Journal of Engineering and Technology for Industrial Applications (JETIA)

O **ITEGAM-JETIA: Journal of Engineering and Technology for Industrial Applications** is a publication of the Galileo Institute of Technology and Education of the Amazon (ITEGAM), located in the city of Manaus since 2008. JETIA publishes original scientific articles covering all aspects of engineering. Our goal is the dissemination of research original, useful and relevant presenting new knowledge on theoretical or practical aspects of methodologies and methods used in engineering or leading to improvements in professional practice. All the conclusions presented in the articles It should be state-of-the-art and supported by current rigorous analysis and balanced assessment. Public magazine scientific and technological research articles, review articles and case studies.
JETIA will address topics from the following areas of knowledge: Mechanical Engineering, Civil Engineering, Materials and Mineralogy, Geosciences, Environment, Information and Decision Systems, Processes and Energy, Electrical and Automation, Mechatronics, Biotechnology and other Engineering related areas.

Publication Information:
ITEGAM-JETIA (ISSN 2447-0228), (online) is published by Galileo Institute of Technology and Education of the Amazon on a every two months (February, April, June, August, October and December).

Contact information:

SUMMARY

INTELLIGENT CONTROL STRATEGIES FOR DFIG-BASED WIND ENERGY SYSTEMS: A COMPARATIVE ANALYSIS OF TYPE-1 FUZZY, INTERVAL TYPE-2 FUZZY, AND ANN APPROACHES **01**
Kouadria Selman, Kouadria Mohamed Abdeldjabbar, Berkouk El Madjid, Rizoug Nassim

MULTI-OBJECTIVE OPTIMIZATION OF CMOS FOLDED-CASCODE OTAS USING DIVERSE EVOLUTIONARY ALGORITHMS **16**
Alpesh M. Patel, Pankaj P. Prajapati, Anilkumar J. Kshatriya, Kirit V. Patel, Ghanshyamkumar Sah, Chintan Dave, Kinjal R. Sheth, Devendra H. Patel

COMPARATIVE STUDY OF HMM AND BPNN IN DETECTING CORONA DISCHARGE ON 20 KV CUBICLE BASED ON VOLTAGE AND SOUND **24**
Christiono Christiono, Miftahul Fikri, Syamsir Abduh

DESIGN AN INTELLIGENT CONTROLLER FOR LOAD BALANCING IN WIND ENERGY SYSTEMS CONNECTED TO THE GRID **35**
Zainab Jamal Mohammed, Mafaz Yahya Damarah

DARK PATTERNS IN DIGITAL DESIGN: A REVIEW AND ASSESSMENT VIA RISK, TRUST AND DIVERSITY SCORES **43**
Preeti Marwaha, Shalu Mahajan, Ishitva Joshi, Kriti Mishra, Ananya Srivastava, Priyanka Sharma, Arunita Chaukiyal

MODELING AND SIMULATION OF TEMPERATURE EFFECTS ON INGAP/INGAAS/GE TRIPLE-JUNCTION SOLAR CELLS WITH PYAMS **59**
Dhiabi Fathi, Okba Benelmir

PREDICTING CARDIOVASCULAR DISEASES THROUGH INTEGRATED DEEP LEARNING FEATURES **69**
Islam Daoud Suliman, D. Vasumathi

AN ENHANCED MULTIMODAL APPROACH FOR SENTIMENT ANALYSIS USING DEEP LEARNING TECHNIQUES **77**
Vinitha V, S.K.Manju bargavi

OPTIMIZING OVERLAP IN TREE-BASED INDEXING STRUCTURES FOR ENHANCED K-NN SEARCH EFFICIENCY **86**
Ala Eddine Benrazek, Ibtissem Kemouguette, Zineddine Kouahla, Brahim Farou, Hamid Seridi, Pr.

MACHINE LEARNING FOR CORONARY HEART DISEASE RISK PREDICTION: A CONVENTIONAL AND ENSEMBLE CLASSIFICATION MODEL APPROACH **104**
Raghavendran Ch V, Chandra Mouli Kathi, Bhargavi Latha S

CARDIOVASCULAR RISK PREDICTION USING AI **115**
Mehek Mohd Meraj Qureshi, Hariram Chavan

DIFFERENTIABLEHMM: NEURAL DIFFERENTIABLE HIDDEN MARKOV MODEL **124**
Arbia Boudaoud, Salheddine Kabou

ENHANCING RENEWABLE ENERGY RELIABILITY: A STUDY ON HYBRID SOLAR-WIND SYSTEMS FOR EFFICIENT POWER GENERATION **133**
Omar Gheyath Ibrahim, Mohammed Tariq Majeed, Ghufran Saad Mohammed, Israa Khalouq Saaed

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

FAULT PROTECTION ANALYSIS OF A DC MICROGRID USING VSC-BASED MODULAR MULTILEVEL CONVERTER (MMC) **147**

Artificial Neural Networks (ANN).

ABSTRACT

In this study, we investigate and compare three advanced control strategies, Type-1 Fuzzy Logic Control (T1FLC), Interval Type-2 Fuzzy Logic Control (IT2FLC), and Artificial Neural Networks (ANN), applied to Doubly-Fed Induction Generators (DFIGs) in Wind Energy Conversion Systems (WECS). As wind energy plays an increasingly critical role in renewable power generation, efficient and robust control of DFIGs is essential to ensure grid stability, reliability, and optimal energy extraction under variable wind conditions. T1FLC offers simplicity and robustness but may suffer from limited adaptability. IT2FLC improves upon this by managing higher levels of uncertainty and noise through the use of fuzzy sets with an additional degree of freedom. ANN-based control, on the other hand, leverages data-driven learning and non-linear mapping to achieve high performance but may require significant training and tuning. Simulations conducted in MATLAB/Simulink evaluate the performance of each controller under dynamic wind profiles, measuring key metrics such as rotor speed regulation, electromagnetic torque response, and power output stability. This comparative study provides insights for selecting suitable control schemes for DFIG-based wind energy systems under varying operational conditions.

I. INTRODUCTION

The increasing global focus on sustainable energy solutions has made wind energy a key part of the renewable energy shift. Known for being environmentally friendly, cost-effective, and abundant, wind power plays a major role in decreasing reliance on fossil fuels and reducing greenhouse gas emissions. At the heart of this change are Wind Energy Conversion Systems (WECS), especially those using Doubly-Fed Induction Generators (DFIGs), which provide better control, higher energy efficiency, and flexibility to adapt to changing wind conditions [1], [2]. DFIG-based Wind Energy Conversion Systems (WECS) are widely adopted due to their ability to operate effectively over a wide range of speeds, maximizing power output through advanced control methods like Maximum Power Point Tracking (MPPT). Unlike fixed-speed systems, variable-speed DFIG systems allow for real-time adjustments to rotor speed, boosting energy capture and reducing mechanical stress. However, controlling DFIGs is difficult because of their nonlinear dynamics, the coupling between control variables, and their sensitivity to parameter changes and external disturbances. [3], [4]. To address these challenges, researchers have shifted away from traditional control strategies like Proportional-Integral (PI) controllers. Although these are simple and commonly used, they often lack robustness in uncertain and variable operating conditions. Consequently, there has been a rise in intelligent control methods that can more effectively handle the dynamic and nonlinear characteristics of wind energy systems [5], [6].

Among these, Type-1 Fuzzy Logic Controllers (T1-FLCs) offer improved adaptability by incorporating linguistic rules and expert knowledge to handle system nonlinearities without requiring precise mathematical models. However, their performance can degrade in the presence of significant uncertainties. To address this, Interval Type-2 Fuzzy Logic Controllers (IT2-FLCs) have been developed, extending the fuzzy logic paradigm by modeling uncertainties within membership functions using a Footprint of Uncertainty (FOU). This allows IT2-FLCs to provide enhanced robustness and tracking performance under turbulent wind conditions and parameter variations [7-9]. Parallel to fuzzy logic approaches, Artificial Neural Networks (ANNs) have emerged as a powerful tool for intelligent control. Leveraging their ability to learn complex nonlinear mappings from data, ANNs can adapt to changing dynamics without explicit system modeling, making them highly suitable for unpredictable environments.

However, their effectiveness is closely tied to the quality of training data and the computational resources available [10], [11]. This study presents a comparative analysis of three advanced intelligent control strategies, Type-1 FLC, Interval Type-2 FLC, and ANN applied to DFIG-based wind energy systems. The objective is to evaluate each controller's performance in terms of robustness, tracking accuracy, and computational efficiency under variable wind and system conditions. Through this analysis, the paper aims to identify optimal control methodologies that can enhance the reliability and efficiency of modern wind energy systems, supporting their broader integration into the power grid. Figure 1 illustrates the global scheme of the proposed control strategy, in which three types of controllers are investigated: Type-1 fuzzy logic controller (T1-FLC), Interval type-2 fuzzy logic controller (IT2-FLC), and artificial neural network (ANN) controller.

This paper is structured into six sections. Section 1 provides an overview of wind energy conversion systems and highlights the motivation for applying intelligent control strategies in Doubly-Fed Induction Generator (DFIG)-based systems. Sections 2 and 3 present the modeling of the wind turbine and describe the implementation of a Maximum Power Point Tracking (MPPT) algorithm, respectively. Section 4 focuses on the mathematical modeling of the DFIG. Section 5 presents the simulation results under various operating conditions to evaluate and compare the performance of Type-1 Fuzzy Logic Control (T1-FLC), Interval Type-2 Fuzzy Logic Control (IT2-FLC), and Artificial Neural Network (ANN)-based control strategies. Finally, Section 6 concludes the paper with a summary of the key findings and recommendations for future research.

II. MODELING OF THE WIND GENERATOR

II.1 MODEL Of WIND TURBINE

The wind turbine is the core component of a WECS, and its mechanical power output is determined by its aerodynamic properties as described by the following formula [4],[5],[12].

$$P_w = \frac{1}{2}\rho\pi R^2 v_t^3 C_P(\lambda,\beta) \tag{1}$$

Where:

$$\lambda = \frac{\omega_t . R}{v_t} \tag{2}$$

The aerodynamic torque is commonly represented as follows[13]:

$$T_w = \frac{1}{2}\frac{\rho.\pi.R^3.v_t^2.C_P(\lambda,\beta)}{\lambda} \tag{3}$$

A fundamental equation is used to represent $C_P(\beta,\lambda)$, which is derived from the aerodynamic characteristics of the turbine [13-16]:

$$C_p\left(\lambda,\beta\right)=0.5176.\left(116.\frac{1}{\lambda_i}-0.4.\beta-5\right)e^{-\frac{21}{\lambda_i}}+0.0068.\lambda \tag{4}$$

With

$$\frac{1}{\lambda_i}=\frac{1}{0.08.\beta+\lambda}-\frac{0.035}{1+\beta^3} \tag{5}$$

II.2 MAXIMUM POWER POINT TRACKING TECHNIQUE

MPPT strategies are essential for maximizing power extraction in WECS and improving efficiency. Two main approaches exist: with or without speed control. This discussion focuses on speed control-based MPPT, which regulates turbine rotation to optimize power extraction [4], [5]. Maximum power is achieved when C_P reaches its highest value at a specific λ , corresponding to an optimal rotor speed for each wind speed. However, wind variability can cause deviations from this optimal point, leading to energy losses. An MPPT system continuously optimizes energy transfer to the grid to mitigate these losses [17].

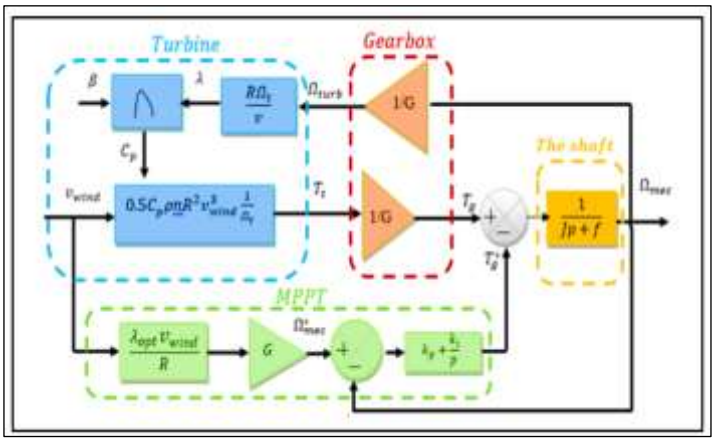

Figure 2: Diagram block of the MPPT extracted with speed control.
Source: Authors, (2026).

The $C_{P\max}=0.48$ is attained when the $\beta=0$ and $\lambda=8.12$ .To sustain this condition, the reference electromagnetic torque is maximized using the given equation [4], [17]:

$$T_{em-ref}=\frac{1}{2}\frac{\rho\pi R_t^5 C_{p\max}}{\lambda_{opt}^3 G^3}\Omega_{mec}^2 \tag{6}$$

Figure 3 presents the $C_P(\beta,\lambda)$ characteristics corresponding to various pitch angle values β [12].

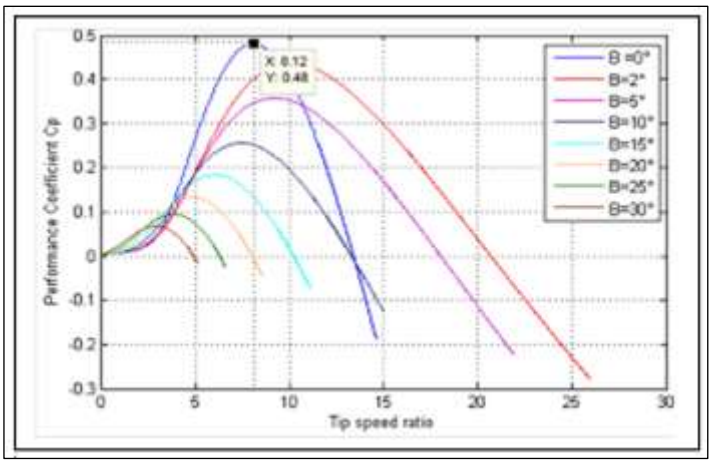

Figure 3: The typical performance coefficient curve.
Source: Authors, (2026).

II.3 DFIG MATHEMATICAL MODELING

The DFIG model is developed using Park's transformation [3-5], [18]. The voltage Equations:

$$\begin{cases} V_{qs} = \dfrac{d\varphi_{qs}}{dt} + R_s I_{qs} - \omega_s \varphi_{ds} \\ V_{ds} = \dfrac{d\varphi_{ds}}{dt} + R_s I_{ds} - \omega_s \varphi_{qs} \\ V_{qr} = \dfrac{d\varphi_{qr}}{dt} + R_r I_{qr} - (\omega_s - \omega_r)\varphi_{dr} \\ V_{dr} = \dfrac{d\varphi_{dr}}{dt} + R_r I_{dr} - (\omega_s - \omega_r)\varphi_{qr} \end{cases} \tag{7}$$

Flux Equations:

$$\begin{cases} \varphi_{ds} = L_m I_{dr} + L_s I_{ds} \\ \varphi_{qs} = L_m I_{qr} + L_s I_{qs} \\ \varphi_{dr} = L_m I_{ds} + L_r I_{dr} \\ \varphi_{qr} = L_m I_{qs} + L_r I_{qr} \end{cases} \tag{8}$$

DFIG electromagnetic torque is:

$$T_{em} = \frac{3}{2} p\left(\varphi_{ds} I_{qs} - \varphi_{qs} I_{ds}\right) \tag{9}$$

P_S and Q_S are determined by:

$$\begin{cases} P_s = \dfrac{3}{2}\left(V_{ds} I_{ds} + V_{qs} I_{qs}\right) \\ Q_s = \dfrac{3}{2}\left(V_{qs} I_{ds} - V_{ds} I_{qs}\right) \end{cases} \tag{10}$$

II.4 DFIG MODEL WITH STATOR FLUX ORIENTATION

The RSC operates in a synchronous reference system with a d-axis aligned to the stator flux, allowing independent control of P and Q power [18]:

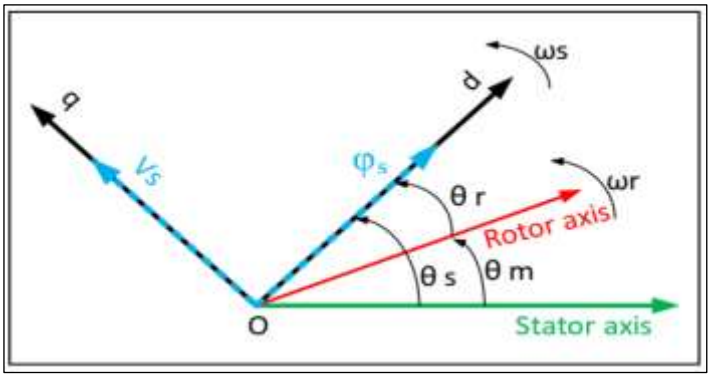

Figure 4: Orientation of the d, q frame.
Source: Authors, (2026).

$$\begin{cases} \varphi_{ds} = \varphi_s \\ \dfrac{d\varphi_{qs}}{dt} = \varphi_{qs} = 0 \end{cases} \tag{11}$$

Apply the following criteria to get the simplified equation for electromagnetic torque:

As a result, we get

$$T_{em} = \frac{3}{2} p \varphi_s I_{qs} \tag{12}$$

Assuming the R_S is ignored, the voltage and flux equations simplify to:

$$\begin{cases} V_{ds} = 0 \\ V_{qs} = \omega_s \varphi_{ds} \end{cases} \tag{13}$$

$$\begin{cases} \varphi_s = L_s I_{ds} + L_m I_{dr} \\ 0 = L_s I_{qs} + L_m I_{qr} \end{cases} \tag{14}$$

Equation (14) defines the correlation between stator and rotor currents.

$$\begin{cases} I_{ds} = \dfrac{\varphi_s}{L_s} - \dfrac{L_m}{L_s} I_{dr} \\ I_{qs} = -\dfrac{L_m}{L_s} I_{qr} \end{cases} \tag{15}$$

P_S and Q_S are given by:

$$\begin{cases} P_s = \dfrac{3}{2} V_s I_{qs} \\ Q_s = \dfrac{3}{2} V_s I_{ds} \end{cases} \tag{16}$$

The electromagnetic torque is determined by integrating equations (12) and (15):

$$T_{em} = -\frac{3}{2} p \frac{L_m}{L_s} \varphi_s I_{qr} \tag{17}$$

By substituting the expressions for the stator currents found in (15), the power equations can be expressed in the following form:

$$\begin{cases} P_s = -\dfrac{3}{2} V_s \dfrac{L_m}{L_s} I_{qr} \\ Q_s = \dfrac{3}{2} V_s \left(\dfrac{\varphi_s}{L_s} - \dfrac{L_m}{L_s} I_{dr} \right) \end{cases} \tag{18}$$

The voltage equations can be represented as follows:

$$\begin{cases} V_{dr} = R_r I_{dr} - g\omega_s \left(L_r - \dfrac{L_m^2}{L_s} \right) I_{qr} \\ V_{qr} = R_r I_{qr} + g\omega_s \left(L_r - \dfrac{L^2_m}{L_s} \right) I_{dr} + g \dfrac{L_m V_s}{L_s} \end{cases} \tag{19}$$

III. INTELLIGENT CONTROL STRATEGIES

III.1 DESCRIPTION OF FUZZY LOGIC SETS

To address the limitations of classical control methods, particularly their reduced performance when actual machine parameters differ from those assumed in the control design, we chose to implement a fuzzy logic controller to manage the behavior of the DFIG wind turbine, focusing primarily on regulating active and reactive power [8].

III.1.1 Overview of Type-1 Fuzzy Logic Sets (T1-Fls)

For any element x within a universe X, a type-1 fuzzy set assigns a membership degree, between 0 and 1, to that element using a function $\mu_A(x)$. We can therefore represent a type-1 fuzzy set as a collection of ordered pairs, where each pair consists of an element and its associated membership degree, as precisely defined by Equation (20). [7-10]:

$$A = \left(x, \mu_A(x) \right) \middle| \forall x \in X \tag{20}$$

Where

$$\mu_A : X \to [0,1]$$

In this definition, $\mu_A(x)$ represents the membership degree of the element $x \in X$ to the set A. In this work, the following notation is used:

$$A(x) = \mu_A(x) \tag{21}$$

For all $x \in X$.

III.1.2 Control of Doubly Fed Induction Generator Using T1-Flc

Figure 5 illustrates the DFIG-based Wind Energy Conversion (WEC) system model simulated using a conventional Type-1 Fuzzy Logic Controller (T1-FLC). Two control loops are presented:

The power control loop regulates the active and reactive power by generating the reference rotor current components I_{rq}^{*} and I_{rd}^{*}, respectively. It employs Type-1 Fuzzy Logic Controllers (T1-FLCs) that process the power errors and their rate of change to provide smooth and adaptive control responses. The current control loop ensures that the actual rotor current components follow the generated references. It also utilizes T1-FLCs to compute the appropriate voltage signals for the rotor-side converter.

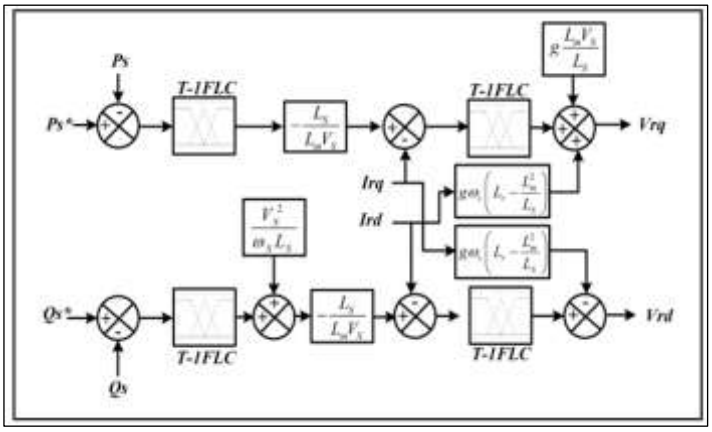

Figure 5: Block diagram illustrating the structure of a type-1 fuzzy logic controller.
Source: Authors, (2026).

III.1.3 Basic Concepts of Interval Type-2 Fuzzy Logic Sets (It-2fls)

According to the definition of Zadeh, A type-2 fuzzy sets are the generalized forms of type-1 fuzzy sets. An interval type-2 fuzzy set, denoted as $\tilde{\tilde{A}}$, is characterized by a type-2 membership function $\mu_{\tilde{\tilde{A}}}(x,u)$ and can be described as [7],[8],[14]-[16],[18]-[22]:

$$\tilde{\tilde{A}} = \left\{ (x,u), \mu_{\tilde{\tilde{A}}}(x,u) \right\} \left| \forall x \in X, \forall u \in J_x^u \subseteq [0,1] \right. \tag{22}$$

In which

$$x \in X, u \in J_x^u \subseteq [0,1] \text{ and } \quad 0 \le \mu_{\tilde{\tilde{A}}}(x,u) \le 1$$

$\left(\tilde{\tilde{A}}\right)$ can be also expressed as:

$$\tilde{\tilde{A}} = \int_{x \in X} \int_{u \in Jx} \mu_{\tilde{\tilde{A}}}(x,u) / (x,u), Jx \subseteq [0,1] \tag{23}$$

Where $\int_{x \in X} \int_{u \in Jx}$ denote union over all admissible input variables x and u.

Here, X is the primary domain of the input variable, x is the value of the input variable, u is the primary grade of a type-2 fuzzy set, and J_x is called the primary membership of a type-2 fuzzy set of x and $\mu_{\tilde{\tilde{A}}}(x,u)$ is the secondary membership function equal to 1.

Another expression for $\left(\tilde{\tilde{A}}\right)$ is:

$$\tilde{\tilde{A}} = \int_{x \in X} \int_{u \in Jx} 1 / (x,u), Jx \subseteq [0,1] \tag{24}$$

$$\tilde{\tilde{A}} : X \to \left\{ [a,b] : 0 \le a \le b \le 1 \right\}$$

The union of all the primary memberships represents the uncertainty about $\left(\tilde{\tilde{A}}\right)$, which is called the footprint of uncertainty (Fou) of $\left(\tilde{\tilde{A}}\right)$ as shown in Figure 3, i.e., [7],[8].

$$Fou\left(\tilde{\tilde{A}}\right) = U_{\forall \in X} J_x = \left\{ (x,u) : u \in J_x \subseteq [0,1] \right\} \tag{25}$$

The (Fou) of $\left(\tilde{\tilde{A}}\right)$ is bounded by two type-1 MFs called upper membership function (UMF) and lower membership function (LMF) as shown in Figure 6. The LMF and UMF are denoted as $\underline{\mu}_{\tilde{\tilde{A}}}(x)$ and $\overline{\mu}_{\tilde{\tilde{A}}}(x)$, respectively, and are defined as follows:

$$\underline{\mu}_{\tilde{A}}(x) = \underline{Fou\left(\tilde{A}\right)}, \forall x \in X \tag{26}$$

$$\overline{\mu}_{\tilde{A}}(x) = \overline{Fou\left(\tilde{A}\right)}, \forall x \in X \tag{27}$$

Note that J_x is an interval set; i.e.,

$$Jx = \left\{(x,u) : u \in \left[\overline{\mu}_{\tilde{A}}(x), \underline{\mu}_{\tilde{A}}(x)\right]\right\} \tag{28}$$

An embedded fuzzy set $\left(\tilde{A}_e\right)$ for a continuous universe of discourse x and u is described as

$$\left(\tilde{A}_e\right) = \int_{x \in X}\left(\frac{[1/u]}{x}\right), u \in J_x \tag{29}$$

The set $\left(\tilde{A}_e\right)$ is embedded in $\left(\tilde{A}\right)$ in such a way that the secondary membership functions (MFs) are always one at each value of x . A large number of such embedded type-1 fuzzy sets (T1-FSs) are combined to form the type-2 fuzzy set (T2-FS), which enables the detailed description of the analytical control surface; the addition of the extra levels of classification gives a much smoother control surface and response. The T2-FS can be considered as a combination of many different type-1 fuzzy sets where each (T1-FS) is embedded to form the (Fou) [7-10],[14],[16].

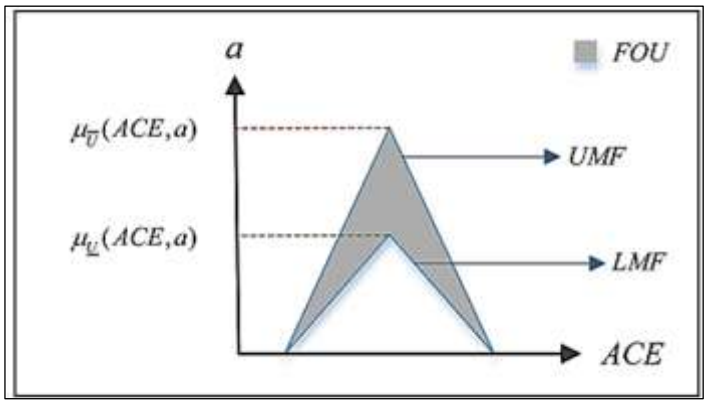

Figure 6: Type-2 fuzzy set with FOU and embedded FS.
Source: [9].

III.1.4 Control of Doubly Fed Induction Generator Using It2-Flc

The Interval type-2 fuzzy logic controller (IT2-FLC) is very useful in circumstances where we need to take into consideration the different uncertainties as the real machine parameters change, and as the controller for a variable speed wind turbine-based on DFIG is used mainly to regulate active and reactive power exchanged with an electrical network. To control a DFIG-based wind energy conversion system easily, we used the independent control of active and reactive power using the stator flux orientation. In the control diagram, the classical rotor currents controllers were replaced by an IT 2-FLC [8],[16].

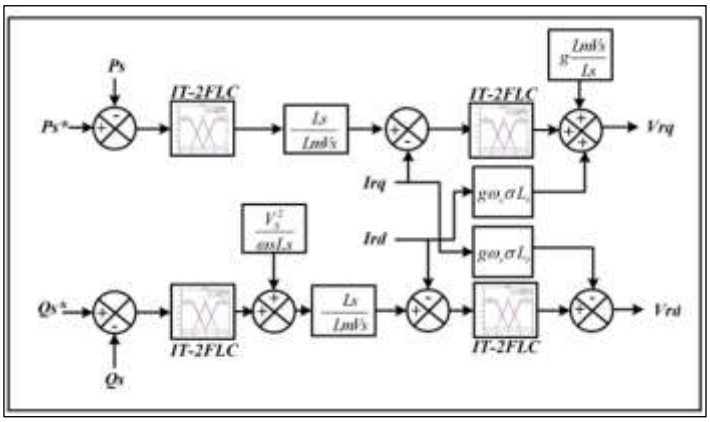

Figure 7: Block diagram illustrating the structure of an Interval type-2 fuzzy logic controller.
Source: Authors, (2026).

The DFIG-based WEC system model was simulated first using a conventional T1-FLC (Figure 5) and then an IT2-FLC. The rule base was the same for both type-1 and type-2 fuzzy logic controllers. The fuzzy control strategy is based on a human operator's experience to interpret a situation and initiate its control action. The scheme of the control of the DFIG-based WEC system using an IT2-FLC is presented in Figure 7.

The core of the type-2 fuzzy logic controller (IT2-FLC) is the type-1 fuzzy logic controller (T1-FLC), as Figure 8 shows. The IT2-FLC is constituted of four functional blocks, the three blocks of type-1 fuzzy and a fourth functional block that ensures the type reducer transforms a type-2 fuzzy set into a type-1 fuzzy set [16]. The structures of IT2-FLS and T1-FLS are shown in Figure 4a and b, respectively [7],[8],[14-16],[19],[20]. The fuzzifier stage is used to translate inputs (real values) to fuzzy values. The inference (reasoning) stage consists of two blocks, the rules base and the inference engine; it works the same way as for type-1 fuzzy systems, except the antecedents' fuzzy sets and the consequent are represented by type-2 fuzzy sets. The process consists of combining the rules base to produce a mapping from input to the output type-2 fuzzy set [7]. It is necessary to calculate the intersection, union and composition of type-2 relations in order to realize this mapping. The type reducer is used to convert all type-2 fuzzy sets into a type-1 fuzzy set on the output. There are several methods to calculate the reduced set, such as joint center, center of sums, height, and center joint, among others [8]. The defuzzification stage translates an output into precise values. A comparison between a T1-FLC and an IT2-FLC is given in the following.

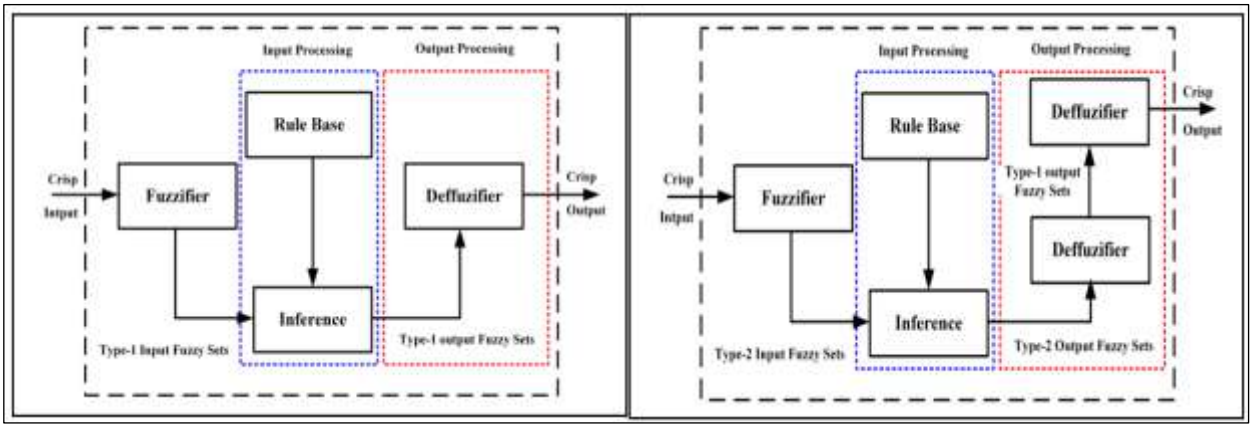

Figure 8: Structures of fuzzy logic control: (a)Type-1 fuzzy logic controller (T1-FLC);
(b) interval type 2 fuzzy logic controller (IT2-FLC).
Source: Authors, (2026).

In this paper, three triangular membership functions were chosen for the IT2-FLC and T1-FLC, because these membership functions are easier to implement in practical hardware, used as the inputs and outputs, which are also shown in Figures 9 and 10, respectively. The maximum and minimum values of the universe of discourse for all inputs and outputs are -1 to +1 [8].]

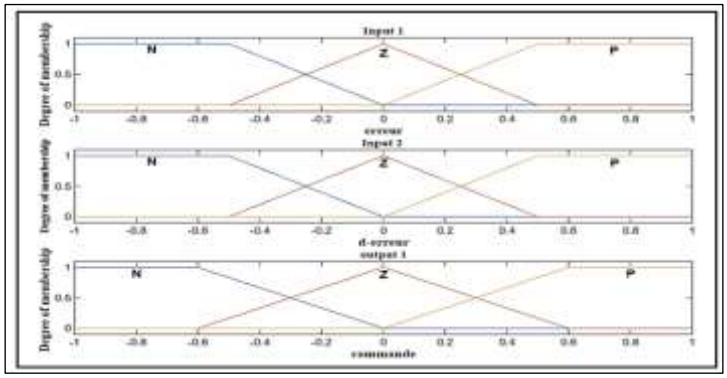

Figure 9: Type-1 fuzzy membership functions (MFs):
MFs corresponding to the input variables 'e' (error)
and 'de' (change in error), as well as the output
variable 'u' of the T1-FLC.
Source: Authors, (2026).

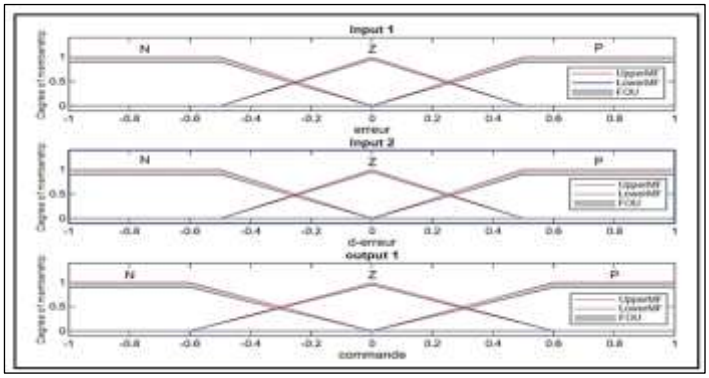

Figure 10: Interval Type-2 fuzzy membership functions (MFs):
MFs corresponding to the input variables 'e' (error)
and 'de' (change in error), as well as the output
variable 'u' of the IT2-FLC.
Source: Authors, (2026).

The controller inputs are error (e) and its derivative (de). The only output of the controller is the control signal (u). Each input and output contain three membership functions, two trapezoidal and one triangular [19]. Input and output membership functions (MFs) of the T1-FLC and IT2-FLC are demonstrated in Figures 5 and 6, respectively. For the optimal performance of the controllers, a 9-rule base was designed for the T1-FLC and IT2-FLC, as shown in Table 1. Referring to this table, N defines the negative. Z is zero while P is positive. The rule base is the core part of the T1-FLC and IT2-FLC design, which is based on process dynamics, experts' knowledge, and experience [23].

III.2. ARTIFICIAL NEURAL NETWORK STRATEGY FOR THE DFIG

An artificial neural network (ANN) is a computational model, inspired by the human brain, made up of interconnected processing units called neurons. These connections have adjustable weights, and each neuron uses an activation function to introduce non-linear behavior. This structure allows the network to learn complex relationships between inputs and outputs. It does this by performing two basic steps: calculating a weighted sum of its inputs and then applying a non-linear activation function to that sum [10],[11].

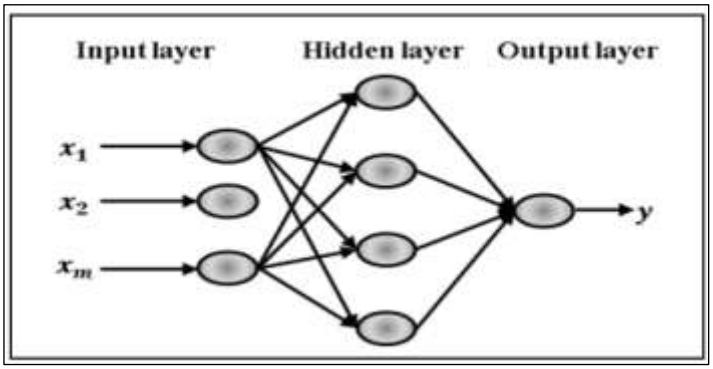

Figure12: Schematic representation of a multilayer Neural Network.
Source [10].

The inherent characteristics of Artificial Neural Networks (ANNs), including parallel processing, learning, and generalization, have established them over the last few decades as one of the most powerful methods for estimation within control systems in various applications. [24], [25]. The following functions represent the operation of the neural network:

$$y = \sum_{k=1}^{n} w_k^2 g\left(\sum_{j=1}^{p} w_{kj}^1 \varphi_j + b_k^1 \right) + b^2 \tag{30}$$

With:

φ_j : ANN input

w_{kj}^1 et b_k^1 : The weights and the bias of the hidden layer

$$g(x) = \frac{2}{1+e^{-2x}} - 1 \tag{31}$$

$g(x)$: The sigmoid function

w_k^2 et b^2 : The weights and the bias of the hidden layer

To take advantage of its advantages, an ANN is proposed in this article to simplify and improve the vector control scheme of the DFIG. The proposed ANN is used to replace the four FLC regulators (T1-FLC and IT2-FLC) in Fig. 4. For the learning of the ANN, it is done offline using a database obtained from the standard vector control diagram. To do this, the inputs and outputs of the FLC controllers are read during the simulation of the vector control for different operating conditions. Then, these data are processed to select a learning base of an appropriate size to ensure a compromise between the sought accuracy and the learning and computing time [26],[27]. Learning is done using the famous retro-propagation algorithm.

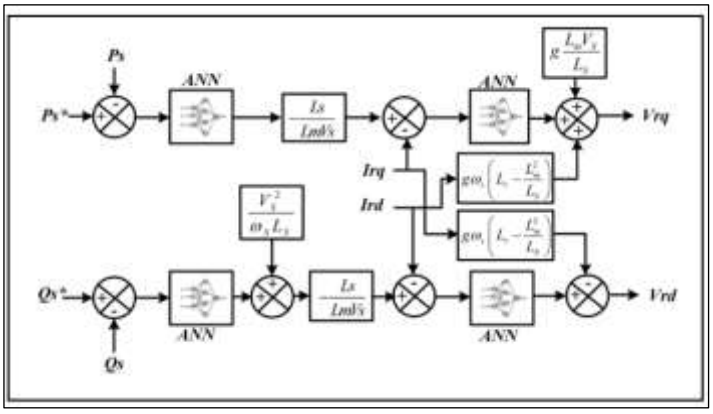

Figure 13: Block diagram illustrating the structure of Interval type-2 fuzzy logic controller.

IV. RESULTS AND DISCUSSIONS

The WECS model utilized in these simulations is based on a 10-kW wind turbine and a 7.5 kW DFIG connected to the grid, and it is implemented in the MATLAB/Simulink environment. The values of the parameters used in the models are listed in the appendix. Figure (14-a) depicts the wind speed profile employed in these simulations. Figures (14-c) and (14-d) show the highest power coefficient $C_{p\max} = 0.48$ and the maximum tip speed ratio $\lambda = 8.12$, for the simulated wind turbine model. The waveforms of optimum angular speed Ω_{opt} and observed angular rotor speed Ω_m of the DFIG are shown in Figure (14-b). The MPPT algorithm determines the reference angular rotor speed Ω_{opt}.

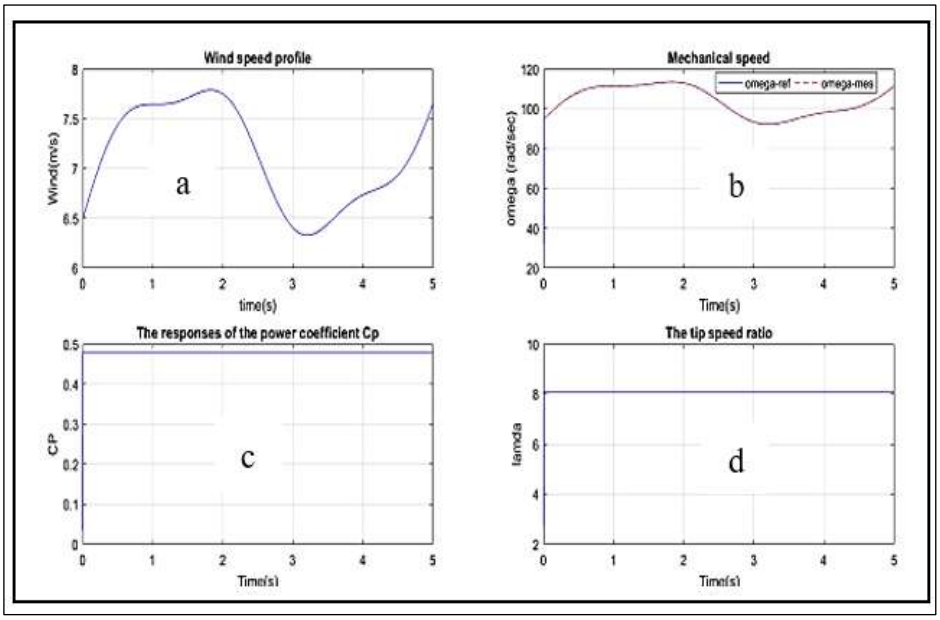

Figure 14: Wind turbine characteristics: (a) Wind speed profile, (b) Mechanical speed, (c) Power Coefficient (Cp), (d) Tip speed ratio (λ).
Source: Authors, (2026).

The simulation results shown in Figures 15, 16, and 17 depict respectively the behavior of the DFIG system under the control of three different intelligent controllers: T1-FLC, IT2-FLC, and ANN. These controllers are used to regulate the active and reactive power generated at the stator, and the control strategy allows for the decoupling of active and reactive power expressions, or equivalently, flux and torque. The simulation confirms that the stator flux follows the reference axis (d) with nearly zero quadrature components, indicating effective decoupling of the machine. The quadrature rotor current (Irq) governs the electromagnetic torque and active power, while the direct rotor current (Ird) manages reactive power exchanged between the stator and the grid. The behavior of these currents directly reflects active and reactive power dynamics, with torque responding rapidly to power demands. Comparatively, T1-FLC demonstrates a moderate transient response with an initial active power spike of approximately (6000 W) and a settling time of (9 ms).

The rotor quadrature current peaks at (20 A) and stabilizes quickly, while the direct current dips to (-20 A) before aligning with its reference of (-15 A) at (0.5 ms). The reactive power shows a dip to (-1000 VAR) and stabilizes to (0 VAR) by (0.7ms), indicating effective voltage support. IT2-FLC, in contrast, exhibits the fastest dynamic performance, with a sharper active power spike (around 16,000 W) but the shortest settling time (around 6 ms). This comes at the cost of a higher (Irq) peak (50 A), showing a more aggressive control effort. The reactive power and (Ird) behaviors are similar to T1-FLC, with stabilization occurring quickly after transients. The ANN controller offers a compromise between these two approaches. It experiences a smaller active power spike (around 8000 W) but with a slower settling time (around 14 ms).

The peak in (Irq) reaches (23.5 A), and (Ird) stabilizes at (-15 A) by (0.4 ms), showing effective control. The reactive power also quickly settles to (0 VAR), confirming proper compensation. In summary, T1-FLC offers balanced and stable regulation with moderate overshoot and fast recovery, making it suitable for smooth operation. IT2-FLC delivers the fastest response and sharpest control action but with higher transient currents and overshoot, which may stress system components. ANN provides robust control with a moderate response and acceptable regulation quality. The choice among these controllers depends on the application's requirements, whether prioritizing speed (IT2-FLC), stability (T1-FLC), or robustness (ANN).]

IV.1. QUANTITATIVE COMPARISONS BASED ON ERROR CRITERIA

This test is based on four criteria, which are determined mathematically as follows [6],[21]-[23]. The integral of the squared error (ISE):

$$ISE = \int_0^T e^2(t)\,dt \tag{32}$$

The integral of the absolute value of the error (IAE):

$$IAE = \int_0^T \left|e(t)\right| dt \tag{33}$$

The integral of the time multiplied by the absolute value of the error (ITAE):

$$ITAE = \int_0^T t \cdot \left|e(t)\right| dt \tag{34}$$

The integral of the time multiplied by the value of the squared error (ITSE):

$$ITSE = \int_0^T t \cdot e^2(t)\,dt \tag{35}$$

The criteria are always calculated for a simulation time of Ts = 5 s and power settings equal to those given in the simulation conditions. Table 2 reports a quantitative comparison based on error and time between the proposed control strategies. The results presented in Table 2 show that interval type-2 fuzzy logic control perform the better in terms of minimizing the criteria ISE, IAE, ITAE and ITSE and gives us the lowest values for active and reactive powers and direct and quadrature current, followed respectively by type 1-fuzzy logic control, interval type-2 fuzzy logic control, and artificial neural network.

Table 2: Quantitative comparisons based on error criteria between the developed commands.

V. CONCLUSIONS

This study evaluated and contrasted three intelligent control strategies, Type-1 Fuzzy Logic Control (T1-FLC), Interval Type-2 Fuzzy Logic Control (IT2-FLC), and Artificial Neural Networks (ANN), for regulating Doubly Fed Induction Generator (DFIG) based wind turbines. Using a comprehensive system model equipped with MPPT for variable wind speeds, our simulations revealed distinct performance trade-offs. The T1-FLC provided a straightforward control solution with adequate performance under standard operating conditions. In contrast, the ANN controller demonstrated a strong capacity for adaptive learning in response to nonlinear system dynamics; however, its effectiveness is contingent on extensive training data and significant computational power. The IT2-FLC, however, emerged as the superior strategy, offering exceptional robustness against parameter variations and wind turbulence. Its advanced membership structure is uniquely capable of managing and mitigating uncertainty. In summary, IT2-FLC delivered the optimal combination of robustness, precision, and adaptability, establishing it as a highly suitable control method for wind energy applications. Future research will explore hybrid intelligent controllers, specifically the integration of IT2-FLC with advanced nonlinear techniques like second-order sliding mode control, to push performance boundaries further, especially under severe and unpredictable operating scenarios.

ABSTRACT

The manual development of CMOS-based analog circuits continues to pose significant challenges, largely due to device scaling, process-induced variations, and the nonlinear interactions among multiple interdependent design parameters. These complexities necessitate the advancement of automated methodologies to improve efficiency, scalability, and reliability in analog design. In this study, the Cuckoo Search (CS) algorithm is investigated as a robust evolutionary framework for the automated sizing of CMOS analog circuits, with particular emphasis on the Folded Cascode Operational Transconductance Amplifier (FOTA) implemented in both 0.18 µm and 0.35 µm CMOS technologies. To provide a rigorous comparative analysis, the performance of CS is benchmarked against two widely employed evolutionary algorithms, namely Differential Evolution (DE) and Particle Swarm Optimization (PSO). All algorithms were implemented in the C programming language, interfaced with the NGSPICE simulator, and executed on an Intel® Core™ i5 processor (2.40 GHz, 8 GB RAM) under the Ubuntu operating system. The experimental findings reveal that CS consistently exhibits superior performance in terms of success rate, convergence reliability, and robustness. Specifically, in the case of the 0.35 µm FOTA design, CS achieved convergence to all target specifications in 9 out of 10 independent runs, outperforming DE (eight successes) and PSO (five successes). Comparable superiority of CS was also observed for the 0.18 µm process, thereby validating its potential across multiple technology nodes. This study demonstrates that CS not only provides superior optimization outcomes compared to DE and PSO but also establishes itself as a highly effective and reliable evolutionary framework for automated analog circuit design. The cross-technology validation and performance benchmarking highlight its practical relevance in advancing analog design automation

I. INTRODUCTION

CMOS analog circuits form the foundation of systems ranging from precision sensors to high-speed communication links, yet their design remains demanding. Device-level variations, parasitic effects, and nonlinear behavior make analog optimization far more intricate than its digital counterpart. At the same time, designers must reconcile requirements for gain, bandwidth, stability, efficiency, and area, a combination that calls for rigorous multi-objective optimization methods.Among circuit-level challenges, transistor sizing is

the most critical. The folded-cascode operational transconductance amplifier (OTA) exemplifies these difficulties: its architecture resolves voltage headroom constraints while retaining high gain, offering wide input range and strong power-supply rejection. Yet its performance is highly sensitive to transistor dimensions, bias allocation, and parasitic interactions. Trade-offs among gain, bandwidth, slew rate, and power dissipation are further complicated by process variation.This study explores evolutionary algorithms (EAs) as a framework for transistor-level optimization, emphasizing their integration with high-fidelity circuit models. Through systematic evaluation, it demonstrates the capacity of EAs to handle the complexity of analog design spaces and to deliver balanced solutions across conflicting performance metrics, thereby advancing the automation and reliability of CMOS analog circuit design.

II. LITERATURE REVIEW

PSO has been widely used for automated sizing of CMOS analog circuits in SPICE-in-the-loop frameworks due to its simplicity, exploratory power, and reliable convergence in complex design spaces. Research has mainly focused on addressing its stagnation tendency and sensitivity to parameter settings. Shreeharsha et al. [1] developed an enhanced-velocity PSO (EV-PSO) with adaptive inertia weight and acceleration factors for CMOS op-amp sizing. The method encouraged broad exploration in the early phase and shifted to precise refinement later, leading to quicker convergence and a larger set of practical solutions than the basic PSO. In high-frequency circuit design, where parasitics and layout effects make optimization difficult, Liu et al. [2] applied a randomized PSO (R-PSO) to the co-design of a 60 GHz subharmonic mixer. Constraint handling is equally critical, since many analog design requirements—such as minimum phase margin or maximum slew rate—are imposed as strict limits rather than soft targets.

Bouali et al. [3] developed a constraint-repaired PSO variant that incorporates adaptive neighborhooding to dynamically adjust the influence topology of particles. According to studies on particle swarm optimization (PSO), which also examined the influence of its hyperparameters, the swarm can vary or converge too early due to improper values of inertia or learning coefficients [4]. These issues have led to the introduction of parallel PSO implementations that employ distributed evaluation of possible solutions. Particle swarm optimization (PSO) has been adapted to many-objective frameworks as the number of these objectives increases. According to Shu et al. [5], PSO works well in problems with a small number of objectives, but as dimensionality rises, its efficacy decreases.In order to overcome this constraint, hybrid approaches that integrate PSO with Pareto-ranking schemes or decomposition-based techniques have been put forth, enabling the algorithm to maintain both population diversity and convergence.

Differential Evolution (DE) has also shown reliable performance in CMOS optimization, especially when the design space is highly irregular, multimodal, and tightly constrained [6]. Zhao et al. [7] demonstrated DE's capability by combining it with a deterministic direct search for fully automated op-amp synthesis. In multi-objective contexts, advanced DE variants such as GDE3 have been employed in conjunction with surrogate models to reduce computational cost. Vişan et al. [8] demonstrated a Gaussian process-assisted GDE3 for optimizing a folded-cascode OTA, achieving wide Pareto front coverage with a significantly reduced number of SPICE simulations. Recently, DE has also been embedded within Bayesian Optimization frameworks to address budget-constrained optimization problems [9]. Cuckoo Search (CS), inspired by the brood parasitism behavior of certain cuckoo species and characterized by Lévy flight-based random walks, has emerged as a powerful alternative for analog sizing problems that demand both aggressive exploration and the ability to fine-tune within narrow feasible corridors.

The heavy-tailed step distribution inherent to Lévy flights enables CS to traverse wide regions of the design space, thereby avoiding premature convergence a common challenge in constrained analog design tasks. In ultra-low-voltage design, where transistor sizing is tightly constrained by near-threshold operation, Fortes et al. [10] applied a standard CS algorithm to the design of a 0.25 V bulk-driven Miller OTA in 130 nm CMOS. CS has also been adapted for parasitic-aware layout optimization, as demonstrated by Abouelyazid et al. [11]. Their modified CS incorporated placement-and-routing-aware performance estimation, enabling the optimizer to maintain post-layout performance metrics closely aligned with pre-layout targets. A broader methodological assessment by Abualigah et al. [12] underscored CS's suitability for highly nonconvex analog design problems, emphasizing its ability to balance exploration and exploitation dynamically without extensive parameter tuning.

