, (2026).

The results indicated a high concentration of job offers, in which a limited group of employers generated a substantial proportion of total vacancies. The data showed that large corporations dominated hiring activity during the analyzed period, while medium-sized companies also appeared among the main job offerers, particularly in the logistics and service sectors.

IV.2.8 Model Validation and Comparative Performance

Figures 6 and 7 presented the visual results of the statistical validation performed using confusion matrices and Receiver Operating Characteristic (ROC) curves, respectively. In both analyses, Random Forest exhibited the highest performance, achieving an area under the curve (AUC) value of 0.99, which surpassed the decision tree (AUC = 0.93) and logistic regression (AUC = 0.96).

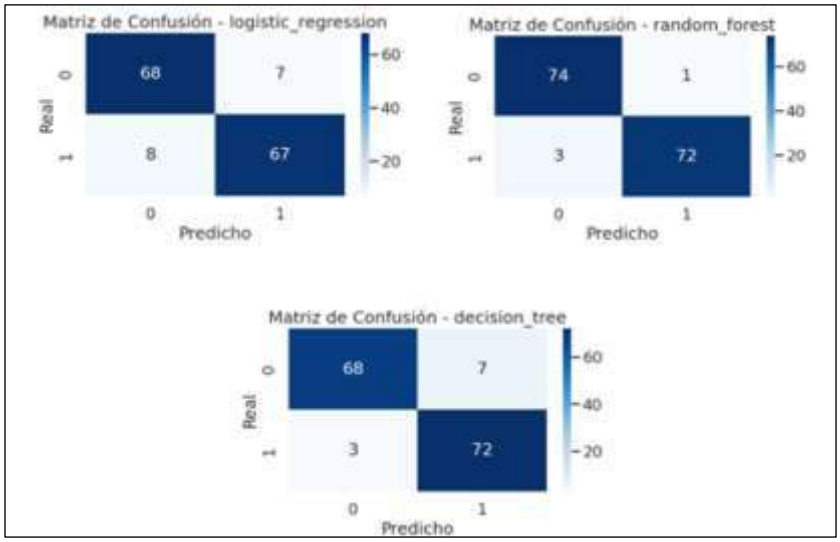

Figure 6: Comparison of confusion matrices between supervised models.
Source: Authors, (2026).

The values shown in Figure 6 indicated that Random Forest achieved 146 correct predictions out of 150 cases, outperforming the decision tree, which recorded 140 correct predictions, and logistic regression, which reached 135 correct predictions in terms of accuracy.

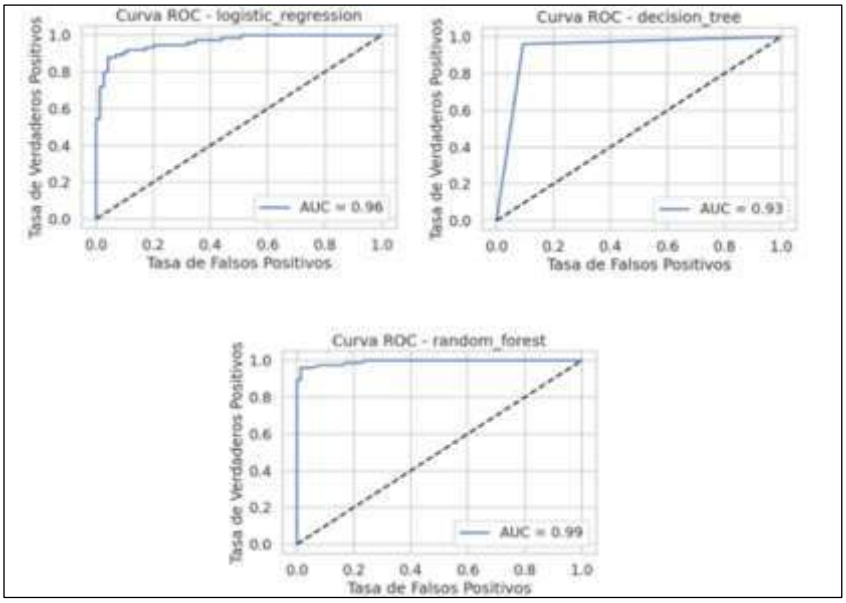

Figure 7: Performance comparison using ROC curves: Logistic Regression, Decision Tree, and Random Forest.
Source: Authors, (2026).

The ROC curves presented in Figure 7 showed consistent performance of the Random Forest model across different classification thresholds, including scenarios characterized by higher semantic variability. These results supported its superior discriminative capacity compared with the other supervised models evaluated.

IV.2.9 Summary of the Comparative Analysis

The results obtained led to the identification of three main findings derived from the comparative analysis. First, the integration of natural language processing with Random Forest provided a favorable balance between accuracy, scalability, and adaptability among the evaluated techniques. Second, the analysis revealed a clear trend toward technical hyper-specialization and the emergence of hybrid professional profiles, accompanied by a strong concentration of job offers in major urban centers. Third, the comparative performance results indicated that hybrid analytical approaches combining semantic analysis with supervised learning achieved higher effectiveness for monitoring professional skill dynamics within the analyzed labor market.

IV.3 DESIGN OF A MODEL FOR DETECTING PROFESSIONAL COMPETENCIES

The analytical model enabled the identification of professional skills in high demand within the Ecuadorian labor market, as well as the hierarchical structure of competencies observed between 2020 and 2024. The results indicated that the integration of structured sources from the National Institute of Statistics and Census (INEC) with unstructured data from digital job portals enhanced the model's predictive performance, achieving accuracy levels above 96%.

IV.3.1 Interactive Visualization and Distribution of Job Offer

The dashboard developed for result visualization integrated geographic, sectoral, and thematic analyses. Figure 8 presented the main interface of the system, which displayed overall dataset metrics, the number of job offers by data source, and dynamic visualizations associated with skills and regions.

Figure 8: Main interface of the dashboard developed in Streamlit.
Source: Authors, (2026).

Figure 8 showed that most job offers originated from private employment portals, with Multitrabajos and BuscoJobs standing out as the sources with the highest volume of vacancies. The indicators revealed a predominance of job offers associated with the commercial, administrative, and technological sectors, together with a clear concentration in the provinces of Pichincha and Guayas.

IV.3.2 Identification of Predominant Skills

The model classified and standardized the competencies identified in thousands of job descriptions, revealing a marked trend toward hybrid skills. Figure 9 presented the main competencies extracted through semantic processing, grouped according to frequency and relevance. The results indicated that the most frequent skills included leadership, customer service, effective communication, logistics management, data analysis, and Python programming, reflecting a convergence between technical and soft competencies within the analyzed dataset.

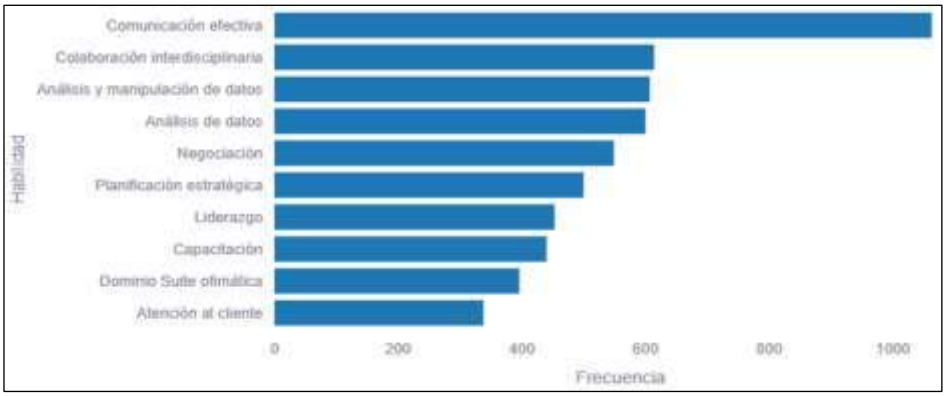

Figure 9: Main skills extracted through semantic processing in Streamlit.
Source: Authors, (2026).

The results showed that job offers across the analyzed sectors frequently required profiles combining technological expertise with management and coordination-related skills. This pattern was observed consistently across all sectors included in the analysis.