This low-sensitivity to parameter configuration is particularly valuable in industrial CAD flows, where rapid algorithm deployment is often prioritized over prolonged parameter calibration. Z. Xu et al. [13] showed that deterministic multi-objective methods can equal or even outperform evolutionary approaches on smaller analog design tasks. Lberni et al. [14] employed deep neural network surrogates to model the nonlinear input–output mapping of analog circuits, embedding these models within the evolutionary loop. This approach reduced the reliance on computationally expensive SPICE evaluations while preserving high-fidelity optimization, enabling larger design spaces to be explored under fixed computational budgets. Complementary enhancements such as yield-aware optimization [15] and feasibility-biased initial population generation [16] have been increasingly incorporated into hybrid EA frameworks.

II.1 MAJOR GAPS IN THE LITERATURE:

- Evolutionary algorithms are effective for analog circuit sizing but struggle with many-objective problems, strict design constraints, and process variability.
- A scalable and unified optimization framework that addresses these challenges is still lacking.
- Current methods rely heavily on SPICE-in-the-loop evaluations and lack smooth integration into industrial CAD flows.
- There is a need for a holistic approach that unites evolutionary search, surrogate modeling, and deterministic refinement to enable practical, automation-ready analog circuit design.

III. MATERIALS AND METHODS

The schematic representation of the automated CMOS analog circuit design framework, as depicted in Figure 1, constitutes a subset of a broader design automation environment. In this framework, the circuit topology is selected beforehand and treated as fixed. The system combines an evolutionary optimization engine with a SPICE-based simulator to synthesize CMOS analog circuits that meet defined performance targets. The optimizer systematically tunes transistor dimensions and bias conditions, while each candidate solution is validated through Ngspice simulations [17]. At every iteration, a parameterized SPICE netlist is generated to capture the electrical behavior of the design. MOS devices are constrained to operate in saturation, verified through bias point analysis and voltage transfer characteristics. The netlist is passed to the simulator to ensure device-level consistency, and a dedicated interface coordinates data flow between the optimizer and SPICE. Optimization begins with EA initialization, defining design variables, bounds, and objectives, followed by population generation and evaluation. This iterative co-simulation process enables detailed exploration of the design space and guides convergence toward high-fidelity solutions that satisfy analog performance requirements. Based on the outcomes produced by the circuit simulator, the fitness function of the circuit is quantitatively evaluated according to the following mathematical formulation [18].

$$Fitness\ Function\ = \sqrt{\sum_{j=1}^{D}\left(\frac{Specification_{desired} - Specification_{simulated}}{Specification_{desired}}\right)_{j}^{2}} \tag{1}$$

Here, D denotes the total number of targeted design specifications. This formulation essentially computes the Root Mean Square (RMS) error, thereby attributing equal weighting to all specifications, irrespective of their individual magnitudes or sensitivities. Consequently, the optimizer is compelled to satisfy each specification with comparable emphasis, ensuring a balanced trade-off among potentially conflicting performance objectives. Following the evaluation of the fitness function, the process proceeds to the termination check. The optimization cycle is concluded only if the pre-defined stopping conditions are fulfilled. In this work, the termination criteria are established as either (i) achieving a fitness function value below a stringent threshold of 1×10^{-6}, or (ii) reaching the upper bound of 100 iterations. Should neither condition be met, the evolutionary algorithm (EA) generates a new candidate set of design parameters, and the cycle is repeated.

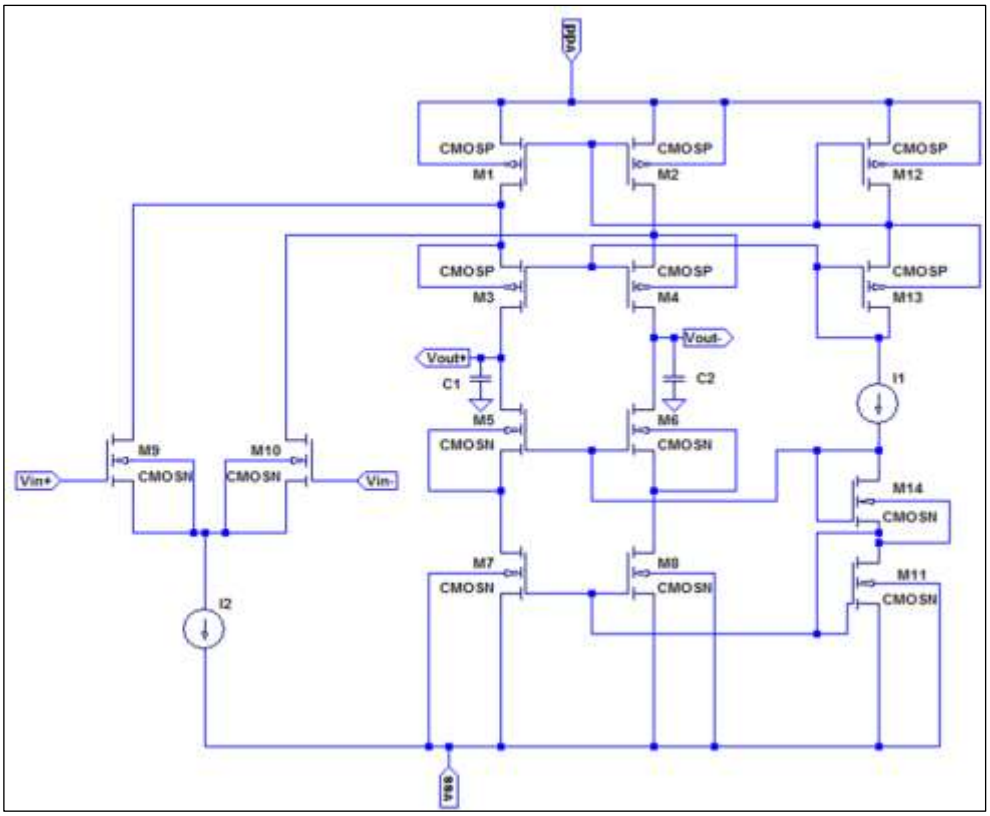

Figure 2: Folded Cascode OTA.
Source: Authors, (2026).

This iterative refinement embodies the optimizer's primary objective: to progressively reduce the fitness function value at each successive iteration until convergence to the desired solution is realized. The optimizer's performance depends on factors such as hyperparameter tuning, design space complexity, variable ranges, and the number of specifications to be met. This work applies three metaheuristic algorithms PSO, DE, and CS to optimize CMOS analog circuits, enabling a comparative assessment of their efficiency, robustness, and suitability for design automation.

IV. RESULTS AND DISCUSSIONS

The circuit diagram of CMOS Folded Cascode OTA (FOTA) is shown in Figure 2 [19]. More theoretical and mathematical analysis of this circuit can be found in [19], [20]. We have considered the width of M1, M2, and M12 transistors as W1 = W2 = W12, the width of M3 and M4 transistors as W3 = W4, the width of M5 and M6 transistors as W5 = W6, the width of M7 and M8 transistors as W7 = W8, the width of M9 and M10 transistors as W9 = W10, the width of M11 transistor as W11, the width of M13 transistor as W13, and the width of M14 transistors as W14 for this circuit. We have set the length of all transistors as L = 1 µm. So, this circuit has nine design parameters namely W1 = W2 = W12, W3 = W4, W5 = W6, W7 = W8, W9 = W10, W11, W13, W14, and I_{bias}. The circuit is optimized to drive the load capacitor of 0.1 pF. The supply voltage is set to ±1.8 V and ±2 V for both 0.18 µm and 0.35 µm CMOS technologies respectively.

Table 1: Search space and optimized parameters by different EAs for FOTA using 0.35 µm CMOS technology.

Sr. No.	Design Parameters	Search Space of Design Parameters	Optimized values of Design Parameters				
			PSO	DE	CS	[20]	[19]
1	$W_{1,2,12}$ (µm)	1 µm to 200 µm	196.24	200	121.31	25.6	28.5
2	$W_{3,4}$ (µm)	1 µm to 200 µm	94.6	93.77	35.11	12.8	49.9
3	$W_{5,6}$ (µm)	1 µm to 200 µm	163.95	200	143.37	4.5	16.4
4	$W_{7,8}$ (µm)	1 µm to 200 µm	163.95	200	143.37	4.5	34.2
5	$W_{9,10}$ (µm)	1 µm to 200 µm	195.34	200	164.99	49.2	49.85
6	W_{11} (µm)	1 µm to 200 µm	200	200	71.37	9	68.4
7	W_{13} (µm)	1 µm to 200 µm	200	200	100.21	25.6	99.8
8	W_{14} (µm)	1 µm to 200 µm	187.98	200	75.07	9	32.8
9	I_{bias} (µA)	1 µA to 200 µA	116.08	133.42	130.54	27.5	30

Source: Authors, (2026).

Table 2 presents a comparative summary of both the targeted specifications and the achieved simulated values corresponding to the optimized design parameters obtained through the application of different evolutionary algorithms (EAs) to this circuit. For this design case, a total of twelve distinct performance specifications are imposed, namely: open-loop voltage gain (Av), unity-gain bandwidth (UGB), phase margin (PM), positive power supply rejection ratio (+PSSR), negative power supply rejection ratio (–PSSR), rail-to-rail swing ratio (RSR), full swing ratio (FSR), common-mode rejection ratio (CMRR), power dissipation (P_{diss}), input-referred noise spectral density (Nin) at 10 kHz, integrated input-referred noise (N_{int}) across the frequency band from 1 Hz to 100 kHz, and the Total MOS Transistor Area (TTA).

The search space and optimized values achieved by different EAs for the design parameters of this circuit using 0.35 µm CMOS technology are found better than [19] and [20] listed in Table 1. Previous investigations have also explored the optimization of this circuit topology under comparable CMOS technologies. Vural et al. [21] reported the application of the standard Particle Swarm Optimization (PSO) algorithm for the design of this circuit, while Mallick et al. [22] extended this line of research by employing a Craziness-based PSO (CRPSO) variant to further enhance the exploration capabilities of the swarm and mitigate premature convergence issues. In comparison, the present results demonstrate improved performance over those reported by Vural et al. [21] using standard PSO and by Mallick et al. [22] with the CS variant, as summarized in Table 2.

Table 2: Desired specifications and obtained specifications by different EAs for FOTA using 0.35 µm CMOS technology.

Source: Authors, (2026).

The desired design specifications, along with the corresponding values obtained through parameter optimization using different evolutionary algorithms (EAs) for this circuit in a 0.35 µm CMOS technology, are summarized in Table 1. The comparative performance of three well-established optimization techniques PSO, DE and CS was systematically evaluated through 10 independent experimental runs, as presented in Table 3. The CS algorithm showed the greatest robustness, meeting all target specifications in 9 of 10 runs, compared with eight for DE and five for PSO. These results position CS as a promising tool for complex analog design tasks involving high-dimensional parameter spaces and tight performance constraints. For the 0.18 µm CMOS implementation, Table 4 lists the parameter search ranges alongside the optimized values obtained by each algorithm. The results highlight the efficiency with which different algorithms navigate the high-dimensional search landscape to satisfy stringent performance specifications.

The desired design specifications are presented in Table 5 for the circuit implemented in 0.18 µm CMOS technology. A detailed performance comparison of PSO, DE, and CS across 10 independent optimization trials is provided in Table 6. The results reveal that both CS and DE consistently achieved convergence to all targeted specifications in every run. PSO achieved full specification compliance in only 4 of 10 runs, reflecting weaker robustness in navigating the circuit's design space. Evaluation of CS showed the most efficient convergence, requiring fewer iterations on average than both DE and PSO. This efficiency reflects CS's stronger balance between exploration and exploitation in high-dimensional spaces. While DE demanded slightly more computation than CS, it remained more reliable and efficient than PSO.

Taken together, these findings establish that while both CS and DE demonstrate strong potential as optimization frameworks for analog circuit design in deep-submicron CMOS technologies, CS holds a distinctive advantage due to its consistent reliability coupled with faster convergence. The weaker performance of PSO in this study highlights the shortcomings of swarm-based heuristics when applied to highly constrained, nonlinear, and multi-objective design problems. By comparison, the results point to CS and DE as more effective optimization strategies for analog design automation at the 0.18 µm technology node.

V. CONCLUSIONS

This work examined the use of the Cuckoo Search (CS) algorithm for automated design of CMOS analog circuits, focusing on the Folded Cascode OTA in 0.18 µm and 0.35 µm technologies. When compared to Particle Swarm Optimization (PSO) and Differential Evolution (DE), CS consistently produced higher success rates, faster convergence, and more robustness under demanding design constraints. In 9 of 10 trials, CS converged for the 0.35 µm process, surpassing DE with 8 and PSO with 5. The effectiveness of CS across technology scales is confirmed by similar results at 0.18 µm.The study emphasizes DE's relative competitiveness while highlighting PSO's shortcomings in complex analogue design. However, CS was able to strike an improved balance between exploration and improvement, which made it a dependable method for circuit automation in the face of complexity and scaling issues. Because of its proven effectiveness, it can be integrated into next-generation CAD platforms for mixed-signal SoCs, which can shorten development cycles and increase design productivity. Future directions include extension to advanced nodes, multi-objective strategies that explicitly recognize trade-offs in power, area, and noise, and hybrid approaches that integrate CS with other heuristics.

ABSTRACT

Corona discharge is a common disturbance in 20 kV cubicles and may lead to insulation degradation, power losses, and potential equipment failure. Early detection is therefore essential to support preventive maintenance and enhance distribution system reliability. This study presents a comparative analysis of the Hidden Markov Model (HMM) and Backpropagation Neural Network (BPNN) for identifying corona discharge based on acoustic signals and voltage variations. Acoustic data were recorded using a needle–rod configuration and processed through Linear Predictive Coding (LPC) to obtain cepstral features. The classification results show that HMM provides high accuracy, achieving 100% in both training and testing for noise-based clustering and 84.44% in voltage-based testing. Meanwhile, BPNN demonstrates stable performance with training and testing accuracies of 95.93% and 82.35% for voltage-based clustering, and 95.69% and 100% for noise-based clustering, respectively. Overall, the findings indicate that although HMM performs more consistently for noise-based classification, BPNN provides competitive accuracy and better adaptability for early detection of corona discharge in 20 kV cubicles. These results support the development of intelligent monitoring systems for improving insulation condition assessment and reducing potential failures in medium-voltage distribution networks.

I. INTRODUCTION

Greater Jakarta is the center of electricity supply. PLN Distribution Jaya and UP3Cikokol have more nearly 7 million consumers, 11,564 MVA of installed power, and 12,426 distribution substations, according to PT PLN (Persero) figures from 2006. Cubicles and feeders are needed for three times as many distribution substations as there are substations.[1]**.** So, if done manually, the inspection in the context of maintenance will be very difficult. A voltage of 20 kV is applied to these cubicles, which can cause corona discharge symptoms and, if left unchecked, cause electrical failure or short circuits, especially under rain or humid environments[2]**.** If the repair is done immediately, the problem can be solved, but you can only find out the condition of the cubicle by visiting it[3]. Many people consider that corona discharge in a medium voltage cubicle (TM) is not enough to cause corona discharge.

However, the fact is that corona discharge can cause a flash jump, causing the cubicle to be unable to deliver electrical power [4]. Due to the high humidity level in Indonesia which allows air ionization to occur easily, the corona discharge problem in the TM cubicle is a unique and uncommon problem because the magnitude of the voltage (20 kV) is technically very difficult to cause corona discharge [5]. For example, PT. PLN (Persero) Jaya and Tangerang sustain more than 300 units of TM cube damage annually. Most of this damage is caused by the release of corona. Therefore, there needs to be a monitoring system that can see data from the entire room but can be accessed from the control center. With the latest condition data, technicians can immediately carry out maintenance to prevent more severe corona discharge, which can cause flashovers[6]. Figure 1 shows the structure and condition after cubicle damage.

(a) (b)

Figure 1: Cubicle Construction 20 kV Voltage (a) visible inside cubicle (b) visible part of the entire cubicle.

Figure 1 shows a 20 kV cubicle that suffered an insulation failure due to a previously unknown corona discharge phenomenon that caused permanent damage to its insulator. Part (a) shows the arrangement of the insulators inside the cubicle, and part (b) shows the overall cubic units; Both have suffered permanent damage due to insulation failure.

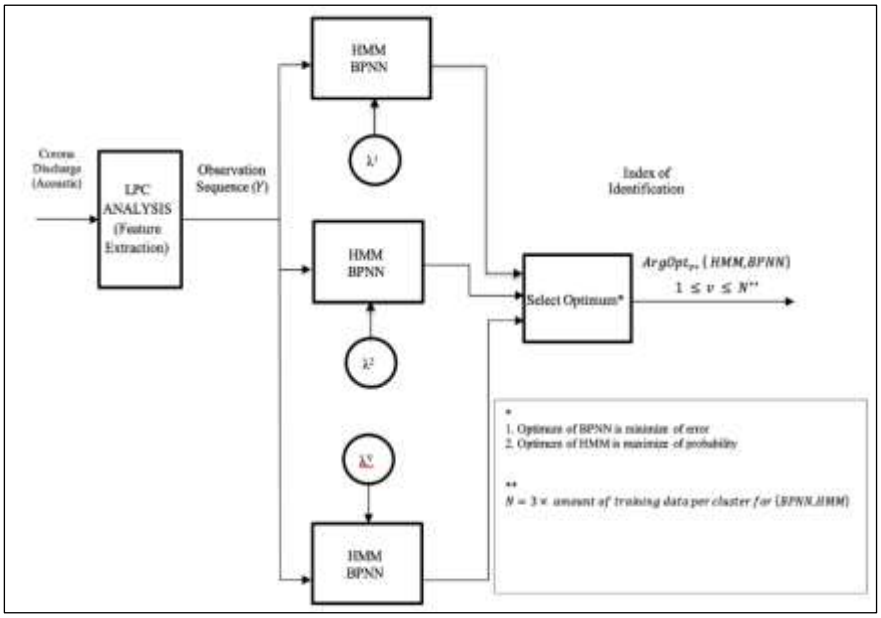

Figure 2: Acoustic Identification Flow Diagram of Corona Discharge Based on Voltage and Noise.
Source: Authors, (2026).

Any kind of medium-voltage or high-voltage electrode may cause corona discharge symptoms in specific situations.[7]. This is because an ionization process that can generate electrons or positive ions at 20 kV cubic insulation occurs when the electrode is subjected to an electric field. At some point, this collection of electrons or positive ions will form into an avalanche electron, which can then produce sound. The more the point group, the more interference the electrode produces. [8]. The noise level can be measured as a parameter of the magnitude of the level of corona discharge symptoms. This can be done by raising the voltage from 20 kV to 33 kV (less than the breakdown voltage).

Some corona discharge studies such as [9]. studying the loose corona on the transmission wire using loose partial measurement,[10]. Talking about corona discharge using unmanned aerial system technology,[11]. talking about how to classify corona discharge based on the pattern of partial discharge, [12]. detects corona discharge sound using fast Fourier transform. Then, using wavelet transformation to identify corona discharge signals based on the level of contamination or pollution. This signal is compared to a partial discharge detector measuring device. Recently, corona discharge sound clustering using geometric distance (ED) has been carried out.[13][14], using fuzzy c-mean (FcM) [15][16].and compare ED, FcM and hidden Markov model (HMM) methods [17].

However, AI uses backpropagation neural network (BPNN) to identify corona discharge sounds. In this study, clustering of the corona discharge phenomenon based on sound was carried out as a first step. This clustering is intended to identify early isolation failures in 20 kV cubicles using BPNN. The characteristic extraction of the recorded corona discharge sound is computed using the linear predictive coding (LPC) approach, which has long been recognized and proven to be dependable for obtaining characteristic extraction from any sound.After the extraction of these traits is obtained, matching is carried out using the BPNN and HMM methods to obtain clustering that is expected to be more accurate.

II. METHODOLOGY

In the acoustic observation of corona discharge, this study refers to IEEE Standard for High-Voltage Testing Techniques 4 2013-1995 IEEE [17] and IEC TS 62478:2016 High voltage test techniques - Measurement of partial discharges by electromagnetic and acoustic using PD data collection method. On the other hand, the use of needle-rod electrodes in vertical testing and microphone placement is at a distance of 3cm. With a standard frequency ranging between 40 and 200 kHz, this study used only 40 kHz. Each classification was done ten times in order to detect the acoustic phenomenon of corona ejection based on voltage and hissing sound. Preliminary observations show that the lowest penetration voltage is 34.3 kV, so the base voltage is clustered into 3 including: low cluster 20–24 kV, medium cluster 25–29 kV, and high cluster 30–33 kV, while sizzle noise is classified into pure Corona Discharger, Corona Discharger with hissing noise, and pure hissing noise. The humidity ranges from 70% to 95%, while the indoor temperature ranges from 27.5°C to 35.3°C. Data was gathered at the PLN Institute of Technology Jakarta's High Voltage Laboratory over a one-year observation period (February 2021–February 2022). The MATLAB Program version 2024b is then used to process the collected data. Figure 2 shows a flow diagram of the clustering of corona discharge phenomena based on acoustics.

II.1 PREDICTIVE LINEAR CODE

According to him, the LPC approach is a long-standing speech recognition methodology. [17]. The LPC method's benefits include its ease of use and compatibility with a wide range of devices. The two primary parts of the LPC method are encoding and decoding. While decoding modifies the recorded sound, encoding breaks down sound signals into their component elements. Here, both procedures are explained. Figure 3 [17].

with

$$\tilde{s}(n) = s(n) - \tilde{a}\, s(n-1), \tag{1}$$

where the acoustic data/signal,$sn$is the amount of data in an acoustic signal

$$0.9 \leq a \leq 1.$$
$$x_\ell(n) = \tilde{s}(M\ell + n) \tag{2}$$

where shows the number of frames,$M\ell = 1,2, \dots, M$.

$$\tilde{x}_\ell(n) = x_\ell(n)\, w(n), \tag{3}$$

Where$w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{N-1}\right), 0 \leq n \leq N-1$

$$r_\ell(m) = \sum_{n=0}^{N-1-m} \tilde{x}_\ell(n)\, \tilde{x}_\ell(n+m) \tag{4}$$

Where$m = 0,1, \dots, p$.

$$a_m = \alpha_m^{(p)} \tag{5}$$

with$1 \leq m \leq p$

$$E^{(0)} = r(0)$$

$$k_i = \frac{\left\{r(i) - \sum_{j=1}^{L-1} \alpha_j^{(i-1)} r(|i-j|)\right\}}{E^{(i-1)}}$$

$$\alpha_i^{(i)} = k_i$$

$$\alpha_j^{(i)} = \alpha_j^{(i-1)} - k_i \alpha_{i-j}^{(i-1)}$$

$$E^{(i)} = (1 - k_i^2)\, E^{(i-1)}$$

$$c_0 = \ln 1 \tag{6}$$

$$y_m = a_m + \sum_{k=1}^{m-1} \left(\frac{k}{m}\right) c_k a_{m-k} \tag{7}$$

Where$1 \le m \le p$.
The following explanation applies to the stages in Figure 2 above. [17]

- Acoustic noise from the original auditory input can be eliminated by the pre-emphasis method. Noise is interference or interference from the surrounding real hearing object.
- The frame-blocking process divides the acoustic signal into acoustic segments.
- Windowing detects and sorts out the differences in separate acoustic signals.
- Autocorrelation analysis ensures that the signals from each frame are comparable.
- The process of converting the magnitude of the LPC parameters—the logarithmic area ratio, reflection coefficient, and LPC coefficient—into the outcome of autocorrelation analysis is known as LPC analysis.
- Using a Fourier transform, the cepstral analysis converts the LPC parameter into a cepstral coefficient.

II.2 HIDDEN MARKOV MODEL

One of the secret Markov models is the Hidden Markov Standard Model (NHMM) $\{X_t, Y_t\}_{t\in\mathbb{N}}$Y which presupposes that it can be observed as long as its distribution is known to be normal. Unfollowed, the event's cause creates a Markov chain with the state space. The hidden Markov model's primary flaw is that it optimizes the Y observation process's potential function, which $Y_t X_t$ $\{X_t\}_{t\in\mathbb{N}}$ $S_X = \{1,2,\cdots,m\}$. [18][19] [17]

$$L_T(\phi) = P(Y_1 = y_1, Y_2 = y_2, \dots, Y_T = y_T|\phi)$$

$$= \sum_{i_1=1}^{m} \dots \sum_{i_T=1}^{m} \left(\pi_{y_1 i_1} \pi_{y_2 i_2} \dots \pi_{y_T i_T}\right) \times \left(\delta_{i_1} \gamma_{i_1 i_2} \gamma_{i_2 i_3} \dots \gamma_{i_{T-1} i_T}\right)$$

$$= \sum_{i_1=1}^{m} \dots \sum_{i_T=1}^{m} \delta_{i_1} \pi_{y_1 i_1} \prod_{t=2}^{T} \gamma_{i_{t-1} i_t} \pi_{y_t i_t}. \tag{8}$$

The acoustic properties of corona discharge, etc., were extracted in this work using the linear predictive coding (LPC) method. Parameter estimation, including mean, variance, and transition matrix, is performed to maximize the probability function. The Expectation Maximization (EM) algorithm is used iteratively to optimize the probability function in the equation (9). Each algorithm is formulated as follows.$y_1, y_2, \dots, y_T$[19]. [17]

$$\mu_i^{(k+1)} = \frac{\sum_{t=1}^{T} \alpha_t^{(k)}(i) \beta_t^{(k)}(i) y_t}{\sum_{t=1}^{T} \alpha_t^{(k)}(i) \beta_t^{(k)}(i)}, \tag{9}$$

$$\sigma_i^{2(k+1)} = \frac{\sum_{t=1}^{T} \alpha_t^{(k)}(i) \beta_t^{(k)}(i) \left(y_t - \mu_i^{(k+1)}\right)^2}{\sum_{t=1}^{T} \alpha_t^{(k)}(i) \beta_t^{(k)}(i)} \tag{10}$$

$$\gamma_{ij}^{(k+1)} = \frac{\sum_{t=1}^{T-1} \alpha_t^{(k)}(i) \gamma_{ij}^{(k)} P^{(k)}(y_{t+1}|j) \beta_t^{(k)}(j)}{\sum_{t=1}^{T-1} \alpha_t^{(k)}(i) \beta_t^{(k)}(i)} \tag{11}$$

Forward and backward algorithms can be used to calculate recursivelyand Furthermore, these findings are used to divide the corona release phenomenon based on voltage and interference taking into account the maximum probability.$\alpha_t(i) = P(Y_1 = y_1, Y_2 = y_2, \dots, Y_t = y_t, X_t = i|\phi)$ $\beta_t(i|\phi) = P(Y_{t+1} = y_{t+1}, \dots, Y_T = y_T|X_t = i, \phi)$.

II.3 BACKPROPAGATION NEURAL NETWORK (BPNN)

The backpropagation neural network (BPNN), an artificial intelligence technique that uses optimization to reduce the function of the objective—that is, the difference between the experimental and model data—is applied to model data based on experimental data. Figure 4 below shows the BPNN architecture. [20][21]:

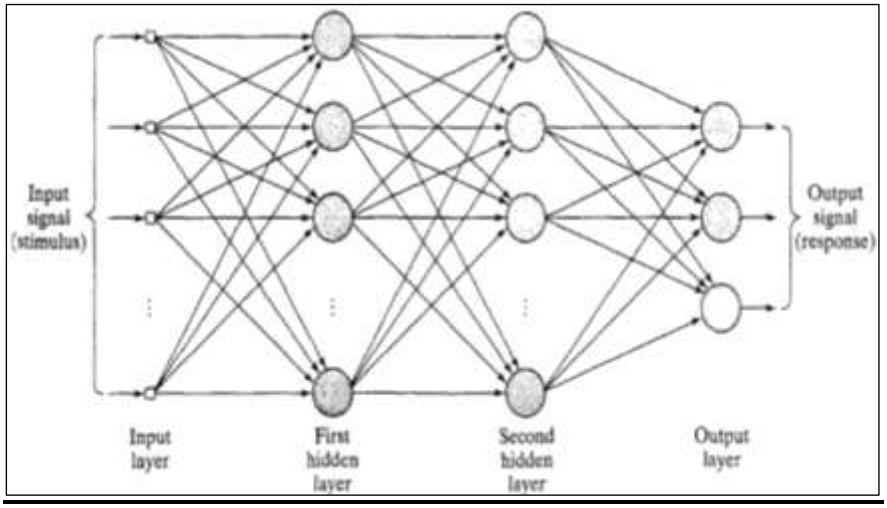

Figure 4: BPNN Architecture.
Source: Authors, (2026).

The objective functions of BPNN are as follows:

$$\xi = \frac{1}{2}\sum_{j\in C} e_j^2(n) \tag{12}$$

with , with is the output signal of BPNN is the experimental output data of the same input. $e_j(n) = d_j(n) - y_j(n) y_j(n)\, d_j(n).$

BPNN learning is achieved by entering the observation data into the BPNN and then reducing errors along with estimating BPNN parameters that match the weight, as shown in Figure 4. To minimize errors in equations (12), various optimization methods are used.

Table 1: Connected functions of the BPNN model.

Connected function	Schema
	BPNN
$z_{in} = f_1 = f_1(X^*, b1, v)$	$b1 + X\ v$
$z = f_2 = f_2(z_{in})$	$\frac{1}{(1 + exp(-z_{in}))}$
$y_{in} = f_3 = f_3(z, b2, w)$	$b2 + z\ w$
$(\alpha, \beta) = f_4 = f_4(y_{in})$	-
$T^* = L = L(\alpha, \beta, C, E, n)$	-
$T^* = f_5 = f_5(y_{in})$	y_{in}
n_1	4
n_2	1

Source: Authors, (2026).

with lifetime input and data$X^*T^{\#}$ [22], the research model for and BPNN in this case is as follows:

$$T^* = f_5\ o\ f_3\ o\ f_2\ o\ f_1 \qquad for\ BPNN \tag{13}$$

In this model, the parameters is b1,v,b2,w for the BPNN scheme.

II.4 PARAMETER MODEL ESTIMATION

To gain a better grasp of the formulation of the model parameters in Table 1, the GD approach is then used to optimize the function based on its objective in equation (13). is the function of the objective model in equation (6), and the model construction is shown in Table 2.T^* Genetic algorithms have phases and function similarly to genes. [23] [24] Initialization, spin wheel, cross-over, mutation, individual assessment, and linear fitness improvement. All of these procedures are executed by default, with the exception of the individual evaluation phase. Change the objective function now in accordance with Table 1 based on [23] [25].

The evolutionary algorithm's stages (1) through (6) guarantee that the BPNN approaches converge, meaning that the model's results get smaller with each iteration, reducing the gap between the experiment and the model. Based on [26][27], to guarantee convergence and minimize errors between models and experimental data. The convergence of the LM technique for BPNN will thus be guaranteed by the modified parameters. Put another way, as the number of iterations increases, the gap between the experiment's and the model's outcomes will narrow. The following table 2 illustrates the entire procedure:

Table 2: Parameters of BPNN Formulation.

Formulation BPNN
$w_{ji}(n+1) = w_{ji}(n) - \alpha e_j(n+1)\, z, \qquad b2_i(n+1) = b2_i(n) - \alpha e_j(n+1),$
$v_j(n+1) = v_j(n) - \alpha e_j(n+1)\left(\frac{1}{(1+exp(-z_{in}))}\frac{exp(-z_{in})}{(1+exp(-z_{in}))}\right) X,$
$b1_j(n+1) = b1_j(n) - \alpha e_j(n+1)\left(\frac{1}{(1+exp(-z_{in}))}\frac{exp(-z_{in})}{(1+exp(-z_{in}))}\right),$
is scalar (learning rate).α

III. RESULTS AND DISCUSSION

III.1 DESIGN AND OBSERVATION SERIES

The design and series of observations made can be seen in figures 5 and 6 below.

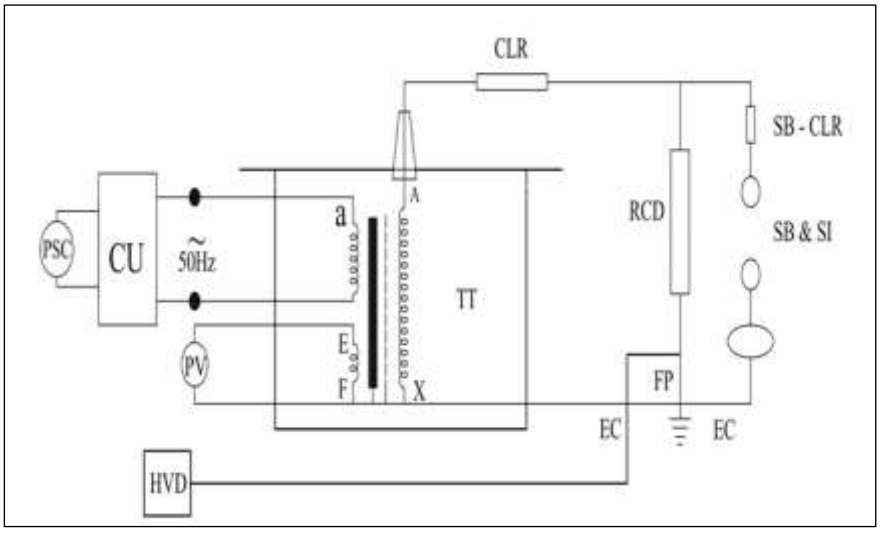

Figure 5: Corona Discharge Acoustic Recording Series in 20 kV Cubic.
Source: Authors, (2026).

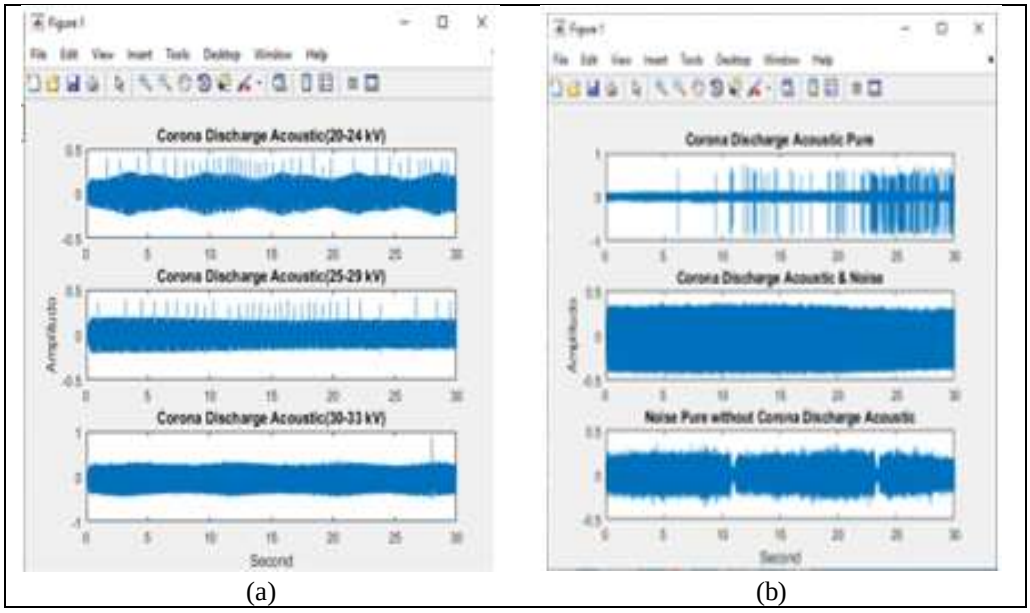

Figure 6: Research Design for Acoustic Recording of Corona Discharge in a 20 kV Cubicle.
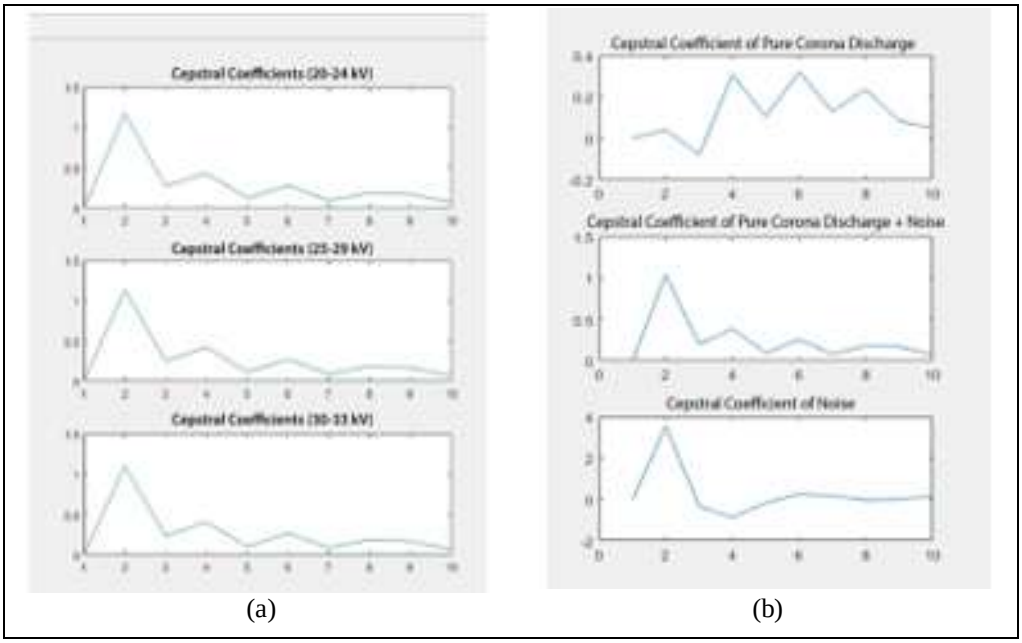
Source: Authors, (2026).

Figure 6 displays the acoustic recording of corona discharge in the High Voltage Oratory Lab at the PLN Institute of Technology. It is generated by a test transformer that can be adjusted to 100 kV and has a 200 V scale ratio. According to the findings of the preliminary observations, the corona discharge's penetration voltage was 34.3 kV. In order to create three clusters, the acoustic recording of corona discharge in this investigation started at a voltage of 20 kV and was thereafter increased gradually. Furthermore, three types of CDs were used to capture the acoustic data: pure CDs, CDs with noise, and CDs with pure noise. The temperature in the room increased from 27.5 to 35.3 degrees Celsius over the data collecting period, and the humidity ranged from 70% to 95%. The corona discharge is recorded acoustically between the two electrodes, which are spaced three centimeters apart.[11]. The microphone is positioned 5 cm away from the electrodes for acoustic recording, and the recordings are saved on a computer for analysis.[32]

III.2 ACOUSTIC CORONA EMISSION DATA AND EXTRACTION



With each pure CD cluster, corona acoustic dissipation was recorded using the research design depicted in figure 5 according to sound and voltage (20–24 kV, 25–29 kV, and 30-33 kV). Figure 6 displays CDs with sound and CDs with only sound. [17]

(a) (b)

Figure 7: Acoustic Coronas Discharge (a) Based on Voltage (b) Based on Noise.
Source: Authors, (2026).

Using equations (1)–(5), the acoustic data in Figures 7 (a) and 6 (b) were calculated to yield the LPC parameters. Moreover, Fourier transformations do a better job of extracting the acquired features.[16]. utilizing equations (6)–(7), which yields Figure 7(a) and 7(b)'s cepstral coefficient of LPC.

(a) (b)

Figure 8: Cepstral Coefficient LPC Acoustic Corona Discharge (a) Based on Voltage (b) Based on Noise.
Source: Authors, (2026).

Figure 8(a) is comparable in that there are no outside disturbances, or noises, so it can only produce sufficient results[17]. In contrast, Figure 8(b) is very different because of the sound effect, so it is expected to produce precise grouping results. Furthermore, the extraction of the cepstral LPC feature was used as an input for the Euclidean, HMM, and BPNN distance methods to identify and classify the corona acoustic discharge.

Table 6 demonstrates how to use an BPNN to identify CDs acoustically based on noise. They achieved 95.69% accuracy for both testing and and 100% accuracy during testing.

Table 7: Recapitulation of CD Acoustic Base Voltage and Noise Using HMM and BPNN.

NOT.	**Method**	**Accuracy Mean (%)**			
		Base Voltage		**Base Noise**	
		Training	Testing	Training	Testing
1	HMM	100	84.44	100	100
2	BPNN	95.93	82.35	95.69	100

Source: Authors, (2026).

Table 7 presents a comparison of the accuracy of the HMM and BPNN methods in classifying Base Voltage and Base Noise conditions in CD acoustic data. HMM shows very high accuracy, particularly for Base Noise, achieving 100% accuracy in both training and testing, while its testing accuracy for Base Voltage reaches 84.44%. BPNN also demonstrates good performance, with training and testing accuracies of 95.93% and 82.35% respectively for Base Voltage, and stable results for Base Noise with 95.69% during training and 100% during testing. Overall, HMM appears more consistent, especially for the Base Noise parameter, although BPNN remains competitive for both parameters.

IV. CONCLUSIONS

This study evaluates the performance of the Hidden Markov Model (HMM) and Backpropagation Neural Network (BPNN) in detecting corona discharge phenomena in 20 kV cubicles using acoustic signals and voltage-based clustering. The application of Linear Predictive Coding (LPC) successfully extracts cepstral features from the recorded corona discharge sounds, enabling effective classification. The results show that HMM achieves outstanding performance for noise-based clustering, reaching 100% accuracy in both training and testing, while its voltage-based testing accuracy reaches 84.44%. In contrast, BPNN provides more balanced and stable results across all categories, with accuracies of 95.93% (training) and 82.35% (testing) for voltage-based clustering, and 95.69% (training) and 100% (testing) for noise-based clustering. These findings highlight that although HMM excels in noise classification, BPNN offers robust performance and better generalization capability for both voltage and noise conditions. Therefore, BPNN is recommended as a reliable early warning method for corona discharge detection in 20 kV cubicles, contributing to improved monitoring, preventive maintenance, and overall distribution network reliability.

V. AUTHOR'S CONTRIBUTION

The authors assisted in the development of a system that detects corona discharge symptoms in 20 kV cubicles using artificial intelligence methods. The authors of this study compared Hidden Markov Model (HMM) and Backpropagation Neural Network (BPNN) techniques to identify sounds resulting from corona discharge symptoms. The authors not only conducted experiments in a high-voltage laboratory to collect sound data, but they also processed the data using the Linear Predictive Coding (LPC) method to identify sound characteristics. The results showed that BPNN can improve identification accuracy compared to HMM. Consequently, BPNN can be used as a more accurate early warning system. This is very important because PLN and related agencies can help detect damage to cubicles quickly, prevent further damage to equipment and improve the reliability of electricity distribution.

VI. ACKNOWLEDGMENTS

The authors would like to thank the PLN Institute of Technology, Jakarta, especially the High Voltage Laboratory, for providing the facilities and opportunity to conduct this research. Appreciation is also extended to fellow lecturers and researchers who assisted in the data collection process and provided valuable input throughout the research.

ABSTRACT

With the rapid expansion of wind energy integration into electrical grids, there is an urgent need for an intelligent control system capable of adapting to the sharp power fluctuations caused by the ever-changing nature of wind and maintaining stable frequency and voltage to meet fluctuating load requirements. This paper aims to provide complete and intelligent control of a combined wind turbine-to-grid power generation system. The intelligent control unit can instantly estimate wind speed and rated power, thereby providing automatic adjustment mechanisms for inverters and load distribution. The system is represented by a detailed simulation in MATLAB/Simulink. The control unit can also analyze instantaneous frequency and voltage deviations, classify load conditions, and compensate for deficits or surpluses in the wind turbine's generated power. This study evaluated the typical performance of the proposed unit for various scenarios, including unexpected fluctuations in wind speed and sudden load changes. Simulation results showed that the intelligent controller eliminated a significant proportion of frequency deviations compared to conventional control systems. Furthermore, the voltage drops and rises were within acceptable specifications.

I. INTRODUCTION

Wind turbines hold a leading position in the context of environmental sustainability and meeting the growing global demand for energy. They are among the most prominent renewable energy technologies. They are used to convert wind energy into electrical power. Wind turbines can be classified based on the amount of energy derived from capturing the wind to operate them [1][2]. Wind turbines reduce dependence on fossil fuels, leading to reduced carbon emissions and combating climate change [3]. Wind turbines increase the efficiency of the electrical system when operated in parallel with the main grid [4]. Furthermore, the generated wind energy is transmitted to the electrical grid, providing greater stability to the power system, as wind turbines can supply electricity when demand is high. However, renewable energy sources, such as wind turbines, face challenges including intermittency and fluctuation due to varying wind speeds. Therefore, it is essential to develop strategies for frequency control, grid stability, and load control.

Smart control technologies can also improve turbine performance by enabling them to respond more quickly to changes in energy demand and handle disturbances such as overloads, faults, or even load shortages. With wind power having grown by an exceptional 14% since 2010, it is the second-fastest-growing new energy source after solar power. Wind power is set to become the third-largest source of global electricity generation after hydropower and solar by 2030, according to estimates by the International Energy Agency [5]. This growth is part of the global shift from using polluting resources as fuels to more efficient and environmentally friendly sources. All of these factors combined demonstrate the importance of wind power in the future energy mix. These forecasts point to profound changes coming to the energy industry as countries seek to reduce their dependence on fossil fuels and transition to a cleaner mix of sources. Improving the efficiency of wind turbines and related technological solutions enhances their ability to compete in the global energy market [6][7].

A connection of a wind power generation system (WPS) with the electrical primary grid is referred to as a GRID-on connection. Grid-tied connectivity refers to how a WPS integrates with load-only devices or an energy storage system. When connected to the grid, it needs to meet synchronisation conditions because the three-phase inverter (VSI) voltage and frequency must be equal to the grid's voltage, since that remains constant. On the other hand, the voltage and frequency of the WECS change with wind speed, which requires the development of a robust and reliable controller to reach synchronisation. The voltage at the DC link should be stable; this is the main goal of grid-side control, and we also need monitoring of DC link input voltage to VSI & power transfer active/reactive power into the grid. To achieve this, there is a need to use advanced control technologies to guarantee the stability of the electrical system and an even better plant performance.

These results are important because the wind power generation system can successfully help to achieve an efficient development of energy budgets, and at the same time ensure the stability in the electric system [8]. All these features and more can be achieved by using a three-level inverter as an interface to the grid, ensuring the quality of the output signals and, in general, the durability and responsiveness of the entire system [9]. Given the importance of maintaining constant voltage and frequency, in addition to all the other advantages of connecting renewable energy systems to the grid, many advanced algorithms are emerging to achieve this. In this paper [10], the researcher used the Wind Driven Optimization Algorithm and the Firefly Algorithm together to balance loads and maintain system stability, in addition to comparing them with another group of algorithms. All of this opens up future horizons for hybrid systems and smart cities. While this study deals with a proposal for a fuzzy logic algorithm to track the maximum point of a hybrid renewable energy system consisting of a wind turbine and solar cells, in addition to smart control units capable of managing the power generated by the system and distributing it between the grid or charging batteries[11].

The use of advanced quasi-ZSI (Z-Source Inverters) technology has a significant impact on the stability of both frequency and voltage, achieving high efficiency and reducing the number of components used, unlike conventional designs, in addition to the overall conversion efficiency. Furthermore, it is possible to connect renewable energy sources directly to the grid without the need for additional conversion stages [12]. The system used in this study combines wind turbines and solar cells with a set of control units. Some of these units work to draw the maximum power generated from the system, defined as MPPT algorithms. Other units control the voltage and frequency and maintain them constant in three scenarios discussed: changing radiation intensity, changing wind speed, and load disturbances using a load-side converter (LSC) control unit [13]. The use of smart control methods and artificial intelligence strategies in renewable energy power generation systems has become a must.

Therefore, an infinite number of these strategies have emerged, all of which serve one goal: increasing the capabilities of prediction and adaptation to overcome all obstacles and achieve a faster and more accurate response for the entire system [14]. After reviewing previous research and methodologies, this research proposes a smart FPI controller that controls a VSI on the grid side to synchronize the electrical power generated by wind turbines with the grid in terms of voltage and frequency, as well as balance the supplied loads and handle additional loads treated as external disturbances. All results of the proposed controller will be compared with those of a conventional PI controller. The proposed system model comprises a wind turbine, various other components, and complex control processes, which will not be the focus of this study. This study will, however, cover an intelligent controller that controls the VSI, an isolation transformer, the grid, and loads. Figure 1 shows the system proposed in this study.

II. THEORETICAL REFERENCE

II.1 WIND TURBINE

The power output of wind turbines varies depending on wind speed, with each wind turbine having its power performance curve. This curve enables the prediction of a wind turbine's power production without considering the technical details of its various components[15]. By analysing performance curves, operators and planners can estimate turbine efficiency under varying wind conditions, thereby contributing to improved energy management strategies and more informed electrical grid planning. Momentum theory is used to analyse the behaviour of wind turbines and make predictions about their performance. In this context, variables are analysed to ensure they have the same value over a specific portion of the air stream pipe, assuming that air is incompressible and fluid motion is constant. The resulting force is expressed by the flow of air, which is moving at a speed. The following equation expresses the mechanical power captured by a wind turbine [16][17]:

The mechanical power captured by a wind turbine

$$P_m = 0.5\rho A v^3 C_p(\beta, \lambda) \quad (1)$$

Where:

ρ = air density (Kg/m^3)
v = wind speed (m/s)
$A = \pi r^2$ (m^2)

The Betz coefficient represents the maximum theoretical value of C_p where:

$$C_{pmax} = 0.593 = 59.3\% \quad (2)$$

II.1.1 Intelligent Controller

A power converter is known as a device that converts DC power into AC power. This device consists of six power switches that utilise IGBT technology with anti-feedback diodes. These keys are divided into two groups: the upper group, which includes keys S1, S2, and S3, and the lower group, which consists of keys S4, S5, and S6[18]. To avoid short circuits, the switching technology used must be intelligent so that two switches on the same terminal do not operate at the same time. As one of the most common methods of switching signal generation, PWM is increasingly used in VSI because it controls the voltage and suppresses the third harmonic of the inverter's output voltage, improving the quality of the generated power [19]. PI controllers remain the most widely used controllers in the wind energy conversion system (WECS) industry due to their robustness and high stability margins. However, to achieve optimal performance from these controllers, tuning key parameters is essential to ensure correct operation and reliable control of the system [20].

Tuning PI controller parameters is a significant challenge in nonlinear or complex systems, where even minor adjustments are difficult for these controllers to handle. In recent years, PI controllers have been replaced by fractional proportional integral (FPI) controllers as a means of overcoming the problems described above. Additional benefits of FPI controllers are based on their ability to adapt to dynamic changes within the system, which in turn makes control more effective and better responsive to changes. The FPI controller is the next generation of PI controllers, offering excellent system performance. FPI controllers have the benefits of increased system stability and reduced sensitivity to parameter changes, making them more suitable for dynamic systems. Moreover, FPI controllers respond faster to reach zero crossing time to dampen oscillation, which directly helps increase the efficiency and stability of the entire system [2][21]. Figure 2 shows how the smart control unit works to enable the effective coordination and work synchronisation between the grid and the wind generator.

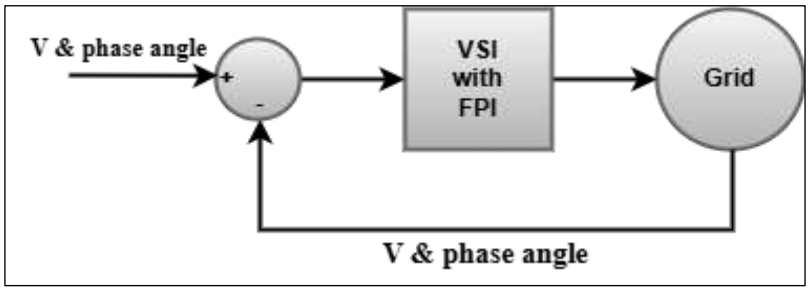

Figure 2: Operation of the intelligent control unit.
Source: Authors, (2026).

Figure 3 demonstrates the load balance between the grid and the wind turbines and how the intelligent unit controls the loads. Rated loads are fed from the wind turbines, and any additional load that introduces disturbances is fed from the grid. When there are no loads, all the power produced by the turbines is transmitted to the grid, maintaining the stability of the electrical system and improving energy efficiency.