IV.3.3 Hierarchical Structure of Competencies

The analysis of semantic hierarchies allowed the representation of the organization of competencies according to levels of generality and frequency. Figure 10 presented the sunburst chart summarizing the relationships between main competencies and sub-competencies derived from the processed textual corpus. The results revealed three dominant hierarchical levels: (i) technological competencies, including data analysis, database management, programming, and Power BI; (ii) management and leadership competencies; and (iii) operational and service-related competencies.

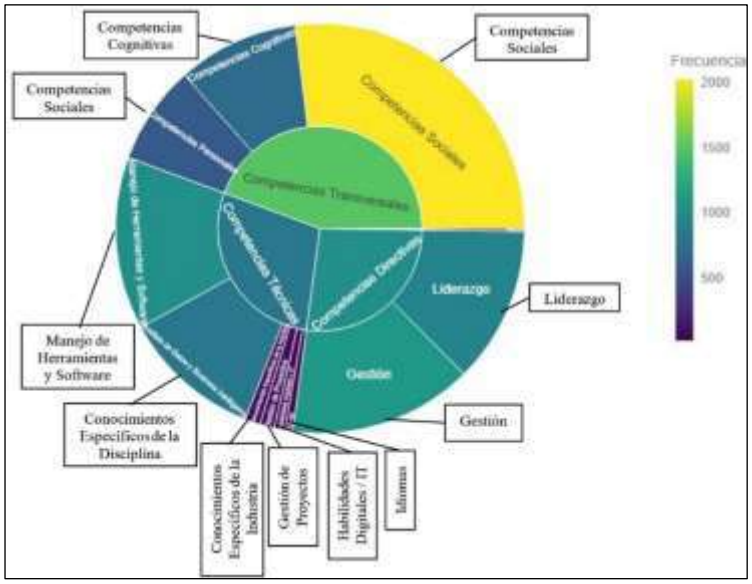

Figure 10: Hierarchy of job skills identified using a sunburst chart.
Source: Authors, (2026).

The technology and commercial sectors exhibited the highest diversity of sub-skills, whereas administrative areas showed lower thematic dispersion. The hierarchical visualization highlighted the interconnection between technical and soft competencies observed in the analyzed data, indicating a structural organization of skills across sectors.

IV.3.4 Model Performance and Consistency of Results

The model's performance showed high accuracy in classifying competencies extracted from unstructured job-related texts. The statistical results indicated an accuracy of 96.67%, a precision of 97.30%, and an F1-score of 96.64%, which validated the robustness of the model under conditions of semantic variability. The consistency observed between the visual outputs and the quantitative performance metrics demonstrated that the model generalized labor demand patterns across different regions of the country.

In addition, the dashboard visualizations enabled the identification of associations between skill types and geographic location. In Quito and Guayaquil, higher demand for technological and administrative profiles was observed, whereas in Manta and Cuenca, operational skills related to logistics and customer service predominated. These spatial patterns were consistently reflected across the visual and quantitative results generated by the system.

IV.3.5 Final Model Architecture

Figure 11 summarized the architecture of the final analytical model, which combined supervised and unsupervised learning techniques within a sequential analysis workflow. The architecture operated through an extraction, transformation, and loading (ETL) process, followed by semantic modeling, statistical validation, and dynamic visualization stages.

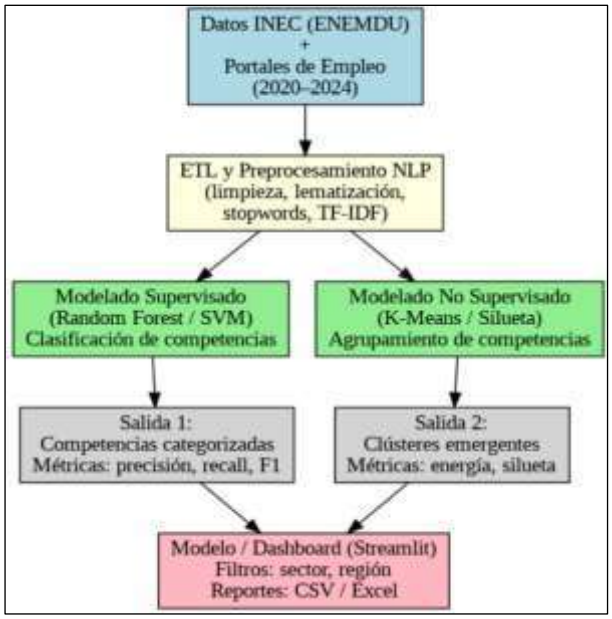

Figure 11: Architecture of the job competency analysis model.
Source: Authors, (2026).