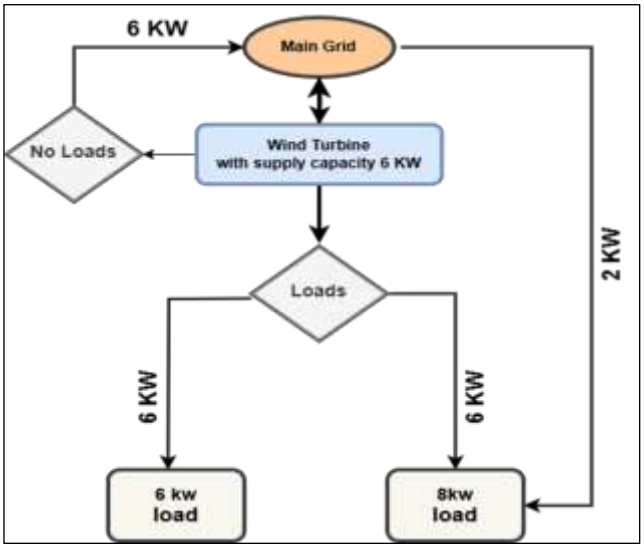

Figure 3: The distribution of loads between the wind turbine and the grid, prioritised according to the diagram, is shown.
Source: Authors, (2026).

II.1.2 Isolating Transformer

Isolation Transformers are utilized to protect sensitive devices from electrical noise and to provide step-up or step-down as required, in addition to coupling two circuits together that cannot be connected directly. These converters remove the DC, while allowing the AC to pass. The proposed three-phase isolation transformer concept is emerging in renewable power system applications due to the improvements in energy transmission and the stability of the electric system [22].

II.1.3 Grid and Loads

The national grid is a complex system designed to transmit and distribute electrical power across large geographic areas, ensuring that consumers' energy needs are met efficiently and reliably. It consists of a group of power plants, transmission lines, and transformer stations, working together to provide electricity to homes, businesses, and industries. Renewable energy sources are often integrated into the national grid, enhancing the sustainability of the electrical system and reducing dependence on fossil fuels. When wind turbines are connected to the grid, they supply the necessary electrical power to the loads. However, it is undeniable that wind turbines alone are insufficient to cover all loads. This is where the intelligent control unit comes in to balance the load distribution between the two sources. Wind turbines supply loads within their rated electrical capacity, while excess or unexpected loads are considered disturbances and are supplied from the main grid, which in turn generates electricity using other sources [23].

III. MATERIALS AND METHODS

This study aims to analyze the performance of a grid-tied wind energy conversion system (WECS) under variable conditions, including changes in load and wind speed, and to demonstrate the adaptability of the control used in the system. During the simulation period ($0 < t < 10$) seconds, the load was constant at 6 kW. Then, in the period ($10 \leq t \leq 12$) seconds, the load was increased by about 34% before returning to its original value. The entire system was modeled using MATLAB, as shown in Figure 4.

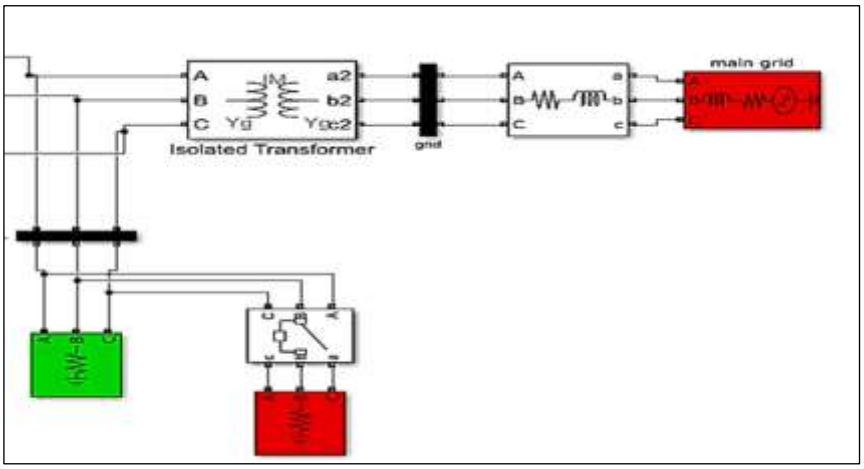

Figure 4: Simulation model of the main grid and loads.
Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

The maximum output capacity of the wind turbine is estimated at 6 kW. Therefore, any load exceeding this limit is considered a disturbance and cannot be handled effectively, which is classified as an overload that requires the intervention of additional power sources to ensure the stability of the electrical supply. The wind speed was adjusted according to the step size as shown in Figure 5. This type of wind speed change is considered unrealistic, as it represents a significant challenge for a grid-tied (WECS) due to sudden and rapid transitions between wind speeds. Through this scenario, the effectiveness and efficiency of the proposed adaptive control system can be evaluated.

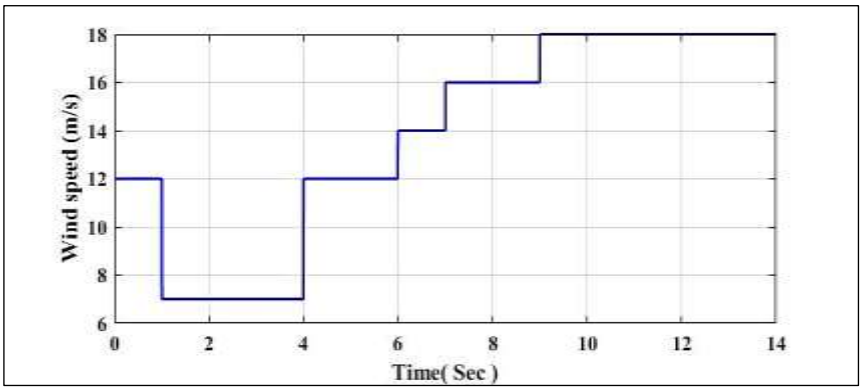

Figure 5: Wind speed variation with time.
Source: Authors, (2026).

Despite fluctuations in wind speed and varying loads, the single-phase voltage waveforms of the load and grid, as shown in Figures 6 and 7, show outstanding performance using both FPI and conventional PI controllers. Voltages remain constant in both methods, but the use of an FPI controller provides better control, as the system exhibits a larger and smoother damped response, reducing oscillations and overshoots in the voltage waveform.

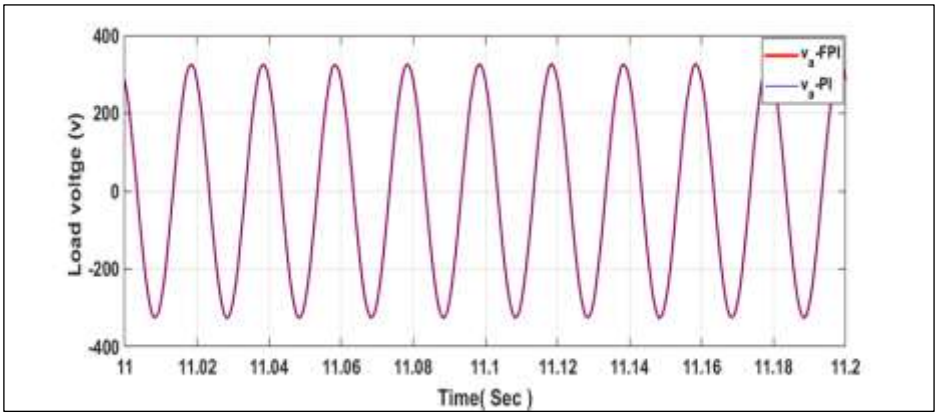

Figure 6: Single-phase load voltage under the intelligent controller.
Source: Authors, (2026).

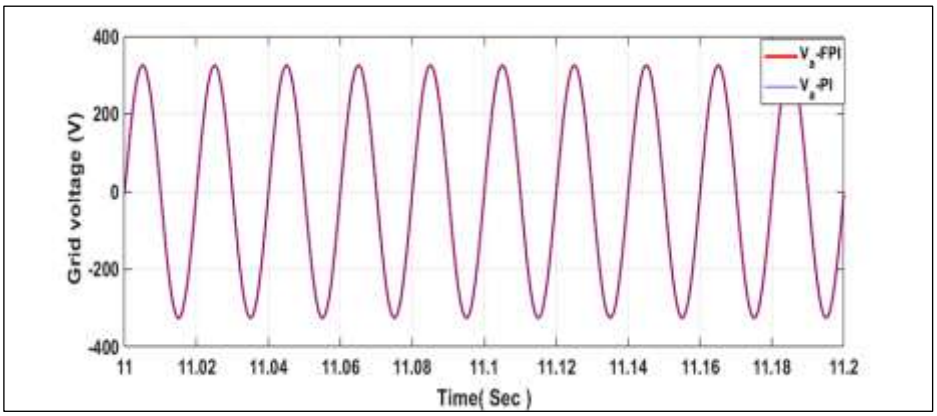

Figure 7: Single-phase grid voltage under the intelligent controller.
Source: Authors, (2026).

Figure 8 shows the single-phase load current. From this figure, it can be seen that the current remains constant at its rated value during the simulation period from (0 to 10) seconds, where the load is 6 kW and is fed entirely from the wind turbine. When the load increases during the simulation period from (10 to 12) seconds to reach 8 kW, this increases the drawing current from the electrical grid, which means that the system draws an additional 2 kW from the grid. The system shows a significant improvement in reducing oscillations and over- and undershoots when using the intelligent controller in the presence of FPI.

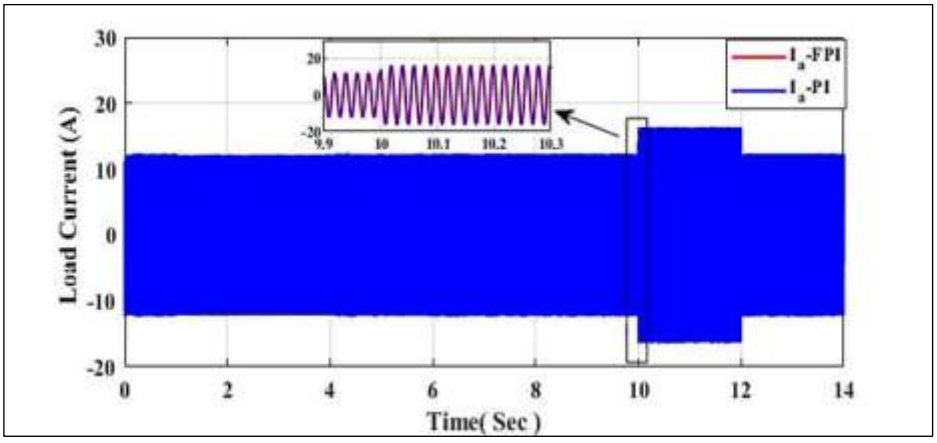

Figure 8: Single-phase load current under the intelligent controller.
Source: Authors, (2026).

Figure 9 shows the single-phase grid current, where it can be seen that the current changes depending on wind speed fluctuations and load changes. Overloads or underloads resulting from low wind speed are always compensated for by the grid, ensuring stability and continuity of electrical supply.

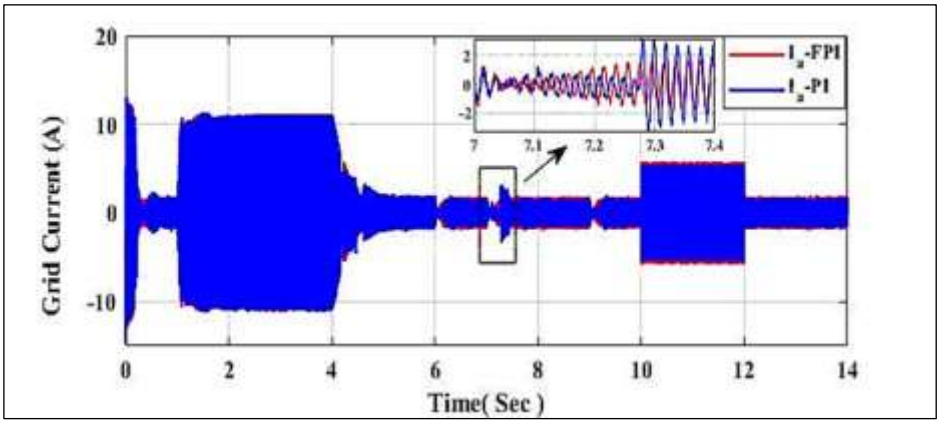

Figure 9: Single-phase grid currents under the intelligent controller.

Using intelligent control technology, the grid frequency is always stable at 50Hz despite abnormal situations. Figure 10 shows the network frequency.

V. CONCLUSIONS

This study is a complete evaluation of the performance of grid-tied WECS under variable conditions, including wind speed fluctuations and load variations. An intelligent controller was used with two strategies: A conventional PI controller and an FPI controller. The last one has been used to improve system performance and reduce oscillations and overshoots in the voltage waveform. The results showed that FPI controllers provide better performance in terms of reducing oscillations, which enhances the stability of the electrical system. Load balance has been achieved between the main grid and the wind turbines, as the rated loads are fed from the turbines, while overloads from the grid are compensated. The single-phase load current was also analyzed, and the current remained constant at its rated

value during all times, indicating the effectiveness of the system in meeting the load needs. When the load increased, the draw current from the grid increased, which emphasizes the ability to handle overload. Finally, it is explained that the grid current changes with wind speed fluctuations and load changes, so overloads or lower power generated from the wind turbine are always compensated by the grid, ensuring the stability of the electrical system. These results are evidence of the effectiveness of using the smart controller unit in improving the performance of grid-connected WECS systems, which enhances the reliability of electrical supply and reduces the negative effects of wind speed fluctuations and variable loads, in addition to managing the supply of loads with power in all circumstances.

Diversity.

ABSTRACT

Digital platforms increasingly shape everyday life, yet their design choices often undermine consumer welfare using dark patterns which are deceptive interfaces that manipulate users' decisions. These practices, ranging from hidden costs in e-commerce to manipulative cookie consent prompts and obstructive subscription cancellations, compromise user autonomy and impose financial, privacy, and psychological harms. The risks vary in severity and reversibility, with some patterns leading to lasting detriment while others create cumulative burdens over time. Beyond immediate harm, dark patterns erode trust in digital systems by fostering frustration, skepticism, and disengagement, weakening the long-term relationship between consumers and platforms. Their persistence reflects strong incentives tied to short-term business metrics such as conversions and sign-ups, combined with weak regulatory oversight. Notably, the diversity of dark patterns like urgency cues, obfuscation, misdirection, and coercion etc. illustrates both their adaptability and the challenges of detection. This paper reviews the dark patterns on digital platforms and proposes a structured framework to evaluate dark patterns across three dimensions: risk, trust erosion, and diversity. It also explores mitigation strategies through fair design, transparency, and accountability, while considering the ethical and legal responsibilities of digital platforms. By centering the analysis on consumer trust and risk, the study highlights the pressing need for robust safeguards to counteract diverse manipulative designs and protect users in digital ecosystems.

I. INTRODUCTION

Trust is a foundational element of user engagement within digital environments, influencing behaviors across e-commerce, social media, mobile applications, and voice interfaces. Users depend on the assumption that digital platforms operate in good faith, offering clarity, protecting user interests, and fostering informed choices [1][2]. This trust is not only technical but also social and psychological, shaped by interface design, past user experiences, and perceived transparency [3]. When systems behave predictably, provide honest feedback, and respect user autonomy, users are more inclined to share data and develop sustained platform relationships [4]. However, this trust is increasingly jeopardized by the widespread use of deceptive interface strategies known as dark patterns, manipulative design tactics that coerce users into unintended actions such as sharing personal data, consenting to cookies, or subscribing without awareness [5]. These practices often emerge when business objectives, such as maximizing engagement or revenue, override ethical concerns [6]. Designers may justify such tactics under commercial pressure, even when user autonomy and welfare are compromised [7]. A common example includes cookie banners that visually emphasize "accept all" options or use misleading phrasing to steer user decisions, undermining genuine consent and eroding trust over time [8]. This erosion can fuel user skepticism, platform backlash, and broader

resistance against the digital economy and its governance mechanisms [9]. Critically, distinguishing between authentic trust and what scholars' term "fake trust", trust that is artificially constructed through manipulation or misrepresentation, is necessary for safeguarding user agency [10]. Fake trust may be built through false information, deceptive designs, or persuasive tactics that blur the line between autonomy and coercion [11]. In response to these challenges, the fields of Human-Computer Interaction (HCI), law, and AI ethics have begun developing systematic frameworks to detect, classify, and regulate dark patterns [12]. This interdisciplinary effort seeks to realign digital systems with principles of fairness, transparency, and user-centered design, advancing legal, technical, and ethical safeguards to ensure digital environments which genuinely respect user autonomy [13][14]. Dark patterns are the interface design strategies that deliberately manipulate, coerce, or mislead users into making choices that are not in their best interest, have become a central concern in the fields of human-computer interaction, design ethics, and digital regulation [15].

Coined by Brignull in 2010, the term originally described deceptive design techniques in user interfaces that were used in specific situations to manipulate user behavior and increase actions like sign-ups, purchases, or other forms of conversion. However, over the past decade, these practices have grown in sophistication and scale, evolving into systematic, pervasive design patterns that exploit cognitive biases and information asymmetries [16]. Today, dark patterns are embedded across a wide range of digital environments, including e-commerce websites that use countdown timers or hidden costs [17], mobile applications that obscure data deletion options [18] , social media platforms that employ infinite scrolls and manipulative notification systems [19], and even newer domains such as voice assistants, digital games, augmented reality (AR), and extended reality (XR), where manipulation can be more immersive and less visible to users [20]. As public awareness and regulatory scrutiny have grown, dark patterns have attracted multidisciplinary scholarly attention, from computer science, law, behavioral psychology, and design ethics. This literature review provides a thematically structured synthesis of the current academic and technical discourse surrounding dark patterns. Specifically, it maps the research landscape across six key domains:

1. **Foundational Work and Taxonomy Development**: These classify dark patterns by intent, technique, and impact, guiding ethical design and regulatory understanding.
2. **Application Domains of Dark Patterns**: Dark patterns are expanding into emerging technologies like voice interfaces, extended reality (XR), and AI-driven systems. These contexts introduce new manipulation risks such as misleading voice prompts, immersive consent traps, or biased AI recommendations, making detection harder. As interfaces evolve, so must ethically design standards to safeguard user autonomy and trust.
3. **Automated Detection of Dark Patterns**: Detection of deceptive design uses machine learning and UI analysis to identify manipulative interface elements. ML models analyze visual layouts, text, and user behavior, while UI analysis applies heuristics and design audits. Together, they reveal patterns that undermine user trust, agency, and experience, supporting efforts toward ethical and transparent design.
4. **Mitigation strategies for dark patterns**: Mitigation strategies for dark patterns include enforcing stricter regulations, ensuring transparent design practices, adopting ethical UX guidelines, and conducting regular audits. Educating users to recognize manipulative tactics, empowering them with clearer choices, and promoting accountability among organizations also reduce risks. Collaboration between policymakers, designers, and watchdogs strengthens long-term protection.
5. **Legal and ethical Analysis**: Deceptive design tricks users, damages trust, limits control over choices, and creates stress, resulting in harmful and unethical digital experiences. These target dark patterns through data protection laws like the General Data Protection Regulation (GDPR) in the European Union, California Consumer Privacy Act (CCPA), and Digital Personal Data Protection Act (DPDP) in India. These frameworks mandate transparency, informed consent, and user control to ensure ethical, user-centric digital experiences and protect privacy.
6. **Methodology for calculating metrics (Risk score, Trust Score and Diversity Score)**: Risk Score evaluates probability and impact of negative outcomes using weighted factors. Trust Score measure's reliability, compliance, and transparency via normalized indicators. Diversity Score quantifies representation across categories using Shannon Entropy.

To trace how Dark Pattern research has evolved, we generated a Storyboard Timeline figure from Scopus bibliometric data (as shown in figure 1 and figure 2) using python. Titles, abstracts, and author keywords were text-mined using curated dictionaries for the major themes: Types, Detection, Mitigation, Psychological Impacts, Ethics/Regulation, and scoring metrics. For each year, we calculated the proportion of publications mentioning these themes and plotted them as continuous lines with annotations that narrate the storyline. The results reveal a clear progression: research initially emphasized defining and categorizing Dark Pattern types, then shifted toward building detection methods, and more recently has begun exploring mitigation strategies. On the psychological–ethical/regulatory–metrics axis, early work focused on user psychology, followed by a growing body of studies addressing ethics and legal regulation, while metrics such as trust, diversity, and risk scores remain only sporadically represented. Taken together, the storyboard timelines show a maturing field that is moving from descriptive taxonomies, through diagnostic tools, toward prescriptive interventions—yet they also highlight mitigation practices and standardized evaluation metrics as key gaps for future research.

II. FOUNDATIONAL WORK AND TAXONOMY DEVELOPMENT

The research around dark patterns revolve around designs that trick users into doing things they might not want to do, like giving up private information or making a purchase. It began with efforts to define and organize them into categories. Two landmark contributions in this area are the works of Gray et al. [5][6] and Gunawan et al. [22]-[21], both of which laid important foundations for understanding and detecting dark patterns in real-world user interfaces. Gray et al. conducted a seminal empirical study that examined real-world user interfaces to identify recurring manipulative design tactics. Their typology was grounded in a qualitative, ethnographic analysis and highlighted the psychological impact of these patterns on user autonomy. Gray et al.'s contribution was foundational, in establishing an ethical lens to assess dark patterns, emphasizing their capacity to erode user trust and agency. Building upon this framework, Gunawan et al. provided one of the most comprehensive classification systems to date. Their research extended the scope beyond web interfaces to include mobile platforms, highlighting the adaptability of dark patterns across different contexts. Their work focused on the structural features of dark patterns and their economic motivations, contributing a more systematic and platform-aware perspective. Zagal et al. [23]-[22] explored how video games use similar tricks like making players spend money to win and showed that these patterns can also appear in entertainment systems. Beyond simply listing and testing these patterns, other researchers have focused on their ethical implications. Devarmani et al. [7] argued that dark patterns aren't just annoying but unfair and morally wrong. They compared them to "nudges" (a term from behavioral science) that push people toward certain decisions in unethical ways. These researchers believe that dark patterns reduce people's freedom to choose and make online experience manipulative, which raises serious concerns about design responsibility and user rights. Table 1 gives the classification of Dark Patterns.

Table 1: Classification of Dark Patterns.

Category	Definition	Techniques / Subtypes	Examples
Information Concealment	Techniques that obscure, hide, or delay the presentation of key information from users, often encourage uninformed decisions.	• Hidden Information • Obfuscation • Alphabet Soup	• Amazon hiding subscription details under interface layers [21]-[23] • Legal/financial information buried in privacy policies [24] • Legalese/acronyms in Term and conditions [5]

Manipulative Wording or Design	Language and visual styles designed to mislead or hide true intent.	• Trick Questions • Misleading Reference Pricing	• Checkbox: "Uncheck this box if you do not want emails" [15] • Inflated original prices to simulate discounts [7]
Choice Architecture Exploitation	Structuring options which manipulate users into making specific, often suboptimal, decisions.	• Preselection • Drip Pricing	• Pre-ticked subscription/ product add-ons [16] • Fees revealed only at final checkout [5]
Coercive Design	Use of emotional pressure or psychological tactics to compel users to act.	• Forced Action • Nagging • Emotional Appeals Urgency	• Provide personal info or accept cookies to proceed [25] • Repetitive exit prompts [26] • "You'll make your cat sad…" [9]. Fake countdown timers [17]
Obstruction	Designs that intentionally make it difficult or time-consuming to take actions against the platform's interests.	• Complete Obstruction • Temporary Obstruction	• Multi-step or call-only cancellations [9] • Privacy settings buried in menus [27]
Sneaking	Actions are performed on behalf of the user without explicit consent or awareness.	• Hidden Costs • Disguised Ads • Drip Pricing • Manipulated Fairness Perception	• Add-ons like insurance, donation preselected [16] • Sponsored content disguised as native posts [5] • Sequential surcharge disclosure [28] • Manipulated Fairness Perception involves designing pricing or presentation tactics that make unfair or inflated costs seem reasonable [29]
Social Proof and Scarcity	Using real or simulated peer activity or limited availability to pressure decision-making.	• Low Stock Claims • Recent Purchase Alerts	• "Only 1 room left!"—often fake [27] • "Maria from London just bought this [17]
Social Engineering	Leverages psychological tricks and peer influence to manipulate behavior.	• Scarcity Claims • Social Proof • Shaming • Countdown Timer • Activity Messages • Fear of Missing Out (FOMO) • Friction in Account Deletion	• Scarcity Claims: "Only 2 left in stock!" to pressure purchases. • Social Proof: "500 people bought this today!" • Shaming: Labels like "No thanks, I prefer to pay full price." • Activity Messages: Fake updates like "Jessica just bought this". • Countdown Timers: Create urgency even if not real.
Gamification	Use of game elements to encourage repetitive use or spending.	• Pay-to-Play • Grinding • Countdown Ads • Infinite Scrolling • Addictive Design • Compulsion Loops • Reduced Friction to Keep Playing/Paying • Artificial Scarcity • Fear of Missing out (FOMO) • Power Imbalance via Purchases • Escalating Rewards • Anticipatory Triggers • Loot Box Rewards • Reward Saturation • Friction in Account Deletion • Bright Patterns Replacement	• Pay-to-Play: Must spend money to progress. • Grinding: Repetitive tasks required for minor rewards. • Countdown Ads: Must watch full ads before proceeding. • Infinite Scrolling: No stopping point to encourage endless use. • Addictive Design: Features like pull-to-refresh or reward loops. • Compulsion loops: Repetitive gameplay cycles that exploit rewards and anticipation to keep players engaged. • Reduced Friction to Keep Playing/Paying: Design choices that minimize obstacles, encouraging seamlessness, continuous engagement and spending without reflection. • Artificial Scarcity: Time-limited Rewards • Escalating Rewards: Rewards increase in value or rarity the longer or more frequently a player engages, encouraging prolonged play and repeated investment. • Anticipatory Triggers: Cues or signals (like animations or sounds) build excitement before rewards, manipulating players' anticipation to boost engagement and spending. • Loot Box Rewards: Randomized Rewards [30]

			• Reward Saturation: Overexposure to frequent in-game rewards diminishes their perceived value, leading players to seek increasingly intense stimuli to stay engaged [31] • Friction in Account Deletion: Deliberate obstacles like hidden settings, multiple confirmations, or delays or making deleting accounts difficult, users discouraged from leaving a platform or game [32] • Bright Patterns Replacement: Substituting transparent, user-friendly defaults for dark-patterned UI elements such as visible opt-outs, clear labels, and honest nudges [33]
Forced Action	Forces users to complete specific actions to access features or proceed.	• Forced Continuity • Forced Registration • Privacy Zuckering • Friend Spam • Granting permissions and Exploiting Interaction flows	• Forced Continuity: Free trials that auto-renew without clear notice. • Forced Registration: Must sign up before browsing content. • Privacy Zuckering: Pushing users to share more data than necessary [34] • Friend Spam: Encouraging users to spam contacts or share invites [35] • Granting permissions and Exploiting Interaction flows: Requiring excessive permission to use a service.
Interface Interference	Manipulates visual hierarchy, wording, or layout to mislead users.	• False Hierarchy • Bad Defaults • Visual Prominence • Small or Moving Close Button • Trick Questions	• False Hierarchy: Highlights or enlarges options like “Accept All”. • Bad Defaults: Pre-selected options benefit the service provider. • Visual Prominence: Important choices are visually downplayed. [36] • Small or Moving Close Button: Makes it hard to close pop ups or ads. • Trick Questions: Confusing language in opt-in/opt-out options. [37]

III. APPLICATION DOMAINS OF DARK PATTERNS

As dark patterns have proliferated across digital ecosystems, research has increasingly focused on specific domains where manipulation is especially pervasive or impactful. Thematic analyses reveal that deceptive design strategies often evolve in tandem with platform-specific affordances, regulatory gaps, and commercial incentives. This section synthesizes findings across four major application areas: e-commerce and consent interfaces, mobile applications, social media platforms, and emerging modalities such as XR, voice interfaces, and games.

A. E-Commerce and Consent Interfaces

Dark patterns, specifically deceptive interface designs, are widely studied in e-commerce platforms due to their direct influence on consumer behavior and revenue generation. These platforms often deploy manipulative tactics such as hidden fees, urgency cues, misleading CTAs, and forced choices to increase conversions and secure consent while undermining transparency and user autonomy. Research on dark patterns highlights widespread manipulative design practices across digital platforms. Singh et. al. [38] audited Indian e-commerce platforms while Chaudhary et. al. [39] studied other E-commerce platforms and found urgency cues (“Only 1 item left!”), misdirection with prominent “Buy Now” buttons, and hidden fees at checkout, exploiting attention limits, creating artificial scarcity, and undermining transparency. Nouwens et al. [8], in a large-scale analysis of EU websites, identified pre-checked boxes, confusing language, and visually dominant “Accept All” buttons in cookie consent banners, showing that consent is manipulated rather than freely given.

Similarly, Santos et al. [40] examined web privacy interfaces and revealed deceptive layouts and text mimicking privacy tools while nudging consent, again demonstrating consent manipulation. Berens et al. [41] analyzed cookie disclaimers, identifying obscured opt-out paths and visual hierarchies favoring acceptance, which subvert informed consent and reduce transparency. Vishvakarma et al. [42] applied Agency Theory to e-commerce platforms, noting deception for profit, conflicts between business incentives and user interests, and information asymmetry that benefits platforms over users. Experimental evidence further illustrates these effects: Santana et al. [43] showed consumers often choose lower base-price options but end up paying more when hidden fees are added through drip or partitioned pricing and anchoring bias exploitation; although transparency reduces the effect, biases persist. Fecher [44] found that later disclosure of surcharges in travel-booking reduces perceived value and trust, particularly for price-conscious consumers, with drip pricing and hidden fees undermining brand trust and purchase intent. Moriuchi et al. [29] studied peer-to-peer lodging platforms like Airbnb,

showing that drip pricing, hidden fees, and manipulated fairness perceptions reduce consumer trust and intent when fees seem deceptive, though transparent pricing can lessen backlash. Finally, Ahmetoglu et al. [45] reviewed behavioral pricing tactics, finding that anchoring bias, partitioned pricing, drip pricing, and price obfuscation distort consumer choice, obscure total costs, reduce transparency, and raise ethical concerns about fairness in marketing. Together, these studies underscore how dark patterns exploit cognitive biases, manipulate consent, and erode consumer trust across contexts.

B. Mobile Apps and OTT Platforms

Mobile platforms introduce unique challenges for dark pattern detection and user experience due to small screen sizes, touch-based interaction, and app-centric ecosystems. These constraints are often exploited to hide options, obscure data deletion, or create misleading pathways. Dark patterns manifest differently across platforms and interfaces, often exploiting either consent, data, subscriptions, or interaction through manipulative navigation and behavioral nudges. Gunawan et al. analyzed cross-platform environments and identified bait and switch, hidden costs, forced continuity, and nagging, noting that limited mobile screen space intensifies hidden costs, preselection, and obfuscated opt-outs, disproportionately affecting users with cognitive or motor impairments. Ramteke et al. examined mobile apps and found friction in account deletion, misleading opt-out buttons, and covert data sharing practices; in freemium models, these deceptive designs drive retention while undermining informed consent and user control over data.

Similarly, Chen et al. used the AppRay tool to detect structural manipulation in app navigation, such as circular menus, disappearing back buttons, and trapped exit paths, showing how subtle UI designs hinder user autonomy and resist regulation. Ramokapane et al. [46] focused on data deletion workflows in mobile apps, uncovering multi-step deletion processes, non-intuitive instructions, and lack of confirmation or feedback, raising serious concerns about resistance to user data rights. In subscription contexts, Nguyen et al. [47] in his case study and Ye et al. [48] found that music streaming platforms like Spotify and Apple Music deploy auto-renewal defaults, friction in cancellation, and habit reinforcement loops, which promote lock-in, reduce autonomy, and influence behavior.

Oyibo et al. [49] investigated awareness of dark patterns in streaming sites such as YouTube and Ivysci, showing that users without knowledge are more susceptible to confirmshaming and trick questions (68% compliance), while awareness reduces compliance to 35%, indicating transparency and education mitigate manipulation and protect platform reputation. Nygren et al. [50] inspected interfaces across YouTube, Netflix, Disney+, and Prime Video, reporting widespread forced continuity, hidden subscription costs, invasive mobile pop-ups, manipulative cookie-consent defaults, and autoplay loops, underscoring the need for regulatory scrutiny and industry audits. Rhomberg et al. [51] and Alashwali et al. [52] emphasized interventions to empower users through tools like browser extensions, educational guides, and transparency features, proposing “bright patterns” such as auto-renewal toggles and clear consent mechanisms to reduce susceptibility.

Extending beyond traditional UI, Mattiuzzo et al. [53] showed that TikTok leverages personalization and design nudges algorithmic sequencing, timing controls, and personalized content loops to influence retention, sometimes overriding user intent, while Dubiel et al. [54] highlighted how enhanced voice fidelity in conversational agents increases trust and compliance even with misleading suggestions, making vocal manipulation a novel non-visual dark pattern that requires ethical regulation. Finally, Franzen et al. [55] explored UX practitioners’ perspectives, revealing that many rationalize privacy-related dark patterns such as default opt-ins, deceptive toggles, and coercive consent designs as necessary trade-offs, highlighting the urgent need for stronger ethical standards, designer training, accountability mechanisms, and regulation around privacy defaults.

C. Social Media and Engagement Loops

Social media platforms are designed around continuous engagement, and as such, they often employ dark patterns that target psychological vulnerabilities to maximize time-on-platform. These manipulations are deeply embedded in algorithmic curation, notification design, and interface dynamics. What distinguishes dark patterns in this domain is their temporal and psychological nature: rather than misleading a user once, they shape ongoing behavior, subtly steering attention and habit formation over time. This raises complex ethical issues, especially for younger users and vulnerable populations. Research on social media platforms shows how design patterns exploit psychological vulnerabilities to maximize engagement, often at the cost of user well-being and autonomy. Beltrán et al. [56] and Clark et al. [57] highlighted how infinite scroll, intermittent rewards such as variable likes, autoplay, and disappearing content create compulsive engagement loops, mirroring gambling mechanisms that exploit variable-ratio reinforcement.

These patterns reduce user well-being, induce anxiety, undermining control, and raise serious ethical concerns over loss of agency. Extending this critique, Mamun et al. [58] and Ahuja et al. [59] argued that platforms deliberately prioritize engagement optimization and manipulative metrics over user autonomy or mental health. They called for systemic reforms, including greater transparency in engagement metrics and regular audits of design practices, to ensure alignment with ethical standards. Together, these studies emphasize how social media dark patterns particularly those rooted in interaction design and reinforcement mechanics erode informed choice, compromise user agency, and necessitate stronger accountability mechanisms.

D. XR, Voice Interfaces, and Game Design

Emerging modalities like extended reality (XR), voice assistants, and digital games introduce novel interaction paradigms that also expand the scope of dark pattern deployment. In these environments, manipulation often exploits spatial, auditory, or reward-based structures that differ from traditional screens. voice-based dark patterns rely on tone, timing, and control of dialogue flow rather than visuals. They exploit listening effort, memory limits, and social cues to manipulate users’ decisions. The evolution of interfaces expands the scope of potential manipulative practices, extending beyond screen-based interactions to encompass bodily gestures, spoken commands, and reward-based systems. They also signal a growing need for modality-specific detection frameworks, legal protections, and design guidelines. Supportive vs. Manipulative Tones in Voice Interfaces. Research on online gaming highlights how dark patterns in design exploit psychological mechanisms, often undermining fairness, autonomy, and player well-being. Freeman et al. [60] examined

competitive games, showing that pay-to-win mechanics and purchase-driven power imbalances erode perceived fairness, reduce trust, and heighten frustration in competitive contexts.

Larche et al. [61] analyzed loot box systems, finding that rare rewards trigger heightened arousal and encourage repeated openings, exploiting variable reinforcement schedules akin to gambling and fostering potentially addictive behaviors. Vulnerable groups such as adolescents with Internet Gaming Disorder (IGD) face intensified risks. Liu et al. [62] revealed that reduced loss aversion and inhibitory control make them more susceptible to compulsion loops and low-friction play/pay mechanics, while Raiha et al. [63] demonstrated altered neural reward processing, where escalating rewards and anticipatory triggers reinforce addictive cycles. Similarly, Zhou et al. [64] found that IGD individuals display heightened sensitivity to in-game over real-world rewards, amplifying reward saturation and reinforcing escapism. Beyond addiction, engagement mechanics can also pressure players. Frommel et al. [65] studied daily quests and incentives, showing how artificial scarcity and fear of missing out (FOMO) can sustain habitual engagement but also generate burnout or pressure-driven play. Together, these studies illustrate how gaming dark patterns, especially through compulsion loops, reinforcement schedules, and reward manipulation, exploit cognitive vulnerabilities to drive monetization and engagement, raising ethical concerns over fairness, player health, and industry responsibility.

IV. AUTOMATED DETECTION OF DARK PATTERNS

As dark pattern research matured, scholars increasingly turned their attention to automated detection techniques aimed at identifying deceptive designs at scale. These efforts span mobile applications, websites, e-commerce systems, and emerging platforms, reflecting growing concern over unethical user interface practices. Approaches can be broadly categorized into language-based, visual/UI-based, and structural/DOM-based methods. Together, these methods reflect a maturing research landscape seeking scalable, generalizable, and explainable solutions.

A. Language-Based Detection

Language-based detection methods harness natural language processing (NLP) and transformer models to uncover manipulative textual content embedded in interfaces. Salminen et al. [66] trained a RoBERTa model on retail scenarios to identify deceptive strategies like drip pricing and false urgency. Their system achieved high F1-scores (up to 0.969), and the use of explainable AI tools such as LIME and SHAP enabled the identification of linguistic markers like scarcity, popularity, or FOMO cues. Sazid et al. [67] extended this line of work using GPT-3 in a few-shot learning setting, showing its ability to classify dark patterns with minimal labeled data, highlighting its adaptability across domains. Similarly, Ramteke et al. combined BERT with a web scraping pipeline to detect urgency-based and misdirection patterns in e-commerce, achieving a 96% accuracy rate. These studies underscore the effectiveness of transformer-based models in decoding subtle cues of manipulation in text-heavy interfaces.

B. Visual and UI-Based Detection

Because many dark patterns rely on visual deception—such as hiding options, contrast manipulation, or misleading layout—visual and UI-based approaches have emerged to interpret interface structure beyond language. Kodmurgi et al. [68] applied YOLOv5, a real-time object detection algorithm, to Android app screenshots, accurately identifying UI components associated with deceptive design choices. Mansur et al. [69] introduced AidUI, a multi-modal architecture that integrates visual layout features, user interaction traces, and semantic understanding to detect manipulation in both web and mobile contexts. These models highlight the importance of interpreting *how* interface components are positioned, styled, and presented to users—particularly when visual tricks are used to nudge behavior. Tools like UIGuard combine computer vision with text recognition and rule-based classification. Their system, built with Faster R-CNN and PaddleOCR, was deployed on mobile interfaces and achieved 0.93 accuracy. It significantly improved users' dark pattern detection recall (from 18.5% to 57.8%), though it remained constrained when handling unfamiliar pattern types. Likewise, Kodandaram et al. designed a detection system for screen-reader accessibility, targeting deceptive ads that harm visually impaired users. Their model combined transformer layers, an LSTM module, and DOM-derived features for high-precision classification, representing an often-overlooked domain in mainstream detection tools.

C. Structural/DOM-Based Detection

This approach focuses on analyzing a webpage's underlying logic and element hierarchy, rather than just its visible content or appearance. Early systems relied on rule-based parsing of HTML to flag patterns like "sneaking" or "misdirection." While these methods work well for known dark patterns, they require frequent manual updates and lack adaptability to new designs. To address these limitations, Nie et al. introduced the *Dark Pattern Analysis Framework* (DPAF), which builds on a taxonomy-driven review of 76 core studies. DPAF identifies 64 dark pattern types—20 of them newly defined—and maps existing detection methods to this taxonomy. Their work highlights significant interoperability issues and the absence of automated updating mechanisms that could keep pace with evolving deceptive design strategies. In a more holistic direction, Stavrakakis et al. introduced a morphological matrix framework that combines HTML parsing, computational linguistics, and image analysis. Their prototype successfully flagged patterns across categories but still faced challenges with UI. A third major category focuses on interface structure, particularly the Document Object Model (DOM) used in web and app design. These methods investigate how manipulation is embedded in the hierarchy, logic, or flow of interface elements. Bajaj et al. [70] modeled DOM trees in mobile apps to detect coercive flows—such as hidden cancel buttons or misleading progress indicators—by analyzing navigation paths and element nesting. Mansur et al. addressed the challenge of cross-platform applicability, proposing a generalization framework to train models that can detect dark patterns across varying UI architectures and environments. Cookie banners, a frequent site of consent manipulation, have been extensively studied through Document Object Model (DOM) analysis. Vedhapriyavadhana et al. [71] introduced a multi-faceted system to detect dark patterns such as deceptive UI/UX practices in shopping websites using Bidirectional Encoder Representations from Transformers (BERT) and DOM.

It used a Chromium browser extension, a machine learning backend, and a companion website to identify manipulative design elements in real-time and highlights them for users. Hausner et al. [72] used Support Vector Machines (SVMs) to classify manipulative designs based on HTML structure, textual cues, and CSS styling, with a focus on contrast tricks (e.g., highlighting "Accept" while hiding "Reject"). Ramokapane et al. applied machine learning to cluster banner components, revealing difficulties with inconsistent layouts and labeling schemes that hamper automated classification. These findings suggest that deception often resides in the interval variability and inconsistent semantics, echoing the call for more flexible, resilient systems. Together, these detection approaches illustrate the field's shift toward scalable, data-driven solutions. While many tools reach high performance in controlled environments, a common limitation persists difficulty generalizing to novel, dynamic, or platform-specific dark patterns. Emerging strategies aim to bridge this gap using transfer learning, explainable AI, and cross-platform models, but success will depend on continuously updated datasets, taxonomies, and more user-centered tools that promote transparency and trust. Despite promising accuracy, real-world deployment of these systems remains limited.

D. Hybrid/Ensemble Approaches

This approach combines two or more of the above strategies to maximize coverage. For example, a system may use NLP for text cues and DOM parsing for structural clues. Kodmurgi et al. introduced *ScrapeAI*, a multi-modal architecture that combines UI screenshots, code structure, and behavioral logs to detect dark patterns with promising accuracy. Abraham et al. proposed three detection algorithms—rule-based, ML-based, and hybrid—which showed complementary strengths in various commercial settings. Its multi-modal nature improves detection accuracy but comes at high computational cost and deployment complexity. In contrast, Abraham et al. advocate a modular hybrid model that balances rule-based interpretability with machine learning generalization. Their approach is more adaptable but struggles with dynamic content. Together, these methods reveal a trade-off between specificity and scalability—a challenge that remains unresolved.

V. MITIGATION STRATEGIES FOR DARK PATTERNS

This area remains underdeveloped compared to advances in detection. While research has focused heavily on identifying manipulative designs, fewer efforts address how to actively counter or prevent them. User-facing interventions show some promise: Schäfer et al. [73] demonstrated that simple design adjustments such as overlays, clearer consent options, and standardized button hierarchies can reduce mis clicks and enhance agency. Similarly, Kronhardt et al. [74] introduced a gamified tool that trains users to recognize manipulative patterns, improving awareness and literacy, though such approaches remain experimental and largely absent from mainstream platforms. From a regulatory and industry perspective, proposals like Rana et al. [75] Legal UX Audits suggest that interface designs could undergo compliance reviews much like financial or security audits. This model shifts the focus from penalizing violations after the fact to proactively setting standards for acceptable design. Yet these ideas remain largely theoretical, with limited institutional adoption. Meanwhile, a major gap persists for developers and designers, who lack real-time ethical evaluation tools comparable to accessibility or performance checkers. Without such support, ethical UI design often depends on ad-hoc expertise or retrospective audits, which are inadequate in fast-moving development contexts. Overall, progress in intervention is fragmented. To move forward, research and practice must embed ethical toolkits into design workflows, establish regulatory sandboxes, build educational infrastructure for users and developers, and standardize protocols for UI evaluation. Without these measures, detection will continue to outpace deterrence, allowing manipulative practices to evolve unchecked.

VI. LEGAL AND ETHICAL ANALYSIS

The legal and ethical analysis of dark patterns shows both convergence and divergence across global and Indian contexts. Globally, scholars like Luguri et al. frame the issue around autonomy and coercion, with regulation focused on consent, cookie banners, and manipulative e-commerce practices. Reports such as the Norwegian Consumer Council's 2018 [76] study spurred EU and US inquiries, and while frameworks like the General Data Protection Regulation (GDPR) and California Consumer Privacy Act (CCPA) set high standards, enforcement remains inconsistent. Studies indicate that platforms often practice strategic compliance rather than genuine design reform, leaving many forms of soft manipulation beyond effective legal reach. In India, by contrast, the framing emphasizes socio-technical vulnerability, reflecting the realities of mobile-first users, low digital literacy, and systemic inequities. The Consumer Protection Act (2019) [77] laid a broad foundation, but the 2023 "*Guidelines for Prevention and Regulation of Dark Patterns*" [78] marked a decisive step. It explicitly classifies manipulative practices and aligns with the Digital Personal Data Protection Act, emphasizing meaningful consent. Enforcement, however, is challenged by weak technical capacity, low consumer awareness, and fragmented oversight [79]. Ethically, the global debates stress autonomy and transparency, Indian discourse prioritizes digital equity, inclusive design, and protection for vulnerable users.

This comparison underscores that while the global approach leans on universal principles of autonomy, India advances a contextual, equity-driven model that addresses both cognitive and structural vulnerabilities [80]. Hence, combating dark patterns demands regulation, ethical design standards, user education, and metrics valuing long-term user welfare over short-term profit [81]. Even minor or small deceptive acts on digital platforms can erode trust [82]. Dark Patterns manipulate users' behavior, reduce autonomy, and undermine enjoyment, highlighting the urgent need for ethical, transparent design on various platforms [83]. Users still limit sharing sensitive data. Firms gain via better targeting, stronger marketing, and greater lock-in, showing regulation can protect privacy *and* support business outcomes [84][85][86]. Dark patterns continue to undermine consumer autonomy across domains such as e-commerce, gaming, and streaming. Hung (2021) highlights how "nagging" patterns create persistent consumer injury, while Li (2022) examines evolving regulatory responses under the FTC and CPRA to manipulative cookie consent notices. Few research focuses on remedies: Yao and Wei [87] propose improved terms-of-service design to reduce user confusion, whereas Singh, Vishvakarma, and Kumar [88] use grey influence analysis to study consumer challenges, and later authors in [89] show how deceptive design erodes brand equity. Zac et al. [90] stress that

consumer vulnerability magnifies harm, aligning with Bhoot et al. [91], who identify patterns through user reactions. Experimental evidence by Koh et al. [92] demonstrates how four common e-commerce dark patterns drive unintended consumption, while Nygren et al. document similar tactics in video streaming services. Parallel work on music streaming by Li, Liu, and Chen [93] underscores that user satisfaction and retention may be compromised by manipulative interfaces. Collectively, these studies suggest that dark patterns are not only prevalent but context-specific, raising urgent questions about ethics, user welfare, and regulatory oversight [94][95].

VII. METHODOLOGY

Step 1: Dataset Creation

A labeled dataset was created to examine 39 categories of dark patterns across widely used platforms. The categories include e-commerce (e.g., Amazon, Flipkart, Meesho, Myntra, Nykaa, Shopsy etc.), finance (Paytm, GPay etc.), gaming (Scribble.io, Minecraft etc.), matrimonial/dating/chatting (Instagram, whatsapp, Bhartmatrimony, Jeevansathi etc.), OTT (Netflix, Zee5, Amazon prime etc.), blockchain/cloud (AWS, GCP, casper, Blockchain.com etc.) and educational (Grammarly, W3 school and various universities) platforms. In this study, the unit of analysis was defined as an observable UI instance such as a text element, widget, flow step, or micro-interaction that exhibited or was suspected of exhibiting manipulative behavior (e.g., drip pricing, urgency cues, scarcity claims, or obstruction). To ensure comprehensive coverage, we examined key user flows across platforms, including the landing or homepage, sign-up and onboarding processes, the cart-to-checkout-to-pricing journey, cookie consent dialogs, settings and privacy options, as well as unsubscribe, refund, and cancellation mechanisms. These flows were tested across multiple user states namely, logged-out visitors, newly created accounts, returning users, and incognito sessions—to capture potential variations in dark-pattern deployment. A hybrid approach was employed, combining manual inspection of user flows with AI-assisted verification. Microsoft Copilot (Edge Sidebar) and Perplexity were used to extract UI text, summarize prompts, and flag potential dark patterns. Every AI prompt and output was logged for traceability, but manual verification remained mandatory to mitigate the risk of AI hallucinations and ensure the accuracy of identified instances.

A systematic process is followed to capture data to ensure consistency and reliability. For session setup, a Chromium-based browser (stable release) in both normal and private modes is used with cache and cookies cleared between sessions. The testing environment was configured to a desktop viewport ranging from 1366×768 to 1920×1080, set to the India locale with English as the default language. Only test accounts were created and used, with no personal data or payment details stored. For evidence collection, each candidate dark pattern was documented using multiple forms of data: screenshots and screen recordings captured before, during, and after user interactions; DOM snapshots that included visible text and relevant HTML snippets (via Inspect/Accessibility Tree); and, when necessary, network traces to verify whether timers or stock counters were dynamically fetched from the server or simply hard-coded and resettable. All captures were timestamped in ISO format to help detect recycled or false countdowns. These artifacts were stored in a structured directory hierarchy, with each session folder containing screenshots, recordings, DOM dumps, and notes for clarity and reproducibility. For AI-assisted review, Microsoft Copilot (Edge sidebar) and Perplexity were used as secondary verification tools. They extracted page text, summarized visible prompts, and suggested possible dark-pattern categories. However, their outputs were never accepted without manual confirmation, and any disagreements or vague categorizations were explicitly flagged as requiring manual adjudication. Candidate instances were assessed using objective and rule-based criteria to minimize subjectivity. A few examples are listed below in Table 2.

Table 2: Examples - Dark Patterns and their Trigger Rule.

Category	Objective	Decision Rule (Pass if…)	Example Triggers
Drip Pricing	Hidden fees, preselected add-ons	Material price element appears only after checkout initiation	“Convenience fee” at payment, gift wrap auto-selected
Urgency / Countdown	Timers, “ends soon” messages	Countdown persists across sessions or resets on reload	“Offer ends today” but reappears next day
Scarcity / Low Stock	“Only X left”	Stock claim static/unrealistic across refresh	“Only 1 left” on many SKUs
Social Proof / FOMO	“N people bought in 24h”	Unverifiable claims, often paired with urgency	“7,421 purchased today”
Disguised Ads	Sponsored content styled as organic	Paid content lacks equal disclosure	“Recommended” tiles w/o “Ad” tag
Friction in Deletion	Multi-step/hidden deletion	Requires >3 steps or off-platform action	“Email support to delete”
Forced Action	Pre-checked boxes, blocked progress	Opt-out harder to find/use than opt-in	“Yes, send me offers” checked by default
Hidden Costs	Late-stage fees	Non-optional fee not disclosed upfront	“Platform fee” added at last step

Source: Authors, (2026).

To evaluate candidate instances systematically, a set of rule checks was applied. The Equal-Prominence Test was used for consent-related choices, requiring that opt-out options carry comparable visual weight to opt-in options (at least 70% in size and positioned at the same panel depth). Failure to meet this criterion was marked as obstruction or misdirection. The Reset/Replay Test was applied to urgency and scarcity claims, where timers and stock counters were reloaded in fresh sessions; if these elements reset or behaved implausibly, they were flagged as false urgency or scarcity. Finally, the Click-Count Heuristic was used to evaluate cancellation flows, with subscribing allowed within two clicks but cancellations or deletions requiring four or more clicks or redirecting users off-platform are considered friction-inducing dark patterns.