The modular structure allowed algorithms to be updated and new data sources to be incorporated without reconfiguring the overall system architecture, ensuring scalable, transparent, and replicable operation. The resulting configuration supported continuous monitoring of professional competencies based on the analyzed datasets and facilitated the systematic analysis of labor demand patterns within the Ecuadorian context.

IV.4 DISCUSSION

The results of this study demonstrate that applying data science techniques to the analysis of the Ecuadorian labor market is an effective approach for detecting patterns of professional demand and anticipating emerging skills trends. Beyond the technical accuracy achieved—exceeding 96%—the findings show that computational models offer a meaningful way to understand how labor behaviors are increasingly shaped by digital platforms and socio-technical ecosystems. Integrating structured and unstructured sources thus provides not only richer predictive capacity but also insights into how digital employment infrastructures structure access to work opportunities. The hierarchical analysis of competencies revealed a clear trend toward skill hybridization, where technical competencies related to programming, data analytics, and digital management are complemented by soft skills such as leadership, effective communication, and problem solving.

This phenomenon, observed globally in digitally mediated labor markets, reflects the transition toward interdisciplinary profiles capable of operating in environments characterized by automation, virtual collaboration, and accelerated technological cycles. These findings are consistent with research in Latin America [26], [27], which documents a sustained rise in demand for professionals who combine advanced digital abilities with cross-cutting competencies needed for platform-based and remote work environments. Likewise, the results coincide with findings by [28], who emphasize that integrating supervised and unsupervised learning enables deeper and more consistent identification of semantic patterns than traditional statistical methods. This study expands that perspective by incorporating large-scale web scraping and text-mining techniques, enabling the analysis of both formal and informal segments of the labor market.

Such a hybrid methodological approach contributes to addressing a documented gap in the regional literature, revealing how platform-mediated employment and uneven digital adoption reshape skill requirements in heterogeneous work contexts [29]. This broader analytical scope also exposes structural inequalities in skill demand and training gaps, which become more visible when analyzing labor markets through digital traces. The empirical evidence obtained has relevant theoretical and practical implications. Academically, it offers a replicable methodological framework for studies on employability and digital skills, reinforcing the potential of data science for building evidence-based labor observatories. In practical terms, the model provides useful inputs for public policy, curriculum design, and business strategies in human-talent management. When combined with an interactive dashboard, the system enables continuous monitoring of the evolution of labor demand by sector, region, and specialization level.

This capability is crucial for digital-transformation agendas and can support governments in designing e-employment policies, anticipating future skill shortages, and reducing territorial gaps in digital labor inclusion. Nevertheless, some limitations must be acknowledged. Reliance on digital sources may underrepresent sectors characterized by low digitization or high informality, reflecting the broader issue of digital inequality in emerging economies. Moreover, variability in the language of job advertisements can introduce semantic noise, despite the model's strong generalization metrics. Future research could expand temporal coverage, incorporate deep learning architectures to enhance contextual understanding of job descriptions, and integrate socioeconomic, gender, and territorial variables to provide a more comprehensive view of inequality in digital labor markets. Such improvements would strengthen both the predictive capacity and social relevance of the system, enabling its evolution into a full digital labor observatory capable of capturing transformations in work, skills, and employment in digitally evolving societies.

V. CONCLUSIONS

This study demonstrated that the application of data science techniques constitutes an effective approach for analyzing and understanding the Ecuadorian labor market in a context increasingly mediated by digital technologies. By integrating structured sources, such as INEC records, with unstructured data from digital job platforms, the proposed model accurately identified professional competencies, revealed training gaps across productive sectors, and captured patterns of hybrid skill demand combining technical and soft skills. The high performance achieved—exceeding 96% accuracy—confirmed the value of combining supervised and unsupervised learning within a modular and scalable analytical framework supported by natural language processing and interactive visualizations. Although reliance on digital job sources may underrepresent informal or low-digitization sectors and introduce semantic variability, the model showed consistent and robust performance. Overall, this research contributes a replicable methodological approach to digital labor analytics and provides a foundation for evidence-based decision making, workforce planning, and future extensions aimed at monitoring emerging skills and addressing territorial and socio-digital inequalities in evolving labor ecosystems.