Step 2: Cleaning of Dataset and Assigning weights using Saaty's AHP (Analytic Hierarchy Process)

For this study, a systematic data cleaning process was applied to ensure reliability and consistency of the binary dataset. First, all collected artifacts (screenshots, DOM snapshots, network traces, and notes) were cross-checked to confirm whether a dark pattern instance was genuinely present. Any ambiguous cases flagged by AI tools were manually reviewed and either validated or discarded to avoid false positives caused by hallucinated outputs. Duplicate records arising from repeated flows (e.g., refreshing pages or testing across user states) were identified and removed to prevent inflation of frequencies. Inconsistent labels across similar instances were standardized according to the predefined taxonomy of 39 dark-pattern categories, ensuring uniform coding. Finally, the binary encoding was verified where 1 consistently denoted the presence of a dark pattern and 0 denoted its absence, producing a clean and structured dataset suitable for pairwise comparison and AHP analysis. To construct the pairwise comparison matrix, the binary dataset was first interpreted. Each row represented an observation i.e., websites, webapps, mobile apps etc., belonging to different categories. Each column in the dataset corresponded to a criterion, such as Hidden Information, Obfuscation, Drip Pricing, Urgency, or Scarcity etc. Each criterion's frequency was then calculated as the number of rows in which it appeared (i.e., where the value equaled 1).

Using these frequencies, a reciprocal pairwise comparison matrix was generated, where the relative importance of criterion i over criterion j was defined as the ratio $a_{ij} = {f_i}/{f_j}$ where f_i and f_j represents frequencies of criterion i and j in the dataset. All diagonal elements (a_{ii}) are equal to 1 and $a_{ji} = {1}/{a_{ij}}$. The Saaty's Analytic Hierarchy Process (AHP) [96] is applied where the matrix was column-normalized, and the priority vector was computed as the row-wise average of the normalized matrix, yielding the relative weights w_i of each dark pattern. Finally, the consistency of the matrix was evaluated using AHP's consistency metrics. The largest eigenvalue λ_{max} was found to be 39.0 (equal to the number of criteria), leading to a Consistency Index (CI) of 0.0 and a Consistency Ratio (CR) of 0.0, indicating perfect consistency. This outcome was expected because the pairwise ratios were derived directly from observed frequencies, making the matrix mathematically transitive and free of contradictions, with the resulting weights directly reflecting the observed distribution of dark patterns in the dataset.

Step 3: Calculation of Risk Score, Trust Score and Diversity score using Weighted Shannon's Entropy Method

Trust Score, Risk Score, and Diversity Score of dark patterns across various categories in dataset are calculated using weighted Shannon's Entropy [97]. The algorithm begins by measuring the uncertainty of each criterion using equation 1 and equation 2. For every feature, Shannon entropy is computed by considering the distribution of its values across all records. Lower entropy indicates that the criterion provides more useful information, so it is transformed into an information utility measure by taking one minus the entropy value using equation 3. Next, it is combined with the Saaty AHP weights w_i computed in step 2. Each criterion's original weight w_i is multiplied by its information utility d_i and then normalized so that the adjusted weights sum to one. Using these adjusted weights w_i', the Risk Score for each row is calculated as the weighted sum of all the dark pattern indicators present, while the Trust Score is defined as one minus the Risk Score. Finally, the Diversity Score reflects the variety of dark patterns influencing each row and is computed as the Shannon entropy across that row's distribution of criteria. This way, Risk Score captures the intensity of dark patterns, Trust Score represents resilience against them, and Diversity Score measures how varied those dark patterns are within a given record.

To compute Trust Score (*TrustScore*), Risk Factor (*RiskScore*), and Diversity Score (*DiversityScore*) with Shannon entropy and AHP weights, with the dataset having m =40 rows (records) and n =39 criteria, with $x_{ij} \epsilon \{0,1\}$ indicating presence of criterion i in row j, and w_i is the AHP weight for criterion i , with $\sum_i w_i = 1$ calculated in step 2. The Shannon entropy of criterion i (normalized to [0,1]] for a binary variable) is given as equation 1:

$$H_i = -\left(\frac{1}{\ln(2)}\right)(p_i \ln(p_i) + (1 - p_i)\ln(1 - p_i)) \quad (1)$$

where p_i is calculated using equation 2 as:

$$p_i = \left(\frac{1}{m}\right)\Sigma_{j=1}^{m} x_{ij} \quad (2)$$

A small ε is used to replace any 0 inside logs if needed. The entropy is converted to information utility using equation 3 as:

$$d_i = 1 - H_i \quad (3)$$

The algorithm adjusts calculated weights using equation 4 to favor more informative criteria:

$$w_i' = \frac{(w_i * d_i)}{\sum_{\{k=1\}}^{\{n\}} w_{k^*} d_k} \quad (4)$$

Then the Risk score for each row i is the adjusted weighted sum of active criteria and is calculated using equation 5.

$$RiskScore_{\ i} = \sum_{i=1,j=1}^{m,n} w_j' * x_{ij} \quad (5)$$

The Trust Score for row i is calculated as complement of Risk Score using equation 6.

$$TrustScore_i = 1 - RiskScore_i \quad (6)$$

The Diversity Score for row i, is calculated using equation 7

$$.q_{ij} = \frac{\{x_{ij}\}}{\left\{\sum_{\{i=1\}}^{n} x_{ij}\right\};} \quad if \ \sum_{\{i=1\}}^{n} x_{ij} > 0$$
$$DiversityScore_i = -\left(\frac{1}{\ln(n)}\right) \sum_{j=1}^{n} q_{ij} \ln(q_{ij}) \tag{7}$$

The next section presents the analysis of results obtained after using above formulas on the dataset.

VII. RESULT ANALYSIS

The values of Risk Score (*RiskScore)*, Trust Score (*TrustScore)* and Diversity Score (*DiversityScore)* for our dataset are calculated using Shannon Entropy (weighted) method which uses Saaty's AHP for weight assignment. The analysis shows that e-commerce websites have the highest level of manipulation, with a very high *RiskScore* (~0.90) and very low *TrustScore* (~0.09). Their *DiversityScore* (~0.94) also suggests that they use wide variety of dark patterns, making them the most deceptive category overall. Educational websites present a more balanced picture, with a moderate *RiskScore* (~0.48) and a relatively higher *TrustScore* (~0.52). Their *DiversityScore* (~0.57) indicates that while some manipulative tactics exist, they are less frequent and less diverse compared to e-commerce. Finance platforms also show moderate levels, with *RiskScore* (~0.49) and *TrustScore* (~0.51) being almost evenly balanced. However, their *DiversityScore* (~0.73) suggests that financial platforms employ a broader set of manipulation techniques than educational sites, even if the overall risk is not excessively high.

Chatting and matrimonial/dating apps display a concerning profile, with a high *RiskScore* (~0.73) and a relatively low *TrustScore* (~0.27). Their *DiversityScore* (~0.87) highlights that they employ a large variety of dark patterns, making them one of the riskiest categories alongside e-commerce websites. Games are perceived far more positively, with a low *RiskScore* (~0.22) and a high *TrustScore* (~0.78). Their *DiversityScore* (~0.46) shows that although some manipulative designs exist (like loot boxes or addictive loops), they are relatively limited in range and intensity compared to other sectors. Finally, Blockchain and cloud platforms emerge as the safest and most trusted category. They have the lowest *RiskScore* (~0.18) and the highest *TrustScore* (~0.82) among all categories. Their *DiversityScore* (~0.37) indicates that they use very few dark patterns overall, reinforcing their perception as the least manipulative sector. These results are visualized using a heatmap and bar chart for different categories of website.

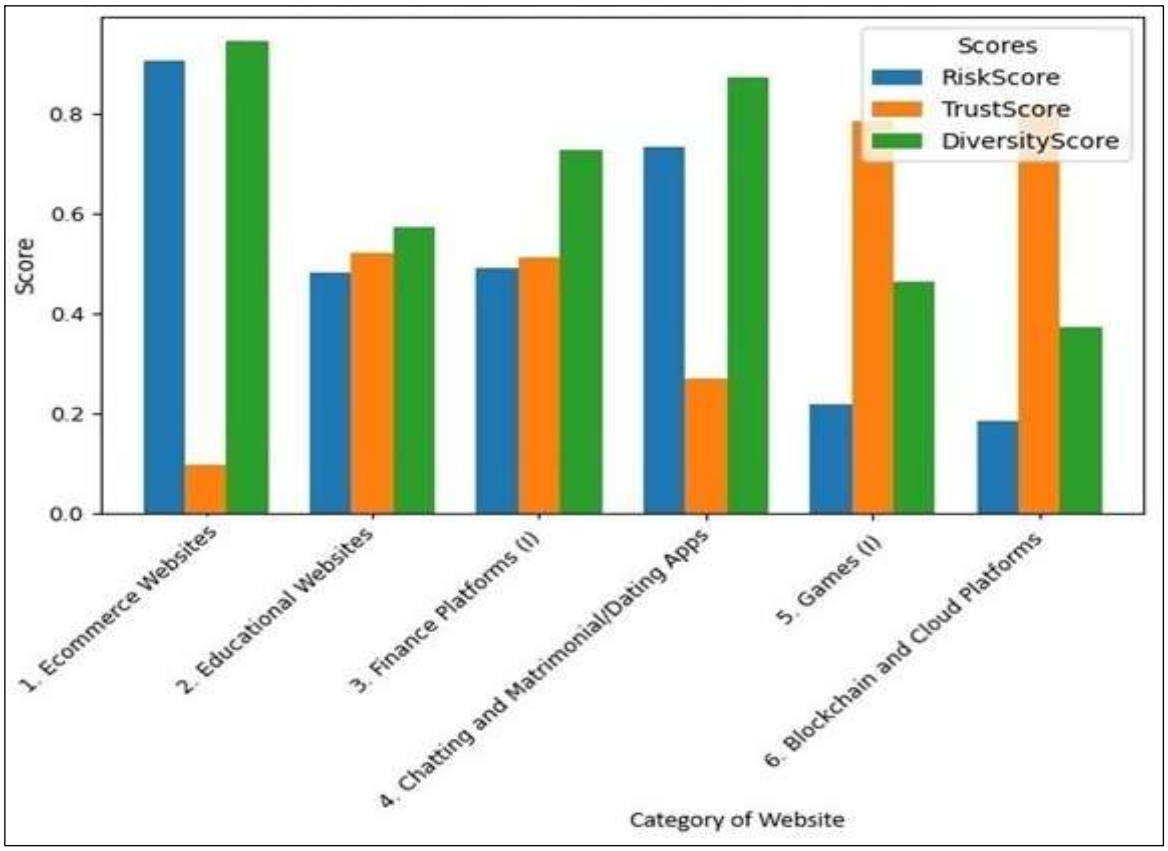

Figure 3:Category-wise Comparison Bar Chart.
Source: Authors, (2026).

The bar chart shows *RiskScore*, *TrustScore*, and *DiversityScore* for each category. In the heatmap, values are shown in matrix using color gradients instead of numbers. The heatmap highlights which scores are high/low with colors for quick comparison.

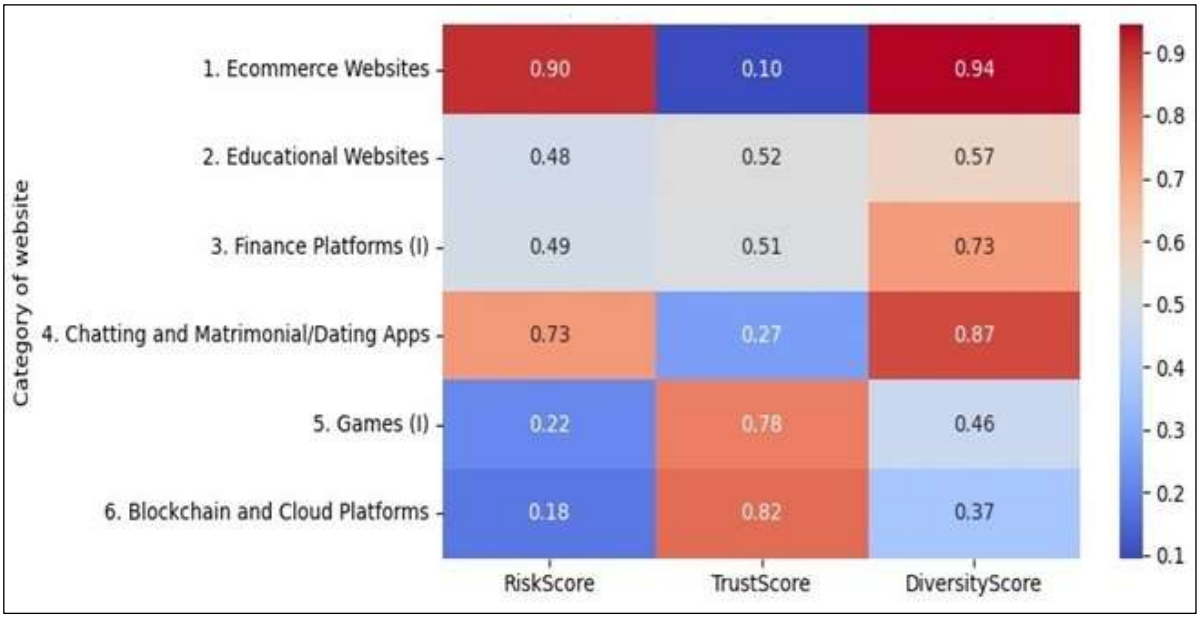

Figure 4: Category-wise Comparison Heatmap.
Source: Authors, (2026).

The charts in figure 3 and figure 4 reveal distinct sectoral differences in the prevalence and perception of dark patterns. E-commerce emerges as the highest-risk domain, characterized by the lowest levels of user trust and the widest variety of manipulative practices, reflecting how aggressive platforms optimize for sales. Dating apps also register as high risk with similarly low trust, as their designs often exploit emotional vulnerability and urgency. In contrast, finance and education platforms occupy a middle ground, showing moderate levels of risk, trust, and manipulation diversity due to stronger regulation in finance and ethical expectations in education. Interestingly, games and blockchain applications appear at the opposite end of the spectrum, with the lowest risk and highest trust, suggesting that users perceive these environments as more transparent or voluntary in nature, even though they operate in highly interactive and experimental domains. Overall, E-commerce and Dating Apps are the most manipulative, Finance and Education are moderately manipulative, while Games and Blockchain/Cloud Platforms are the least manipulative and most trusted.

V. CONCLUSIONS

To effectively mitigate dark patterns, a multi-stakeholder approach is essential. For designers and developers, the priority should be integrating ethical design toolkits and real-time pattern checkers into everyday workflows, alongside adopting standardized UI guidelines that reduce manipulative elements. Regulators and policymakers can play a crucial role by establishing regulatory sandboxes, where platforms can test interfaces for compliance, introducing legal UX audits or certification schemes modeled on GDPR and CCPA, and mandating enforceable design standards backed by penalties for non-compliance. Moreover, India's regulatory trajectory demonstrates a growing commitment to curbing digital exploitation, but sustained investment in technical expertise, consumer education, and coordinated enforcement is essential to ensure that these protections deliver on their promise. Users and communities should be empowered through digital literacy campaigns and gamified tools that enhance their ability to recognize manipulative interfaces, while participatory co-design with vulnerable groups, such as low-literacy, mobile-first, and multilingual population which ensure that regulations and design practices reflect diverse needs. Finally, researchers must shift focus from detection towards intervention, developing frameworks that can address dark patterns in emerging domains like extended reality, voice interfaces, and algorithmic platforms. Together, these strategies can move governance from reactive detection towards proactive prevention, fostering more transparent, equitable, and trustworthy digital environments.

ABSTRACT

Multi-junction solar cells, particularly those based on *III–V* semiconductor materials; achieve high conversion efficiencies by employing multiple *P–N* junctions with different band gap energies to absorb distinct portions of the solar spectrum. Among them, the *InGaP/InGaAs/Ge* triple-junction photovoltaic cell stands out as a benchmark for efficiency. However, temperature variations strongly influence the electrical and thermal behavior of these subcells, often leading to performance degradation. In this work, we employ PyAMS to model and simulate the thermal response of InGaP/InGaAs/Ge solar subcells under varying temperature conditions. The developed model is validated against experimental data, ensuring accurate representation of the current–voltage (*I–V*) and power–voltage (*P–V*) characteristics. Key performance indicators—including short-circuit current density (Jsc), open-circuit voltage (*Voc*), fill factor (*FF*), and overall efficiency (η) are analyzed as functions of temperature. Our results demonstrate that while *Jsc* remains almost unaffected by temperature, *Voc* decreases significantly beyond 60°C under concentrated illumination (10 Suns). This drop in *Voc* strongly impacts both *FF* and *η*, highlighting the critical role of thermal management. The findings of this study provide useful guidelines for the design of cooling strategies in triple-junction solar cells, thereby improving their long-term performance, reliability, and integration into high-efficiency photovoltaic systems.

I. INTRODUCTION

III–V multi-junction solar cells are photovoltaic devices composed of multiple P–N junctions fabricated from different semiconductor materials with distinct band gap energies. Each junction absorbs and converts a specific portion of the solar spectrum into electrical energy, thereby enabling high conversion efficiency [1], [2]. The triple-junction photovoltaic (*TJ*) cell, consisting of Indium Gallium Phosphide (*InGaP*, top cell), Indium Gallium Arsenide (*InGaAs*, middle cell), and Germanium (*Ge*, bottom cell), is widely recognized as one of the most efficient architectures. However, like all electronic devices, the performance of these subcells is strongly influenced by temperature variations. Understanding their thermal behavior is thus crucial for optimizing performance and ensuring long-term reliability [3-6].

Realistic modeling of photovoltaic (*PV*) devices and accurate extraction of equivalent circuit parameters are of great importance for both design and operation, as they provide the foundation for future optimization strategies [7-14]. Thermal modeling, in particular, facilitates the development of efficient cooling systems for solar panels, helping to maintain high efficiency under concentrated illumination [15-18]. Among available simulation tools, PyAMS (Python for Analog and Mixed Signals) [19-22] has emerged as a powerful framework for studying the behavior of solar cells once their analytical equivalent circuits are established. PyAMS allows accurate representation of multi-junction devices while incorporating temperature dependence, making it possible to analyze critical performance parameters such as short-circuit current density (J_{sc}), open-circuit voltage (V_{oc}), fill factor (*FF*), and overall efficiency (η) [9].

This study focuses on investigating the performance of InGaP/InGaAs/Ge subcells under varying temperature conditions, with the objective of identifying the maximum allowable operating temperature that ensures optimal performance without degradation. To achieve this, the PyAMS software [22] is employed to develop a detailed model, which is then validated against experimental data. Subsequently, we analyze J_{sc}, V_{oc}, FF, and η as functions of temperature to determine the cooling requirements for stable operation.

The main contributions of this work can be summarized as follows:

1. Development of a PyAMS-based electrical and thermal model for InGaP/InGaAs/Ge triple-junction solar cells, incorporating temperature-dependent parameters such as saturation current, thermal voltage, and bandgap energy.
2. Validation against experimental data, confirming the accuracy of the model in reproducing *I–V* and *P–V* characteristics under different thermal and illumination conditions.
3. A comprehensive thermal performance analysis, showing that J_{sc} remains nearly stable with temperature, whereas V_{oc} decreases sharply above 60 °C under concentrated illumination.
4. Identification of the thermal operating limit of the Ge subcell (~60 °C at 10 Suns), which determines the overall system stability and directly affects fill factor and efficiency.
5. Providing practical design insights, offering guidelines for the integration of effective cooling strategies to enhance the long-term reliability of high-efficiency photovoltaic systems.

By addressing these aspects, this work advances beyond previous studies [3], [8], [9], [11], [13] by providing a validated PyAMS-based framework that simultaneously captures electrical and thermal behavior, while explicitly identifying practical cooling requirements for InGaP/InGaAs/Ge triple-junction solar cells.

II. SOLAR CELL MODELING

Modeling is a crucial step in understanding the electrical and thermal behavior of photovoltaic (*PV*) devices. In this section, we first discuss the equivalent circuit representation of a single-junction solar cell, which serves as the foundation for many studies in the literature. Then, we extend this representation into the PyAMS environment, highlighting its advantages in incorporating temperature-dependent relations and preparing the ground for triple-junction modeling [9], [23].

II.1 CLASSICAL EQUIVALENT CIRCUIT

As shown in Figure 1(a), the conventional single-diode equivalent circuit has been widely employed in the literature [9],[23],[24]. It consists of:

- A photocurrent source (I_{ph}), representing the current generated by photon absorption,
- A diode (*D*), describing the nonlinear behavior of the P–N junction according to the Shockley equation,
- A shunt resistance (R_{sh}), modeling leakage and parasitic currents across the junction, and
- A series resistance (R_s), accounting for ohmic losses in the semiconductor and electrical contacts.

This representation has proven effective in reproducing the current–voltage (*I–V*) behavior of solar cells. However, its classical formulation does not easily allow the integration of temperature-dependent effects, which are crucial for accurately modeling InGaP, InGaAs, and Ge subcells.

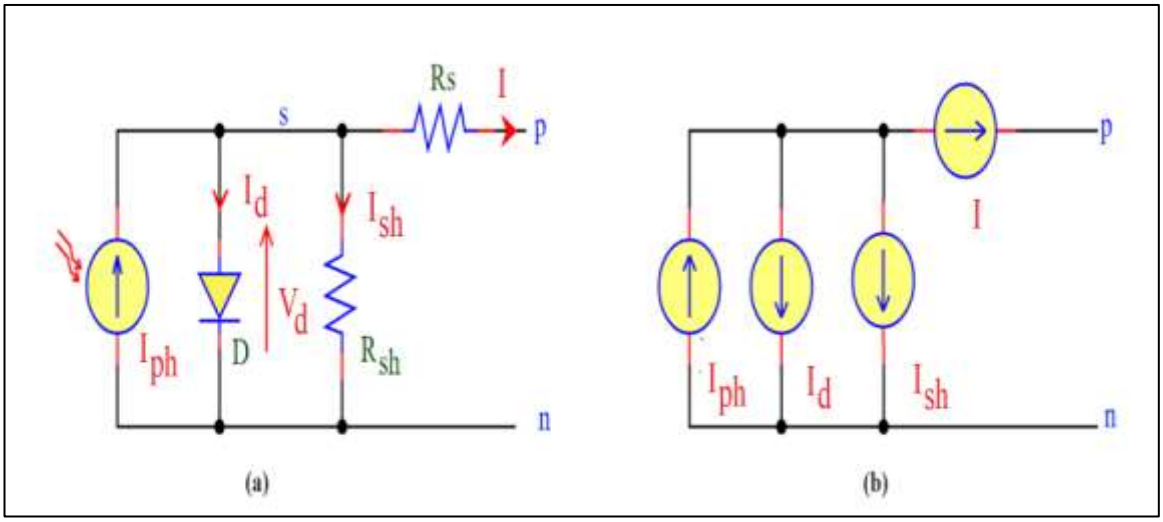

Figure 1: Equivalent electrical circuit of the solar cellM: (a) using discrete electronic components (b) using an independent current source as a function of voltage and parameters.
Source: Authors, (2026).

The photocurrent (I_{ph}) of the PV cell (Figure 1) depends on both the incident radiation and the temperature, as described by equation (1) [5], [23], [25], [26].

$$I_{ph} = [I_{sc} + K_i\,(T - 298)]\frac{Sun}{1000} \quad (1)$$

Where Isc represents the short-circuit current, K_i is a coefficient (*0.0017A/°C*), *T* denotes the temperature, and Sun stands for solar irradiance (W/m^2). The Id in Figure 1 is the current flowing through the diode D. The current is expressed by the following equation:

$$I_d = I_s\left(\exp\left(\frac{V_d}{V_t}\right) - 1\right) \tag{2}$$

For I_s [24], [27], [28], [29]:

$$I_s(T) = I_{so}\left(\frac{T}{300}\right)^3 exp\left(\left(\frac{T}{300} - 1\right)\frac{E_g}{V_t}\right) \tag{3}$$

The saturation current in the diodes of types InGaP, InGaAs, and Ge is expressed by the following formula [9], [23], [30]:

$$I_s(T) = I_{so}\left(\frac{T}{300}\right)^{\frac{3+\gamma}{2}} exp\left(\left(\frac{T}{300} - 1\right)\frac{E_g}{V_t}\right) \tag{4}$$

For V_t:

$$V_t = n\,\frac{KT}{q}. \tag{5}$$

In equations (2), (3), and (4), V_d represents the voltage applied across the diode, I_s is the reverse saturation current of the diode, q is the charge of an electron, V_t is the thermal voltage, K is Boltzmann's constant, T is the junction temperature, n is the ideality factor of the diode, I_{so} is the initial reverse saturation current of the diode, γ is a constant and E_g is the band gap energy of the semiconductor. The relationship between band gap energy and temperature is described by equation (6) below [8], [9], [10], [31]:

$$E_g(T) = E_g(0) - \frac{\alpha\, T^2}{T+\beta} \tag{6}$$

where α and β are a constant. The current in the resistor R_s or R_{sh} (Figure 1) is expressed by ohm's law:

$$I_{sh} = \frac{V_d}{R_{sh}} \tag{7}$$

and:

$$I = \frac{V_s}{R_s} \tag{8}$$

For V_s is the voltage applied across the resistor R_s. The open circuit voltage, V_{OC}, is the maximum voltage available from a solar cell, and this occurs at zero current. An equation for V_{OC} is found by setting the net current equal to zero in the solar cell equation to give [3]:

$$V_{oc} = \frac{nKT}{q}\ln\left(\frac{I_{sc}}{I_s} + 1\right) \tag{9}$$

II.2 PYAMS-BASED CURRENT-SOURCE MODEL

To overcome these limitations, we reformulate the equivalent circuit into a PyAMS-based current-source model, illustrated in Figure. 1(b). In this representation, each element of the solar cell is implemented as an independent current source defined as a function of voltage and physical parameters. This novel reformulation enables seamless integration of temperature-dependent relations into the model equations. The implementation in PyAMS is shown in Figure 2, where:

- The photocurrent (I_{ph}) is calculated as a function of irradiance, short-circuit current (I_{sc}), and temperature,
- The diode current (I_d) follows the Shockley relation with a temperature-dependent reverse saturation current $I_s(T)$,
- The shunt current (I_{sh}) is derived from the voltage across R_{sh}, and
- The series resistance contribution is expressed as an additional current component (I).

These currents are combined according to Kirchhoff's Current Law (*KCL*) within the `analog(self)` function in PyAMS. Temperature-dependent parameters such as the thermal voltage (V_t), the bandgap energy $E_g(T)$ (Varshni equation), and the reverse saturation current $I_s(T)$ are precomputed in the `start(self)` function before the simulation. Figure 3 presents the symbolic representation (symbol) of the single-junction solar cell in PyAMS. This symbol provides a reusable and modular block that can be directly inserted into larger circuit simulations, such as those involving triple-junction configurations.

II.3 CONTRIBUTION OF THE PYAMS REPRESENTATION

While Figure 1(a) reflects the standard baseline model used in most prior works, Figures 1(b), 2, and 3 illustrate the novelty of this study. By translating the conventional circuit into a PyAMS current-source framework, we enable:

- Direct integration of thermal effects, including $I_s(T)$ and $E_g(T)$,
- Modularity, as each current component is explicitly modeled and can be modified or extended, and
- Flexibility for multi-junction extension, since the single-junction block can be replicated and connected in series to form the InGaP/InGaAs/Ge triple-junction solar cell.

This approach bridges the gap between purely mathematical models and practical circuit-level simulations, offering a more accurate and flexible framework for analyzing both the electrical and thermal behaviors of high-efficiency photovoltaic devices.

II.4 MODELING OF TRIPL- JUNCTION SOLAR CELL

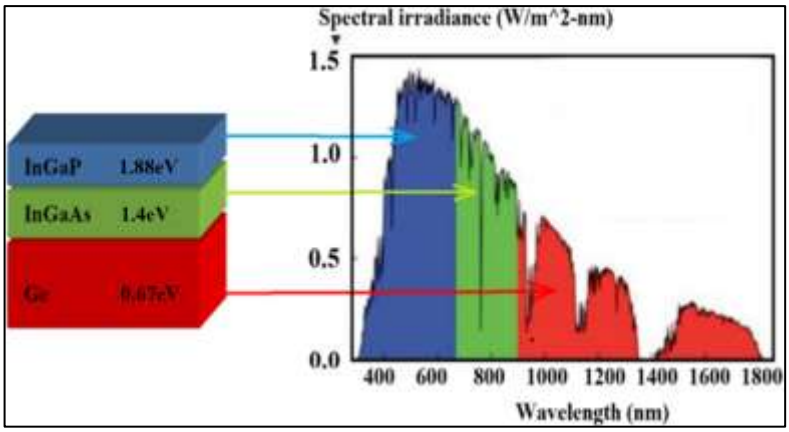
Building upon the single-junction framework, the structure of a triple-junction solar cell (TJSC) is illustrated in Figure 5(a). It consists of three subcells stacked in series:

- The top cell (InGaP) with a bandgap of approximately 1.9 eV,
- The middle cell (InGaAs) with a bandgap of 1.4 eV, and
- The bottom cell (Ge) with a bandgap of 0.6 eV [32-35].

This configuration is carefully designed so that each subcell absorbs a specific portion of the solar spectrum (Figure 4, right). The high bandgap top and middle subcells absorb shorter wavelengths, while the low bandgap Ge bottom cell absorbs longer wavelengths. This spectral division allows triple-junction devices to achieve significantly higher conversion efficiencies compared to single-junction solar cells [9]. The electrical model of the InGaP/InGaAs/Ge TJSC can be derived by connecting three single-junction submodels in series, each represented by its PyAMS-based equivalent circuit. This is shown in Figure 5(a), where the triple-junction equivalent circuit is constructed from three diode-based subcells. In the PyAMS implementation (Figure 5(b)), each subcell is replaced by its corresponding PyAMS model (developed in Section II.2). The series connection ensures that the same current flows through all three subcells, while the output voltage of the TJSC is the sum of the voltages of the individual cells. However, the lowest-performing subcell (typically the Ge bottom cell) determines the overall current, making it the limiting factor in device efficiency. By adopting this PyAMS-based modular approach, the TJSC model:

1. Accurately captures the spectral and electrical characteristics of each subcell,
2. Allows for the integration of temperature-dependent effects ($I_s(T)$, $E_g(T)$) for all three junctions, and
3. Provides a scalable framework that can be extended to simulate more advanced multi-junction architectures.

Thus, the novelty of our work lies in transforming the traditional equivalent circuit representation into a flexible PyAMS model, where each junction is explicitly defined and thermally coupled, enabling detailed analysis of the electrical–thermal behavior of the InGaP/InGaAs/Ge triple-junction solar cell.



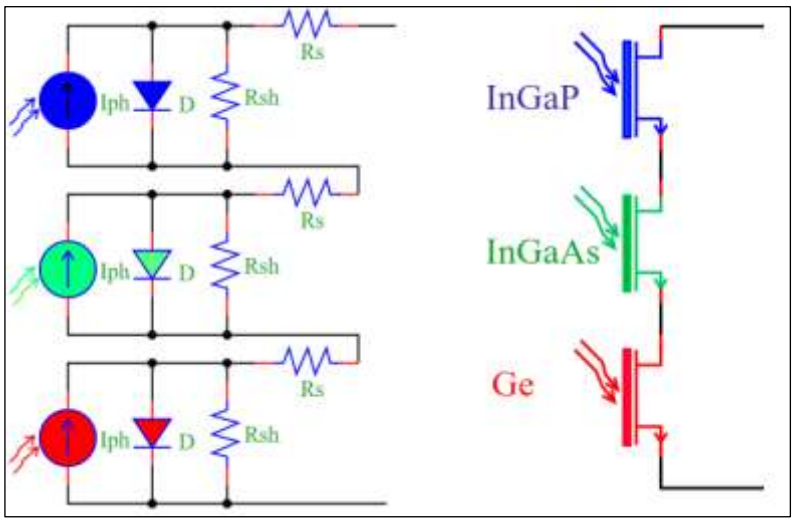


Figure 4: Triple junction solar cell: (a) Structure of a triple junction cell InGaP/InGaAs/Ge (b) The solar radiation spectrum versus wavelength and its useful spectrum portion.
Source: Authors, (2026).

This combination of materials was chosen because the P-N junction of each material would convert certain wavelengths of sunlight into electrical energy (Figure 5.b). Multi-junction solar cells with different band gap energies have high conversion efficiency [9]. The electrical modelling of the InGaP/InGaAs/Ge triple-junction photovoltaic cell can be implemented by the circuit shown in Figure 5(a) structure of circuit by triple circuit it presented in ref [8-11], where each sub-cell is represented by an independent single photovoltaic cell, in a way that gives the three cells the ability to be connected in series with decreasing gaps from top to bottom Figure 5(a) below shows the model for a triple junction solar cell, the PyAMS model of the triple-junction solar cell is developed based on this equivalent circuit, by replacing cell by equivalent Figure 5(b).

III. SIMULATION RESULTS AND DISCUSSION

To validate the proposed PyAMS-based model, simulations were performed for the InGaP/InGaAs/Ge triple-junction solar cell and compared with published experimental data. The equivalent circuit of the three-junction device (Figure 5(b)) was implemented in PyAMS using the parameter values listed in Table 1, which were extracted under standard test conditions (air temperature of 27 °C and irradiance of 1000 W/m²).

Table 1: The parameters of the three junctions.

Parameter	Junction (InGaP)	Junction (InGaAs)	Junction (Ge)
Short circuit current I_{SC}	18mA	15.5mA	34mA
Bandgap energy E_g	1.89eV	1.40eV	0.683eV
Series resistance R_s	0.2190Ω	0.0219Ω	0.0219Ω
Shunt resistance R_{sh}	600kΩ	600kΩ	600kΩ

III.1 MODEL VALIDATION AGAINST EXPERIMENTAL DATA

The simulated current–voltage (I–V) and power–voltage (P–V) curves of the individual subcells (InGaP, InGaAs, Ge) and the full TJSC are shown in Figure 6. A close agreement is observed between simulated and experimental characteristics [32], confirming the accuracy of the PyAMS model. Quantitative performance metrics are summarized in Table 2, where the deviation between simulation and experiment is negligible (<1%). For example, the simulated short-circuit current density (Jsc) of the InGaP subcell (17.99 mA/cm²) is nearly identical to the experimental value (18.08 mA/cm²). Similar consistency is found for V_{oc}, *FF*, and η across all subcells and the complete *TJSC*.

Table 2: Performance parameters of simulated multijunction cell compared with experimental.

Junction	Result	Jsc(mA/cm²)	Voc(V)	Pmax(mW)	FF(%)	η (%)
InGaP	Simulation	17.99	1.50	23.18	85.37	23.18
	Experimental	18.08	1.49	22.9	84.90	23.00
InGaAs	Simulation	15.50	0.89	11.19	80.66	11.19
	Experimental	15.63	0.88	11.14	80.50	11.14
Ge	Simulation	33.99	0.24	4.59	54.31	4.59
	Experimental	34.23	0.25	4.57	54.17	4.57
TJSC	Simulation	15.76	2.60	34.50	84.15	34.90
	Experimental	15.79	2.58	34.33	84.06	34.33

Source: Authors, (2026).

This validation demonstrates that the PyAMS-based approach is capable of reproducing the performance of III–V multi-junction devices with high accuracy, comparable to experimental measurements.

III.2 TEMPERATURE-DEPENDENT ANALYSIS

To determine the maximum temperature tolerance of the sub-cells and the operating temperature efficiency of the triple-junction solar cell, we conducted simulations across a temperature range of 0°C to 80°C under concentrated illumination of 1000 Suns. The performance of each subcell analyzed as a function of temperature using PyAMS. The temperature limit deduced by observing the point at which the open circuit voltage dropped to almost zero.

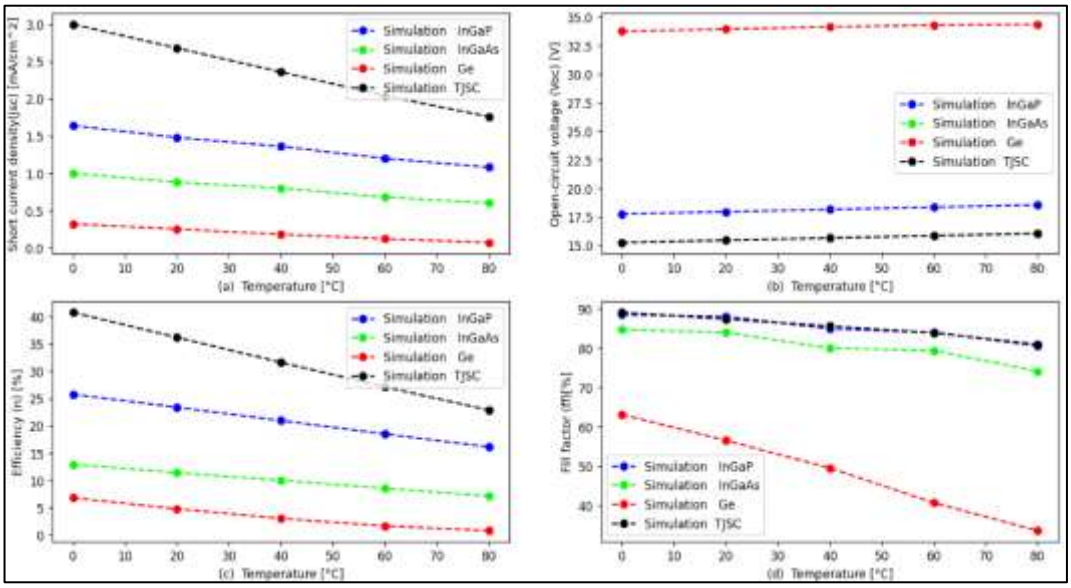

Figure 7: Effect of temperature on open-circuit voltage (a), current density (b), efficiency (c), and fill factor (d) for InGaP, InGaAs, Ge, and TJSC.
Source: Authors, (2026).

Figure 7(a) illustrates the short-circuit current density as a function of temperature of the three sub-cells and tandem cell. Interestingly, we observe no significant effect of temperature on the short-circuit current. In Figure 7(b), the open-circuit voltage plotted against temperature for the three sub-cells and the tandem cell. It is evident that the open-circuit voltage decreases significantly with increasing temperature. This decrease reflected in the slope, which diminishes across all concentration levels. Notably, for the Ge subcell, the open-circuit voltage approaches zero, resulting in a collapse of the current-voltage (*I-V*) curves for temperatures exceeding 60°C, whereas the upper and middle sub-cells can withstand temperatures exceeding 60°C. This decrease in open-circuit voltage significantly affects the fill factor and overall efficiency of the solar cell, as depicted in Fig. 7(c) and Figure 7(d). Consequently, the temperature tolerance range for this cell is limited to 0°C to 80°C. Figure 8 demonstrates this for the Ge subcell when exposed to various levels of solar radiation, showing that the open-circuit voltage completely disappears at a temperature of 60°C under concentrated illumination of 10 Suns.

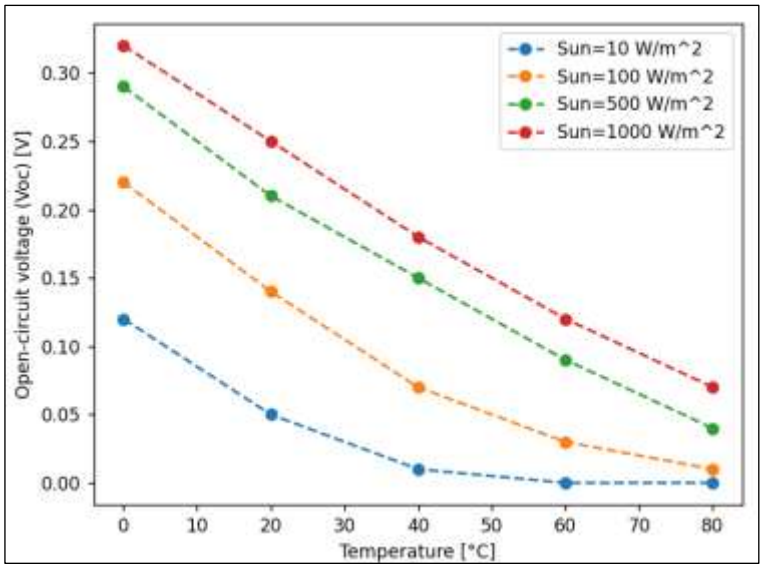

Figure 8: Effect of temperature and concentrated sunlight on open circuit voltage V_{oc} for bottom subcell.
Source: Authors, (2026).

After creating the InGaP/InGaAs/Ge equivalent model and comparing the experimental results in [32] with the same method of calculating the effect of temperature in [13], we obtained the same characteristics. Finally, we can conclude that the temperature limit is 60°C when exposed to concentrated illumination of 10 Suns, necessitating a cooling system to prevent the degradation of the InGaP/InGaAs/Ge MJSC.

III.3 DISCUSSION AND COMPARISON WITH PREVIOUS WORKS

The results highlight that while the upper InGaP and InGaAs subcells can tolerate elevated temperatures, the Ge subcell dictates the maximum operating limit of the TJSC. The identified threshold of ~60 °C under 10 Suns is consistent with experimental findings reported by Ota [9] and Djermane [13], but our model extends these works by providing a validated **PyAMS framework** that integrates both electrical and thermal effects. Unlike conventional SPICE-based or purely mathematical models, the PyAMS implementation offers two key advantages:

1. Explicit thermal coupling, by incorporating Is(T), Vt, and Eg(T) directly into the circuit-level model.
2. Modularity and scalability, enabling straightforward extension to multi-junction configurations while maintaining consistency with experimental behavior.

III.4 KEY FINDINGS

From this analysis, the following points can be emphasized:

- The PyAMS model reproduces experimental I–V and P–V data with high accuracy.
- Temperature has negligible influence on Jsc but a strong negative impact on Voc.
- The Ge bottom cell defines the thermal operating limit (~60 °C), beyond which FF and η rapidly degrade.
- Effective thermal management is essential to maintain stable performance of InGaP/InGaAs/Ge TJSCs under concentrated illumination.

IV. CONCLUSION

In this study, we developed and validated a PyAMS-based model for InGaP/InGaAs/Ge triple-junction solar cells. By reformulating the classical equivalent circuit into a modular current-source representation, the model successfully integrates temperature-dependent parameters such as saturation current, thermal voltage, and bandgap energy. Validation against experimental data confirmed that the PyAMS framework reproduces the *I–V* and *P–V* characteristics of individual subcells and the complete TJSC with high accuracy.Through systematic thermal analysis, we demonstrated that:

- The short-circuit current density (J_{sc}) remains nearly unaffected by temperature variations.
- The open-circuit voltage (V_{oc}) decreases significantly with increasing temperature, with the Ge subcell approaching zero Voc at ~60 °C.
- This drop in Voc strongly impacts the fill factor (*FF*) and overall efficiency (η), establishing the Ge subcell as the limiting factor in high-temperature operation.

These findings emphasize the critical role of thermal management in maintaining the stability and performance of multi-junction solar cells under concentrated illumination. The proposed PyAMS modeling framework not only provides accurate reproduction of experimental behavior but also offers a scalable and flexible tool for extending the analysis to advanced photovoltaic architectures. Future work will focus on integrating spectral effects, dynamic cooling strategies, and exploring the application of the PyAMS framework to other multi-junction material systems, thereby enhancing its potential as a versatile platform for photovoltaic device design and optimization.

ABSTRACT

This research investigates the effectiveness of various machine learning models for classifying multimodal heart signals, specifically using electrocardiogram (ECG) and phonocardiogram (PCG) data from the EPHNOGRAM and PhysioNet Cardiology 2016 datasets. The proposed architecture, particularly the hybrid (LSTM, BiLSTM) model, achieved an impressive accuracy of 92.3% on the PhysioNet dataset, surpassing existing techniques and demonstrating significant potential for clinical applications. This study evaluates several architectures, including CNN, RNN, CNN and hybrid(RNN, LSTM), BiLSTM, and hybrid(LSTM, BiLSTM). By leveraging the EPHNOGRAM dataset, which contains synchronised ECG and PCG signals, the model aims to enhance classification accuracy for various heart conditions, including normal heartbeats, arrhythmias, murmurs, and other cardiovascular diseases (CVDs). Experimental results indicate that the proposed model outperforms traditional deep learning methods, achieving superior classification accuracy. These findings underscore the promise of multimodal deep learning models in healthcare diagnostics, particularly in detecting cardiac diseases. Future research will focus on optimising hyperparameters, utilising larger datasets, and integrating additional modalities, such as cardiac imaging and demographic data, to improve cardiovascular disease classification further.

I. INTRODUCTION

Heart disease remains one of the leading causes of mortality worldwide, emphasising the importance of early detection to improve outcomes. Traditional diagnostic methods typically rely on either electrocardiogram (ECG) or phonocardiogram (PCG) signals, both of which provide vital insights into heart health. However, using only one modality limits the scope of diagnosis. ECG captures electrical activity and is effective for detecting arrhythmias, while PCG focuses on heart sounds, aiding in the diagnosis of murmurs and valve issues. Relying solely on one of these approaches can overlook complementary information[1]. Recent advances in machine learning, particularly deep learning, have opened new opportunities for analysing complex medical data, such as heart signals[2].Single-modality approaches often fail to provide a comprehensive diagnostic perspective. As highlighted by[3], multimodal methods that combine ECG and PCG signals significantly enhance diagnostic accuracy by leveraging their complementary strengths. This multimodal approach not only provides richer data but also helps reduce false positives by cross-validating information from different sources. Challenges in Multimodal Analysis Despite their benefits, the simultaneous processing of ECG and PCG signals presents challenges. Traditional machine learning models struggle to fully exploit the complex nature of multimodal data, as they require simultaneous extraction of spatial features from ECG and temporal features from PCG. Synchronisation and alignment issues between the signals further complicate this process. Standard algorithms relying on manual feature extraction are often insufficient for capturing the intricate relationships within multimodal data[4]. To address these limitations, this study proposes a hybrid deep learning model to advance heart disease diagnostics.

The model combines Convolutional Neural Networks (CNNs) to extract spatial features from ECG signals with Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM), to capture temporal sequences from PCG signals. Research by[5], demonstrates that hybrid CNN-RNN models outperform traditional approaches in multimodal contexts. By applying this strategy to ECG and PCG data, the proposed model aims to deliver more accurate and reliable diagnoses, addressing the shortcomings of single-modality systems. Research Objectives The primary goal of this research is to evaluate the effectiveness of various machine learning models in classifying multimodal heart signals, specifically focusing on ECG and PCG data. The study seeks to enhance classification accuracy for a range of heart conditions, including normal heartbeats, arrhythmias, murmurs, and other cardiovascular diseases (CVDs), using advanced deep learning architectures.

The main contributions include:

- Proposed a deep learning framework that integrates multiple architectures (CNN, RNN, LSTM, BiLSTM, and hybrid(LSTM, BiLSTM)) to classify multimodal heart signals.
- Demonstrated the effectiveness of synchronised ECG and PCG signals in enhancing classification precision.
- Improved classification capabilities for a wide range of heart conditions.
- Highlighted potential areas for future research, including optimising hyperparameters, leveraging larger datasets, and incorporating additional modalities like cardiac imaging and demographic information.

The structure of this paper is organised as follows: Section 2 presents the related work. Section 3 outlines the methodologies and techniques employed. Section 4 presents the results and discusses, and finally, Section 5 summarises the conclusions drawn from the research.

II. RELATED WORK

Deep learning has transformed cardiac diagnostics using ECG and PCG signals, improving the prediction of heart conditions. CNNs capture spatial patterns, RNNs handle temporal dynamics, and hybrid models show strong potential. Multimodal approaches combining ECG and PCG enhance accuracy, though challenges like data synchronisation persist. Cheng, et al[6]. Analysed both electrocardiogram (ECG) and phonocardiogram (PCG) signals. Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), including Long Short-Term Memory (LSTM) and Bidirectional LSTM (BiLSTM), were widely used for cardiac diagnostics. CNNs demonstrated strong performance in feature extraction from ECG data due to their ability to capture spatial dependencies, while RNNs proved effective in handling the temporal nature of both ECG and PCG signals. In one study, a deep CNN combined with BiLSTM achieved notable improvements in ECG classification, reporting up to 98.7% accuracy in arrhythmia detection. According to et al[7]. Focused on PCG analysis using deep learning, which was less explored at the time but had great potential. A multimodal framework integrating both ECG and PCG signals was proposed to enhance diagnostic accuracy, especially under noisy conditions. However, challenges such as data synchronisation and feature alignment between ECG and PCG modalities persisted.

IDS Aabdalla, et al[8]. Explored ECG classification as a key approach for diagnosing heart disease, with a growing focus on prediction using machine learning techniques. The study aimed to improve cardiovascular disease classification accuracy by applying machine learning models to data from the PhysioNet database. They developed multi-class classification models to distinguish between heart failure rhythm (HFR), normal heart rhythm (NHR), and arrhythmia (ARR) using 162 ECG signals. Techniques such as frequency-time domain analysis and wavelet scattering were used for feature extraction. Their SVM model achieved a training accuracy of 97.1% and a testing accuracy of 92%, offering an efficient, accurate tool for heart disease diagnosis and a useful foundation for future research. Qiu, Yue, et al[9]. Examined multimodal learning approaches that combined multiple data types such as ECG and PCG. This direction was promising for cardiac diagnostics, as it allowed models to leverage complementary information from various physiological signals. A multimodal deep learning system was developed to integrate ECG and PCG signals for early detection of cardiovascular diseases. Despite the advancements, issues like data alignment, signal noise, and computational complexity limited the practical application of these multimodal systems, particularly in real-time scenarios like wearable and home-based monitoring systems.

Rai, Hari Mohan[10]. Demonstrated that hybrid architectures combining CNNs with RNNs were highly successful in analysing time-series data like ECG and PCG signals. For instance, a hybrid CNN-LSTM model proposed for ECG-based arrhythmia detection achieved an accuracy of 99.5% in recognising five types of arrhythmias. Another hybrid model combining CNN with BiLSTM showed superior performance by capturing both spatial and temporal patterns in ECG data, improving generalisation, and reducing overfitting across datasets. Islam, Md Shofiqul, et al. [11].Introduced the HARDC model, which used a dilated CNN and a bidirectional recurrent neural network (BiGRU-BiLSTM) architecture. By incorporating local and global feature information, alongside an attention mechanism, the model achieved a classification accuracy of 99.60%, with high F1 scores, precision, and recall. This approach also demonstrated reduced computation time, making it an innovative and cost-effective strategy for ECG signal compression and recognition. Negin, et al[12]. Developed a lightweight deep learning approach for detecting eight different cardiac arrhythmias and normal rhythms, achieving a diagnostic accuracy of 98.24%.

They used resampling and baseline wander removal techniques to preprocess ECG signals. The model, combining CNN and LSTM layers, was applied to ECG data from PhysioNet databases, demonstrating higher accuracy compared to previous methods. Rajakumar[13]. Proposed a novel approach for predicting fetal arrhythmias from cardiotocographic (CTG) signals using an Ensemble Feature Extraction (EFE) model. This model tackled the variability in CTG signals through sophisticated feature extraction methods and classification using the XGBoost algorithm. The model achieved an accuracy of 96.34%, precision of 96.7%, and recall of 97.3%, providing valuable insights into improving signal classification accuracy. Baharoon[14]. Enhanced multimodal deep learning systems by combining fundus images with demographic data (age and gender). Their model, HyMNet, outperformed other multimodal frameworks, achieving an AUC of 0.791 for heart disease prediction by fusing features from multiple sources, showcasing the potential of combining imaging with other data types in cardiac diagnostics.

Zeeshan, et al[15]. Presented two multimodal fusion frameworks, MIF and MFF, for ECG heartbeat classification by converting ECG signals into images and using deep learning techniques for feature extraction. These approaches significantly improved the detection of arrhythmias and myocardial infarctions, outperforming traditional methods by integrating diverse representations.
Suliman, I. D., & Vasumathi, D[2]. Highlighted the critical role of the heart in circulating blood throughout the body and addressed the global impact of cardiac disease (CD) as a leading cause of death. Detecting and predicting heart diseases remains challenging for healthcare professionals, given common but nonspecific symptoms such as rapid heartbeats, chest pain, and breathing difficulties. Early detection of CD can help individuals take preventive actions before the disease progresses. The study aimed to apply and compare various classification models, including K-Nearest Neighbours (KNN), Decision Trees (DT), Naive Bayes (NB), Logistic Regression (LR), and Random Forest (RF), using five cardiac disease datasets. The models were implemented in Anaconda Jupyter Notebook, utilising its robust libraries for greater accuracy.