Environmental degradation,
Fossil fuel depletion,
Hydrogen fuel,
Dual-fuel mode

ABSTRACT

Renewable fuels are critically required for internal combustion engines because of environmental degradation and the exhaustion of fossil fuels. Hydrogen, possessing a higher auto-ignition temperature and zero emissions has recently surfaced as a feasible alternative to biodiesel and other renewable fuels. Integrating hydrogen with an alternative liquid fuel and operating the engine in dual-fuel mode reduces the self-ignition temperature of the compression ignition engine. This study aims to investigate the impact of including a natural antioxidant on the performance of a diesel engine operating on biodiesel with an elevated hydrogen concentration. During the testing method, hydrogen is injected into the system by the intake manifold, while a B15 mixture of Karanja biodiesel is delivered into the combustion chamber. The experimental fuel samples comprised Diesel, B15, and B15 augmented with hydrogen at flow rates of 6, 9, 12, 15, and 18 lpm. The combination of B15 with hydrogen results in an enhancement of brake thermal efficiency (BTE). Blends of B15 with 15 liters of gasoline and B15 with 18 liters of gasoline demonstrated superior performance compared to the traditional engine at full load CO, achieving BTE improvements of 28.60% and 27.62%, respectively. HC emissions from B15 at 15 lpm and B15 at 18 lpm are reduced in comparison to other mixtures, however NOx emissions from diesel are elevated by 25 and 27 %, respectively. The combination of B15 + 15 lpm with 1000 ppm of Azadirachta indica (AI), a natural antioxidant, diminished NOx emissions to 1074 ppm, reflecting a reduction of 21.9% relative to B15 + 15 lpm without AI. The outcome was a 2.17% enhancement in BTE relative to B15 + 15 lpm without AI. Consequently, numerous test mixes are inferior than B15 + 15lpm with additive.

1. INTRODUCTION

Growing environmental concerns and the depletion of fossil fuels have accelerated the search for cleaner and more sustainable alternatives for compression ignition engines. Dual-fuel operation, combining biodiesel with hydrogen, offers the potential to enhance combustion efficiency while reducing harmful emissions. The addition of natural antioxidant additives further improves fuel stability and performance characteristics. Optimization of such blends enables a balanced approach to achieving higher efficiency with lower environmental impact. L-ascorbic acid (LA) antioxidant effects were explored in a lanthanum oxide-coated low heat rejection engine using AME, WCOME, and JME biodiesel blends.

AME20 recorded the highest BTE (30.3%) with lower HC, CO, and smoke emissions than diesel, though NOx slightly increased (2.1%). Adding LA200 mg further reduced HC by 15.8%, CO by 10.4%, and smoke by 9.3%, indicating antioxidant-assisted blends can reduce oxidation-induced NOx without major efficiency losses [1]. Natural antioxidants (NA) explored from Albizia lebbeck leaves in an LHR engine (zirconia-coated piston and head) using SBME20 (80% diesel + 20% sesame biodiesel). NA addition reduced BSFC to 0.38 kg/kW-hr (from 0.42 in CE), CO to 0.2 g/kWh, and NOx to 0.5 g/kWh at higher loads. Smoke opacity fell by 10%, showing NA's role in stabilizing biodiesel and improving combustion in high-temperature LHR conditions [2]. This study examined the addition of diphenylamine (DPA) and ceria nanoparticles (CeO_2) to a B30 Jatropha biodiesel blend. The optimal B30+DPA50+$CeO_2$50 blend achieved a 6.35% reduction in brake-specific fuel consumption (BSFC) and an 8.68% decrease in NOx emissions, with a 5.74% increase in brake thermal efficiency (BTE). Machine learning modelling showed that the K-nearest neighbors algorithm provided the most accurate predictions compared to multilayer perceptron and random forest regression [3]. ANN and Taguchi-based optimization confirmed improved stress transfer and eco-friendly applicability for packaging and building materials [4]. This study evaluated N-isopropyl-N′-phenyl-1,4-phenylenediamine (IPPD) as an antioxidant in Jatropha methyl ester (JME) for thermal barrier coated (TBC) diesel engines. The piston crown was coated with YSZ–CeO_2 (0.3 mm) to improve thermal efficiency. The optimal 1000 ppm IPPD-doped JME reduced NO emissions by 8.9% while increasing BTE by 18.8% and reducing BSFC by 11.7%. HC, CO, and smoke emissions were also reduced by over 22% at maximum load compared to the JME-fueled conventional engine [5]. Palm biodiesel blends with 10% dimethyl carbonate (DMC) were prepared and tested in a CI engine across speeds from 1100 to 2100 rpm.

DMC addition improved brake power (up to +1.70%) and BTE (up to +4.90%), while reducing BSFC (up to −2.93%) and EGT (up to −4.54%). Emissions decreased significantly, with CO reduced by up to 26.47% and HC by up to 33.33% compared to biodiesel blends without antioxidant [6]. Lemongrass oil (5–20 mL/L) was used as an antioxidant in B20 Calophyllum inophyllum methyl ester (CIME) blends to improve oxidation and thermal stability. The best blend (B20LG20) extended the induction period to 9.6 h, reduced peroxide value by 51%, and limited acid number growth by 42%. Engine tests showed BTE of 31.2%, with CO and smoke emissions reduced by 15% and 25%, and NO reduced by 6% compared to B20 [7].Hybrid composites of Holoptelea integrifolia bark fiber and Ziziphus jujuba seed particles were developed using a tannic acid-based bio-epoxy resin (BBER). Mechanical testing data were modeled using fuzzy logic, achieving an 87% prediction accuracy for tensile, flexural, and impact strengths. The composites demonstrated strong mechanical performance potential with renewable resin systems for sustainable structural applications [8]. Four antioxidants—BHT, BHA (phenols), and DPPD, PPD (aromatic amines)—were tested in neat sunflower biodiesel and B20 blends. PPD showed the greatest NOx reduction (52%) compared to other antioxidants. Adding 1000 ppm antioxidants to B20 reduced NOx more effectively than in neat biodiesel. CO and HC emissions dropped slightly, while smoke number increased with antioxidant concentration and load [9]. Biodiesel was extracted from Scenedesmus obliquus (S1) and Scenedesmus dimorphus (S2) using Ni/H_2 transesterification with a Ni(II)–Schiff base promoter. Blends (S1B10–S1B50, S2B10–S2B50) showed slightly higher SFC and lower brake power but reduced greenhouse gas emissions, except for NOx. The fuels also exhibited antimicrobial, antioxidant activity, and improved thermal and corrosion resistance [10]. Waste cooking oil biodiesel (B20) was enriched with hydrogen (10 L/min) and synthetic antioxidant TBHQ (1000–2500 ppm).

The B20 + 2000 ppm + H_2 blend achieved the highest oxidation stability, 7.39% higher BTE, and 11% lower BSFC than diesel, while reducing NOx by 3.63%. Hydrogen-antioxidant synergy improved performance but lowered ICP and HRR [11]. Diphenylamine (DPA, 100 ppm) was added to B30 Jatropha biodiesel, with performance modeled using RSM and ANFIS. B30 + DPA100 reduced NOx by up to 15.53% compared to B30, with minor changes in BTE and BSFC. BMEP increased by 1.3% over B30, indicating feasibility for use without engine modification [12]. AA2024 metal matrix composites reinforced with nano-ZrO_2 were produced by squeeze casting, with process parameters (melt/die temperatures, pressure) optimized for mechanical and wear performance. The study applied TOPSIS-EWM to identify ideal electrical discharge machining (EDM) settings, ensuring minimal nanoparticle damage and consistent dimensional accuracy. Findings support precise process control for high-quality MMC fabrication [13]. Orange peel methyl ester (OPME) biodiesel was doped with butylated hydroxytoluene (250–1000 ppm) and tested in both conventional and YSZ-coated low-heat rejection engines. At 750 ppm BH, BTE increased by 3.04%, BSFC dropped by 15.3%, and CO and HC fell by 36.6% and 39.1%. Antioxidant addition improved efficiency and lowered emissions [14]. Pongamia methyl ester (PME20) biodiesel was combined with natural antioxidant from Mangifera indica leaves (1000 ppm) and hydrogen enrichment (16 L/min). PME20 + 16lpm + NA1000 achieved 29.17% BTE and 13.5% lower NOx than PME20 + 16lpm. Hydrogen improved efficiency but increased NOx, which was mitigated by the antioxidant [15]. This review highlights the role of additives, especially antioxidants in improving biodiesel stability, combustion, and emission characteristics. Antioxidants enhance storage life, reduce corrosion, and maintain engine cleanliness.