After ten iterations, Logistic Regression (LR) achieved the highest accuracy of 96.67% on the Cleveland dataset, outperforming existing algorithms. Hemaxi, et al[16]. Explored deep learning models like Gated Recurrent Unit (GRU), LSTM, and CNN for cardiovascular disease classification using ECG data. Their research, using the PTB-XL dataset, found that 1D ECG representations were more effective in capturing temporal patterns essential for classification compared to 2D image-based approaches, particularly for GRU models, which exhibited superior sensitivity and specificity. Azemi[17]. Addressed the challenge of classifying heart sound recordings (PCGs) as normal, abnormal, or uncertain. The PhysioNet Challenge 2016 facilitated the development of algorithms for PCG classification, and top models used techniques like CNNs, AdaBoost, and SVMs, with sensitivity reaching 0.94 and specificity 0.78, providing valuable data for future research in heart sound classification. Zhou, F., & Fang[18]. Applied a fusion of image representations from ECG signals for arrhythmia classification, achieving an accuracy of 99.6%. Their method used recurrence plots (RP), Gramian angular fields (GAF), and Markov transition fields (MTF) to improve recognition accuracy, demonstrating the efficacy of image-based models in ECG classification.

Mohamed, et al[19]. Reviewed lightweight deep learning approaches, such as LSTMs and wavelet transforms, to enhance ECG signal classification efficiency. Their study proposed a simplified multimodal deep fusion model that reduced computational complexity while maintaining high accuracy (98.80%), particularly beneficial for small datasets. Shao, Zhe[20].Presented an Image Fusion Model (IFM) for ECG heartbeat classification. This model converted heartbeats into three distinct image types—GAF, RP, and MTF—merging them into a single modality. Using AlexNet for feature extraction, the model achieved high accuracy, precision, and recall, surpassing earlier approaches on the PhysioNet MIT-BIH and PTB datasets. While significant advancements have been achieved in deep learning-based cardiac diagnostics, especially concerning ECG data, there remains a critical need for further research in PCG analysis. Our studies have focused on various types of feature extraction, utilising different datasets and exploring diverse deep learning approaches.

III. METHODOLOGY

The proposed framework combines a CNN for spatial feature extraction and an RNN (specifically LSTM/BiLSTM) for capturing temporal dependencies from ECG and PCG signals. This hybrid model processes the data in two stages: first, it extracts key morphological patterns with CNN layers and then learning the sequential relationships between heartbeats through RNN layers. This integrated approach is designed to improve heart condition classification by leveraging both spatial and temporal features effectively.

Dataset

The PhysioNet/Computing in Cardiology 2016 dataset contains over 3,100 recordings of ECG and PCG signals, which help in classifying heartbeats as normal, abnormal, uncertain, or artefact. These recordings span various durations and provide synchronised data crucial for multimodal analysis in heart disease detection[21]. The EPHNOGRAM dataset includes synchronised ECG and PCG signals from over 200 patients, capturing both the electrical activity of the heart (ECG) and its mechanical functions (PCG). It features a multimodal approach, which enhances classification performance for various cardiovascular conditions like arrhythmias and murmurs. The dataset is significant for its high sampling rate (typically 1,000 Hz) and the complementary nature of the data, making it highly valuable for detecting intricate heart conditions that may be missed using a single modality[21].

Preprocessing

Data Balancing

Both the PhysioNet Challenge 2016 and EPHNOGRAM datasets exhibit class imbalance, with conditions like normal rhythms being more common than arrhythmias. This imbalance can lead to biased model predictions. To address this, oversampling techniques like SMOTE were used to enhance minority class representation, while undersampling was applied to reduce the size of the majority class. Data augmentation, including time-shifting, noise addition, and random cropping, was employed to increase the diversity of ECG and PCG signals while maintaining their physiological characteristics.

Signal Normalization

ECG and PCG signals from both datasets were collected from various devices, resulting in differences in amplitude and baseline drift. To standardise these signals, Min-Max normalisation scaled them to a [0, 1] range, while Z-score normalisation stabilised their distribution by adjusting for mean and standard deviation variations.

Noise Reduction

Noise in ECG and PCG signals, often due to muscle activity or stethoscope artefacts, was minimised using bandpass filtering. For ECG signals, frequencies between 0.5 Hz and 50 Hz were retained, while for PCG signals, a range of 20 Hz to 200 Hz was applied to preserve critical heart sound information and reduce unwanted noise.

Model Architecture

CNN for Feature Extraction:

CNNs are employed to extract spatial features from both ECG and PCG signals. The architecture consists of convolutional layers followed by ReLU activation and max-pooling layers, which downsample the data while preserving key features. This process reduces the input dimensionality and helps identify patterns in heart signals crucial for classification.

RNN for Temporal Learning:

After CNNs extract spatial features, RNNs, particularly Long Short-Term Memory (LSTM) or Bidirectional LSTM (BiLSTM), are used to capture the temporal relationships in the heart signals. These models are essential for processing sequential data like heartbeats, where dependencies between past and future information significantly influence the classification of heart conditions.

CNN+RNN Hybrid Model:

The hybrid CNN+RNN model leverages the spatial feature extraction capabilities of CNN and the temporal learning strength of RNN. This architecture efficiently captures both spatial patterns in the heart signals and the sequential dependencies over time, making it highly effective for analysing ECG and PCG data.

III.3 LSTM AND BILSTM MODELS:

LSTM captures long-term dependencies in ECG and PCG data by retaining key information from previous heartbeats, improving signal pattern analysis. BiLSTM extends this by processing data in both forward and backward directions, offering a deeper understanding of temporal dynamics. The LSTM+BiLSTM hybrid model combines both strengths, excelling at identifying complex patterns in ECG and PCG signals.

III.4 TRAINING AND EVALUATION

The training of the model was conducted using a cross-entropy loss function, which is commonly used for classification tasks. This loss function measures the performance of the classification model by comparing the predicted probability distribution to the actual class labels, penalising incorrect predictions.

Optimizer: The Adam optimiser was employed for training. Adam (Adaptive Moment Estimation) is popular because it combines the benefits of both the AdaGrad and RMSProp optimisers, using adaptive learning rates for each parameter to speed up convergence while maintaining stability.
Learning Rate: A fixed learning rate of 0.001 was used throughout training. This learning rate was chosen as a balance between training speed and model performance, allowing the model to converge without overshooting the optimal point.
The model parameters were updated iteratively based on the gradients calculated from the loss function, and training was conducted for multiple epochs to ensure that the model learned both spatial and temporal features effectively.
Evaluation Metrics:
The model's performance was evaluated using metrics, including:
Accuracy: The percentage of correctly predicted labels out of the total number of predictions. This metric indicates how well the model performs, but it may be less effective when classes are imbalanced.
Precision: The proportion of true positive predictions (correctly predicted positive class) out of all predicted positives. Precision is crucial for determining how well the model identifies true positives without mistakenly labeling negatives as positives.
Recall: The proportion of true positives out of the actual positives. It measures the model's ability to identify all relevant instances of the positive class.
F1-Score: The harmonic mean of precision and recall, providing a single metric that balances both. The F1-score is useful when the dataset has an imbalance between classes, since it penalises extreme values of either precision or recall.

IV.RESULT AND DISCUSSION

In our evaluation of the heart disease classification models using the PhysioNet Cardiology 2016 and EPHNOGRAM datasets, the hybrid LSTM+BiLSTM model achieved the highest performance, with an accuracy of 92.3%, precision of 91.9%, recall of 91.5%, and an F1-score of 91.7%. This suggests that combining long short-term memory networks with bidirectional LSTMs effectively captures temporal dependencies in the data. For the PhysioNet dataset, models based on CNN outperformed RNNs, highlighting the importance of convolutional feature extraction. In contrast, the performance of models on the EPHNOGRAM dataset was slightly lower overall, with the RNN+CNN model achieving a notable accuracy of 90.1%.

Table 3: Comparison of Model Performance DATASET 1.

DATASET	Models	Accuracy	Precision	Recall	F1-score
ECG and PCG PhysioNet Cardiology 2016	CNN	85.2	84.1	83.8	83.9
	RNN	88.5	87.9	88.1	88
	CNN	89.7	89.1	88.9	89
	RNN+CNN	90.4	90	89.8	89.9
	LSTM	91.1	91	90.7	90.8
	BiLSTM	92.3	91.9	91.5	91.7
ECG and PCG EPHNOGRAM	LSTM+BiLSTM	85.4	84.9	86.7	85.3
	RNN	88.2	87.5	89.1	88.3
	CNN	90.1	89.4	90.5	89.9
	RNN+CNN	84.7	83.5	85.2	84.3
	LSTM	86.9	86.2	87.1	86.6
	BiLSTM	89.4	88.8	89.9	89.3

The table4 compares the performance of various models for classification tasks, highlighting accuracy, precision, recall, and F1-score. For instance, Diker et al.'s CNN achieved an accuracy of 83.82% with a precision of 82%, while Pengpai Li et al.'s LSTM+GA model excelled with an accuracy of 93.6%. Zeng et al.'s Bi-GRU model also performed well, achieving an F1 score of 93.27%. Our proposed LSTM+BiLSTM model achieved competitive results with an accuracy of 92.3%, a precision of 91.9%, and a recall of 91.5%. These results indicate its strength in handling time-series data, comparable to state-of-the-art methods like Zeng's Bi-GRU and Pengpai's LSTM+GA.

Table 4: Performance Comparison of Different Studies with Existing Work

Reference	Model	Accuracy	Precision	Recall	F1-score
A. Diker et al[1]	**CNN**	83.82	82	95	88.02
C. Pang et al[2]	**RF-RESNET**	87.2	88.8	79.5	83.9

V.CONCLUSION

This research has demonstrated the effectiveness of various machine learning models for classifying multimodal heart signals, specifically using ECG and PCG data from the EPHNOGRAM and PhysioNet Cardiology 2016 datasets. The proposed architecture, particularly the LSTM+BiLSTM model, achieved a notable accuracy of 92.3% on the PhysioNet dataset, surpassing existing techniques

and highlighting its potential for clinical use. Future research will optimise hyperparameters, leverage larger datasets, and incorporate modalities such as cardiac imaging and demographics for the classification of cardiovascular disease.

VI.ACKNOWLEDGMENT

We sincerely express our gratitude to the Department of Computer Science and Engineering, Jawaharlal Nehru Technological University Hyderabad (JNTUH), for providing the essential infrastructure, resources, and guidance that made this research possible.

ABSTRACT

Social media has become a prominent medium through which individuals express their perspectives, sentiments, and experiences, frequently exhibiting apparent indications of mental health conditions such as depression. The identification of depression through nonverbal behaviour has garnered considerable interest. Implementing previous research concerning the detection of depression within real-world scenarios presents challenges, primarily because the research predominantly concentrated on identifying depressive individuals within controlled laboratory settings. Depression affects millions worldwide therefore, early and accurate detection is critical for prompt intervention. Conventional diagnostic methodologies are often subjective in nature and require considerable time to implement. This study introduces a hybrid remora-optimized multimodal deep learning (HRO-MDL) approach to incorporate multi-modal data such as audio, video, and text for enhanced performance in the assessment of depressive emotional states and sentiments. The proposed framework accurately predicts sentiment across modalities by integrating feature extraction from various modalities using a deep convolutional neural network optimized with hybrid optimization. The model's performance was assessed using the D-Vlog and Depression Cleaned Reddit datasets, demonstrating notable accuracy levels 94.00% for text data, 92.00% for audio data, and 93.00% for video data. In contrast to traditional methodologies, the presented work exhibits enhanced efficiency and underscores its suitability for diverse multimodal sentiment analysis applications.

I. INTRODUCTION

The significant influence of mental health on both individual and societal well-being has resulted in increased focus on this issue among diverse populations. Mental health disorders, such as depression, are commonly occurring conditions that drastically impact millions of people worldwide. The disease results with constant pain, deep despair and considerably impaired functional capacity that leads to serious limitation in daily life [1]. Current method for diagnosing depression is primarily self-reported questionnaires, interviews, and clinical measurements. However, these approaches can be costly, time-consuming and subject to human perception bias [2]. To assess people's emotional states, clinicians are using modality data including text, audio and visual [3]. An accurate and real-time detection can be realized if the analysis is considering multiple depression data sources including text, voice, and visual to learn depression more explicitly [4]. The combination of multiple modalities in such systems is helpful in improving result of confidence, as it uses the strengths of different signals that reduces the chances of signal failure and misinterpretation. The approach maintains the continuous monitoring with increased precision with effect of early detection [5] and even in the analysis of large data such as text, audio and video data, there are various more advanced models (such as CNN's, RNN's and transformers) showing increased effectiveness. Medical professionals can leverage these models to identify signs of depression, which may present as subtle behaviours that includes inclination toward the condition. The methods for detecting depression support the advancement of deep learning technologies, enabling precise and

early identification of depressive symptoms [6]. Current state-of-the-art approaches, including CNNs, RNNs, and transformers, demonstrate robust performance in analysing multimodal data comprising text, audio, and video that involves substantial textual content. The model assists healthcare providers in identifying the symptoms of depression and detects subtle behavioural changes indicative of a tendency toward depressive patterns [7]. The primary challenge is to improve model efficiency while maintaining generalizability across diverse populations with varying linguistic and socioeconomic attributes [8].

This method offers a significant degree of accuracy independently however, the necessity for these models to be resilient and effective leads to overfitting due to insufficient real-world applicability [9]. This study explores a multi-modal deep learning approach incorporating hybrid remora- Integrated Grey Wolf Optimizationtechniques. This method is structured to preprocess various types of input data (text, audio, video) through multiple stages, including data preprocessing and subsequently proceeding to multimodal feature extraction. DenseNet-201 classification is utilized to predict emotional states of depression and sentiments, as it is well-suited for diverse input modalities. Additionally, this optimization technique is employed to refine the models and improve system performance. The hybrid optimization enhances system accuracy, rendering it robust for practical applications. Below is the major contribution of the proposed approach:

- To develop a multi-modal deep learning approach with hybrid remora optimization and to predict the emotional state of depression and sentiments across various modalities.
- The proposed model processes the sentiment of each modality (text, acoustic, visual) by modelling the verbal and non-verbal behaviour over the modalities.
- The Hybrid Remora-Integrated Grey Wolf Optimizationwith the DenseNet-201 approach is utilized to compare with current baseline models and achieve the best feature set with the highest accuracy.

II. LITERATURE REVIEW

Depression is one of the most prevalent and severe mental health disorders identified on social media. The development of an attention-based approach for detecting depression. This model emphasized the most important features of the input data and increased its interpretability. The observed overfitting was due to the model's increasing complexity [10]. Spatial attention networks are created to detect depression in facial images. The approach demonstrated significant efficacy and improved the detection parameters. The dataset for this model was significantly smaller and more complex [11]. Four hybrid deep learning models were created specifically to identify symptoms of melancholy. This method may function as an efficient instrument for detecting symptoms of depression on social media platforms, owing to its improved accuracy and relevance to real-world textual data. This method largely analysed textual data, overlooking potentially beneficial multimedia data such as images or video snippets, that could offer a more comprehensive understanding of depression [12], [13]. They devised an attention technique that amalgamated voice and text analysis to detect depression. This method derives contextual dependencies from both prior and later segments of the sequence by analysing data in both forward and reverse directions.

The bidirectional data processing incurred computational costs and led to an overfitting problem [14]. A fusion fuzzy model was used to identify depression from facial expressions. For visual data, this approach demonstrated strong feature extraction capabilities, but it becomes challenging when working with large datasets [15]. The deep learning model performed better at detecting depression in terms of accuracy rate and using data from Twitter. The model is susceptible to overfitting to the specific dataset, which could restrict its effectiveness when applied to newly obtained, unseen data [16]. A method for identifying depression and capturing local dependencies as well as sequential relationships within the text was introduced using deep learning. By capturing the semantic substance of sentences not explicitly present in the lexicon, this approach enhanced the model's ability to interpret subtle verbal indicators of depression. It required a substantial amount of computational power, especially when handling big datasets [17].

Experimental outcomes emphasize the advantages of integrating deep learning with multi-aspect data, indicating that it exceeds several established and robust baseline methods [18]. The Particle Swarm Optimization algorithm was developed for the diagnosis of depression. This approach enhances both precision and the rate of convergence. The accuracy of the model is significantly influenced by the quality and diversity of the dataset. Imbalanced datasets can negatively impact the model's performance, resulting in inaccurate melancholy detection, despite the attention given to recognizing melancholy in social media [19-21]. Their research has enhanced the model's interpretability and demonstrated the significance of features within the input data. Due to the increased complexity of the models, overfitting occurred. For the purpose of detecting depression in facial images, this study employed spatial attention networks [22], [23]. The primary benefits of this methodology were its enhanced performance characteristics and the improved pertinence of the generated features for detection purposes. The resultant model was both decreased in quantity and increased in complexity [24].

III. PROPOSED METHODOLOGY

This study focuses on the Hybrid RemoraOptimizedMultimodal Deep Learning (HRO-MDL) approach which is proposed to predict the emotional state of depression and sentiment detection. Depression detection through the integration of multi-modal data (video, audio, and text) utilizing different methods. It encompasses a variety of phases, including data preprocessing, parameter tuning, classification, and optimization, as illustrated in Figure 1.

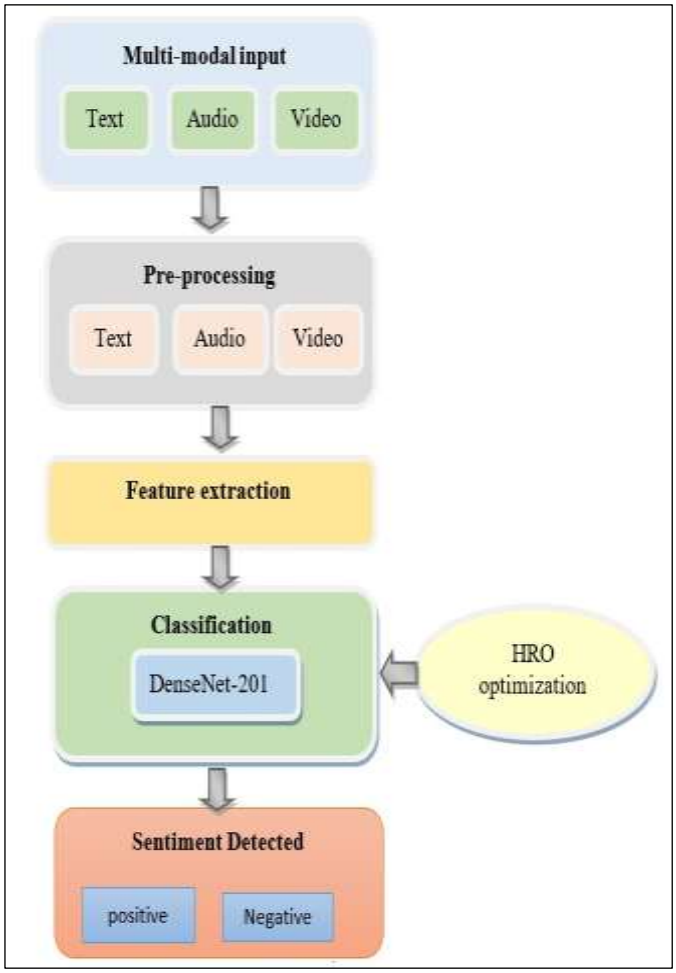

Figure 1: Proposed Multi-Modal Framework.
Source: Authors, (2026).

III.1 DATA COLLECTION

The input source audio and video data are collected from the D-Vlog dataset. The textual dataset is taken from Cleaned Reddit dataset. The audio features that supply important cues to diagnose depression, such as facial expressions, speech patterns, and emotional response signals, are also taken from the D-Vlog dataset, which also includes video logs of human life experiences. It consists of depression-related linguistic patterns as well as sentiment indicators and psychological markers for depression assessment. The mathematical representation of multi-modal input is represented as follows.

The D-Vlog dataset is the source of the input audio and video data. Cleaned Reddit depression dataset used for textual data. Also extracted D-Vlog datasetincludes video records of human life experiences, audio elements that provide crucial clues to diagnose depression, such as speech patterns, facial expressions, and emotional response signals. It includes sentiment indicators, psychological markers for depression assessment, and linguistic patterns associated with depression. Multi-modal input can be represented mathematically as follows:

$$Y = \{Y_T, Y_A, Y_V\} \tag{1}$$

Whereas, audio and video data from the D-Vlog dataset is represented byY_A,Y_V, and text data denoted as Y_T from the Reddit Cleaned depression dataset.

III.2 PRE PROCESSING

Preprocessing of audio, video, and textual data is utilized to extract multimodal features for sentiment prediction and depression detection. Speech is pre emphasized, framed, and converted to the Mel Frequency Cepstral Coefficients (MFCC), which are used to measure speechand ambient clues. Videos are converted into frames, resized, normalized, and spatially featured positions captured by the CNNs and temporally motion patterns learned by optical flow. Text data preprocessing, involving tokenization, lemmatization, stop word removal, and embedding generation, is conducted to preserve the semantics and context of the text data for analysis. Let the text input be expressed in Equation 2.

$$Y_T = \{m_1, m_2, \ldots . m_n\} \tag{2}$$

Where, mi represents the individual sentence

III.3 FEATURE EXTRACTION

The Audio, visual, and text are all used to extract multimodal features to model sentiment detection using the Dvlog dataset and Reddit dataset. Then texts are pre-processed through tokenization and cleaning and are transformed into contextual embeddings based on XLNet, which can obtain deep semantics and syntax relations. Also, the audio streams are pre emphasized, framed, and converted to Mel Frequency Cepstral Coefficients (MFCC) suitable for time sequence modelling with XLNet on temporal acoustic patterns. Videos are split into frames and resized, and then normalize, spatial features are extracted with CNNs (e.g., DenseNet), and temporal dependencies models such as XLNet transformers with optical flow for motion dynamics. Given a sequence of input tokens $\boldsymbol{y} = [\boldsymbol{y_1}, \boldsymbol{y_2}, \ldots \boldsymbol{y_T}]$, XLNet models the joint probability of a given input sequence of tokens as per Equation 3.

$$P(y) = \prod_{t=1}^{T} P(y_t | y_{<t}) \tag{3}$$

The set of tokens that have been proceeding in the permutation is depicted. XLNet's ability to analyse all sequence permutations, which makes each token accessible to all other tokens, can be interpreted to serve as an alternative to the traditional prediction approach systems, where tokens are only conditioned on a fixed left-to-right context through an autoregressive model. As a result, it achieves bidirectional dependency understanding. The anticipated log likelihood is optimized by the model for each possible sequence of manufacturing order permutations as per Equation 4

$$\hat{\theta} = arg\, \max_{\theta} E_{Z\sim\Im}\left[\sum_{t=1}^{T} log\, P\left(y_{Z(t)} | y_{z(<t)}\right)\right] \tag{4}$$

III.4. CLASSIFICATION

Once that features are gathered, they are used as input to the DenseNet-201 deep learning model for classification, which includes efficient dense connections elements that includes feature reuse but also improves gradient flow. The applicability of the model parameters is enhanced through Hybrid Remora-Integrated Grey Wolf Optimization with the faster converging speed, and the highest classification accuracy. The collaboration of extraction methods and optimized classification techniques leads to solid outcomes in both depression evaluations and sentiment analysis processes. Each layer of Dense Net- 201 is based on the dense block concept, Ds receive the output of all preceding layers 〖D〗_1,D_2,....D_(s-1). The output of the s-th layer in a dense block can be represented as follows for a particular input feature map as per Equation 5.

$$Y_s = H_s([Y_0, Y_1, \ldots Y_{s-1}]) \tag{5}$$

Where, the output of the s-th layer is indicated by Y_s, while the function is shown by $H_s$applied at layer s,$[Y_0, Y_1, \ldots Y_{s-1}]$ representing the concatenation of all previous layer output. DenseNet-201 runs several dense blocks, transition layers, and a fully linked layer for classification to provide its final output. The SoftMax function is used to generate the output probability vector at the end of the classification process represented in Equation 6.

$$P(x|Y) = soft\, max(WY_T + b) \tag{6}$$

Where Y_T denotes the final feature map after being passed through all layers, W and b are weights and bias of the fully connected layer,$P(x|Y)$ denotes the probability distribution over classes after the softmax activation. The usage of a SoftMax function for classification and DenseNet-201's dense connection are reflected in the above formulation.

III.5 HYBRID REMORA OPTIMIZATION ALGORITHM

It is a kind of population based metaheuristic optimization algorithm that imitates hierarchical hunting strategy of Grey Wolf Optimization (GWO) for group hunting and embodies the symbiotic follow-and-adapt behaviour of remora fish in oceanic ecosystems. Within this hybrid framework, the leadership hierarchy of Grey Wolf serves as the primary search approach, steering global exploration of solution space. The follow-and-adapt mechanism as a biologically inspired approach underlies remora integration strategyand serves as an effective mechanism for both exploration and exploitation balance and thus enhancing convergence speed and solution quality. The positions of remora agents will be updated in each iteration according to the associated position update formulation defined in Equation (7) during the remora adaptation phase.

$$Y_i(t+1) = Y_{best} + \beta(Y_{best} - Y_i(t)) \tag{7}$$

The new position of remora i is represented as Yi(t+1), the optimal solution is indicated as Y_best , and the adaptive parameter governing fine-tuning is denoted as β . The Eat Thoughtfully Phase enables remoras to leverage possible solutions, resulting in accelerated convergence and enhanced accuracy, particularly in complex optimization challenges such as hyperparameter tuning in deep learning. However, it achieves better exploration and exploitation balance through an integration with RSO. The purpose behind this modification serves to stop early convergence while simultaneously enabling better global exploration and effective optimization of deep learning models. This proposed method enables superior performance with optimal accuracy and robustness.

IV. RESULTS AND DISCUSSION

This section focuses on assessing the performance of the proposed system and comparing it against baseline approaches using standard benchmark datasets. To make the model more robust, 2 standard datasets (DVLOG, CLEANED REDDIT), are used to integrate to form a hybrid model.

IV.1. DATASET DESCRIPTION

- D-Vlog Dataset [19]: It consists of 961 YouTube vlogs (160 hours) used for depression detection using non-verbal behaviour. The dataset contains 816 subjects (406 controls, 555 sufferers of depression) with audio and visual features saved as NumPy files. This supports the automated depression detection in research with AI-based analysis of facial expressions, gestures, and speech patterns as they naturally occur in everyday life.
- DepressionReddit Dataset: This dataset contains 7,000 labelled text data that are collected from depression related subreddits. Text data reflects real emotional and mental health conditions through self-expressed content. It is valuable for sentiment and depression detection, offering linguistic markers that help identify psychological distress using natural language processing techniques.

IV.2. EXPERIMENTAL SETUP

In the context of this study, where training, testing is done, after was 70% data trained and other thirty percent is imposed to test. The study done on a 2.4 GHz Intel(R) processor with 16 gigabytes of random-access memory (RAM).

IV.3. EVALUATION METRICS

Several evaluation metrics were used to assess the global classifying efficiency. Table 1 was used to evaluate the proposed approach for different evaluation criteria to analyse the sentiments with various performance metrics as shown in Table 1 and Fig.4.

IV.4. CONFUSION MATRIX HEATMAP

It denotes the evaluation of a classification model. It shows real classifications versus predictions in a matrix arrangement across modalities shown in below Figure 2, the confusion matrix shows how well system predict accurate and inaccurate predictions across depression vs normal classes over different attributes. Darker cells correspond to high-accuracy predictions, and lighter cells are misclassifications. In Figure 3. Shows Training and validation accuracy and loss curve for various modalities, Figure 4 shows ROC Curve across thresholds on classifier performance, AUC of 0.95–0.98 indicates that our sentiment classification is highly sensitive and specific.

IV.5. COMPARATIVE STUDY WITH VARIOUS BASELINE MODELS

The proposed depression detection system is a webbasedapplication that contains multiple interactive modulestoexecute regular mental health assessments. The Base line models such as Tensor fusion Network (TFN), Depression Detector, Time-Aware Attention Multimodal Fusion Network (TAMFN), STST Spatiotemporal Semantic Transformer (STST) were tested over problems in depression detection like inability of handling sequential data, high computation complexity and slower execution on very large datasets shown by Table 1 and Figure 5. However, these methods consistently underperform due to issues related to hyperparameters, overfitting, and convergence. Issues can be addressed through integrationof Hybrid Remora-Integrated Grey Wolf Optimization, usingDenseNet-201 for classification and Adam optimizer was used for fine tuning to improve the performance. It also provides a real time facial landmark detection, contributes to depression assessment and there other several use cases. The different baseline models are discussed below.

1. **TFN (Tensor Fusion Network):** This is a multimodal sentiment baseline that models unimodal, bimodal and trimodal interactions explicitly through tensor outer-products, it's strong but it has many parameters, it works poorly when the data is very sparse.
2. **Depression Detector:** Audio + Text bi-modal depression detector with GRU/BiLSTMmodel for temporal modeling, which is strong base-midline for clinical/interview-style data.
3. **TAMFN:** Time-Aware Attention Multimodal Fusion Network is used for learning the temporal salience and cross-modal fusion for depression detection which deals with the temporal handling issue better than TFN.
4. **STST:** Spatiotemporal Semantic Transformer uses attention over visual/text/audio streams with semantic alignment, improved long-range temporal modeling and fusion.
5. **TVLT**:(textless pretraining) token-based vision-language transformer, re-purposed for cross-modal understanding and strong generic prior, moderate domain gap without task-specific pretraining.

Table 1: Comparison across various baseline models.

V. CONCLUSION

Despite the field of deep learning is constantly expanding, there is still a lot of work accessible for depression identification. This study proposes to use multimodal data (text, video, and audio) that is effectively incorporated to detect emotional states of depression and classify sentiment. High-level features between modalities can then be extracted using feature extraction techniques. The Dense Net-201 model is then used to achieve an accurate classification, and a Hybrid Remora-Integrated Grey Wolf OptimizationAlgorithm has been introduced to further improve the classification accuracy. Initially, it preprocesses the various input data so that it can support text, audio, and video data separately with the available data. Thus, it has been demonstrated that this suggested method outperforms current methods in the comparative analysis, with greater accuracy rates for text data with 94%, audio data is 92%, and video data is 93%. The integration of real-time sensor physiology will be the focus of future research in order to create a more interpretable visualization of the information that the mental health professionals are actually acquiring from the decisions being performed.

ABSTRACT

The proliferation of interconnected devices in the Internet of Things (IoT) has led to an exponential increase in data, commonly known as Big IoT Data. Efficient retrieval of this heterogeneous data demands a robust indexing mechanism for effective organization. However, a significant challenge remains the overlap in data space partitions during index construction. This overlap increases node access during search and retrieval, resulting in higher resource consumption and performance bottlenecks and impedes system scalability. To address this issue, we propose three innovative heuristics designed to quantify and strategically reduce data space partition overlap. The volume-based method (VBM) offers a detailed assessment by calculating the intersection volume between partitions, providing deeper insights into spatial relationships. The distance-based method (DBM) enhances efficiency by using the distance between partition centers and radii to evaluate overlap, offering a streamlined yet accurate approach. Finally, the object-based method (OBM) provides a practical solution by counting objects across multiple partitions, delivering an intuitive understanding of data space dynamics. Experimental results demonstrate the effectiveness of these methods in reducing search time, underscoring their potential to improve data space partitioning and enhance overall system performance.

I. INTRODUCTION

The Internet of Things (IoT) has rapidly emerged as one of the most transformative technologies of the 21st century. This paradigm is characterized by intelligent, self-configuring devices capable of communicating with one another through a global network infrastructure [1]. Since Kevin Ashton introduced the concept of IoT in 1999 [2], the number of connected devices has skyrocketed from 8 billion in 2018 to an estimated 75 billion by 2025 [3]. Alongside this growth, the volume of generated data has increased from 33 ZB in 2018 to a projected 175 ZB by 2025 [4], marking the dawn of the big IoT data era [5](see Figure 1).

This exponential growth of data in IoT-based applications offers significant opportunities for value creation but also highlights the urgent for efficient data storage and retrieval mechanisms [6]. Similarity search-based data retrieval is widely adopted for its ability to retrieve complex data based on intrinsic characteristics [7]. However, its effectiveness is often limited by high computational costs, especially in big data settings. To effectively leverage this technique and avoid the brute force sequential scan, robust indexing methods are essential for organizing large datasets in a manner that facilitates the efficient retrieval of similar data [8], [9]. In this context, the concept of metric space plays a crucial role, allowing objects to be mapped into a domain where they can be compared using a distance function [10].

Typically, indexing techniques within this space divide data into hierarchical regions centered around selected representative objects, known as pivots, each with a defined covering radius. While each region is associated with a pivot, every object within the region must be explicitly assigned.

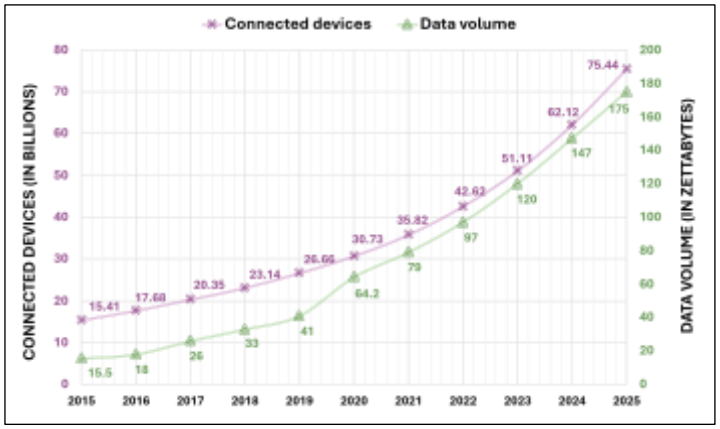

Figure 1: Growth of Connected Devices and Data Volume (2015-2025).
Source: Authors, (2026).

Several metric index methods, such as the M-tree [11], Slim-Tree [12], and more recently, the BCCF-tree [6] and its extension, the B3CF-tree [13], have been developed to enhance similarity searches in metric spaces. Despite these advancements, the issue of space overlap in index structures persists, leading to increased node accesses, longer search times, and higher computational costs—sometimes even exceeding those of sequential scans. Rather than resorting to solutions that eliminate all elements within the overlap area or minimize partitioning radii—both of which can lead to information loss—there is a critical need for a new mechanism to more effectively quantify, measure, and address the overlap problem. Such a mechanism should incorporate advanced metrics for accurately detecting overlaps and sophisticated methods for evaluating them during the partitioning process. To bridge this significant research gap, we propose three innovative heuristics designed to quantify and strategically manage data space partition overlap:

- Volume-Based Method (VBM): This heuristic provides a detailed measure of overlap by calculating the intersection volume between partitions. It offers a nuanced understanding of spatial relationships, enabling reliable quantification of overlap areas and optimizing partition boundaries.
- Distance-Based Method (DBM): This approach evaluates overlap by analyzing the distance between partition centers and their radii. By focusing on the geometric relationships between partitions, this method ensures a computationally efficient process without sacrificing accuracy.
- Object-Based Method (OBM): Notable for its practicality, this heuristic uses the count of objects shared between partitions as a straightforward yet insightful indicator of overlap. It facilitates a more intuitive interpretation of data space dynamics by directly linking overlap to data distribution.

This paper is organized as follows: **Section 2** offers an overview of the essential background information. **Section 3** reviews relevant existing works. **Section 4** presents the proposed heuristics in detail. **Section 5** analyses the comparative experimental results. Finally, **Section 6** concludes the study and outlines future research directions.

II. THEORETICAL BACKGROUND

The metric space is a mathematical structure, introduced as a universal abstraction for data [14], excels by relying solely on a distance function that satisfies the triangle inequality, thereby eliminating the need for specific content or intrinsic structure [15], [16]. This versatility allows it to effectively index a wide variety of data types seamlessly.

Definition 1 (Metric Space). *A metric space $\mathcal{M}$ is defined as a pair $(\mathcal{S}, d)$, where $\mathcal{S}$ denotes a domain of objects, and $d: \mathcal{S} \times \mathcal{S} \rightarrow \mathbb{R}^+$ represents a distance function to quantify the "similarity" between objects within $\mathcal{S}$. This distance function typically satisfies four distinct properties:*

- $\forall (x, y) \in \mathcal{S}, d(x, y) \geq 0$ $\quad (p1: non-negativity)$
- $\forall (x, y) \in \mathcal{S}, d(x, y) \geq d(y, x)$ $\quad (p2: symmetry)$
- $\forall (x, y) \in \mathcal{S}, d(x, y) = 0 \iff x = y$ $\quad (p3: identity)$
- $\forall (x, y, z) \in \mathcal{S}, d(x, y) + d(y, z) \geq d(x, z)$ $\quad (p4: triangle\ inequality)$

According to [17], the problem of indexing metric spaces can be formally stated as follows:

Definition 2 (Problem of Data Indexing). *Let $\mathcal{M} = (\mathcal{S}, d)$ be a metric space. Consider a subset $\mathcal{X} \subseteq \mathcal{S}$, representing a set of objects, commonly referred to as the dataset, within which we perform searches. The problem of indexing metric spaces involves determining how to preprocess or structure the objects in $\mathcal{X}$ so that similarity queries can be answered efficiently.*

As mentioned in Section 1, indexing techniques in this context typically involve partitioning a set $\mathcal{X} \subseteq \mathcal{S}$ of objects in the metric space $\mathcal{M} = (\mathcal{S}, d)$ into hierarchical regions centered around pivots using various partitioning techniques. One widely used method is Generalized Hyperplane (GH) partitioning, which is commonly employed in these indexes [8], [16]. In GH partitioning, two specific objects $(p_1, p_2) \in \mathcal{X}$ are chosen arbitrarily or specifically. The dataset $\mathcal{X}$ is then divided into subsets $\mathcal{X}_1$ and $\mathcal{X}_2$ based on Definition (3) and as illustrated in Figure 2.

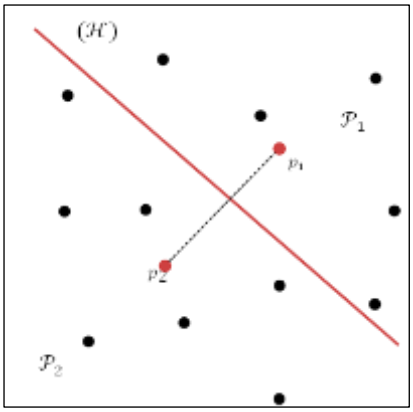

Figure 2: GH partitioning $\mathcal{H}(\mathcal{S}, d, p_1, p_2)$.
Source: Authors, (2026).

Definition 3 (Generalized Hyperplane Partitioning). *Let $\mathcal{M} = (\mathcal{S}, d)$ be a metric space, where $\mathcal{X} \subseteq \mathcal{S}$ represents the set of objects to be indexed. Assume $(p_1, p_2) \in \mathcal{X}$ are two pivot objects such that $d(p_1, p_2) > \mathcal{X}$. The generalized hyperplane $\mathcal{H}(\mathcal{S}, d, p_1, p_2) = \{o \in \mathcal{X} : d(p_1, o) = d(p_2, o)\}$ partitions the space into two regions as follows:*

$$\begin{cases} \mathcal{P}_1 = \{o \in \mathcal{X} : d(p_1, o) \leq d(p_2, o)\} \\ \mathcal{P}_2 = \{o \in \mathcal{X} : d(p_1, o) \geq d(p_2, o)\} \end{cases}$$

In metric space theory, a similarity query is defined by a query object q and a specified proximity criterion, typically expressed as a distance. The objective of such queries is to retrieve objects $\{o_1, \ldots, o_n \,|o_i \in \mathcal{X}\}$ that satisfy the proximity conditions relative to the query object q [18]. Among the various types of similarity queries, the k nearest neighbor (k-NN) query is the most popular and widely used [19], [20]. The k-NN query retrieves the k closest objects to a given query object q based on their distance in the metric space. If the dataset, contains fewer than k objects (i.e., $|\mathcal{X}| \leq k$), the query returns the entire dataset (i.e., $|\mathcal{A}| = |\mathcal{X}|$) [17]. The following definition formalizes this query type (see Figure 3).

Definition 4 (k-NN Query). *Let $\mathcal{M} = (\mathcal{S}, d)$ a metric space, $q \in \mathcal{S}$ a query point, and $k \in \mathbb{N}^+$ the required number of answers.*

$$k - \mathcal{NN}(\mathcal{S}, d, q, k) = \{\mathcal{A} \,|\, \mathcal{A} \subseteq \mathcal{X} \subseteq \mathcal{S}, |\mathcal{A}| = k \;\wedge \forall\, (o_i \in \mathcal{A})\, \forall \left(o_j \in \{\mathcal{X} \backslash \mathcal{A}\}\right) : d(q, o_i) \leq d(q, o_j)\}$$

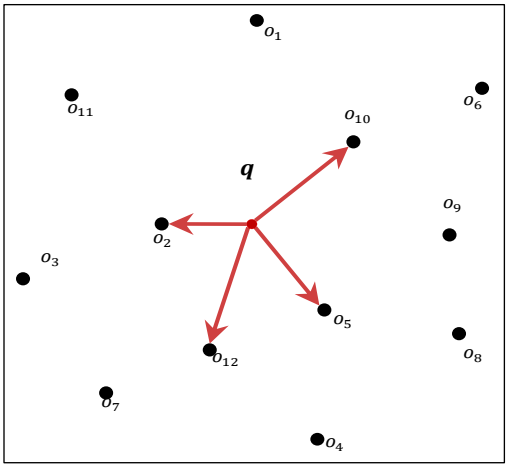

Figure 3: k-NN query, $k - \mathcal{NN}(\mathcal{S}, d, q, k)$.
Source: Authors, (2026).

During the partitioning process, distant points can sometimes be assigned to partitions, leading to a significant increase in their radii r_i. Since these partitions are modeled as hyperballs (see Definition 5), the inclusion of such outlier points can substantially expand the partition's coverage, potentially causing overlap in areas of the data space that do not reflect the actual data distribution.

Definition 5 (Hyperball). *Let $\mathcal{M} = (\mathcal{S}, d)$ a metric space, $\mathcal{X} \subseteq \mathcal{S}$ represents the set of objects. Consider $p \in \mathcal{S}$ as a pivot object, and $r \in \mathbb{R}^+$ as the radius of coverage. The notation $\mathcal{P}(\mathcal{S}, d, p, r)$ defines a closed ball that defines analogously the partitions, where:*

$$\mathcal{P}(\mathcal{S}, d, p, r) = \{\forall o \in \mathcal{X}: d(o, p) \leq r\}$$

Theoretically, overlap between two partitions occurs when the farthest point within a partition (determined by its r_i value) lies farther from the partition's reference point (p_i) than the reference points are from each other. This scenario means that any query ($q \in \mathcal{S}$) within the overlapping space must be processed in each overlapping partition, even if some partitions contain no relevant data at the query location. As a result, distance calculations increase, search response times are prolonged, and computational costs rise, sometimes surpassing those of sequential scans, especially in cases of significant overlap. For example, as illustrated in Figure 4, every partition intersected by the query sphere ($\mathcal{P}_1$ and $\mathcal{P}_2$) must be searched, regardless of whether they contain relevant data points.

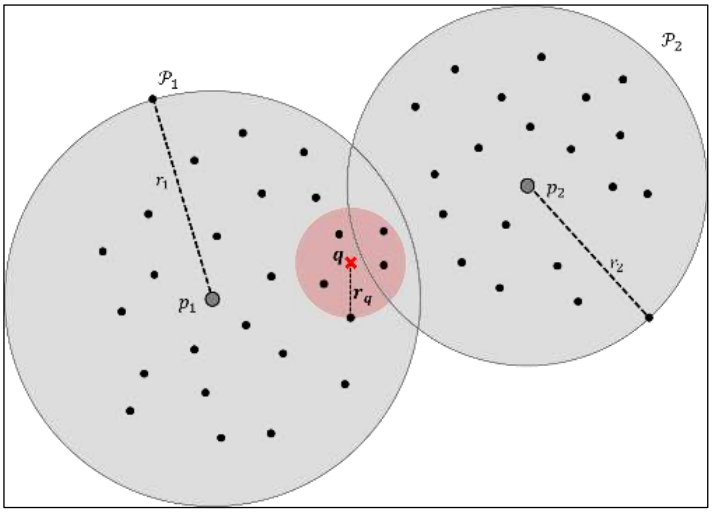

Figure 4: An example of overlapping partitions.

III. RELATED WORKS

In the field of data indexing, numerous techniques have been developed to enhance query efficiency and retrieval speed. These challenges are particularly critical in modern data management systems, especially in IoT. Various indexing techniques have been proposed to address efficient data retrieval in such settings, with several noteworthy structures standing out. One such technique involves Voronoi Diagram-based structures, such as GNAT [21], which leverage Voronoi Diagrams to address node overlaps through static partitioning. While this method effectively prevents node overlaps, it struggles in dynamic environments, particularly when maintaining non-overlapping partitions during real-time updates. The EGNAT [22], a dynamic variant of GNAT and a generalization of the GH-Tree [23], introduces flexible node organization to manage updates following an initial bulk load. However, it continues to face challenges in maintaining the non-overlapping principle of Voronoi diagrams [24], [25], and its search operations can be computationally intensive.

In contrast to static structures, the M-Tree [11] and its variations, such as the M+-Tree [26] and BM+-Tree [27], are known for their balanced structures and effective handling of dynamic updates. Nevertheless, these structures encounter challenges with overlapping nodes at the same level, especially in higher-dimensional spaces. The Slim-Tree [12] builds on the M-Tree by introducing innovative algorithms like the Slim-Down technique to minimize node overlap. However, the effectiveness of overlap reduction varies depending on the characteristics of the data distribution, and the need for object reinsertion during updates adds further complexity. OMNI [28], [29] technology, a notable alternative to the M-Tree, significantly improves search efficiency by using strategically placed vantage points to increase the likelihood of node elimination. However, it still struggles with reducing the number of intersecting nodes, which can negatively impact overall search performance.

Hybrid techniques, such as the IM-Tree [30], XM-Tree [31], and NOBH-Tree [32], combine multiple strategies to mitigate overlap by utilizing pivot-based partitioning and non-overlapping regions. The IM-Tree partitions space around two pivots into five non-overlapping regions, but encounters difficulties when distant regions accumulate too many objects. The XM-Tree addresses this by eliminating partitions without objects, introducing an external limiting area, and using linked lists for storing distant objects. The NOBH-Tree, another hybrid structure, combines Voronoi-shaped and ball-shaped partitions, utilizing two pivots, covering radii, and a hyperplane to create non-overlapping regions. It introduces a sixth region using the hyperplane to manage overlaps caused by the ball-shaped partitions, allowing for flexible tree compositions while ensuring that partitions meet the criteria for non-disjoint regions and symmetric space division relative to the pivots. Despite their potential, these hybrid structures involve complex partitioning and management strategies and do not fully resolve overlap issues, thus limiting their scalability and efficiency in large-scale deployments.

Recently, the BCCF-tree, introduced by [6], presented an innovative approach to real-time IoT data indexing, improving k-NN searches and achieving balanced partitioning using the k-means algorithm. Its extension, the ABCCF-tree, addresses unique labeling challenges in Internet of Video Things (IoVT) networks [33], [34], [35]. Another variant, the QCCF-tree [36], divides space into four regions and enhances query retrieval by enabling concurrent searches at each node, demonstrating superior performance in both construction and similarity searches. However, despite these advancements, these structures still struggle with overlap issues, particularly when managing large-scale datasets.

While the reviewed structures have shown effectiveness in various data environments, they continue to face significant challenges in efficiently managing node overlaps in large databases. Overlap complicates index construction and maintenance, and it undermines query performance by necessitating additional computations and data traversals. These ongoing challenges highlight a clear research gap: the need for a new mechanism that can more effectively quantify, measure, and address the overlap problem. Bridging this gap is essential for improving the efficiency of data indexing techniques.

IV. PROPOSED SOLUTION

Our proposed solution divided into three successive stages. (i) preprocessing, (ii) overlapping estimation, and (iii) decision-making and indexing.

IV.1 PREPROCESSING

To enhance indexing structures, we propose applying a clustering algorithm to the data before indexing. The goal is to organize similar data into compact groups, facilitating efficient indexing and retrieval processes. In our approach, DBSCAN (Density-Based Spatial Clustering of Applications with Noise) [37], [38], [39] is selected as the most suitable algorithm, supported by its proven effectiveness in previous studies [13], [38]. DBSCAN identifies clusters of arbitrary shapes based on density, dynamically adjusting without the need to pre-determine the number of clusters, unlike k-means. This method relies on two key parameters: (i) $\epsilon \in \mathbb{R}^+$, the radius of the spherical neighborhood around each object $o \in \mathcal{X}$ (see Definition 6), and (ii) $MinPts$, the minimum number of objects required for a neighborhood to be considered a valid cluster.

Definition 6 (ϵ-Neighborhood of an Object). *Let $\mathcal{M} = (\mathcal{S}, d)$ be a metric space, and $\mathcal{X} \subseteq \mathcal{S}$ represent the set of objects to be grouped. The ϵ-neighborhood of an object o, denoted as $\mathcal{N}_\epsilon(o)$, is defined as:*

$$\mathcal{N}_\epsilon(o) = \{q \in \mathcal{X} \mid d(o,q) \leq \epsilon\}$$

Despite DBSCAN's ability to cluster without requiring centroids or radii for each group, it does not fully align with all our specific needs. Therefore, we will enhance the DBSCAN algorithm (Algorithm 1) to better suit our unique requirements in the subsequent stages of this research.

Algorithm 1: DBSCAN Clustering Algorithm		
Require: $\begin{pmatrix} \mathcal{X} \subseteq \mathcal{S}, \\ d: \mathcal{S} \times \mathcal{S} \to \mathbb{R}^+, \\ \epsilon \in \mathbb{R}^+, \\ MinPts \in \mathbb{N} \end{pmatrix}$ **Ensure:** $\begin{pmatrix} \{\boldsymbol{\mathcal{P}}\} \in \boldsymbol{\mathcal{X}}, \\ \{\boldsymbol{p}\} \in \boldsymbol{\mathcal{S}}, \\ \{\boldsymbol{r}\} \in \mathbb{R}^+ \end{pmatrix}$		
1 :	clusterId ⟵ nextId(noise)	
2 :	**forall** $o \in \mathcal{X}$ **do**	
3 :	**if** o.Cid = UNDEFINED **then**	
4 :	**if** ExpandCluster($\mathcal{X}$, o, clusterId, ϵ, $MinPts$) **then**[1]	
5 :	clusterId ⟵ nextId(clusterId)	
6 :	**endif**	
7 :	**endif**	
8 :	**endfor**	
9 :	$\{\boldsymbol{\mathcal{P}}\}_{i=1}^{clusterId} = \{\forall o \in \mathcal{X} \mid o.Cid = i\}$	
10 :	$\{\boldsymbol{p}\}_{i=1}^{clusterId} = \left\{\frac{1}{\lvert\boldsymbol{\mathcal{P}}_i\rvert}\sum_{o \in \mathcal{P}_i} o\right\}$	
11:	$\{\boldsymbol{r}\}_{i=1}^{clusterid} = \max_{o \in \mathcal{P}_i}\{d(p_i, o)\}$	

Source: Authors, (2026).

IV.2 OVERLAPPING ESTIMATION

In this subsection, we introduce our innovative heuristics designed to minimize the impact of the overlap space problem discussed in Section 2. These heuristics aim to enhance metric space indexing without compromising query retrieval accuracy or the overall quality of the index.

Please note that the function "*ExpandCluster*" from Algorithm 1 remains unchanged. We used it as is and therefore did not include its details here. For further details on "*ExpandCluster*", refer to [37].

IV.2.1 Volume-Based Method (VBM)

The first proposed heuristic is the Volume-Based Method (VBM). This approach provides a detailed measure of overlap by calculating the intersection volume between partitions. As outlined in Section 2, partitions in a metric space are modelled as hyperballs (see Definition (5)). To accurately assess the degree of partition overlap, we measure the overlapping volume between these corresponding hyperballs. The intersection volume between two hyperballs (Figure 5) depends solely on the distance between their centers and the sizes of their radii, as outlined in Definition (7).