Metal-based additives also aid emission control, making biodiesel more viable for CI engine applications [16]. A low heat rejection (LHR) diesel engine with a TBC piston coated in YSZ and CeO_2 (0.3 mm) was fueled with Jatropha Methyl Ester (JME20) doped with 500–2000 ppm N,N′-diphenyl-p-phenylenediamine (DPPD). The coated engine (CE) running on JME20B4 reduced NO by 6.5%, HC by 17.4%, and CO by 34.6% at full load. Smoke opacity also dropped by 15.3%, though peak HRR and cylinder pressure decreased by 5–6% [17]. Clove (CEO), thyme essential oils (TEO), and synthetic BHT (3000 ppm) were added to B20 colza biodiesel–diesel blends. While antioxidants slightly raised SFC (0.9–2.4%) and reduced thermal efficiency (1.1–2.2%), BHT cut NO emissions by 21% but increased CO by 3.68%. CEO improved overall performance and emissions more than TEO, while all antioxidants reduced smoke and CO_2 [18].Karanja oil biodiesel B20 was blended with carbon nanotubes (CNTs) using QPAN80 surfactant (1:4 NP:surfactant ratio). The B20CNT50 blend boosted BTE by 9.8% and reduced BSFC by 18.7%. Emissions reduced significantly—CO by 7.7%, CO_2 by 11.2%, HC by 10.2%, smoke by 5.7%, and NOx by 10.9%—while machine learning models (SVR, RF) accurately predicted performance and emissions [19]. Karanja oil biodiesel was produced using cobalt-doped zinc oxide (CZO) nanoparticles (~75 nm) by a dual-step esterification–transesterification process. At optimal conditions (1:25 oil:methanol, 0.3 wt% catalyst, 70°C, 180 min), biodiesel yield reached 98.5%. CZO provided high purity, easy glycerol separation, and reusability, making it a commercially viable catalyst for biodiesel production [20]. A single-zone, zero-dimensional progressive combustion model was developed in Python to predict CI engine performance, combustion, and emissions. Validated against experimental data for diesel, Pongamia biodiesel, and blends, the model accurately estimated in-cylinder pressure and HRR.

Results showed blending up to 30% biodiesel had minimal performance impact, though exhaust oxygen concentration increased with blend ratio [21]. Pongamia biodiesel blends (20BD, 50BD, 100BD) were tested in a CI engine with and without thermal barrier coatings (TBC) of NiCrAl (1 mm) and TiO_2 (4 mm). With 20BD in the coated engine, fuel consumption dropped by 10.6% and BTE increased by 4.7% compared to the uncoated engine. Enhanced heat retention improved fuel vaporization, shortened ignition delay, and increased mechanical efficiency [22]. B20 biodiesel blends from Pongamia, Juliflora, and Calophyllum were evaluated in a low heat rejection engine with zirconia-coated components. Adding 2.5% neem leaf extract improved BTE and reduced NOx compared to blends without additives. Biodiesel blends lowered CO, HC, and PM emissions, while increasing cylinder pressure and HRR. Neem extract further minimized ignition delay and enhanced combustion stability [23]. This study presents the findings of a CI engine utilizing Karanja B15 biodiesel-hydrogen in dual fuel mode, enhanced with a natural antioxidant additive, focusing on performance and emission characteristics. The incorporation of the additive into the biodiesel-enhanced hydrogen blend resulted in an elevation of BTE and a reduction in NOx emissions. In addition to diesel engines, this study evaluates the performance and emission parameters of CI engines that use other fuels. This study does not require engine modifications; instead, it necessitates a specialized fuel system for hydrogen fuel, enabling the gas to reach the intake manifold in conjunction with air.