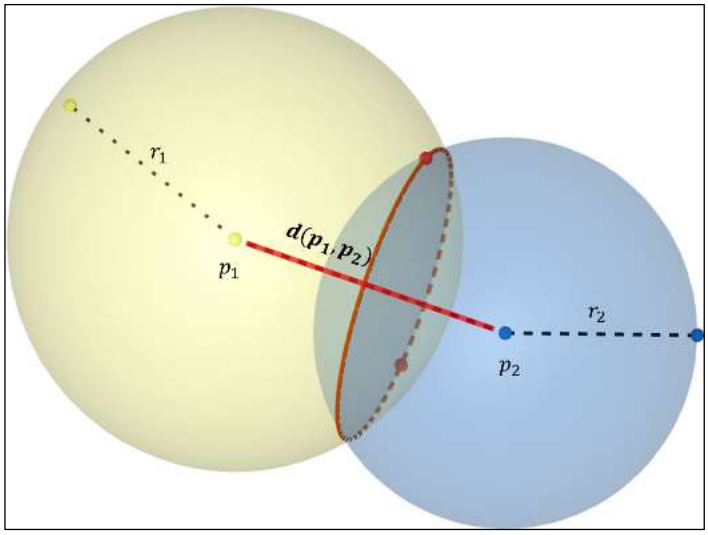

Figure 5: Geometry of the intersection of two hyperballs.
Source: Authors, (2026).

Definition 7. *Let $\mathcal{M}(\mathcal{S}, d)$ a metric space. Consider two partitions $\mathcal{P}_1(\mathcal{S}, d, p_1, r_1)$ and $\mathcal{P}_2(\mathcal{S}, d, p_2, r_2)$, representing hyperballs centered at p_1 and p_2 with radii r_1 and r_2, respectively. The overlap volume (V) and overlap volume rate ($V_\cap$) are defined as*:

$$V = \begin{cases} 0, & if\ d(p_1, p_2) \geq r_1 + r_2 \\ min\{V_{\mathcal{P}_1}, V_{\mathcal{P}_2}\}, & if\ d(p_1, p_2) \leq |r_1 - r_2| \\ \sum_{i=1}^{2} V_{\triangle}(r_i, p_i), & otherwise \end{cases}$$

$$V_\cap = \begin{cases} 0, & if\ d(p_1, p_2) \geq r_1 + r_2 \\ 1, & if\ d(p_1, p_2) \leq |r_1 - r_2| \\ \frac{\sum_{i=1}^{2} V_{\triangle}(r_i, p_i)}{V_{\mathcal{P}_1} + V_{\mathcal{P}_2}}, & otherwise \end{cases}$$

where:

- *$V_{\mathcal{P}_1}$ and $V_{\mathcal{P}_2}$ are the volumes of hyperballs $\mathcal{P}_1$ and $\mathcal{P}_2$, respectively, as defined in Definition (8).*
- *$V_{\triangledown}(r_i, c_i)$ is the volume of the spherical cap of the hyperball $\mathcal{P}_i$ and is calculated using Definition (9).*

Definition 8 (Volume of a Hyperball). *Let $\mathcal{M}(\mathcal{S}, d)$ be a metric space. Consider a partition $\mathcal{P}_i(\mathcal{S}, d, p_i, r_i)$, representing an n-dimensional hyperball centered at c_i with radius r_i. The volume $V_{\mathcal{P}_i}$ is given by [40]:*

$$V_{\mathcal{P}_i} = \frac{\pi^{\frac{n}{2}}}{\Gamma(\frac{n}{2} + 1)} \times r_i^n$$

where Γ denotes the gamma function [41]:

$$\Gamma(x) = \int_0^\infty t^{x-1}\, e^{-t}\, dt$$

As demonstrated in Definition (7), the volume of the intersection between two hyperballs corresponds to the combined volume of the spherical caps formed by a hyperplane cutting through them (see Figure 6).

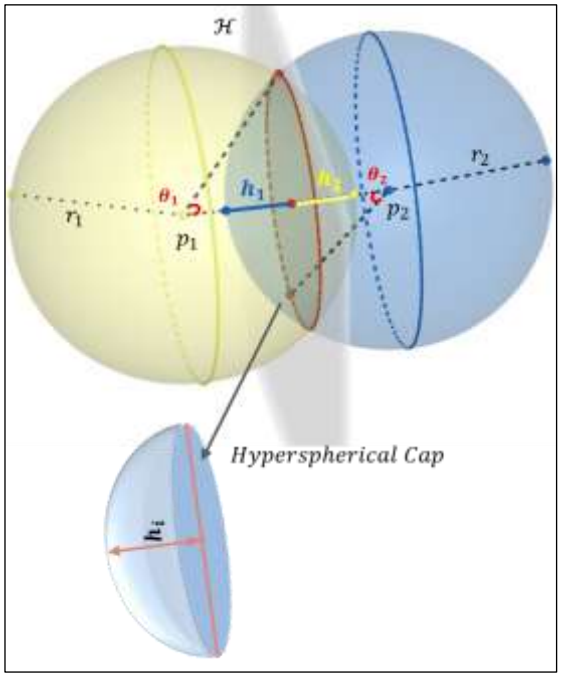

Figure 6: An example of a spherical cap.
Source: Authors, (2026).

To determine the n-dimensional volume $V_{\nabla}(r_i, p_i)$ of a hyperspherical cap with height hi and radius r_i, we apply the methodology described in [40]. The formula for calculating this volume is formalized by the following definition:

Definition 9 (Volume of Hyperspherical Cap). *Let $\mathcal{M}(\mathcal{S}, d)$ denote a metric space. Consider two partitions, $\mathcal{P}_i(\mathcal{S}, d, p_i, r_i)$ and $\mathcal{P}_j(\mathcal{S}, d, p_j, r_j)$, representing n-dimensional hyperballs centered at p_i and p_j with radius r_i and r_j, respectively. The volume of a hyperspherical cap of $\mathcal{P}_i$ with height h_i is calculated using the formula from [40] as follows:*

$$V_{\nabla}(r_i, p_i) = \frac{\pi^{\frac{n-1}{2}} r_i^n}{\Gamma\left(\frac{n+1}{2}\right)} \int_0^{arccos\left(\frac{r_i - h_i}{r_i}\right)} sin^n(\theta_i) d\theta_i$$

where :

- *h_i is the height of the cap, calculated by:*

$$h_i = r_i(1 - cos(\theta_i))$$

- *θ_i is the polar angle between the rays from the center pi of the sphere to the apex of the cap (the pole) and the edge of the disk forming the base of the cap, calculated as:*

$$\theta_i = \cos^{-1} \frac{r_i^2 + d(p_i, p_j)^2 - r_j^2}{2 r_i d(p_i, p_j)}$$

IV.2.2 Distance-Based Method (DBM)

The Distance-Based Method (DBM) is a simpler heuristic for evaluating overlap between partitions by calculating the distance between their centers and radii. Unlike the VBM, the DBM focuses exclusively on distance relationships, ensuring a computationally streamlined process without compromising accuracy. As illustrated in Figure 6, the overlap distance between partitions is represented by the combined height of the caps. Calculating the rate of this overlap, as defined in Definition (10), is crucial for accurately quantifying the degree of overlap. This quantification helps optimize partition boundaries and enhances the efficiency of the indexing structure.

Definition 10 (Overlapping Distance Rate). *Let $\mathcal{M}(\mathcal{S}, d)$ denote a metric space. Consider two partitions, $\mathcal{P}_1(\mathcal{S}, d, p_1, r_1)$ and $\mathcal{P}_2(\mathcal{S}, d, p_2, r_2)$, representing n-dimensional hyperballs centered at p_1 and p_2 with radius r_1 and r_2, respectively. The distance rate of their intersection ($D_{\cap}$) is calculated as follows:*

$$D_{\cap} = \begin{cases} 0, & if\ d(p_1, p_2) \geq r_1 + r_2 \\ 1, & if\ d(p_1, p_2) \leq |r_1 - r_2| \\ \dfrac{\sum_{i=1}^{2} h_i}{d(p_1, p_2)}, & otherwise \end{cases}$$

where h_i represents the height of the cap of hyperball $\mathcal{P}_i$ as defined in Definition (9).

IV.2.3 Object-Based Method (OBM)

The Object-Based Method (OBM) is particularly practical, using the count of objects shared between partitions as a straightforward yet insightful indicator of overlap. This method allows for a more intuitive interpretation of data space dynamics by directly linking overlap to the actual distribution of data. Unlike previous methods that calculate overlapping space—potentially leading to inaccuracies in cases of large but empty overlaps—OBM addresses this issue by focusing on the number of overlapping objects, providing a more accurate representation of data overlap. The mathematical foundation of this approach is illustrated in Definition (11).

Definition 11 (Overlapping Objects Rate). *Let $\mathcal{M}(\mathcal{S}, d)$ be a metric space and let $\mathcal{X} \subseteq \mathcal{S}$ be a set of partitioned objects. Consider two partitions, $\mathcal{P}_1(\mathcal{S}, d, p_1, r_1)$ and $\mathcal{P}_2(\mathcal{S}, d, p_2, r_2)$, representing hyperballs centered at p_1 and p_2 with radius r_1 and r_2, respectively. The set A of objects located in the overlapping area of the two hyperballs is defined by:*

$$A = \mathcal{P}_1(\mathcal{S}, d, p_1, r_2) \cap \mathcal{P}_2(\mathcal{S}, d, p_2, r_2)$$

Explicitly, this is defined as:

$$A = \{o \in \mathcal{X} \mid d(o, p_1) \leq r_1 \; and \; d(o, p_2) \leq r_2\}$$

The rate $A_\cap$ of objects in the overlapping area A is calculated as:

$$A_\cap = \begin{cases} 0, & if\ d(p_1, p_2) \geq r_1 + r_2 \\ 1, & if\ d(p_1, p_2) \leq |r_1 - r_2| \\ \dfrac{|A|}{|\mathcal{P}_1| + |\mathcal{P}_2|}, & otherwise \end{cases}$$

Here,

- *$|A|$ denotes the number of objects in set A.*
- *$|\mathcal{P}_1|$ and $|\mathcal{P}_2|$ represent the number of objects in partitions $\mathcal{P}_1$ and $\mathcal{P}_2$, respectively.*

IV.2.4 Decision-Making and Indexing

After estimating the overlap between partitions, the next step is to create the indexes. We establish two thresholds, and , to quantify the degree of overlap. Based on these thresholds, we categorize overlap into three levels: (i) Low overlap $[0, \xi_{min}]$, (ii) Medium overlap $[\xi_{min}, \xi_{max}]$, and (iii) High overlap $[\xi_{max}, 1]$. These classifications enable us to balance the trade-offs between index complexity and retrieval efficiency by applying tailored strategies to different levels of overlap, thereby ensuring optimal performance. By defining these thresholds, we can adapt our indexing approach to the specific characteristics of the data and the nature of the overlap.

- Low overlap $[0, \xi_{min}]$: In cases of low overlap, we extract all objects from the partition with the smaller cap and merge them into the other partition. This results in two separate indexes, one for each partition. This minimal overlap can be efficiently managed by redistributing objects, which maintains a clear separation between partitions and reduces redundant searches.
- Medium overlap $[\xi_{min}, \xi_{max}]$: For medium overlap, we create three indexes: one for each partition, excluding the overlapping objects, and a third specifically for the overlapping objects. This third index is labeled as a neighbor of the original indexes (partitions) to ensure easy access during the search, particularly when the required number of objects has not yet been reached. This approach provides a balance between merging and maintaining separate partitions. By isolating overlapping objects into a separate index, searches within each primary partition remain efficient while the overlap is accounted for in a dedicated index.
- High overlap $[\xi_{max}, 1]$: In cases of high overlap, we merge the two partitions to create a single index structure for all objects. Significant overlap would lead to excessive redundancy and inefficient searches if the partitions were kept separate. Merging them into a single index simplifies the structure and optimizes retrieval by eliminating the need for extensive overlap management.

The thresholds ξ_{min} and ξ_{max} are crucial for classifying the degree of overlap. Their values directly influence how overlap is quantified and subsequently managed. Setting these thresholds requires careful consideration of the dataset's characteristics and the desired balance between indexing complexity and search efficiency. By finetuning these thresholds, we can develop an optimal indexing strategy that minimizes computational overhead while ensuring accurate and efficient data retrieval. For our index structures, we employ the BCCF-tree [6], an efficient metric index structure designed for big IoT data retrieval. The BCCF-tree partitions the data space into disjoint regions using a recursive k-means algorithm [42], which is effective in minimizing overlap between partitions. However, the construction of the BCCF-tree can be complex due to the recursive nature of the k-means algorithm. By addressing this challenge through the steps outlined earlier, the intricate nature of the k-means algorithm becomes less critical, allowing for the use of a simpler partitioning technique. Therefore, we propose a refined approach utilizing GH partitioning, as defined in Definition 3. GH partitioning is widely recognized for its effectiveness and relatively lower computational complexity compared to other methods. The complexity of hyperplane partitioning typically ranges from $O(n \times log(n))$ to $O(n^2)$, depending on the specific implementation and the dimensionality of the data, where n represents the number of data points [16].

Definition 12 (BCCF-tree). *Let $M(\mathcal{S}, d)$ a metric space, and let $\mathcal{X} \subseteq \mathcal{S}$ represent the set of indexed objects. The BCCF-tree structure is composed of two levels:*

- *Internal nodes $\mathcal{N}$ is a sextuplet:*

$$(p_1, p_2, r_1, r_2, \mathcal{N}_L, \mathcal{N}_R) \in \mathcal{X} \times \mathcal{X} \times \mathbb{R}^+ \times \mathbb{R}^+ \times \mathcal{N} \times \mathcal{N}$$

where:

  - *(p_1, p_2) are two pivots, with $d(p_1, p_2) > 0$.*
  - *(r_1, r_2)represent the distances to the farthest object in the sub-tree rooted at that node $\mathcal{N}$ with respect to p_1 and p_2, respectively, i.e., $r_i = max\{d(p_i, o), \forall o \in \mathcal{N}\}$.*
  - *$(\mathcal{N}_L, \mathcal{N}_R)$ are two sub-indexes (left and right child nodes).*
- *Leaf nodes, denoted as E_C, consist of a subset of the objects stored within a bucket.*

$$E_C \subseteq \mathcal{X}$$
$$where, |E_C| \leq c_{max}, c_{max} = \sqrt{n}, and\ n = |\mathcal{X}|$$

In this paper, we employ the BCCF-tree structure without modification, using the same construction algorithm detailed in [6], [18]. However, during the search phase, we introduce a new algorithm to manage the multiple indexes generated. This algorithm selects the appropriate index or indexes based on their proximity to the query object (see Algorithm 2). Once the closest indexes are identified, the kNN search algorithm of [6], [18] is applied in parallel across all selected indexes, ensuring efficient and accurate query processing while leveraging parallelism for enhanced performance.

Algorithm 2: Recherche kNN

Require: $\begin{pmatrix} indexes \in \mathcal{N}, \\ d: \mathcal{S} \times \mathcal{S} \to \mathbb{R}^+, \\ q \in \mathcal{S}, \\ k \in \mathbb{N}^+, \\ A \in \mathcal{X} = \emptyset \end{pmatrix}$

Ensure: $A \in \mathcal{X}, |A| \leq k$

V. SIMULATION AND RESULTS

V.1 OVERLAPPING ESTIMATION

The prototype was implemented in Python on a workstation equipped with an Intel® Core™ i5-4200U CPU at 1.6 GHz, 4 GB of RAM, and running the Linux (Ubuntu) operating system.

Two datasets were used in the experiments. Table 1 provides an overview of the dataset characteristics, along with the parameters used in the DBSCAN algorithm (ϵ and $MinPts$) for each dataset. Additionally, the table includes the fixed overlap thresholds (ξ_{min} and ξ_{max}) used in the experiments.

- DB1: This dataset consists of feature vectors from moving objects obtained from an object tracking simulator in an IoVT environment using wireless cameras [43].
- DB2: Knownasthe Wearable Action Recognition Database (WARD)[2], this dataset is a benchmark database used for recognizing human actions using a wearable motion sensor network [44].

Table 1: Parameter values

Dataset	Size	Dimensions	C_{max}	ϵ	$MinPts$	ξ_{min}	ξ_{max}
Tracking	62,702	20	250	248	250	0.4	0.8
WARD	1,000,000	5	316	91	23		

Source: Authors, (2026).

To comprehensively evaluate the effectiveness of the proposed solution, a series of experiments were conducted, benchmarking its performance against the baseline BCCF-tree structure. The experiments were designed to assess the solution across three key dimensions: (i) Structure evaluation, (ii) Construction cost, and (iii) Search efficiency.

V.2 STRUCTURE EVALUATION

This section provides a detailed analysis of the quality of the indexes generated by the proposed heuristics—DBM, OBM, and VBM—applied to the Tracking and WARD datasets. The analysis primarily evaluates these heuristics based on their effectiveness in managing data space and optimizing tree structures. Key metrics assessed include the distribution of leaf nodes, their balance between the left and right sides of the binary trees, the number of nodes at each index level, and the overall height of the index.

V.2.1 Tracking dataset

In the Tracking dataset, both DBM and OBM performed well in maintaining balanced data distributions within the leaf nodes, with bucket sizes peaking around 250 in most trees and median values ranging from 140 to 215, as illustrated in Figures 7 and 8. However, a slight imbalance was observed in Tree 5, where bucket sizes were significantly smaller. VBM demonstrated its adaptability by effectively managing varying data volumes, with median bucket sizes ranging from 25 to 60 and peaks nearing 110, as seen in Figure 9, underscoring its effectiveness in optimizing tree structures for datasets of different sizes.

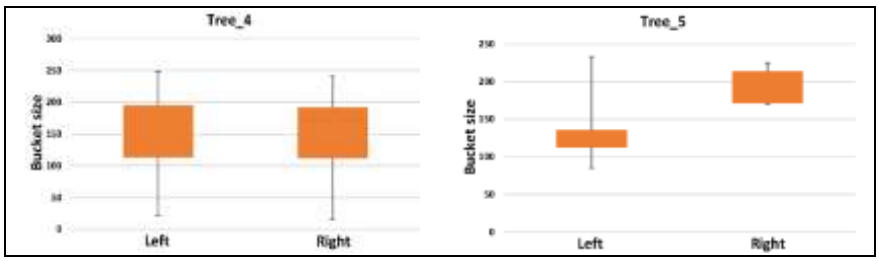

Figure 8: Bucket data distribution using OBM for Tracking datasets.
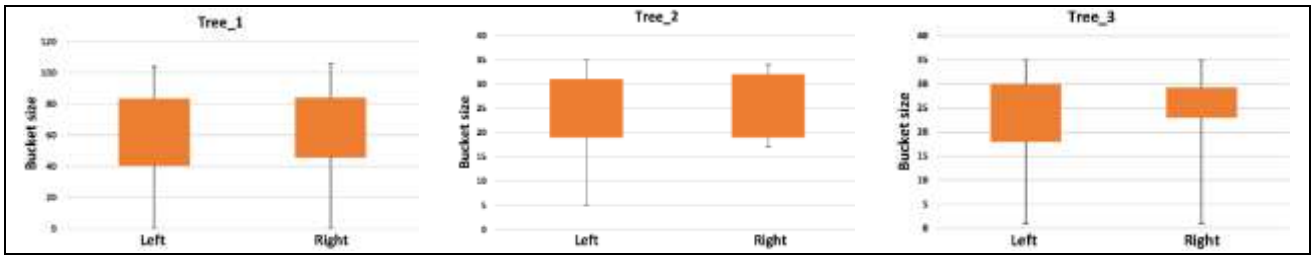
Source: Authors, (2026).



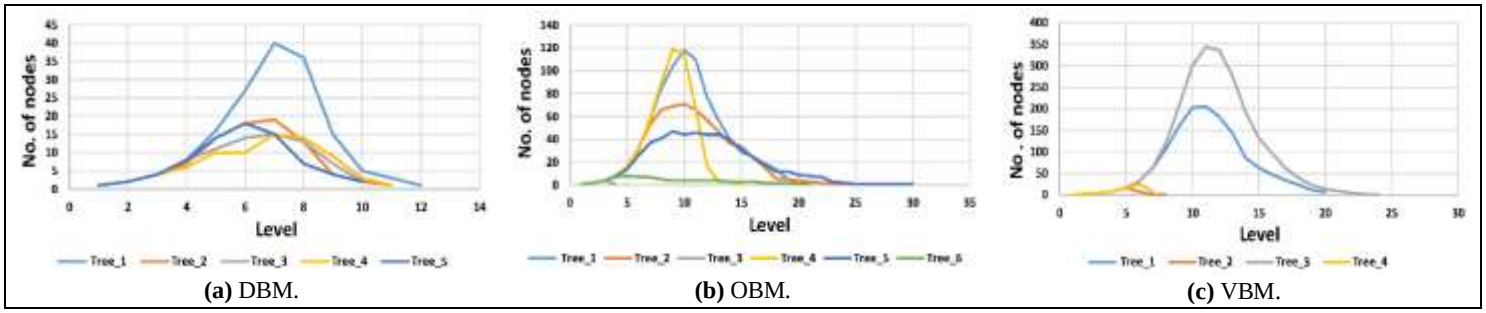


Figure 9: Bucket data distribution using VBM for Tracking datasets.
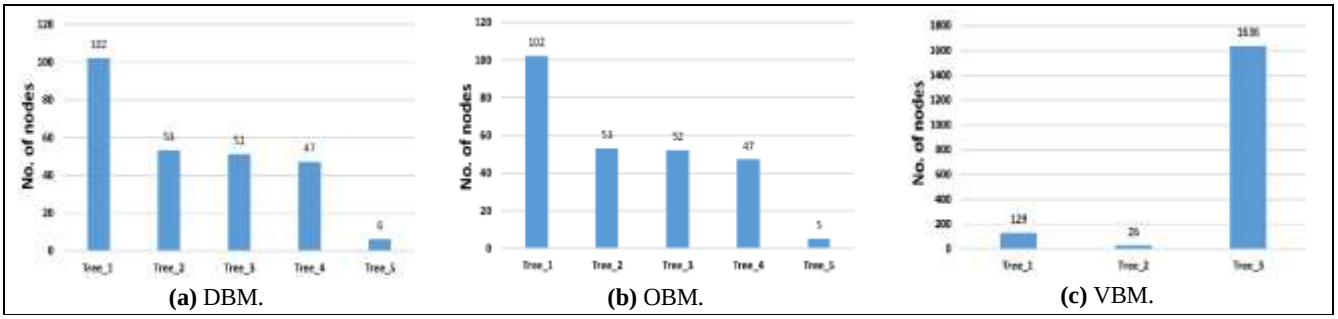
Source: Authors, (2026).



The distribution of nodes at each tree level, shown in Figure 10, further underscores the structural efficiency of these methods. DBM produced trees with a gradual increase in nodes per level, peaking between levels 6 and 8 with a median of 15–20 nodes (Figure 10a). The gradual slope suggests that the tree may remain balanced as the data increases. However, in Tree 5, the slope rapidly decreases, indicating an unbalanced tree, as previously observed. OBM exhibited a similar range of levels, from 6 to 12, but with an increased number of nodes ranging from 17 to 22 and peaks reaching up to 40 nodes. This structure suggests deeper trees with concentrated nodes, which may enhance data partitioning but could also increase traversal costs (Figure 10b). Unlike DBM, OBM's rapid slope suggests that the tree may become unbalanced as the data grows. In contrast, VBM, shown in Figure 10c, displayed a broader node distribution, peaking at around 350 nodes, with levels extending up to 24. The slow slope in VBM indicates its ability to maintain a balanced node distribution across various levels, contributing to a more stable and efficient search process.

(a) DBM. **(b)** OBM. **(c)** VBM.

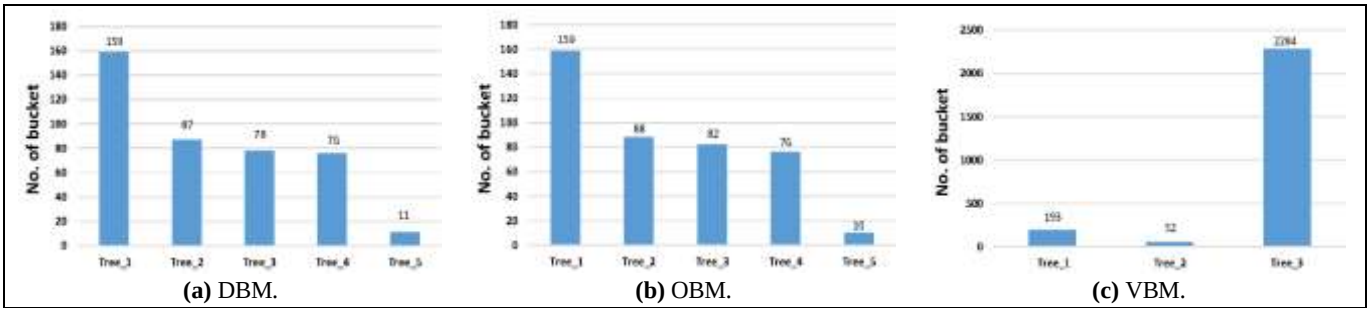


Figure 10: Distribution of nodes across tree levels in the Tracking dataset.
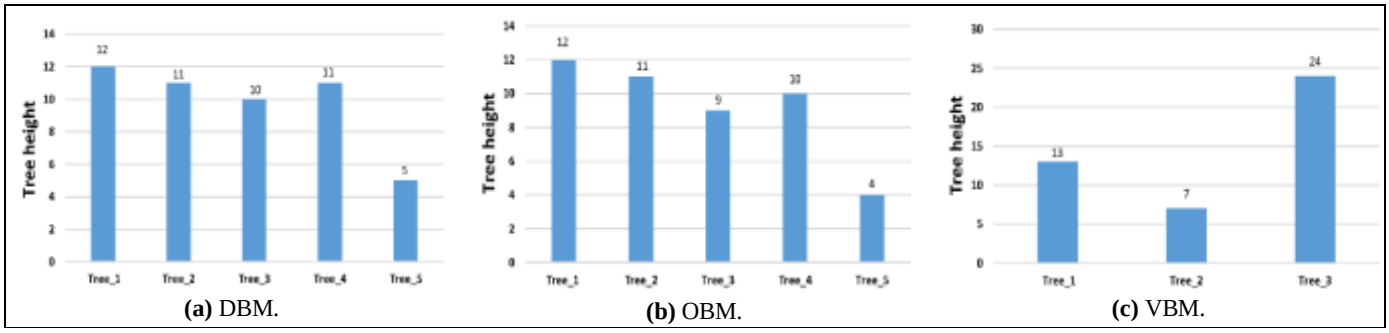
Source: Authors, (2026).

Figures 11, 12, and 13 provide additional insights into the internal structure of the trees. Both DBM and OBM consistently produced balanced trees, with internal nodes ranging from 47 to 102, tree heights between 9 and 12, and leaf nodes ranging from 76 to 159. These results suggest that both methods are effective in maintaining moderate tree depth and efficient partitioning, supporting reliable data retrieval. In contrast, VBM exhibited greater variability, with internal nodes ranging from 26 to 1636, tree heights from 7 to 24, and leaf nodes from 52 to 2284. Despite its larger size across these dimensions, VBM demonstrates a well-filled and balanced structure, making it a highly adaptable solution for managing more complex data distributions.



(a) DBM. **(b)** OBM. **(c)** VBM.

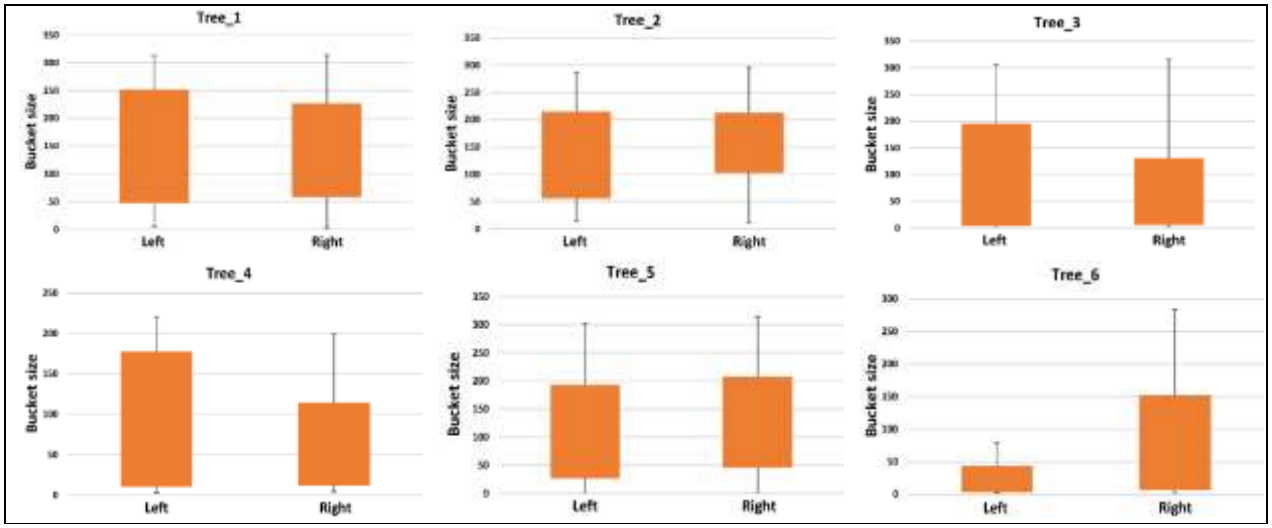
Figure 13: Height of the Trees in the Tracking dataset.
Source: Authors, (2026).

V.2.2 WARD dataset

In the WARD dataset, all three methods continued to perform strongly, showing consistent results across various metrics. DBM maintained median bucket sizes around 120 to 160 in most trees (Figure 14), with only a slight reduction observed on the left side of Tree 6. OBM exhibited uniform distributions, as seen in Figure 15, with median bucket sizes also around 120 to 160 and a peak around 230. VBM similarly maintained median bucket sizes around 250, with a slight reduction on the left side of Tree 6 (Figure 16).



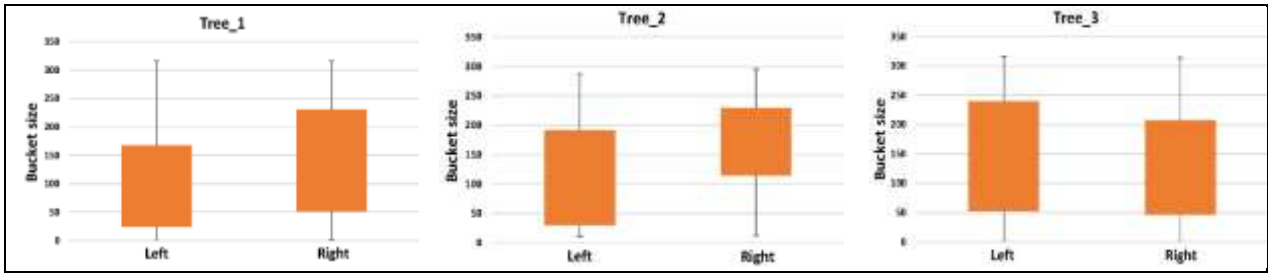


Figure 14: Bucket data distribution using DBM for WARD datasets.

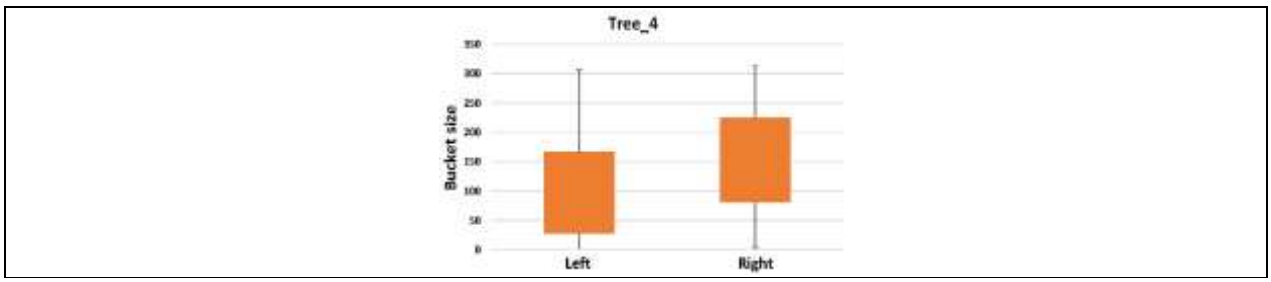

Figure 15: Bucket data distribution using OBM for WARD datasets.
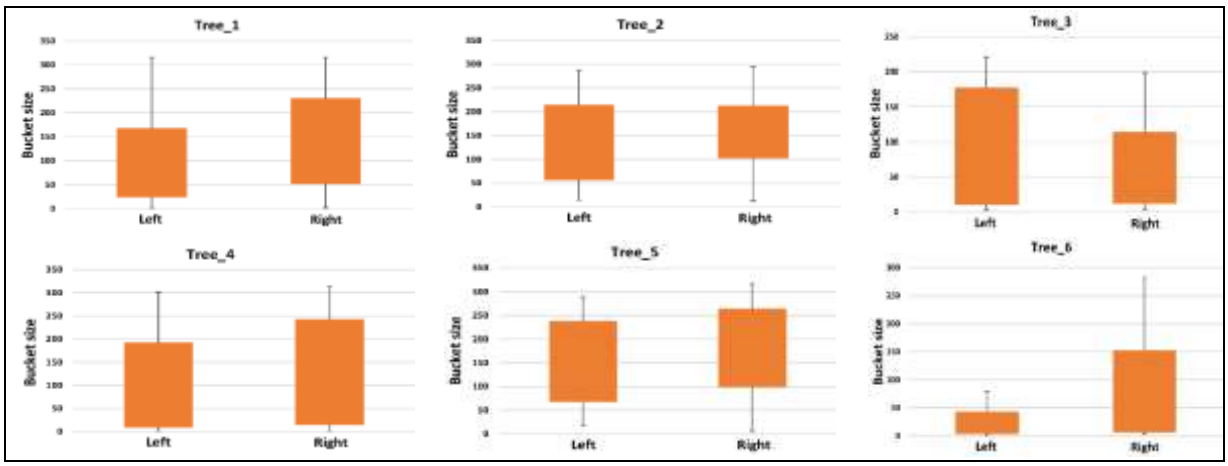
Source: Authors, (2026).



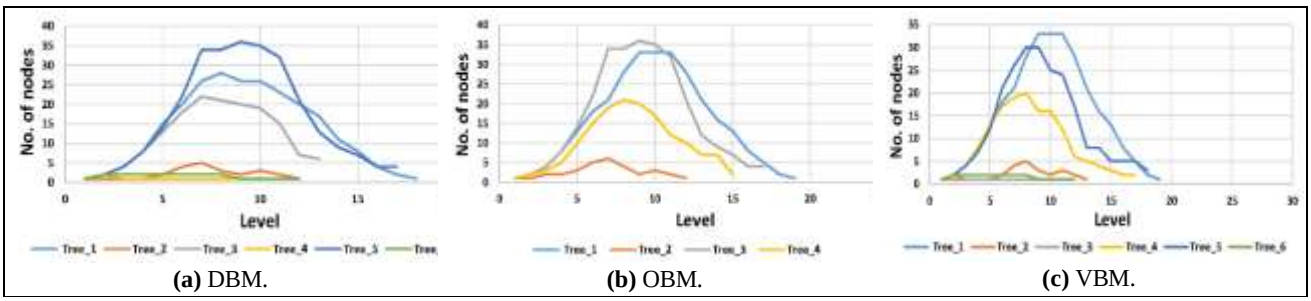


Figure 16: Bucket data distribution using OBM for WARD datasets.
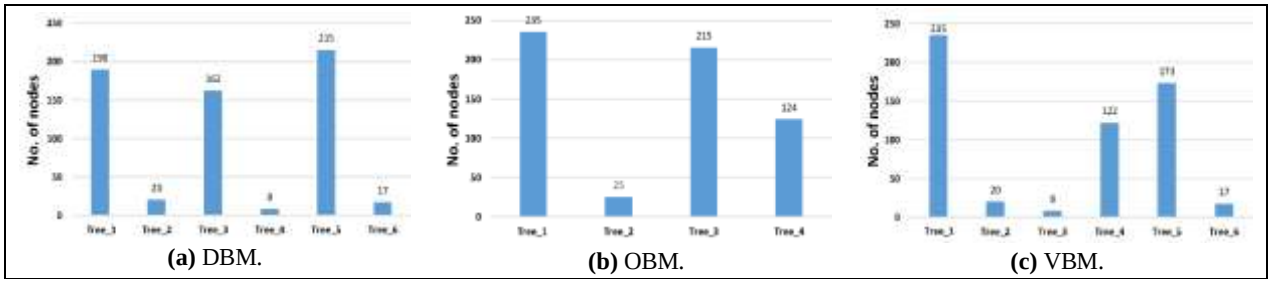
Source: Authors, (2026).



The results of node distribution across tree levels, as shown in Figure 17, reveal consistent performance across all three methods—DBM, OBM, and VBM—with node counts peaking between 30 and 36 at levels 10 to 18. The gradual slopes indicate that each method effectively maintains a balanced distribution of nodes, with tree levels being always well-filled, thereby promoting efficient search operations.

(a) DBM. **(b)** OBM. **(c)** VBM.

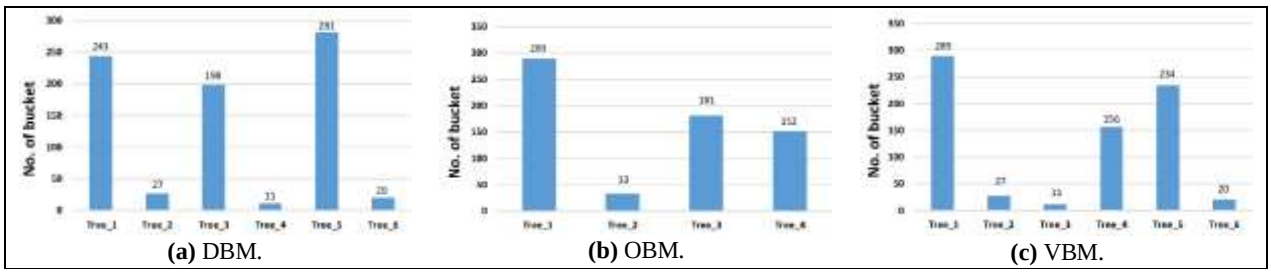


Figure 17: Distribution of nodes across tree levels in the WARD dataset.
Source: Authors, (2026).

Finally, Figures 18, 19, and 20 illustrate the number of internal nodes, leaf nodes, and tree heights for the WARD dataset. DBM and OBM continued to demonstrate balanced structures, with internal nodes ranging from 17 to 215, tree heights between 9 and 19, and leaf nodes ranging from 11 to 281. VBM, once again, displayed a broader range, with internal nodes varying from 8 to 235, tree heights from 9 to 19, and leaf nodes from 11 to 289. This variability highlights VBM's flexibility in managing diverse data complexities and its ability to adapt the tree structure to the specific demands of the dataset.

V.3 CONSTRUCTION COST

To evaluate the performance of the proposed structures compared to the BCCF-tree, we analyzed the construction costs in terms of the number of distances calculated and the number of comparisons made during the construction of indexes. The results, presented in Figure 21, provide a clear comparison of these metrics, with the container size fixed as specified in Table 1.

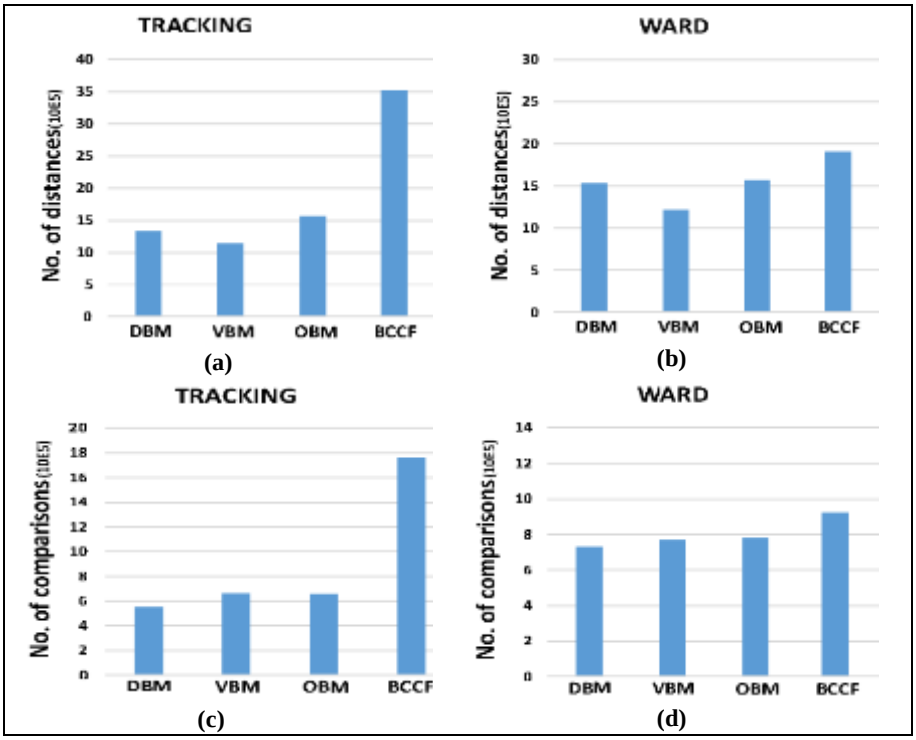

Figure 21: Construction cost.
Source: Authors, (2026).

Across both the Tracking and WARD datasets, the VBM method consistently emerges as the most effective approach. Structural evaluations revealed that VBM produces balanced trees with the flexibility to adapt to varying data complexities, which is directly reflected in its construction costs. In the Tracking dataset, VBM recorded the lowest distance cost at 11.7, compared to 13.6 for DBM and 16.1 for OBM (see Figure 21a), while managing a comparison cost of 6.8, slightly higher than DBM's 5.7 and OBM's 6.5 (see Figure 21c). The trends are reaffirmed in the WARD dataset, where VBM again demonstrates its superiority with a lower distance cost of 12.5, compared to 15.7 for DBM and 16.1 for OBM, as shown in Figure 21b. According to Figure 21d, the comparison cost of VBM in WARD is slightly higher at 7.8, compared to DBM's 7.4, but it remains competitive. Compared to the BCCF-tree, which recorded much higher costs (36.6 in the distance and 17.6 in comparisons), all three methods, particularly VBM, show significant improvements in efficiency across both datasets. This efficiency underscores VBM's ability to maintain a well-distributed structure with minimal overlap.

V.4 SEARCH EFFICIENCY

The similarity search algorithm's performance was evaluated against the BCCF-tree structure by analyzing the average number of distance calculations, comparisons performed, and execution times for fulfilling 100 kNN requests across different k values (k=5, 10, 15, 20, 50, 100). The results of these experiments are presented in Figure 22. In the Tracking dataset, VBM consistently demonstrates superior performance across all metrics. At k = 5, VBM records just 126 distance calculations, significantly lower than DBM's 442 and vastly outperforming OBM's 11,457 and BCCF's 10,573 (see Figure 22a). This trend continues as k increases, with VBM consistently maintaining the lowest distance counts, highlighting its efficiency in managing proximity calculations during searches. In terms of comparisons (see Figure 22c), VBM again outperforms the other methods, recording only 532 comparisons at k = 5, compared to DBM's 1,997, OBM's 13,696, and BCCF's 16,447. This efficiency is further reflected in the search time, where VBM consistently requires the least time across all values of k.

For example, at k = 100, VBM completes the search in just 0.02 seconds, significantly faster than DBM's 0.045 seconds and OBM's 0.07 seconds, while BCCF lags considerably at 1.2 seconds (see Figure 22e). Similarly, in the WARD dataset, VBM continues to outperform the other methods. At k = 5, VBM records 10,686 distance calculations, slightly lower than DBM's 11,268 and significantly better than OBM's 28,717 and BCCF's staggering 191,421 (see Figure 21b). This pattern persists across all k values, with VBM consistently maintaining lower distance and comparison counts, demonstrating its efficiency in processing large datasets. In terms of comparisons, VBM remains strong, with 47,147 comparisons at k = 5, compared to DBM's 50,660, OBM's 129,011, and BCCF's 922,127 (see Figure 22d). This superior performance in both distance and comparison metrics underscores VBM's ability to handle complex data efficiently. Regarding execution time, VBM continues to be competitive, often matching or slightly exceeding DBM's performance while still vastly outperforming OBM and BCCF, especially as k increases (see Figure 22f).

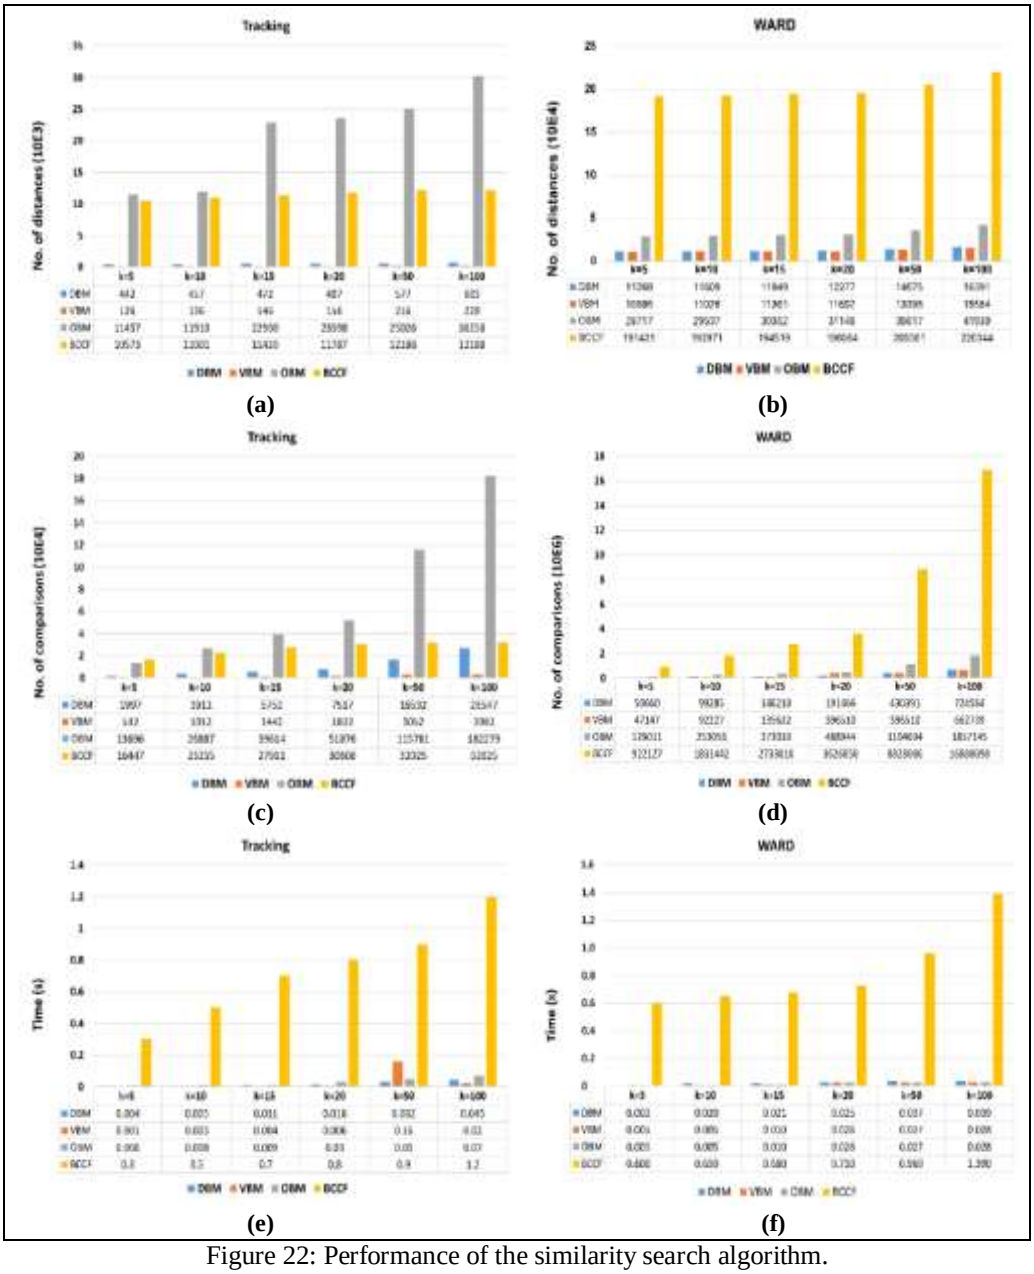

Figure 22: Performance of the similarity search algorithm.
Source: Authors, (2026).

In the final analysis, VBM emerges as the most efficient method for k-NN searches, offering an optimal balance between distance calculations, comparisons, and execution time across both datasets. This superiority is rooted in VBM's advanced approach to overlap management, which minimizes unnecessary computations by precisely calculating intersection volumes, thereby ensuring that search operations remain focused and efficient. DBM, while slightly trailing VBM, demonstrates strong performance with its proximity-based partitioning, which strikes a commendable balance between computational simplicity and effectiveness, though it incurs marginally higher costs. On the other hand, OBM typically incurs increased computational overhead, making it less suitable for large-scale searches. The baseline BCCF-tree consistently underperforms, underscoring the significant advancements and optimizations introduced by the proposed methods, particularly the VBM, in enhancing k-NN search efficiency.

VI. CONCLUSIONS

This paper has addressed the critical challenge of optimizing tree-based indexing structures in the context of massive IoT data. The overlap in data space partitions during index creation has been a significant obstacle, leading to inefficiencies in data retrieval and increased computational costs. To overcome this, we introduced three innovative heuristics: the Volume-Based Method (VBM), the Distance-Based Method (DBM), and the Object-Based Method (OBM), each designed to strategically minimize overlap and enhance the overall performance of the indexing process. Through extensive simulations and comparative analyses, we demonstrated that the VBM consistently outperforms both DBM and OBM, particularly in terms of structural balance, search efficiency, and construction costs. VBM's ability to maintain a well-distributed and adaptable tree structure while minimizing overlap was evident across both the Tracking and WARD datasets, making it the most effective method among the three. DBM followed closely, providing robust performance with slightly higher costs, while OBM, although effective in specific scenarios, generally incurred higher computational overhead due to its detailed partitioning strategy. Moreover, in future work, we aim to further enhance the system's adaptability by exploring dynamic adjustments of overlap thresholds (ξ_{min} and ξ_{max}) tailored to the context and specific characteristics of the data. Additionally, we plan to introduce traceability mechanisms to ensure reliable data monitoring and management across different index structures, optimizing the search space and facilitating more efficient parallel search operations.

ABSTRACT

Coronary Heart Disease (CHD) is the leading cause of illness and mortality worldwide. This is driven by risk factors such as high cholesterol, hypertension, smoking, diabetes, obesity and genetic predisposition. Early detection and management of CHD are critical and involve lifestyle changes, pharmacological interventions, angioplasty, or bypass grafting. Traditional diagnostic methods require effective and timely medical interventions or the early detection of CHD. The proposed work suggests a stacking classifier for early prediction of CHD. Conventional classification models are typically simple, interpretable and efficient, making them suitable for classification problems. The performance of these models is limited when dealing with complex or high-dimensional data. Ensemble models address this limitation by combining the predictions of several models to improve accuracy. Bagging, Voting, and stacking classifiers are more sophisticated ensemble methods that use this concept further by using a metamodel to aggregate the predictions of multiple base models. In this study, several conventional models, such as the SGD Classifier, Logistic Regression, K-Nearest Neighbor, Naive Bayes, Decision Tree, and Random Forest Classifiers are applied to the dataset to predict whether the patient has 10 year risk of Coronary Heart Disease (CHD). Boosting models such as Gradient Boosting, AdaBoost, and XGBoost are also applied. The proposed voting classifier resulted in better accuracy, precision, recall, and other metrics compared with the conventional, boosting, and bagging models.

I. INTRODUCTION

Coronary Heart Disease (CHD), also known as ischemic heart disease, is one of the most common cardiovascular diseases and a major cause of death worldwide. Atherosclerosis, a disorder marked by the build-up of fatty deposits, cholesterol, and other materials in the coronary arteries, is the main cause of CHD, which is a condition that impairs blood flow to the heart muscle. The myocardium receives less oxygen when these arteries gradually narrow or get blocked, it may cause myocardial infarction, angina pectoris, and sudden cardiac death, among other clinical signs. [1]. With millions of deaths annually, CHD continues to be a major global public health concern. The World Health Organization (WHO) has reported that 32% of fatalities worldwide are attributable to cardiovascular illnesses, including CHD. Low- and middle-income countries have disproportionately high illness burdens because they have less access to healthcare and preventive measures. Globally, the incidence of CHD is on the rise owing to aging populations and the rising prevalence of risk factors including diabetes and obesity. The persistent inflammatory condition of atherosclerosis inside arterial walls functions as the main cause of CHD. Chemicals from LDL cholesterol enter the endothelium to form deposits inside artery walls during the first stage because of endothelial dysfunction. An immunological reaction gets launched after oxidized LDL draws monocytes and macrophages which later turn into foam cells that help to form fatty streaks [2]. Artery lumen becomes narrower because fibrous plaques form out of previously developed streaks and reduce blood flow. The formation of a thrombus after plaque rupture leads to total artery blockage thus

causing heart attack or other acute coronary syndromes [3]. The development of CHD depends on both risk factors that people can change and those that cannot be changed. Conflicting variables that people can change include smoking alongside high blood pressure and high cholesterol together with diabetes and obesity while a sedentary lifestyle and poor eating choices complete the list [4]. Two important non-controllable CHD risk factors involve sex-based differences (men face greater risk) and the existence of cardiovascular disease in family history. The development of CHD depends on several newly emerging risk variables that include stress factors together with persistent inflammatory responses and particular gene sequences. The risk of CHD can be considerably decreased by effectively managing modifiable risk factors. Asymptomatic phases to severe, life-threatening illnesses are only a few of the many clinical presentations of congenital heart diseases. Palpitations, exhaustion, shortness of breath, and chest pain or discomfort (angina) are typical symptoms [5]. Stable angina is typified by consistent chest discomfort caused by emotional or physical stress, whereas unstable angina occurs suddenly and is related to a greater risk of myocardial infarction. Prolonged chest discomfort, nausea, sweating, and, in extreme situations, unconsciousness are typical symptoms of myocardial infarction, sometimes known as a heart attack.

Imaging methods, laboratory testing, and clinical evaluation are all used for the diagnosis of CHD. While biomarkers, such as troponin levels, aid in confirming myocardial injury, electrocardiography (ECG) and stress tests are frequently used to evaluate heart function. Imaging techniques that show the amount of blockage and provide thorough visualization of the coronary arteries include echocardiography, computed tomography (CT) angiography, and coronary angiography. Non-invasive techniques for risk assessment and early subclinical disease diagnosis are provided by emerging technologies, such as coronary artery calcium scoring. Medical treatment of CHD requires surgical interventions combined with drugs along with changes to individual lifestyles. Sustaining healthy changes in lifestyle including stopping smoking while starting physical exercise and maintaining proper weight and eating well remain fundamental for slowing disease advancement. Patients with CHD need beta-blockers and statins in combination with ACE inhibitors as well as antiplatelet medications to manage their symptoms while reducing health risks [6]. The medical procedure of both CABG and PCI serves to rebuild cardiovascular blood flow in conditions where substantial artery obstructions occur [7]. Current developments in personalized medicine united with risk-prediction tools have boosted the accuracy of managing CHD.

Primary prevention strategies aim at managing risk factors throughout the general population to reduce CHD incidence [8]. The primary prevention approach relies on three foundational elements that consist of prompt hypertension and hyperlipidemia testing along with community-wide healthy life education and expanded preventive health care facilities. The prevention of future cardiovascular events requires secondary prevention protocol to address patients with high-risk CHD profiles or established CHD through intense risk-factor management and scheduled follow-up. In eight villages in Indonesia's East Java Province's Malang District, Maharani A et al. [9] performed comprehensive household screenings for cardiovascular threat issues in persons aged 40 years and older. The World Health Organization/ International Society of Hypertension's region-specific charts, which take into account factors such age, sex, blood pressure, diabetes status, and smoking behavior, were used to create 10-year cardiovascular risk scores. Adults in Indonesia who are 40 years or older are at high cardiovascular risk, and preventative treatment rates are poor. Population-based and clinical strategies for CVD prevention should be emphasized in both urban and rural regions. This work applies various classification algorithms and ensemble models for the early diagnosis of CHD based on the number of features including sex, age, smoking habit, diabetes, blood pressure, heart rate, and glucose. Section II summarizes the existing work in the field of CHD and the use of conventional and ensemble classification algorithms. Section III discusses the proposed model and the results of the data preprocessing techniques applied to the dataset. The experimental investigations and results are discussed in Section IV. Conclusions of the work are stated in Section V.

II. RELATED WORK

For Heart Disease Prediction (HDP), Jawalkar, A.P., et. al., [10] suggested a method using a Decision Tree-based Random Forest (DTRF) classifier with loss optimization. The findings show that the proposed HDP-DTRF method outperforms conventional techniques, achieving an 85% F1-score, and 96% accuracy on publicly accessible datasets. H. Yang et.al, [11] proposed the HY_OptGBM prediction model, which uses the optimized LightGBM classifier to predict CHD. The most sophisticated hyperparameter optimization framework (OPTUNA) was used in this study to optimize the hyperparameters of the prediction model. CHD data from the Framingham Heart Institute's CHD data was used in this study to assess the prediction model. The proposed model outperformed other comparative models with an AUC score of 97.8%. C. Bemando et. al. [12] developed coronar, the model draws its information from public Cleveland heart disease patient data located at UCI repository. The study confirms that Random Forest achieves 75.00% accuracy while Gaussian Naïve Bayes and Bernoulli Naïve Bayes deliver 85.00% accuracy each. The data analysis demonstrates that the Gaussian and Bernoulli Naïve Bayes models show superior performance compared to Random Forest regarding precision and recall and F-measure which proves their worth for treatment forecasting. The research by Dulani et al. [13] provides an extensive system design approach which combines machine learning methods with Explainable AI (XAI) for developing dependable Coronary Artery Disease (CAD) prediction models.

The main purpose combines two critical tasks: prediction model development in conjunction with SHapley Additive exPlanations (SHAP) analysis which expands model understanding. Different machine learning algorithms were applied through careful system design to determine which model is best for CAD prediction. This study emphasizes the significance of interpretability and predicted accuracy in medical decision making. Shah, D., et. al. [14] discussed heart disease-related features and a model based on algorithms such as random forest, Naïve Bayes, decision tree, and K-nearest neighbor algorithms. This makes advantage of the Cleveland database, which is a UCI archive of people with cardiac illness with 303 samples and 76 features. Only 14 of these 76 characteristics were considered for testing, which is crucial for verifying the effectiveness of various algorithms. The findings showed that K-nearest neighbor yielded the highest accuracy score. In order to provide supplemental medical services, Shan Xu et. al. [15] concentrated on developing a more precise and useful risk prediction system. Both the Cleveland Heart-Disease Database (CHDD) and the PKU People's Hospital Cardiology inpatient dataset were examined to verify their accuracy and usefulness. Our system's accuracy of 91.6% in the CHDD test is noticeably greater than that of other approaches. With the exception of SVM (98.9%), it outperforms most other classifiers with an accuracy of 97% in the People's Hospital dataset test; nevertheless, random forest takes half as long as SVM. A. N. Repaka et.al., [16] focused on diagnosing cardiac disease by taking into account prior data and knowledge to build Smart Heart Disease Prediction (SHDP) using Navies Bayesian

that predicts heart disease risk variables. Dataset collection, application-based user registration and login, Navies Bayesian classification, prediction, and secure data transfer using AES (Advanced Encryption Standard) are the steps in the suggested methodology. The results show that the current diagnostic approach predicts risk factors for cardiac illnesses in an effective manner. Zhenzhen Du et.al., [17] sought to develop a high-precision CHD forecast method using big data and machine learning techniques, based on a sizable group of hypertension patients in Shenzhen, China. With an area under the receiver operating characteristic curve (AUC) score of 0.943, the ensemble approach XGBoost demonstrated significant accuracy in predicting the beginning of CHD within three years for the independent test dataset. On the same datasets, comparison study revealed that machine-learning techniques greatly outperformed fixed models or traditional risk scales, while nonlinear models (K-nearest neighbor with AUC 0.908, random forest with AUC 0.938) perform better than linear models (logistic regression with AUC 0.865). The development of an accurate predictive model by Bhatt CM et.al, [18] aims to reduce cardiovascular disease death numbers. The accuracy rates can rise through implementation of k-modes clustering with Huang beginning as a suggested technique. The analysis utilizes XGBoost (XGB) and Multilayer Perceptron's (MP) as well as Random Forest (RF) and Decision Tree classifier (DT). The evaluation of Area Under the Curve show 0.94 for decision trees alongside 0.95 for XGBoost and 0.95 for random forests and 0.95 for multilayer perceptron's. The accuracy analysis of multilayer perceptron with cross-validation has demonstrated the superior performance among all employed methods reaching 87.28% accuracy.

A combination of a pre-trained Deep Neural Network (DNN) followed by Principal Component Analysis (PCA) for dimensionality reduction through which the prediction occurs by a Logistic Regression (LR) model was presented by Diman Hassan et.al., [19] as a novel approach for Heart Disease (HD) prediction. A DNN + PCA + LR combination was tested on Cleveland HD dataset which is available to the public. The proposed methodology achieved superior accuracy rates compared to existing methods through most measurements according to evaluation results. Mert Ozcan and Serhat Peker analyzed the Classification and Regression Tree (CART) algorithm that serves as a supervised machine learning method for finding decision rules which connect input data to output values and performs cardiac disease predictions [20]. Furthermore, the study's conclusions prioritize the characteristics that affect heart disease. The model's dependability is confirmed by the prediction's 87% accuracy when all performance metrics are taken into account. On testing data, which makes up 85.70% of the entire NHANES dataset, Aniruddha Dutta et.al., [21] developed a CNN architecture with a classification power of 77% to properly classify the existence of CHD patients and 81.8% to successfully classify the nonappearance of CHD cases. This outcome shows that other healthcare studies with a comparable sequence of features and imbalances can use the suggested architecture. Although our suggested CNN model's recall values are similar to those of other machine learning techniques like SVM and random forest, our model is more accurate at predicting negative (non-CHD) cases. C. Beulah Christalin Latha and S. Carolin Jeeva [22] studied ensemble classification, a technique that combines several classifiers to increase the accuracy of weak algorithms. The study's findings show that ensemble methods, such bagging and boosting, perform satisfactorily in determining heart disease risk and are useful in increasing the prediction accuracy of weak classifiers. Ensemble classification helped weak classifiers achieve an accuracy gain of up to 7%.

III. DATA PRE-PROCESSING AND PROPOSED MODEL

The machine learning pipeline requires data pre-processing as its essential first step in order to increase algorithm performance while promoting data quality standards. Data pre-processing requires the transformation of unorganized data into ready-to-train format which organizes information into a structured shape. Regular data pre-processing duties involve encoding categorical data into numbers together with outlier adjustment and feature scaling to normalize ranges and different methods to handle missing data values [23] [24]. Multiple techniques such as feature selection and data augmentation and dimensionality reduction help both boost model effectiveness and stop overfitting phenomena. The pre-processing of data enhances machine learning algorithm efficiency and prediction accuracy because it helps find meaningful patterns [25]. This research delivers a system to detect early coronary heart disease onset among patients and non-patients. Multiple ensemble techniques enhanced both accuracy and prediction stability throughout refined classification modelling processes on the Otto dataset. Bagging, voting, and stacking techniques were used to build ensemble frameworks, and the outcomes of these techniques were carefully examined. The process flow of the suggested model is shown in Figure 1.

III.1 DATASET AND ITS FEATURES

The "Framingham" dataset, which comes from a current cardiovascular study on the people of Framingham, Massachusetts, is openly accessible on the Kaggle website [26]. Determining the patient's 10-year risk of increasing coronary heart disease is the classification goal. Figure 2 displays details about the five patients in a dataset consisting of 4,240 records and 15 features.

III.2 PERFORMANCE METRICS

Classification algorithm performance measures are used to assess the performance of the model with respect to predicting the target classes. The most popular metrics are as follows:

Accuracy – In this measure the ratio of successful instance classifications reflects all total instances.

$$Accuracy = \frac{True\ Positives\ (TP) + True\ Negatives\ (TN)}{Total\ Instances}$$

Precision – The proportion of correctly predicted positive instances among all instances predicted as positive.

$$Precision = \frac{True\ Positives\ (TP)}{True\ Positives\ (TP) + False\ Positives\ (FP)}$$

Recall (Sensitivity or True Positive Rate) – The proportion of correctly predicted positive instances among all actual positive instances.

$$\text{Recall} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}}$$

F1-Score – The harmonic mean of precision and recall, providing a balanced metric.

$$\text{F1} - \text{Score} = 2\text{x}\frac{\text{Precision x Recall}}{\text{Precision} + \text{ Recall}}$$

Specificity (True Negative Rate) – The rate at which negative cases are predicted correctly out of all the real cases of negative.

$$\text{Specificity} = \frac{\text{True Negatives (TN)}}{\text{True Negatives (TN)} + \text{False Positives (FP)}}$$

ROC-AUC (Receiver Operating Characteristic – Area Under the Curve) – This measurement evaluates how effectively the model manages true positive recognition rates (Recall) and wrong positive classifications. A model achieves higher performance when it displays increased AUC values.

Log Loss (Logarithmic Loss) – Quantifies the uncertainty of the model's predictions. Lower values indicate better performance.

$$\text{Log Loss} = -\frac{1}{\text{N}}\sum_{\text{i=1}}^{\text{N}}[\text{y}_\text{i}\log(\text{p}_\text{i}) + (1 - \text{y}_\text{i})\log(1 - \text{p}_\text{i})]$$

Confusion Matrix – The following Table 1 shows a tabular representation of predictions vs. actuals, showing TP, FP, TN, and FN.

Table 1: Confusion matrix.

		Predicted Value		
		Yes	No	
Actual Value	Yes	True Positives (TP)	False Negatives (FN)	**Recall**
	No	False Positives (FP)	True Negatives (TN)	**Specificity**
		Precision	**Negative Predictive Value**	**Accuracy**

III.3 MODELLING AND COMPUTATIONAL ENVIRONMENT

A correlation matrix is a table that illustrates the correlation coefficients among variables in a dataset. It is frequently used in machine learning to find redundant or strongly correlated variables as well as to comprehend the links between various aspects. This improves interpretability by using colour gradients and annotation to visualize the matrix and is shown in Figure 3. Compared to all the independent data, the correlation coefficient between education and target variable TenYearCHD is very low and actually negative.

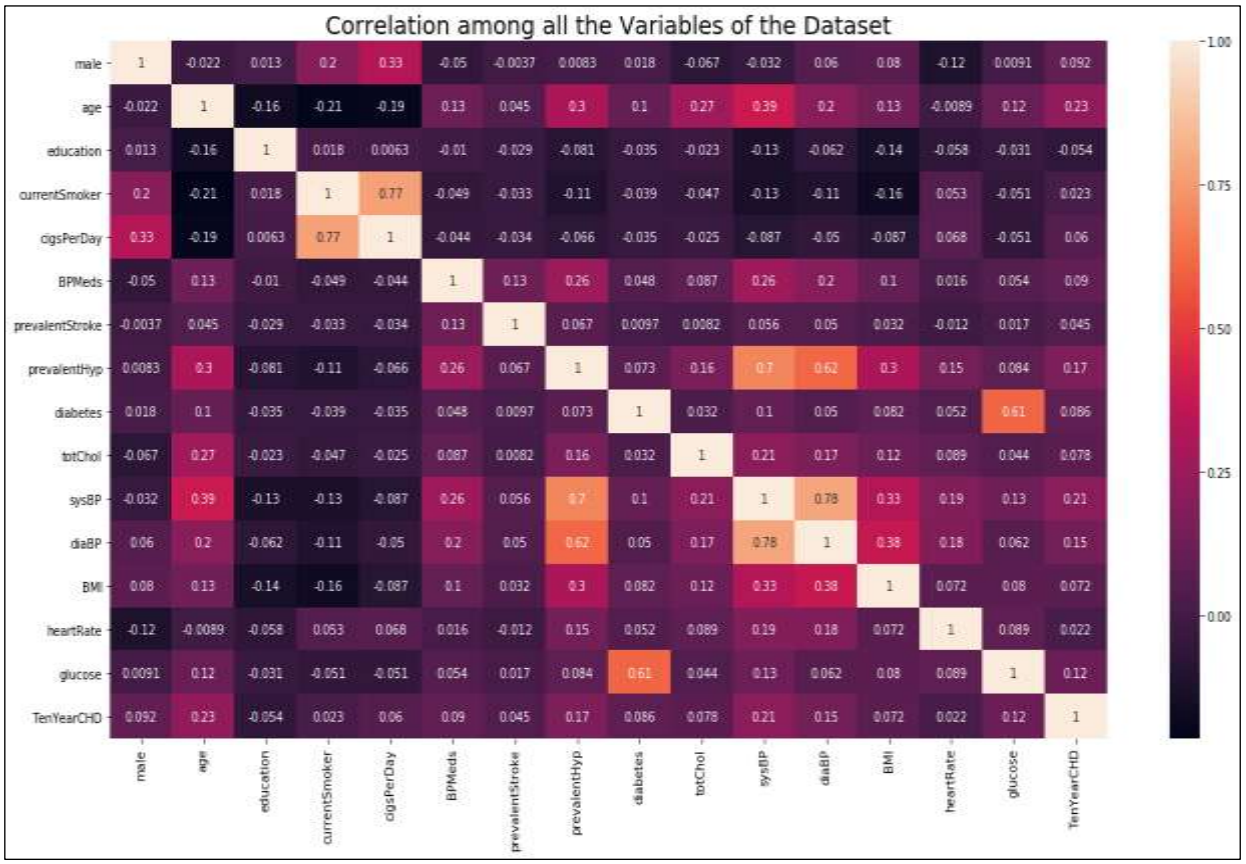

Figure 3: Correlation heatmap for dataset.
Source: Authors, (2026).

III.4 DATA ANALYSIS

III.4.1 Univariate Analysis

The study and analysis of a single variable within a dataset is known as univariate analysis. Summarizing and comprehending the properties of individual variables, such as their distribution, central tendency, dispersion, and possible anomalies, is a basic stage in exploratory data analysis (EDA). Observations from the categorical features

- BPmeds, prevalentStroke and diabetes are highly imbalanced.
- There are four levels of education whereas the rest categorical features are all binary.
- CurrentSmoker has nearly an equal number of Smokers and non-Smokers.

For the plots shown in Figure 4 observations made for numerical features are

- cigsPerDay does not have even distribution but the majority of the data is at 0
- The majority portions of the following columns lie in the range:
  - totChol: 150 to 300
  - sysBP: 100 to 150
  - diaBP: 60 to 100
  - BMI: 20 to 30
  - heartRate: 50 to 100
  - glucose: 50 to 150

The class distribution of data in the dependent feature TenYearCHD is highly imbalanced. As it were, the number of negative cases are more than the number of positive cases. This would cause class imbalance issue during the process of fitting our models. Consequently, this issue needs to be managed and handled. So, the dataset is resampled by oversampling positive cases and the classes are now balanced for model fitting. The Fig. 5 shows the distribution before and after resampling.

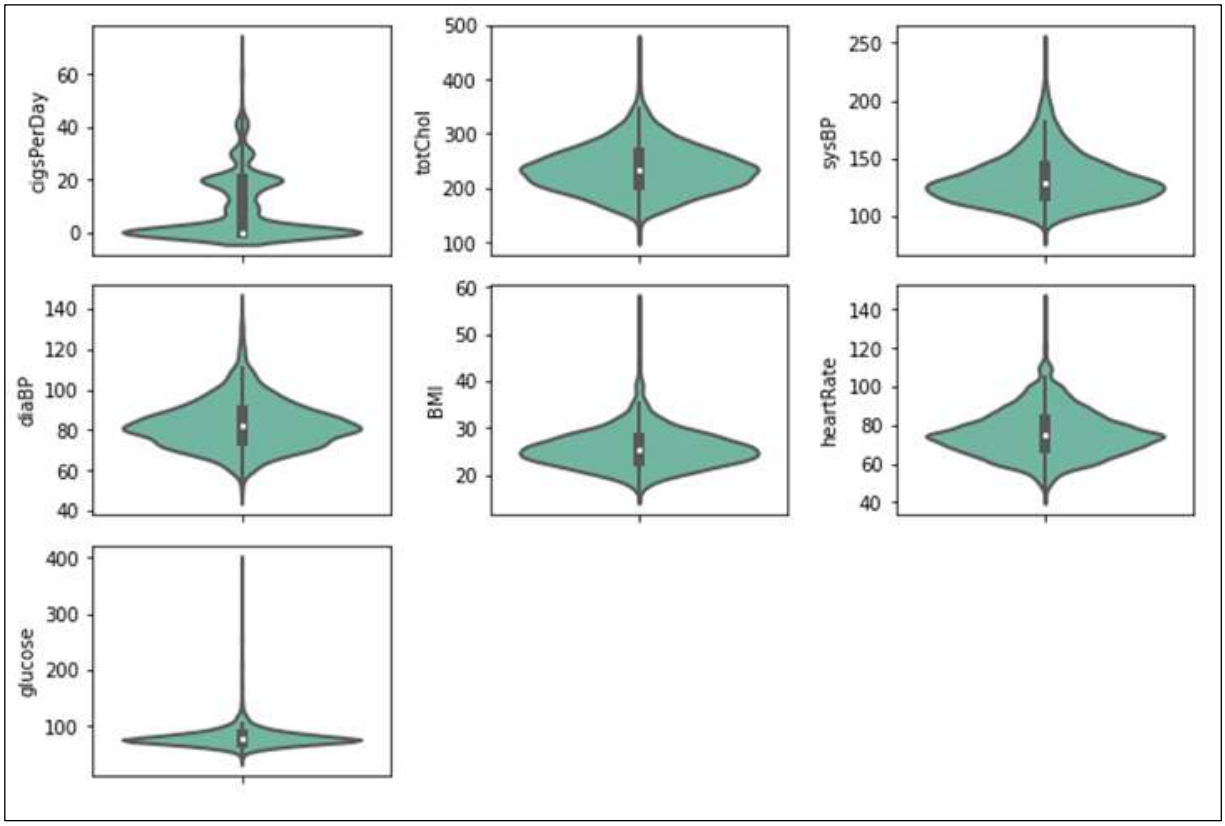

Figure 4: Data distribution in numerical features.
Source: Authors, (2026).

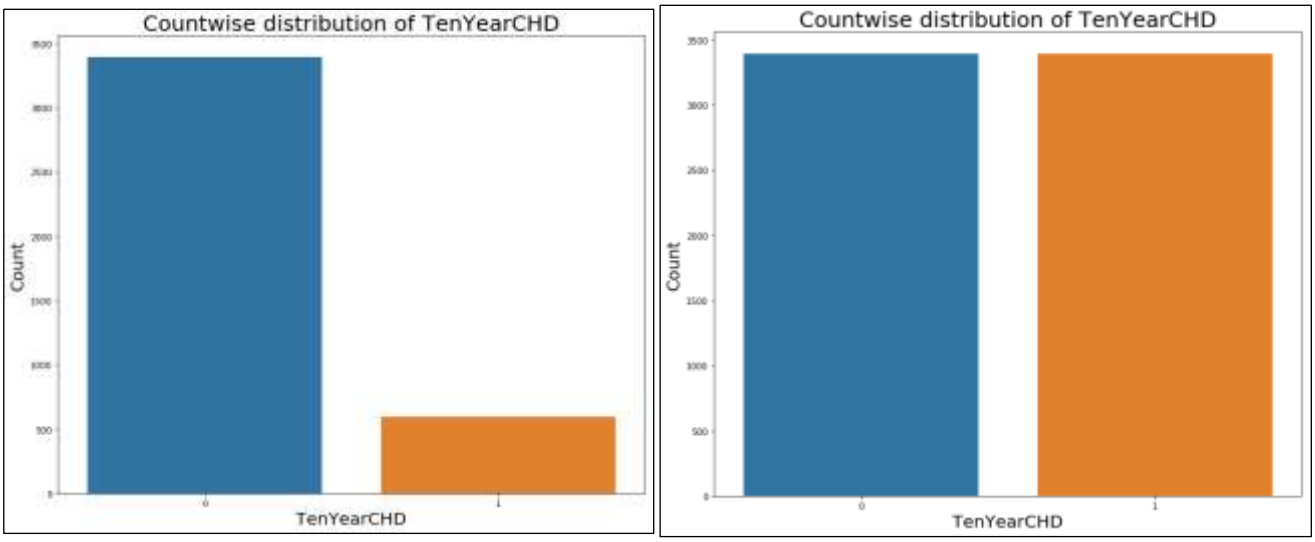

Figure 5: Before and after resampling TenYearCHD.
Source: Authors, (2026).

III.4.2 Bivariate Analysis

Bivariate analysis looks at how two variables in a dataset relate to one another. It is a crucial phase in exploratory data analysis (EDA) and aids in identifying patterns, trends, or relationships. Different methods and visualizations are employed depending on the kind of variables (numerical, categorical). From the visualization shown in Figure 6, it can also be seen that Mid-age groups between or after age 38-46 contain more currentSmokers. There is no below 32 year old currentSmokers and the maximum age of a currentSmokers is 70. The upward shift of the boxplots in Figure 7 indicates that adults had higher levels of cholesterol (bad cholesterol in general). Other observations made in this bivariate analysis are

- Non-smokers, i.e. a cigsPerDay of 0.0, are at a very low risk of developing the disease.
- Those with sysBP between 72-130 have a reduced risk of getting the disease.
- Minor relation found between higher risks of TenYearCHD with higher diaBP.
- Individuals who have diaBP of up to 80.0 are less likely to be affected by the disease.

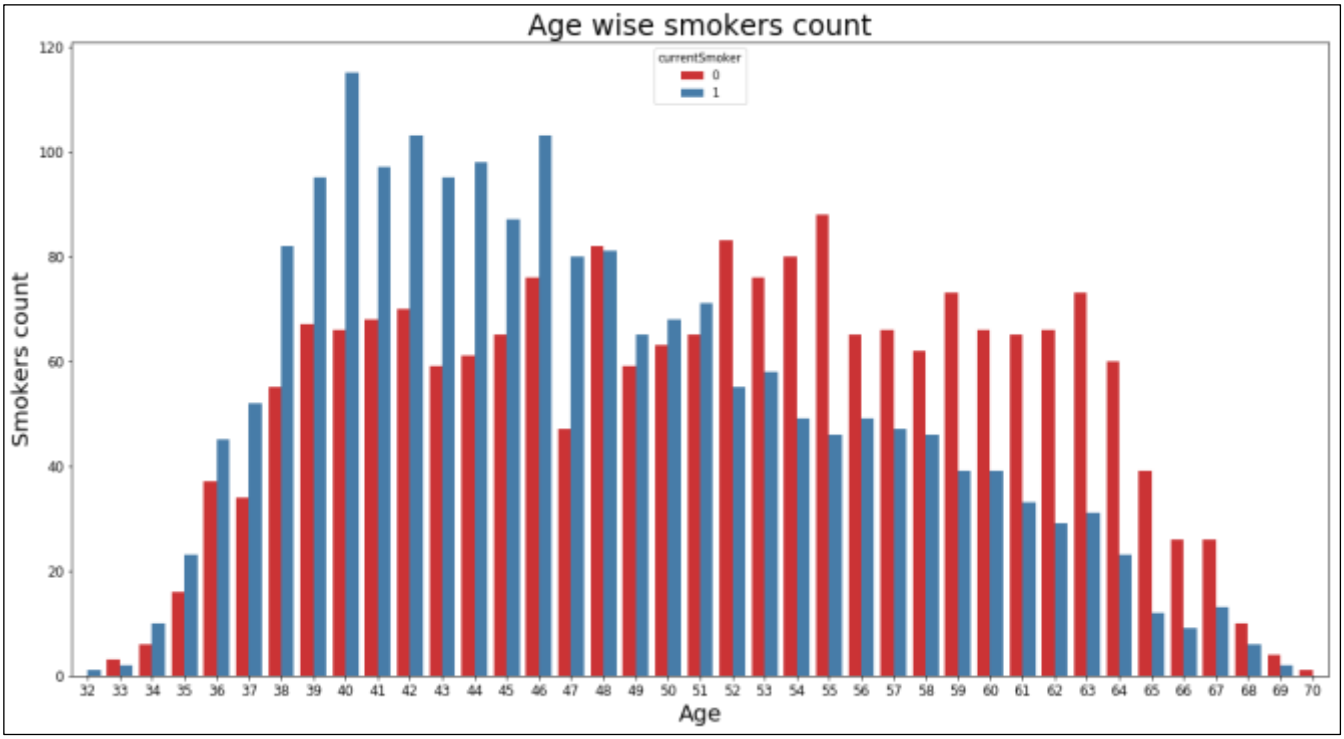

Figure 6: Age vs Smokers count.
Source: Authors, (2026).

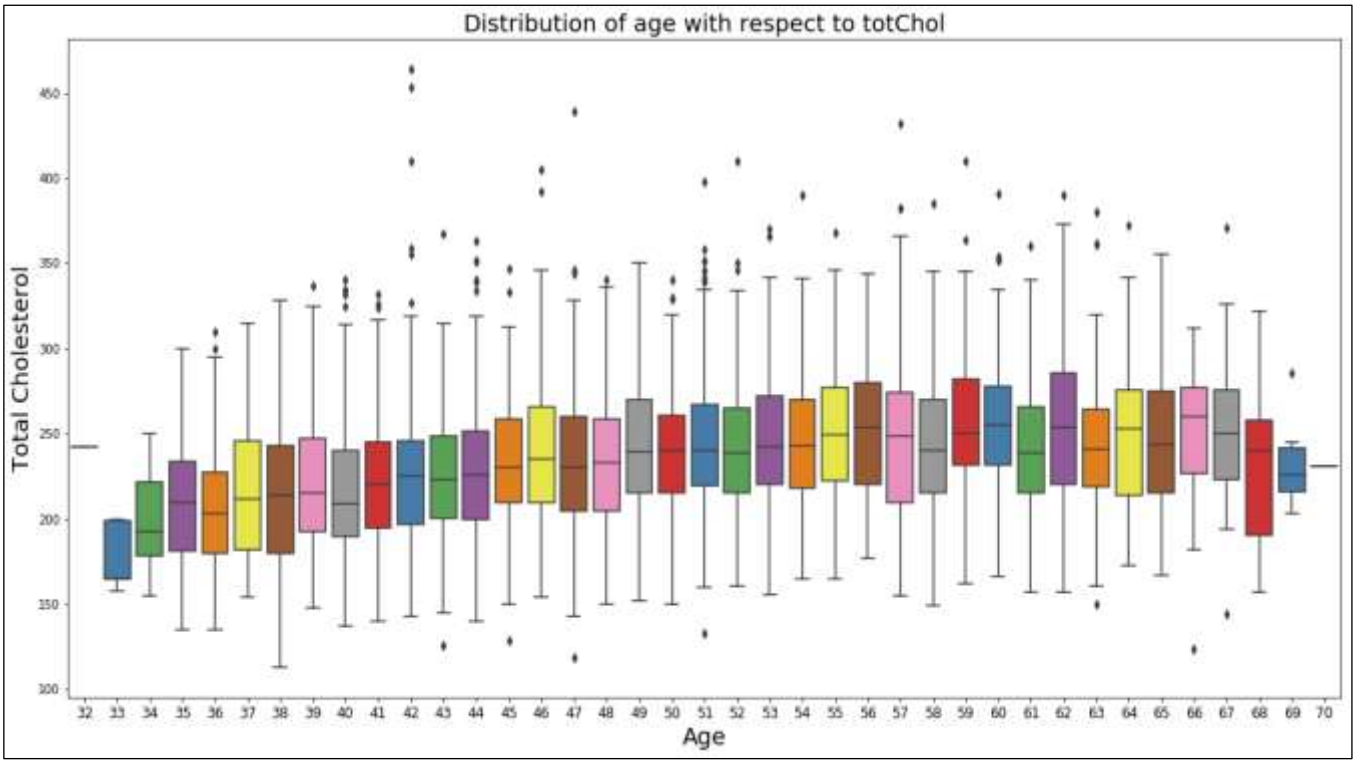

Figure 7: Distribution of Age with respect to Total Cholesterol.
Source: Authors, (2026).

III.4.3 Feature Selection

Using machine learning requires identifying and choosing the most important features contained in a dataset in order to enhance model accuracy as well as lower its complexity. It eliminates irrelevant or redundant data, which can lead to overfitting, increased computational cost, and decreased interpretability. The plot in Figure 8 shows the features and their respective chi-square test scores. The top ten features are selected for implementing the algorithms.

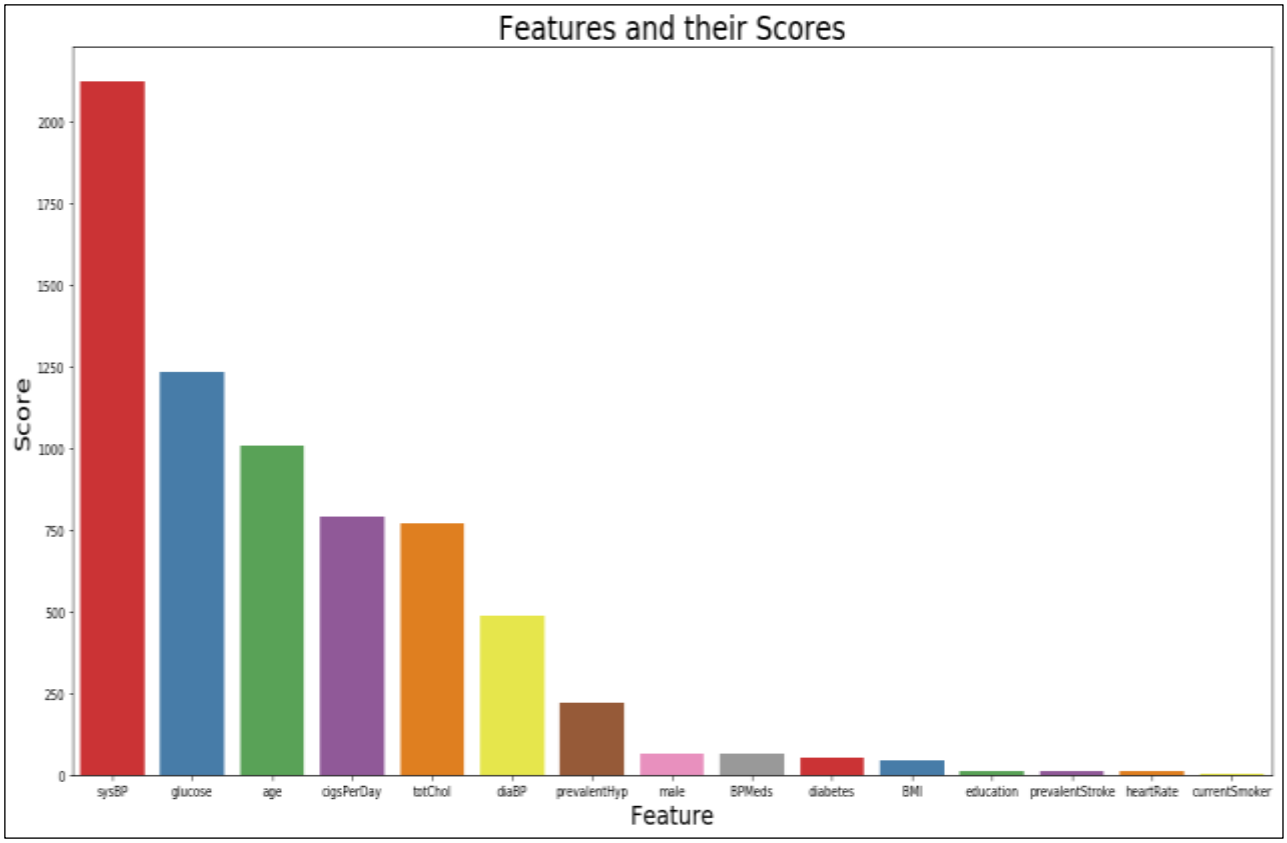

Figure 8: Features and their Chi-scores.
Source: Authors, (2026).

III.5 DATA PREPARATION

In general, the data in numerical features are of different scales and it needs to ensure that all features are on the same scale, making the model training process more stable and effective. In data science, normalization is the process of standardizing numerical data to fall into a predetermined range, usually between 0 and 1. It ensures that every feature makes an equal contribution to the analysis and keeps models from favouring features with larger scales. Min Max Scalar is applied to scale the data. The dataset is split into train and test in the ratio of 80:20.

IV. RESULTS ANALYSIS AND DISCUSSION

IV.1 CLASSIFICATION ALGORITHMS RESULTS

In this study, the dataset is trained using ten classification algorithms. Performance of these algorithms is related with respect to the metrics – Accuracy, Specificity, Precision, Recall, F1-Score and F2-Score. The Table 2 and Table 3 illustrates the results of classification algorithms on the train and test dataset respectively. From the Table 2 it is evident that, KNN Classifier, Decision Tree Classifier and XG Boost are giving 100%, 100% and 98.95% accuracy and it needs to be verified for test data also. For the test data, these algorithms are giving 93.37%, 90.86% and 91.23% accuracy. These results shows that KNN Classifier not fall under overfit problem. The confusion matrices for these three classifiers are shown in Figure 9 and KNN Classifier has made 90 wrong predictions out of 1358 samples.

Table 2: Train set results.

S.No.	Model	Accuracy	Precision	Recall	F1 Score	F2 Score

IV.2 ENSEMBLE MODEL RESULTS

Ensemble models are a dominant tool in machine learning that combine multiple individual models to increase overall performance and robustness. By leveraging the strengths of diverse algorithms, ensemble methods can attain higher accuracy and superior generalization compared to single models. Techniques such as bagging, boosting, and stacking help reduce variance and bias, leading to more reliable predictions. The model creation process of bagging produces several models with different training data segments while boosting applies successive model optimization to tackle past prediction mistakes. A stacking method consists of creating an additional model which learns to combine predictions made by various base models. Ensemble models which use the Voting Classifier produce improved performance through the combination of multiple machine learning models. The model assembles multiple model predictions into one prediction through a majority vote for classifications and average value computation for regression problems. The two voting forms include hard voting which depends on the models' majority class predictions as well as soft voting that utilizes the individual models' averaged prediction probabilities.

Other than their practicality Ensemble models become the preferred framework for complex prediction problems which span across different application domains. Several techniques under ensemble models work together to improve predictive performance while maintaining unique methods for uniting multiple models. The current research applied three ensemble models which included bagging and stacking in addition to voting. Tables 4 and 5 exhibit the results for train and test data after the top-performing algorithms from Table 3 are chosen. XG Boost, KNN, and Random Forest classifiers are used in the suggested voting classifier, which produced an accuracy of 94.25% for test data. XG Boost, Random Forest, and Decision Tree are used as base classifiers for stacking classifier, while KNN is used as the final classifier. For both train and test data, this classifier produced 100% and 92.19% accuracy, respectively. Fig. 10 displays the confusion matrices for the three proposed ensemble models. The voting classifier outperforms the KNN classifier in terms of accuracy. Table 6 presents the results of other performance metrics and voting classifier resulted with 98.87 for ROC AUC mean.

V. CONCLUSION

A unique ensemble approach for categorizing patients and predicting their risk for CHD was proposed in this paper. Make sure to perform pre-processing in order to comprehend the data, identify correlations between features, eliminate noisy data, balance data in two classes in the dependent feature, and extract contributing features. To manage the entire experiment with different evaluation factors such as specificity, recall, sensitivity, precision, accuracy, F-score, and confusion matrix, a Python implementation platform was used. The dataset was integrated with 4240 patients who may have a risk of coronary heart disease. KNN Classification has the best accuracy among the eight classification algorithms: SGD Classifier, Logistic Regression, Naïve Bayes, Decision Tree, Random Forest, Gradient Boosting, Ada Boosting, and XGBoost. Its training and testing accuracies are 1.0 and 0.93, respectively. The dataset is subjected to ensemble techniques like bagging, voting, and stacking classifiers. Using the best-performing classifiers – KNN, Random Forest, and Decision Tree—a voting classifier is suggested. For both train and test data, the suggested approach achieved model accuracy of 0.99 and 0.94. The ROC AUC Mean and Accuracy Mean for the work are 98.87 and 96.02, respectively.

ABSTRACT

A silent epidemic, cardiovascular diseases (CVDs) continue to be the primary reason for loss of life around the globe. This emphasizes the critical need for early-stage risk prediction models for CVDs. This implementation aims to use an existing model for CVD risk prediction, which will be AI-driven and reliable. The main objective is to use machine learning techniques on medical datasets, it also focuses on transparency of the model along with user experience to ensure its implementation in the healthcare sector. The model utilized key clinical features that were selected using distinct feature selection methods, namely analysis of variance, mutual information, and chi-square. The feature groups selected were CRF-1, CRF-2, CRF-3, CRF-4, and CRF-5, respectively. The dataset was preprocessed with SMOTE (Synthetic Minority Oversampling Technique), which helps to resolve class imbalance. All machine learning algorithms were evaluated using Stratified K-Fold Cross Validation and Randomized Search Cross Validation. The final model's interpretability was enhanced by integrating Explainable AI (XAI) techniques, especially Shapley Additive Explanations (SHAP) and Local Interpretable Model-agnostic Explanations (LIME). Among the algorithms tested, the Multi-Layer Perceptron (MLP) Classifier with CRF-1 achieved an AUC of 0.98 with an accuracy of 96.72%. This makes the prediction more interpretable for the healthcare professionals and patients.

I. INTRODUCTION

The implementation focuses on the cardiovascular system present in the body. The cardiovascular system has the responsibility of circulating oxygenated blood in the body. If this cardiovascular system malfunctions, it can lead to various cardiovascular diseases (CVDs). These malfunctions arise from factors like blocked arteries or impaired heart function and thus pose significant health risks across the globe. This highlights the condition's prevalence on the rise, and it is therefore crucial to implement effective strategies to manage and reduce its impact. The rapid integration of computer science into healthcare has shown significant advancements in biomedical devices. These biomedical devices are responsible for generating vast amounts of complex medical data. The traditional manual analysis of these data is not only time-consuming but also inefficient.

Machine Learning (ML) models are capable of processing these large medical datasets and extracting meaningful insights, thus helping healthcare professionals in the decision-making process. Significant advancements have been made in recent years in machine learning to develop predictive models for cardiovascular disease by leveraging both private and publicly available datasets. Some research has successfully addressed data imbalance using techniques like SMOTE. [1] Similarly, other studies have highlighted how the integration of ML is helpful in identifying the early symptoms of cardiovascular risks. The evaluation of various algorithms has demonstrated ML's capacity to enhance predictive accuracy and assist healthcare professionals. [2]

Building on these foundations, the Cardiovascular Risk Prediction (CVRP) model aims to develop an ML model that analyzes various patient attributes and generates predictions to assist doctors and physicians as a pre-report. To ensure the reliability of our model, we assess the accuracy of multiple algorithms and fine-tune them for comparative analysis.

II. THEORETICAL REFERENCE

II.1 LITERATURE SURVEY

Numerous researchers have applied diverse ML techniques to predict CVDs. These researchers leverage the utilization of well-known datasets such as the Cleveland, UCI, and Framingham Heart Disease datasets. As detailed in Table 1, an author Hosam F. El Sofany et al. demonstrated the effectiveness of combining multiple classifiers like Decision Tree, SVM, Naïve Bayes, XGBoost, and AdaBoost for enhanced prediction. Another study in 2023, Mana Saleh Al Reshan et al. proposed a distinct method by introducing a hybrid deep learning-based architecture that used preprocessing and feature learning techniques to analyze these same public datasets.

Table 1: Related work.

Year	Author	Dataset Used	Technique used
2024	Hosam F. El-Sofany et al.[1]	Cleveland HD dataset, private HD dataset (from Egyptian specialized hospitals)	SVM, NB, DT, XGBoost, KNN, RF, Voting, AdaBoost
2023	Mana Saleh Al Reshan et al.[6]	Cleveland HD dataset	DL, Hybrid architecture, feature learning, data preprocessing
2021	Liu et al.[7]	UCI Heart Disease	RF, KNN, SVM, NB
2021	Aqsa Rahim et al [8]	Framingham, Cleveland HD and Cleveland	LR, KNN, SMOTE
2020	Hussein et al. [9]	Cleveland HD	DT, KNN

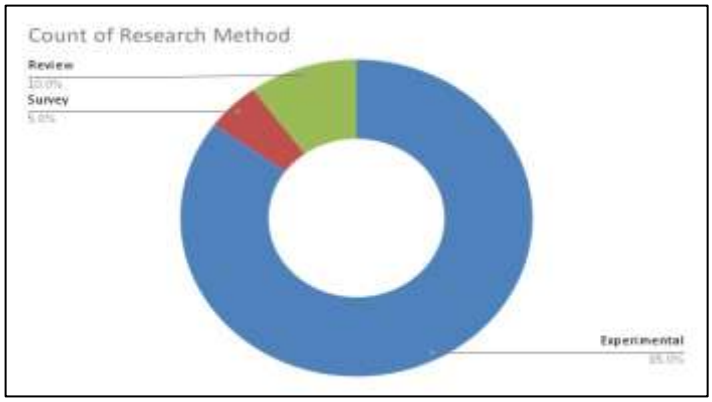

Figure 1: Distribution of different Research Methods in Research Papers
Source: Authors, (2026).

In the Figure 1, the distribution of different research methods used by researchers in 20 papers is shown. A total of 85% of the research is experimental, as shown by the largest slice. For review-based studies, it is a smaller portion of 10%. The smallest slice represents that a survey-based approach was used, accounting for 5%. Figure 2 provides a summary of ML algorithms that are most frequently used in the research papers. The size of each bar corresponds to the total number of research papers that have used a particular algorithm. This helps to identify the most prevalent algorithms in this specific domain. It also indicates which techniques are currently favored by the research community.

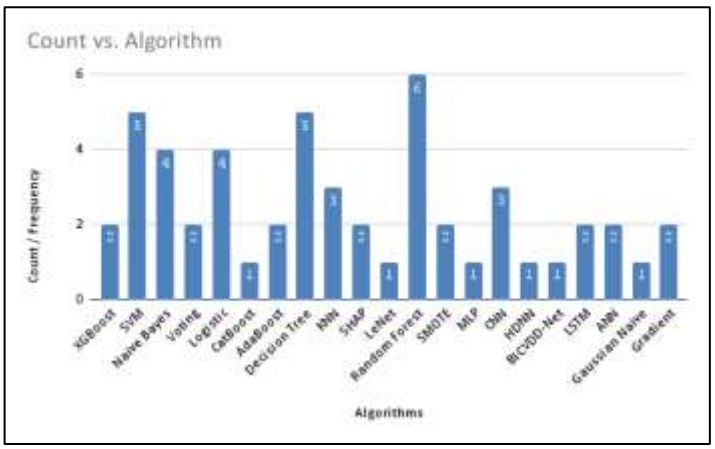

Figure 2: Frequency of Algorithms Used in Research Papers.

II.1.1 Working Principles of Classifiers

i) XGBoost / LightGBM: XGBoost/LightGBM train trees sequentially, correcting previous errors (boosting). LightGBM specifically optimizes by leaf-wise tree growth and uses Gradient-based One-Side Sampling (GOSS) for efficiency.
General form of prediction (As shown in equation 1)

$$\hat{y}_i = \sum_{k=1}^{K} f_k\,(xi), \qquad f_k \in F \tag{1}$$

where f_k are decision trees and K is the number of trees.
Objective function (As shown in equation 2):

$$\text{Obj} = \sum_{i=1}^{n} l\,(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega\,(f_k) \tag{2}$$

where l is the loss and Ω is the regularization term, which helps to avoid overfitting. ii) MLP (Multi-Layer Perceptron): It is characterized by feedforward structure and multiple layers.

Forward pass equation (Refer to equation 3):

$$h^{(l)} = \sigma\,(W^{(l)} h^{(l-1)} + b^{(l)} \tag{3}$$

where $h^{(l)}$ is the output of layer l, W is weight matrix, b is bias, and σ activation (ReLU, sigmoid, etc.).
Final prediction (As shown in equation 4):

$$\hat{y} = \sigma(W^{(L)} h^{(L-1)} + b^{(L)} \tag{4}$$

Training uses backpropagation with gradient descent (represented by equation 5):

$$W \leftarrow W - \eta \frac{\partial L}{\partial W} \tag{5}$$

where L is the loss function and η is the learning rate.

iii) Random Forest: It builds multiple independent decision trees on different bootstrapped samples of the dataset. It trains all trees independently in parallel (bagging). It is represented in equation 6.

$$\hat{y} = \frac{1}{T} \sum_{t=1}^{T} h_t(x) \tag{6}$$

where T = number of trees, $h_t(x)$ is the prediction from tree t and $\hat{y}$ is final aggregated prediction. iv) AdaBoost: It combines weak learners into a strong classifier. After each round, it increases the weights of misclassified samples, and then the next learner is allowed to focus more on those "hard" cases. The final prediction is a result of the weighted vote of all the weak learners.
Mathematical Representation:

a. Assign initial equal weights:

$$w_i = \frac{1}{N},\ i = 1,2,\ldots,N \tag{7}$$

b. Train weak learner $h_m(x)$ Compute weighted error.

$$\epsilon_m = \frac{\sum_{i=1}^{N} w_i I(y_i \neq h_m(x_i)}{\sum_{i=1}^{N} w_i} \tag{8}$$

c. Compute learner weight (importance):

$$\alpha_m = \frac{1}{2} \ln\left(\frac{1-\epsilon_m}{\epsilon_m}\right) \tag{9}$$

d. Update sample weights:

$$w_i \leftarrow w_i \cdot e^{\alpha_m I(y_i \neq h_m(x_i))} \tag{10}$$

e. Final strong classifier:

$$H(x) = sign\left(\sum_{m=1}^{M} \alpha_m h_m(x)\right) \tag{11}$$

II.1.2 CVRP System Architecture

The CVRP model is designed to analyze the risk of having CVD using various ML classification algorithms. The system architecture comprises three main layers: Frontend, Backend, and Database (As shown in Figure 3). The database used is available on the Kaggle platform. It comprises of 13 key clinical features that help to analyze the potential risks of having CVD. These attributes include a patient's age, gender, chest pain types, maximum heart rate reached, cholesterol, and more. The frontend is designed to provide a user-friendly interface that can be used to input health data by healthcare professionals and patients. This was made possible by using Gradio, it allows user to enter health data and receive an instant output about their cardiovascular risk level. The backend is responsible for the core logic. It includes data preprocessing using SMOTE, the evaluation of the ML algorithms, and the selection of the MLP Classifier model based on performance. The backend also integrates XAI techniques, which helps maintain the transparency of the model. A downloadable PDF report is generated for a summary of results.

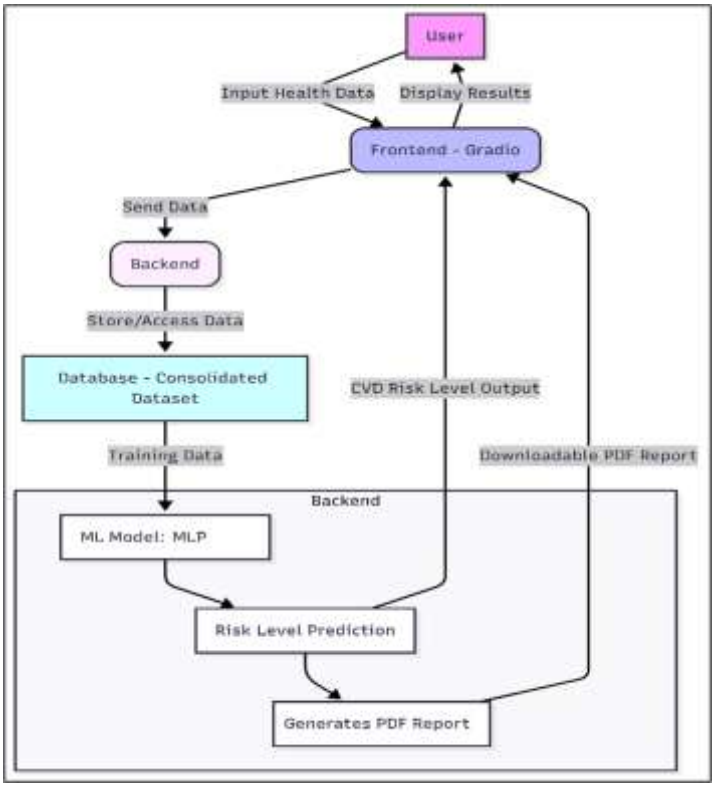

Figure 3: The CVRP System Architecture.

III. MATERIALS AND METHODS

The approach used for the CVRP model is explained in this section. The first step starts with gathering and preprocessing the dataset to prepare it for model training.

III.1 DATA PREPROCESSING

The dataset used is publicly available, it consists of 13 features, an entire summary of these features and their descriptions is mentioned in Table 2. For building any model, the most crucial task is data preprocessing. As we are dealing with medical data, data preprocessing was done with the help of tools like NumPy and pandas to ensure that we have a clean and ready dataset for training. All the missing values were handled carefully, and duplicated records were eliminated. This helps to prevent any bias or errors in the training process. The processed data was then split into two portions: 80% for training, 20% for testing.

Table 2: Features in the Dataset.

Sr. No	Attribute	Variable Name	Attribute Description	Values of Attributes
1	Age	age	Age of the person	Age in number
2	Gender	gen	The gender of the patient (0 represents female and 1 represents male)	F = 0, M = 1
3	Chest_Pain_Types	cpt	The type and severity of chest pain felt by the patient (ASY, ATA, NAP, TA)	0,1,2,3
4	Resting_BP	rbp	Denotes the patient's resting blood pressure (mm Hg)	Values between 94 and 200
5	Cholesterol	chol	Reflects the chol level measured (mg/dL)	Values between 126 and 564
6	Oldpeak	op	During physical exertion, the maximum heart rate	Values between 0 to 9.0
7	Resting_ECG	recg	Shows the patient's resting electrocardiogram. (LVH, Normal, ST)	0,1,2
8	Fasting_BS	fbs	Range of fasting blood sugar (greater than 120 mg/dL (1 = true, 0 = false))	0,1
9	Exercise_Angina	ang	Exercise-induced chest pain. (1=yes, 0=no)	0,1
10	Slope	st	ST-segment slope during peak exercise (Upsloping=2, Flat=1, and Downsloping=0), which helps assess the patient's cardiac response to stress.	0,1,2
11	Max_HR	thalach	shows the maximum heartbeat of the patient	71 to 202
12	Fluoroscopy	ca	Fluoroscopy colored main vessels count	0 to 3
13	Thallium	ths	Thallium stress (negative=0, positive=1 and inconclusive=2)	0 to 2
14	Target		This is the target or output variable in the dataset, representing binary classification. A value of "0" = lower likelihood of heart disease, while "1" = a higher risk. This classification is determined based on patterns across the other 13 input attributes.	0,1

Source: Authors, (2026).

III.2 CLASS IMBALANCE IN THE DATASET

The data was successfully preprocessed, and now we had to tackle the issue of data imbalance. Medical datasets usually have this common problem where one outcome occurs far less frequently than the other. To resolve this problem, we applied SMOTE to the training data. SMOTE balanced the dataset by creating synthetic examples for the less frequent class. This ensures that the model would not become biased towards the more common outcome (majority class). This step was crucial for building a more reliable CVRP model that provides fair and accurate predictions across all classes, especially for those at higher risk.

III.3 THE CVRP MODEL IMPLEMENTATION

To find the most accurate and consistent model for our problem, we evaluated five different machine learning algorithms, including RF, MLP, XGBoost, LightGBM, and AdaBoost. After extensive testing, the MLP Classifier was chosen according to the performance metrics. (As shown in Table 4) The final CVRP model used the MLP Classifier due to its several advantages (as shown in Table 5 and Figure 6). It learns non-linear mappings via backpropagation. It is useful for capturing interactions from features that may not be explicitly modelled in tree-based methods. It also allowed us to compare traditional machine learning with deep learning approaches in this medical domain.

III. 3.1. Model Selection and Hyperparameter Tuning

Model selection is a crucial step that helps in selecting the best model architecture or algorithm from a set of models. On the other hand, hyperparameter tuning consists of optimizing the settings of the chosen model in order to improve its performance. Feature selection methods was used to identify distinct feature that has an impact on the model's output. These methods include analysis of variance, mutual information, and chi-square. As shown in Table 3, the feature groups selected were named as Cardiac Risk Factors (CRF), a total of five groups, namely CRF-1, CRF-2, CRF-3, CRF-4, and CRF-5, were used.

Table 3: Selected Feature groups (CRF).

Selected Group of Features	Attributes
CRF-1	age, gen, chol, cpt, thalach, op, ang, ca, st, ths
CRF-2	chol, op, fbs, cpt, thalach, ang, ca, st, ths
CRF-3	gen, chol, op, recg, fbs, cpt, thalach, ang, ca, st, ths
CRF-4	op, cp, thalach, ths, ang, chol, ca, st, fbs, recg, gen, rbp
CRF-5	age, gen, chol, rbp, op, recg, fbs, cpt, thalach, ang, ca, st, ths

Source: Authors, (2026).

We employed Stratified K-Fold Cross Validation in combination with Randomized Search CV. Stratified K-Fold Cross Validation was useful because it ensured that each data fold maintained the same proportion of target classes, which is essential for medical data. Randomized Search CV efficiently found the optimal hyperparameters for each algorithm, which saved the time of manual tuning.

III.4 INTEGRATING EXPLAINABLE AI (XAI) IN CVRP MODEL

Our CVRP model goes beyond a simple yes/no prediction. It extends the output to three meaningful risk levels: low, moderate, and high. This makes the results more practical in the healthcare domain. To ensure the model is transparent and trustworthy, we integrated XAI tools. We have used SHAP values to generate a plot (Fig.4) that clearly explains the impact of each feature on a prediction. We also used LIME to generate visuals (Fig.5), which help users understand exactly how a specific prediction was made.

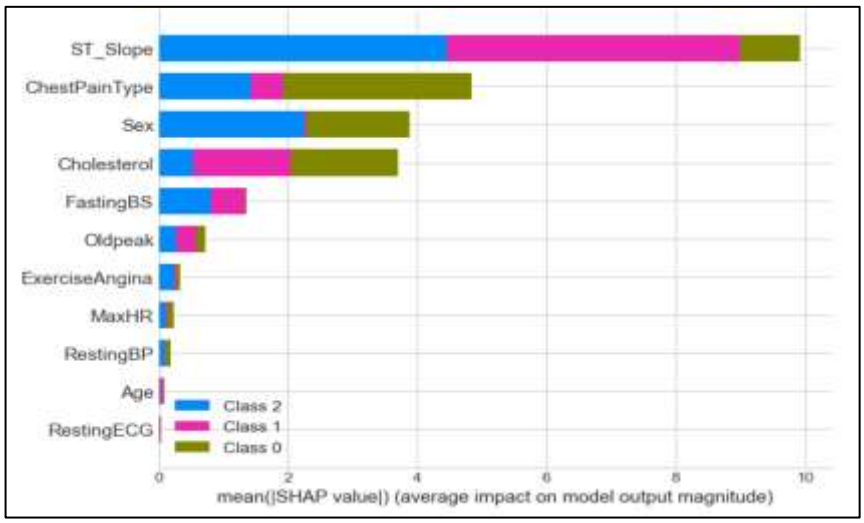

Figure 4: SHAP Bar Plot (Feature Importance).
Source: Authors, (2026).

The bar plot in Figure 5 shows the overall feature importance for the model. It helps understand that, on average, features like ST_Slope and ChestPainType are the most effective features for the predictions.

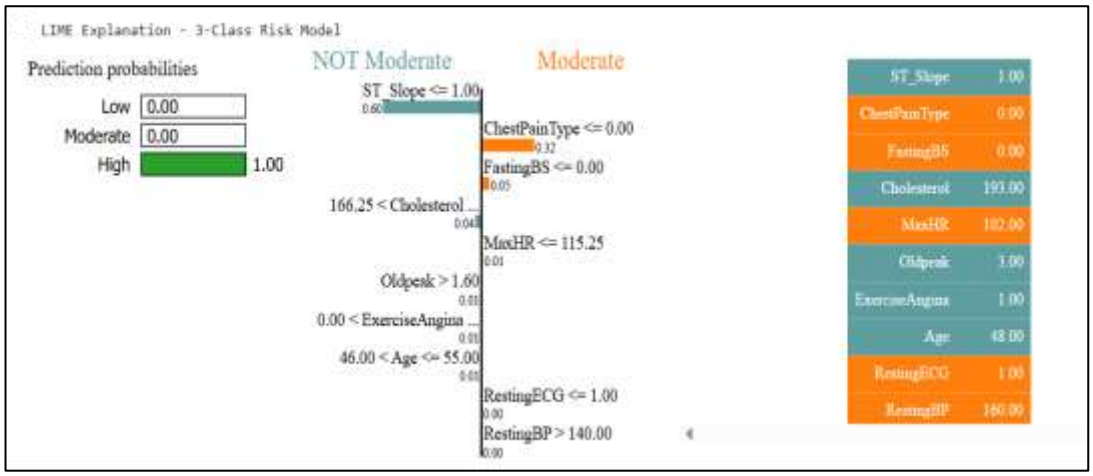

Figure 5: LIME explanation for a patient.
Source: Authors, (2026).

Figure 5: This LIME plot helps analyze which feature value positively or negatively influenced the model's result for an individual patient. In the final step, we saved the best model and built a user-friendly platform for healthcare professionals and patients. This web-based app was built using Gradio. It allows to enter health data and instantly the app will give an output about the level of cardiovascular risk. It even generates a downloadable PDF report that summarizes the results. This made the tool both intelligent and efficient to use for patients and healthcare professionals.

IV. RESULTS AND DISCUSSIONS

For the CVRP model, it is crucial to understand the model's ability to generalize across diverse patient data and detect CVDs. This can be done using performance evaluation techniques. These techniques help evaluate the accuracy and effectiveness of a model. It also helps to identify the areas for improvement (As shown in Table 4).

IV.1 PERFORMANCE EVALUATION TECHNIQUES

For evaluation of the CVRP model's performance, the following parameters were utilized:

1. **Accuracy:** It represents the percentage of correctly predicted cases of CVDs, which shows the overall effectiveness of the model. It is given as in Eq.12

$$\text{Accuracy} = \frac{True\ Positive\ (TP) + True\ Negative\ (TN)}{TP+TN+FN+FP} \tag{12}$$

2. **Precision:** This represents the proportion of true positive (TP) results out of all the positive predictions. This signifies the reliability of the model's positive outcomes. It is given as in Eq.13

$$\text{Precision} = \frac{True\ Positive\ (TP)}{TP+FP} \tag{13}$$

3. **Recall (Sensitivity):** Recall is used to identify the proportion of all actual cases of CVDs that were classified correctly as positives by the model. It is given as in Eq.14

$$\text{Recall} = \frac{True\ Positive\ (TP)}{TP+FN} \tag{14}$$

4. **F1 Score:** A consolidation of precision and recall is F1 score. It is given as in Eq.15
5.

$$\text{F1} - \text{Score} = 2\frac{Precision*Recall\ (Sensitivity)}{Precision+Recall\ (Sensitivity)} \tag{15}$$

6. **Execution Time:** It denotes the time required to process the dataset and generate predictions.

7. **ROC-AUC Score:** This helps to understand the ability of the model to distinguish between the healthy patients from the at-risk patients. As shown in Figure 7.

8. **Cost:** It is the expenses associated with data storage, processing, and cloud services utilized during model implementation.

Table 4: Performance evaluation results of ML techniques using CRFs.

ML Algorithm		MLP	RF	XGBOOST	LIGHTGBM	ADABOOST
CRF-1	Accuracy %	96.72	93.44	95.89	95.08	93.44
	Sensitivity %	97.00	94.00	96.00	95.00	94.00

IV. 2. LIMITATIONS AND FUTURE SCOPE

The CVRP model's aim was to enhance the predictive accuracy of CVD prediction by integrating machine learning techniques. It will be a reliable platform that will help healthcare professionals and patients. As there were dataset limitations, the model couldn't reach a comparable accuracy with the existing solutions. Future plans include integrating datasets from different sources, including medical imaging, along with telehealth services. This will further improve the CVRP model's accuracy and effectiveness. This system can also be enhanced by analyzing and defining the stages of CVDs, which will help identify the risk of CVDs in early stages.

IV. 3. D]ISCUSSIONS

The CVRP model used MLP Classifier which achieved a high accuracy of 96.72% with AUC of 0.98. The model has a user-friendly frontend, which makes it convenient to identify CVD risk by healthcare professionals and patients. The system also maintains transparency and interpretability by using XAI techniques. It makes predictions more understandable, thus making it effective in real-time usage. This system aspires to develop a high-confidence model for early risk detection and management of CVDs.

V. CONCLUSIONS

The CVRP model's aim was to enhance the overall predictive accuracy of CVD prediction. This was achieved by using a publicly available dataset and integrating machine learning techniques. CVRP will be a reliable platform that will help healthcare professionals assess patient health reports. ML algorithms are evaluated and selected depending on dataset characteristics to improve the model reliability and effectiveness in cardiovascular risk prediction. CVRP helps prioritize user experience while addressing privacy concerns and ensuring accessibility for healthcare providers. The integration of Explainable AI (XAI) introduces an approach to improving model transparency and interpretability, making cardiovascular risk predictions more reliable and understandable.

ABSTRACT

Modeling clinical time series demands interpretable patient states alongside the ability to capture long-range dependencies. Classical HMMs provide discrete, clinically meaningful states but ignore distant history; RNNs capture rich temporal patterns but act as black boxes. We introduce DifferentiableHMM, a unified, end-to-end differentiable probabilistic model, not a simple stacking of an HMM and a neural net. An LSTM encoder produces history-aware representations that condition both transition probabilities and GMM emission mixture weights via a small MixtureSelector network; transitions, emissions and the selector are optimized jointly by backpropagating through EM-like inference, producing a single coherent model in which inference and learning reinforce one another. On a MIMIC-III ICU benchmark, DifferentiableHMM reduces sequence negative log-likelihood by 40%, increases one-step R^2 by 5%, and lowers calibration error by 24% versus HMM and LSTM baselines. Discrete latent states retain clinical interpretability (mutual information = 0.824) and ablations show the performance gains disappear if components are trained separately. DifferentiableHMM therefore reconciles interpretability, calibrated uncertainty, and neural expressivity in a principled framework for healthcare sequence modeling.

I. INTRODUCTION

Modeling patient trajectories in intensive care units presents a dual challenge: capturing interpretable clinical states while leveraging long-range temporal dependencies. Traditional Hidden Markov Models (HMMs) provide a clear, discrete representation of latent physiological regimes, enabling clinicians to associate each state with recognizable patterns such as “stable,” “deteriorating,” or “recovery.” However, their first-order, memoryless transition structure limits the ability to incorporate extended patient history, often leading to oversimplified dynamics. On the other hand, recurrent neural networks—particularly long short-term memory (LSTM) architectures—excel at learning complex temporal patterns over long horizons but yield continuous latent representations that lack direct interpretability and clinical semantic grounding. To address these limitations, we introduce DifferentiableHMM, a hybrid framework that unites HMM interpretability with RNN expressivity. Our key contributions are: LSTM-based history encoder for aware transition matrix, Fully Differentiable Inference and Bayesian-Informed Initialization.

To demonstrate the effectiveness of DifferentiableHMM, we evaluate on the MIMIC-III benchmark of de-identified ICU stays. Because clinical time-series are highly sensitive, developing and evaluating models on datasets like MIMIC-III also requires careful attention to privacy-preserving dynamic data publishing techniques (e.g., anonymization, sanitization, and synthetic data generation) to enable safe sharing of patient trajectories [1]. Compared to classical HMMs and pure LSTM baselines. Ablation studies confirm that each component (history conditioning, differentiable inference, and informed initialization) is essential to these gains. DifferentiableHMM thus offers a principled, high-fidelity, and interpretable approach to sequence modeling with broad potential applications in healthcare analytics and beyond. The remainder of this paper is organized as follows. Section 2 surveys related work. Section 3 explore the key concepts and fundamental components of the DifferentiableHMM method. Section 4 outlines the experimental protocol and discusses the resulting performance. Finally, Section 5 concludes the paper and outlines directions for future research.

II. RELATED WORK

The fusion of neural sequence models with Hidden Markov Models (HMMs) has been pursued in diverse domains—ranging from video action segmentation and speech processing to healthcare risk prediction—but existing hybrids universally either fix the HMM transitions or learn neural and probabilistic components in separate stages. Below, we summarize key prior contributions and contrast them with our end-to-end DifferentiableHMM.

II.1 VIDEO ACTION SEGMENTATION

[2] tackle weakly supervised temporal action segmentation in long, untrimmed videos. Their hybrid RNN–HMM framework first employs a bidirectional RNN to produce frame-level 'action scores' (emission probabilities), then applies an HMM with a fixed transition matrix to enforce temporal consistency and infer segment boundaries. [3] similarly use a BLSTM RNN to generate precise phonetic emission probabilities in speech tasks, which an HMM then decodes with static transitions to impose temporal and phonotactic constraints. In both cases, the neural component enhances the emissions, but does not influence the transition dynamics.

II.2 SEMI-MARKOV AND DURATION MODELING

To model explicit state durations, [4] introduce the Recurrent Hidden Semi Markov Model (RHSMM), where an RNN predicts dwell-time distributions before EM estimates semi Markov parameters. While more expressive than standard HMMs, RHSMM still decouples neural training from transition learning. [5]. apply a hybrid NN–HMM for automatic story segmentation, using a feed-forward network for emission posteriors and a fixed HMM for temporal smoothing, again without enabling neural influence on transitions.

II.3 SPEECH SYNTHESIS AND RECOGNITION

[6] pioneered CNN–HMM hybrids for speech recognition by replacing GMM emissions with convolutional neural networks, but retained a transition matrix learned solely via EM. Zen [7] reviews the evolution from HMM to LSTM RNN acoustic models in statistical parametric speech synthesis, showing that recurrent networks markedly improve emission quality while leaving transitions intact. [8] present NeuralHMM, parameterizing both transitions and emissions with deep networks for attention-free TTS; however, their training does not backpropagate through the HMM inference, and transitions are optimized only for frame-level synthesis.

II.4 HEALTHCARE AND RISK PREDICTION

[9] propose a hybrid GRU–attention–HMM for ICU mortality and length of stay prediction. A GRU with attention produces time-point saliency weights that guide a fixed HMM transition matrix and a Mixture Density Network emission layer; training proceeds in two stages (neural likelihood then Baum–Welch), with no joint optimization. In contrast to all the above, our DifferentiableHMM fully merges an LSTM based history encoder into the transition network and employs a differentiable Expectation–Maximization algorithm that back propagates through the forward–backward recursions. This unified, end to end approach yields discrete, interpretable latent states whose dynamics are both history aware and jointly optimized with emissions—capabilities absent in prior work.

Table 1: Comparative overview of sequence modeling approaches.

Methods	Area of Concern	Neural Component	Transition Parameterization	Joint E/M-Step Differentiability	HistoryConditioning	Objective
Kuehne et al.[2]	action segmentation	BLSTM	Fixed HMM	No	✗	Discriminative
Sun et al. [3]	speech recognition	BLSTM	Fixed HMM	No	✗	Discriminative

III. METHODOLOGY

III.1 BACKGROUND

III.1.1 Hidden Markov Models (HMM)

A Hidden Markov Model (HMM) [10] is a doubly stochastic process with a discrete latent state sequence $\{s_t\}$ and observations $\{x_t\}$ .At each time step:

Transition Matrix: $A_{ij} = P(s_t = j|s_{t-1} = i)$ probability of moving between states

Emission Probabilities: $B_j(o_t) = P(o_t|s_t = j)$ likelihood of an observation given a hidden state

HMMs enjoy interpretable, discrete "modes" of behavior and exact inference algorithms. However, their first-order, memoryless transitions and fixed transition matrix limit their ability to capture long-range dependencies in complex time series.

III.1.2 Expectation–Maximization for HMMs

Parameter estimation in HMMs is traditionally performed via the Baum–Welch algorithm, an instance of the Expectation–Maximization (EM) [11] framework:

E-step: Compute the posterior state marginals and pairwise transition counts given current parameters.

M-step: Update transition and emission parameters to maximize the expected complete-data log-likelihood.

While EM guarantees non-decreasing likelihood, it treats the transition matrix as a free parameter, preventing integration with continuous function approximators and end-to-end gradient flows.

III.1.3 Recurrent Neural Networks for Sequence Modeling

Recurrent neural architectures—especially LSTMs—[12] have achieved strong predictive performance on sequential data by learning rich, continuous hidden representations:

$$h_t = LSTM(x_t, h_{t-1}), \hat{x}_{t+1} = f_\theta(h_t)$$

However, purely neural models lack discrete latent states, which are often desirable for interpretability and downstream decision support in domains such as healthcare.

III.2 DIFFERENTIABLEHMM MODEL

Figure 1 illustrates the overall DifferentiableHMM architecture. The observed time series is first passed through an LSTM history encoder; its hidden representation conditions two modules — a transition network that produces history-aware transition probabilities over discrete latent states, and a MixtureSelector that outputs logits for the GMM components used by each state's emission model. Emissions are represented by per-state GMMs, and EM-like inference is unrolled and differentiated so that transitions, mixture weights, and GMM parameters are optimized jointly via backpropagation. The result is a single, end-to-end trainable model that provides history-dependent predictions while preserving interpretable discrete states.

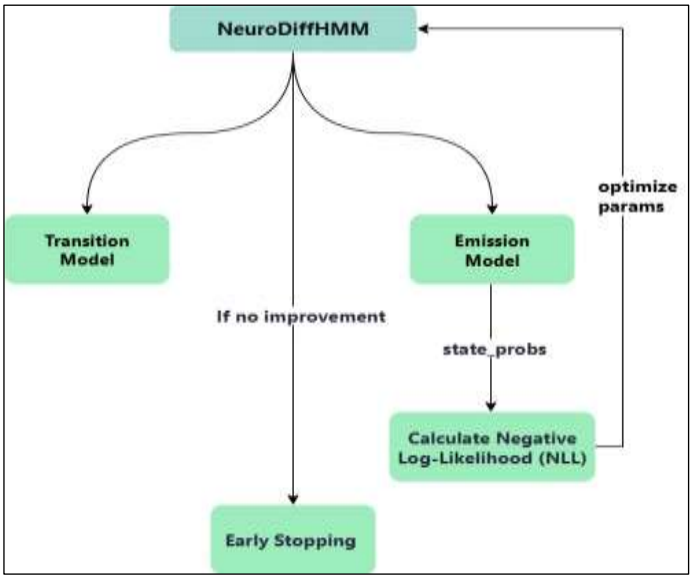

Figure 1: Overall architecture of DifferentiableHMM.
Source: Authors, (2026).

III.2.1 Step 1: Data Preprocessing

Objective: Transform raw ICU time series into structured sequences

- Excluding non-informative columns (e.g., icustay_id, charttime).

- Standardizing all features using the mean and standard deviation computed across the training set.
- Segmenting each patient's time-series into fixed-length sequences (length 50) for model input.

III.2.2 Step 2: Model Design (DifferentiableHMM)

The Differentiable Hidden Markov Model (DifferentiableHMM) is a neural extension of the classical HMM, tailored for modeling complex ICU time-series data. Unlike traditional HMMs, which rely on fixed transition and emission probabilities, the DifferentiableHMM incorporates neural network components to enable end-to-end differentiable learning and greater modeling flexibility. The model consists of a learnable transition network, typically parameterized by an LSTM-based history encoder, which captures temporal dependencies and patient-specific context. Emission distributions are modeled as mixtures of Gaussians, with mixture weights and parameters learned via backpropagation. Initialization of emission means leverages k-means clustering for stability, while mixture variances are set based on data statistics. The model supports regularization through entropy and L2 penalties, and temperature scaling is used to control the sharpness of the state assignmentdistributions. Training is performed by minimizing the negative log-likelihood of the observed sequences, with gradients propagated through both the transition and emission networks.

A. Transition Model

The Transition Model in the DifferentiableHMM is responsible for determining the probabilities of moving from one hidden state to another at each time step. Unlike traditional HMMs with static transition matrices, this model incorporates a history-aware, dynamic mechanism using neural networks to adapt transitions based on the patient's past observations and previous latent state.

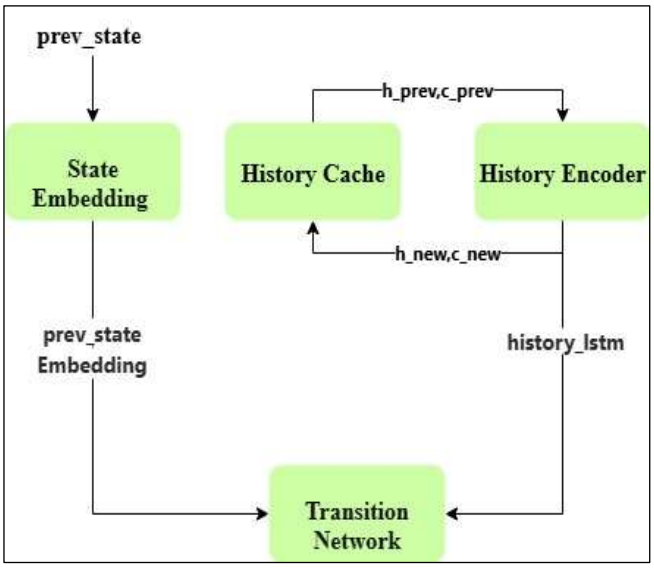

Figure 2: Transition Model Components.
Source: Authors, (2026).

Components of the Transition Model:

- **History Cache:**This component stores and retrieves the hidden and cell states of an LSTM for each patient across different batches. It ensures that the model can maintain a continuous memory of a patient's history, even when sequences are processed in batches.
- **History Encoder:**This is an LSTM network that processes the input observations (x) over time to generate a hidden state history (history_lstm). This history_lstm provides a rich, temporal context that informs the transition probabilities. The LSTM's states (hnew,cnew) are updated and stored in the history cache for subsequent time steps or future batches involving the same patient.
- **State Embedding:** Before being used in the transition calculation, the estimated latent state at the previous time step (prev_state_Embedding) is converted into a dense, continuous vector representation (embedding). This allows the discrete state to be effectively integrated into the neural network computations (see Figure 3).

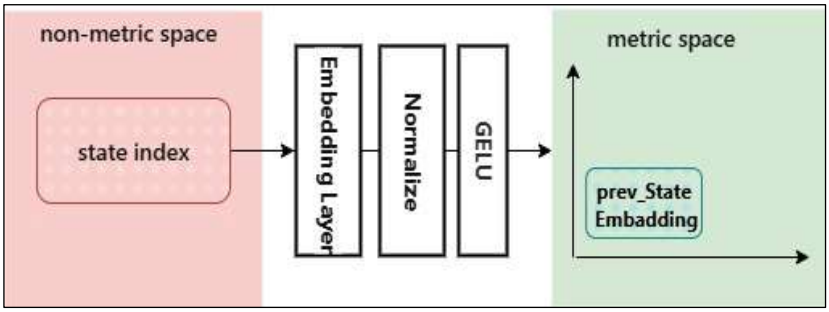

Figure 3. Hidden State Embedding.
Source: Authors, (2026).

- **Transition Network:** This is the core neural network that computes the raw logits for transitions between states. It takes the contextualized representation (from prev_state_Embedding and history_lstm) and outputs the log-probability of transitioning from one state to another. Finally, a softmax function is applied to the adjusted logits along the last dimension to ensure that the transition probabilities sum to 1 for each possible previous state.

B. Emission Model

The Emission model defines the conditional probability $p(x_t|z_t)$ of observing physiological measurements x_t given the current latent state z_t. To accommodate the complex, often multi-modal distributions of medical measurements, each latent state is associated with a Gaussian Mixture Model (GMM) in which each latent state z_t is associated with learnable component means and softplus-transformed scales ($means_{mixture}\backslash scales_{mixture}$) and a full covariance captured via a lower-triangular factor combined with a masking strategy to encode inter-feature dependencies. At each time step, a compact MixtureSelector network ingests sliding-window summaries of recent observations (x, x_{mean}, x_{std}) to produce dynamic mixture weights, providing a differentiable analogue of the expectation–maximization update in classical HMMs. During inference, component log-densities are aggregated via a numerically stable logsumexp and subjected to adaptive temperature scaling based on observed variance to sharpen the posterior over states. This design enables the model to flexibly capture complex, multi-modal medical measurement distributions and their temporal dynamics without assuming diagonal covariance or static mixture proportions.

III.2.3 Stepe3: training procedure

The training procedure for the DifferentiableHMM is meticulously designed to optimize its parameters for robust performance in medical time-series analysis. To this end, the model is trained by minimizing its negative log-likelihood (NLL) of the observed sequences, calculated based on the model's emission probabilities. Gradients for this loss are primarily propagated through the neural emission network, specifically involving the MixtureSelector that dynamically predicts Gaussian mixture weights based on input features. This primary loss objective is complemented by regularization terms for entropy and L2, serving to prevent overfitting and encourage diverse latent state utilization, with L2 regularization applying across all model parameters. A crucial initialization step involves setting the emission mixture means using K Means clustering on the training data, while emission scales are derived from the overall data standard deviation, enhancing training stability.

IV. EVALUATION

IV.1 DATASET AND EXPERIMENTAL SETUP

We evaluate DifferentiableHMM on the publicly available MIMIC-III intensive-care database [13], which includes de-identified records for over 40 000 ICU patients (2001–2012). Following prior work [14-16], we extract 100 patients with multiple ICU stays and six routinely monitored signals: DiastolicBP, HeartRate, Platelet, RespRate, Sodium, and SpO_2. Each patient trajectory is represented as a fixed-length sequence of 50 hourly measurements. We randomly stratify by patient into 80 % training and 20 % test sets. Hyperparameters (Table 2) are selected via greedy grid search on the validation split, optimizing the average MSE across prediction horizons k=1.10 We tune:

- Hidden units in the LSTM encoder and transition MLP
- Number of Gaussian mixtures per state
- Softmax temperature, entropy & L2 regularization
- Dropout rate, learning rate

To benchmark our approach, we compare against two strong baselines on held-out intensive-care time-series from the MIMIC-III dataset :

Classical HMM, trained via Baum–Welch with fixed transitions and Gaussian emissions.

Pure LSTM,LSTM networktrained to predict the next discrete state by cross-entropy.

Table 2: Key hyperparameter grid and chosen values.

Hyperparameter	Description	TypicalValues
n_components	Number of hidden states in the HMM	9
input_dim	Number of input features	6
hidden_dim	Hidden dimension for LSTM/history encoder and transition net	128
n_mixtures	Number of Gaussian mixtures per state	3
lr	Learning rate for optimizer	0.01
n_epochs	Number of training epochs	100
seq_length	Length of each time-series sequence	50

Source: Authors, (2026).

IV.2 QUANTITATIVE RESULTS

IV.2.1 Model Fit and Generalization

Table 3: Quantitative comparison of model fit and generalization metrics.

Model	LogLikelihood [17]	SeqNLL(perstep)	$R^2_{k=1}$	ECE
ClassicalHMM	8076.15	48.07	–	0.529
PureLSTM	–	–	0.530	0.473
DifferentiableHMM	4852.84	28.89	0.556	0.401

Source: Authors, (2026).

Sequence Negative Log Likelihood [18]: DifferentiableHMM's average per step NLL is 28.89 versus +48.07 for the classical HMM.

One Step PredictiveR2[19]: DifferentiableHMM (0.556) exceeds LSTM (0.530), demonstrating more accurate immediate forecasts.

ExpectedCalibration Error (ECE)[20]: DifferentiableHMM's lower ECE (0.401) shows its probability estimates are better calibrated.

IV.2.2 Multi Step Forecasting

To assess long-range dependency modeling, we forecast x_{t+k} for horizons k=1.10 and compute mean squared error (MSE).

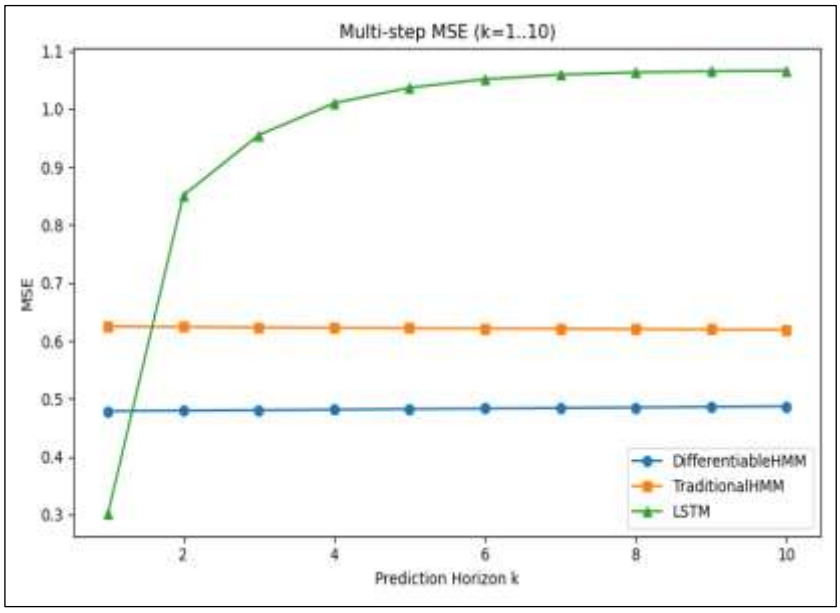

Figure 4: Multi-step MSE vs. prediction horizon.
Source: Authors, (2026).

In Figure 4 DifferentiableHMM (blue) maintains the lowest error across all, outperforming both Classical HMM (orange) and LSTM (green). DifferentiableHMM's flat MSE curve highlights its ability to leverage long histories via differentiable, history-conditioned transitions.

IV.3 INTERPRETABILITY AND CLINICAL ALIGNMENT

Table 4: Interpretability and Clinical Alignmentmetrics.

Model	State–Event MI	Cluster Purity	LatentEntropy	TransEntropy
Classical HMM	0.26	0.64	0.53	0.02
Pure LSTM	0.35	–	0.48	0.31
DifferentiableHMM	0.82	0.46	1.12	0.97

Source: Authors, (2026).

State–Event Mutual Information [21]: DifferentiableHMM's discrete states yield an MI of 0.82 with notated clinical events, far surpassing baselines.

Cluster Purity[22]: Although classical HMM exhibits higher raw clustering in feature space, DifferentiableHMM's superior alignment with events underscores its clinically meaningful state assignments.

Latent State Entropy[23]: At 1.12, DifferentiableHMM uses its nine-state capacity effectively (max2.20nats), avoiding collapse.

Transition Entropy[24]: DifferentiableHMM (0.97nats) balances state persistence and progression, whereas the classical HMM is near deterministic (0nats).

IV.4 ABLATION STUDY

We assess the impact of each core component by removing (i) the history encoder, (ii) differentiable EM, or (iii) Bayesian GMM initialization: To quantify the contribution of each core component of DifferentiableHMM, we performed three targeted ablations. For each variant, we reuse the emission parameters from the fully trained model to ensure a fair comparison. We then report the change (Δ) in three key metrics—Negative Log-Likelihood (NLL), one-step R^2, and State–Event Mutual Information (MI)—relative to the full DifferentiableHMM.

IV.4.1 Ablation Configurations

I. **Without History Encoder :**

Purpose: Evaluate the role of the history encoder (History Cache → LSTM → StateEmbedding → Transition Network) in capturing long-range patient context and informing transition probabilities.

Implementation: To disable the influence of the history encoder, a custom class, NoHistoryEncoder, was formulated. This class inherited from DifferentiableHMM, overridden to bypass the prev_state input, exclusively returning state probabilities derived from the emission model. The emission parameters (e.g., means_mixture, scales_mixture) were explicitly copied from the fully trained baseline model to ensure that any observed performance degradation was attributable solely to the absence of the history encoder and not to differing emission characteristics.

II. Without Differentiable EM (Mixture Selector)

Purpose: This experiment aimed to evaluate the contribution of the MixtureSelector neural network. This component is pivotal to the "differentiable EM" aspect, enabling the dynamic prediction and end-to-end learning of Gaussian mixture weights within the emission model via backpropagation.

Implementation: The NoDifferentiableEMHMM class was developed for this ablation uniform mixture weights were assigned. This effectively removed the adaptive, learned weighting mechanism, compelling each mixture component within a given state to contribute equally. As with the previous ablation, emission parameters were transferred from the trained full model.

III. Without GMM Initialization

Purpose: Probe the benefit of K-Means/GMM-based initialization of emission mixture means and scale parameters for stable convergence.
Implementation: the $(\text{means}_{\text{mixture}} \backslash \text{scales}_{\text{mixture}})$ parameter was populated with random normal values instead of the K-Means derived centres.

Table5: Ablation study results.

Variant	Δ NLL	Δ $R^2_{k=1}$	Δ State–Event MI
WithoutHistoryEncoder	+278.34	-0.0153	–0.0092
WithoutDifferentiable EM	+11.19	-0.0199	+0.0044
Without GMM Initialization	+272.47	-0.0105	–0.0001

Source: Authors, (2026).

History Encoder: Removing the LSTM-based history raises NLL by 278 and reduces $R^2_{k=1}$ by 0.015, confirming history conditioning is critical for both fit and predictive accuracy.

Differentiable EM: Disabling joint gradient flow increases NLL by 11 and slightly degrades R^2, illustrating the importance of end-to-end learning.

Bayesian GMM Initialization: Omitting informed emission priors also incurs a large NLL penalty (272), showing that robust state clustering at initialization is essential.

IV.5 DISCUSSION OF RESULTS:

DifferentiableHMM demonstrates superior performance over both classical HMMs and pure LSTMs across all evaluated dimensions—likelihood, forecasting accuracy, calibration, and interpretability. This consistent outperformance underscores the effectiveness of our core innovation: a differentiable, history-aware transition mechanism that captures complex clinical dynamics more faithfully than memoryless or black-box alternatives. Moreover, our ablation study reveals that removing any single component—whether history Encoder, end-to-end differentiability, or Bayesian-informed emission initialization—leads to measurable declines in model fit, predictive accuracy, and interpretability. These findings confirm that each element is indispensable to DifferentiableHMM's overall performance and validate the methodological contributions of this work.

V. CONCLUSIONS

We have presented DifferentiableHMM, a hybrid sequence-modeling framework that seamlessly integrates the interpretability of discrete Hidden Markov Models with the representational capacity of recurrent neural networks. By conditioning transition probabilities on an LSTM-encoded history, employing a fully differentiable EM algorithm for joint optimization, and initializing emission mixtures via Bayesian Gaussian mixture clustering, our approach addresses the fundamental limitations of classical HMMs—namely, their memorylessness and rigid transition structure—as well as the lack of transparent latent states in purely neural models. Comprehensive experiments on the MIMIC-III intensive-care dataset demonstrate that DifferentiableHMM substantially outperforms both a standard HMM and a pure LSTM baseline. In particular, our method achieves markedly lower sequence negative log-likelihood, higher one-step predictive R2, improved calibration, and considerably stronger alignment between inferred states and clinically annotated events. Moreover, the learned transition dynamics exhibit a realistic balance between state persistence and progression. An extensive ablation study confirms that each architectural component contributes critically to these gains. Looking forward, we plan to extend DifferentiableHMM in several directions. First, we will incorporate patient-level covariates (such as demographics and treatment interventions) directly into the transition network to enable personalized state dynamics. Second, deployment in real-time monitoring scenarios could facilitate early detection of critical events by tracking interpretable state transitions online. Finally, we will integrate formal differential privacy guarantees into the learning process, thereby enabling privacy-preserving state inference and synthetic data generation with provable protection of sensitive patient information.

ABSTRACT

Hybrid solar–wind plants offer an effective resolution of the real problem of intermittency, ensuring steady electricity supply and minimizing the need for technology of storage. Although they cost more upfront, they provide savings over time, aid the environment and advance decarbonization targets. HOMER simulation for Basra also showed the predominance of solar power where the total annual capacity was 10.54 kWh/m², while wind provided 1.21 kWh, confirming the efficiency of hybrid system integration for Basra as a typical example. Worldwide experience, including Germany, China and the U.S., have also shown that systems such as hybrids are more reliable and cost effective than single platforms. These results emphasize how important the phasing control will be in the upcoming energy transitions, and the importance of advances in storage technologies, AI-based control, and the role of legislation in making these precedents.

I. INTRODUCTION

Amid the global concern regarding climate change and the dissipation of fossil fuel supplies, the need for sustainable, and renewable sources of energy has never been so pressing. Traditional, fossil fuel-based energy systems cause the release of greenhouse gases and pollution, and drive a spiraling global disaster 1. In this field, renewable energies, among these the solar, wind and hydro power sources, are increasingly the focus of interest in order to obtain clean, yet abundant and sustainable electricity. Among these, solar and wind energy are two of the most promising and widely-used technologies for the massive energy generation [3]. However, both energy sources suffer from intermittency, low efficiency and reliability, which makes it difficult to satisfy the whole global energy need when vertically used [4]. The solar energy, which is obtain through photovoltaic (PV) cells, entirely relies upon sunlight that varies greatly according to weather conditions, time frame and geographical locations [5].

Likewise, wind energy produced by wind turbines varies as a result of change in wind speed and it is affected by seasonal variations and local weather condition. However, these natural intermittencies are causing problems with maintaining a consistent and dependable electricity supply, at least in places where the grid has high dependence on renewable sources[6]. To counter these challenges, hybrid energy systems involving solar and wind power have emerged as an attractive alternative to mitigate intermittency challenges while enhancing the overall reliability and efficiency of renewable energy generation [7]. A combination of wind and solar in a single system can use the complementary characteristics on these two sources. Solar power works best during the day, while wind energy can be more prevalent at night or when it is not enough light [8]. The collaboration between both systems can help make sure that the power supply is more dependable and stable all day throughout the year.

This renders hybrid systems an excellent option for producing electricity in a way that is good for the environment [9]. Hybrid energy systems had several important advantages over traditional energy generation systems that operate on its own. First, they have a greater capacity factor, which is a ratio of actual energy produced to the greatest possible energy output. It's due to their ability of making power from both solar and wind sources [3]. So, the system works better overall and doesn't need as many backup power sources, such fossil fuel-based power plants, which are employed when renewable energy supply is low [10]. Combining wind and solar electricity can also lower the cost of storing and sending power because it means you don't need massive storage facilities to handle times when one of the sources is making a lot of power [11]. The creation and use of hybrid energy systems also fits with the global goal of moving to a low-carbon economy. A lot of countries are now establishing high goals for cutting greenhouse gas emissions and raising the amount of renewable energy in their energy mix [12]. Hybrid systems can help fulfil these goals by offering a more steady and reliable source of renewable energy that can help integrate renewables into the grid as a whole [13].

In this context, renewable energy sources such as solar, wind, and hydropower have gained significant attention due to their potential to provide clean, abundant, and sustainable electricity. Figure (1) shows how the quantity of renewable energy capacity added will change between 2019 and 2024. It also shows that wind energy will grow faster than solar energy. Wind energy won by a long shot in 2019, with 119.1 GW, while solar energy only added 59.4 GW. This pattern continued in 2020, when wind power rose to 153.2 GW and solar power grew to 107.8 GW. In the next few years, wind energy increased a lot faster. It grew to 232 GW in 2022 and then to 426.3 GW in 2023, which was faster than the constant rise of solar energy. Solar energy started getting better, but it was still slower than other kinds of energy, especially between 2021 and 2022. By 2024, wind energy had risen to an incredible 553 GW, but solar energy had only expanded to 120 GW. Because of new technology like offshore wind farms and cheaper costs, this research suggests that wind energy will become the dominant source of renewable energy capacity. Solar energy, on the other hand, has been accepted more slowly. This is partly because it doesn't always work, it costs more to install at initially, and there are issues with how to use the land. Both of these sources of energy are still very vital for the global endeavor to make the future low-carbon. Wind energy is becoming the main focus of big renewable energy projects, while solar energy is still a big part in locations with a lot of sun [14].

Source: Authors, (2026).

II. HYBRID SOLAR-WIND SYSTEMS:

Hybrid energy systems use both solar and wind power to make it easier and more dependable to get electricity from renewable sources. Figure (2) shows that these systems try to solve the problems of intermittency and variability that each source has when used alone by combining both technologies [15].

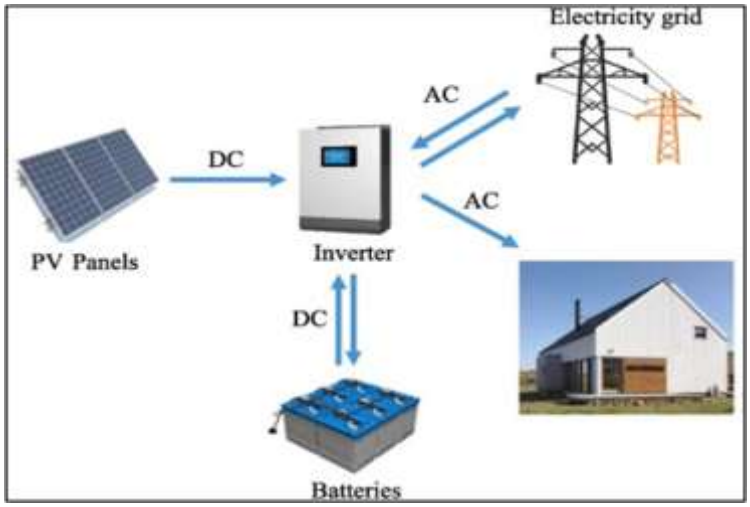

Figure 2: Hybrid Energy System.
Source: Authors, (2026).

II.1 KEY FEATURES OF SOLAR-WIND HYBRID SYSTEMS:

- Complementary Generation:

Solar and wind power operate well together. During the day, when there is sunlight, solar energy is usually abundant. Wind energy, on the other hand, is generally more useful at night or on overcast days when solar energy is low. [16].

- Improved Efficiency and Reliability:

Combining both sources makes energy generation more reliable resulting in fewer occasions when energy isn't available and a more stable power supply overall. This is especially helpful in areas where the weather changes a lot or the sun shines differently. [17].

- Reduced Need for Energy Storage:

The integration of solar and wind energy reduces the requirement for large-scale energy storage systems. The hybrid system can alleviate periods of underperformance from a single source, reducing dependence on storage devices and lowering costs.[18].

- Geographical Versatility:

These systems can be deployed in regions where either solar or wind alone might not be sufficient. Areas with both wind and solar potential can benefit greatly from hybrid systems, providing a more balanced and consistent energy output [19].

II.2 ADVANTAGES OF SOLAR-WIND HYBRID SYSTEMS

- Increased capacity factor: The system generates electricity more reliably, even during periods when one source is not performing.
- Lower dependence on backup generation: Reduces reliance on fossil-fuel-based power plants or expensive storage systems [20].
- Environmental benefits: Decreases greenhouse gas emissions and supports a sustainable energy transition.
- Scalability: Hybrid systems can be expanded or adjusted according to the energy demands and geographical conditions [21].

III COMPARISON BETWEEN STANDALONE AND HYBRID SYSTEMS:

Standalone systems are renewable energy systems that only use one source of electricity, such solar or wind power. These systems can be helpful in some situations, but they often have problems with variability and intermittency. Based on a lot of different things, Table 1 shows how solar-wind hybrid systems compare to standalone systems [22][23][24]:

Table 1: Comparison of Solar-Wind Hybrid Systems vs. Standalone Renewable Energy Systems.

Feature	Solar-Wind Hybrid Systems	Standalone Systems (Solar or Wind Alone)
Energy Generation Reliability	High reliability due to complementary nature of solar and wind; stable power output across the day and seasons	Lower reliability; dependent on the availability on one source, leading to gaps in generation
Intermittency	Reduced intermittency, as wind can generate power when solar is not available and vice versa	High intermittency; solar energy is unavailable at night and on cloudy day; wind energy depends on wind conditions
Efficiency	Higher overall efficiency, both sources contribute to consistent power generation	Lower efficiency; relies solely on on ernergy source, leading to periods od low generation
Cost of Installation	Higher initial costs du to the complexity of integrating both systems	Lower initial costs for installation compared to hybrid systems, as only one energy source is used
Energy Storage Needs	Reduced need for large scale energy storage systems; excess energy generation can be stored in batteries or used in real-tine	Higher energy storage requirments, especially during periods of low generation, requiring expansive battries or backup systems
Space Requirements	Requires more space for both solar panels and wind turbines, but offers better land utilization when integrated	Less space required compared to hybrid systems but still needs significant space for either solar panels or wind turbine
Operational Complexity	More complex to manage and operate; requires advanced control systems to optimize energy production and integration	Simple operation but may require backup or grid connection to maintain reliability
Scalability	Scalable; can be easily expand by adding more solar panels or wind turbines as demand increases	Limited scalability as each system relies on a single source of energy. Expanding capacity requires increasing the size of the same source
Geographical Suitability	Suitable for areas with variable weather conditions and diverse climates where both solar and wind potential exists	Best suited for areas where either solar or wind is highly predictable and abundant

Source: Authors, (2026).

IV. PERFORMANCE AND ENVIRONMENTAL/ECONOMIC ASPECTS:

Sunlight, wind, temperature, and seasons substantially affect hybrid systems. Where you reside affects solar and wind resource availability, which affects energy generating reliability and efficiency. Figure (3) shows that hybrid energy systems using solar and wind energy function differently depending on location.

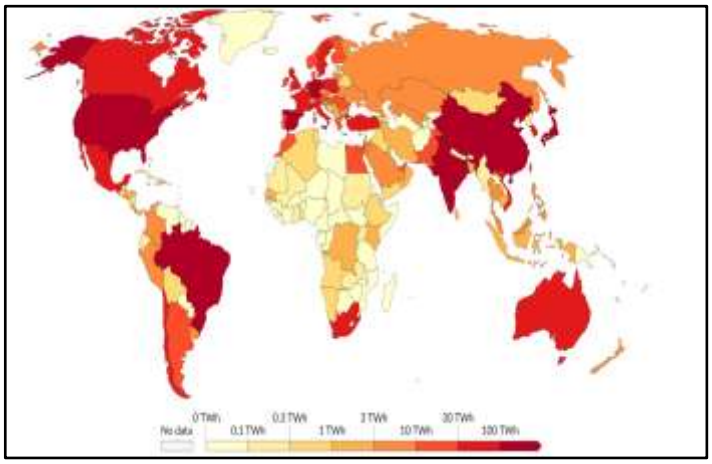

Figure 3: Solar and wind power generation, 2024.
Source: [25].

In deserts with a lot of sunshine and little wind, solar panels function more effectively than wind turbines. Wind turbines produce more electricity as the wind is steady, like on the coast or in mountainous areas, solar backups is used. Hybrid systems work better in these areas because they use the light during the day and the wind at night or on cloudy days. It makes the energy supply more stable [26]. Some island nations and remote areas have both solar and wind potential, and hybrid systems can be very useful there. They make sure that energy is always available and that you do not have to rely on outside grids. Hybrid systems may not work as well or cost as much in places where one source is more common. The performance and productivity of hybrid systems depend on environmental factors. In places with a lot of both wind and solar energy, like the coast or the desert [27], hybrid systems work better than solar or wind systems on their own. In desert areas, for instance, a solar-wind hybrid system mostly uses solar power. Wind turbines, on the other hand, make most of the power in places with a lot of wind along the coast [28]. Hybrid systems make sure that the amount of energy produced stays the same by making up for low performance from one source with the other. Hybrid systems make things more reliable in places where the seasons change a lot by using wind energy when the sun is not shining as much [29].

IV.1 SEVERAL WEATHER AND CLIMATE FACTORS PLAY A CRUCIAL ROLE IN DETERMINING THE PERFORMANCE OF HYBRID ENERGY SYSTEMS. THESE INCLUDE:

- Solar Radiation and Sunshine Hours:

The amount and length of sunlight hours are very important for solar power generation. These change with the seasons and latitude. For example, areas near the equator have longer days all year, which means they get more solar energy. Conversely, areas at higher latitudes, like those near the poles, have shorter days in the winter, which can make solar panels less effective [29].

- Wind Speed and Patterns:

The strength and steadiness of the winds determine how much wind energy can be made. The area's geography, its height, and how close it is to the coast or mountains are some of these things. Wind turbines work better on the coast and in the mountains because the winds are stronger and more steady there. The wind also changes with the seasons, and in some places, these changes can change how much power turbines make. [30].

- Temperature and Humidity:

The efficiency of both solar panels and wind turbines depends a lot on the temperature. In general, solar panels work better when it is cooler outside. This is because extreme heat can make the cells less efficient by making them more resistant. Wind turbines, on the other hand, are affected by the density of the air, which goes down as the temperature goes up. This makes them less efficient at making energy. Humidity is also important because high levels of moisture in the air can block solar radiation, which makes solar panels work less well. [31].

- Cloud Cover and Precipitation:

Cloud cover and rain can block sunlight from reaching solar panels, especially in places where the sky is often cloudy [32]. Rain or snow can also make wind turbines work less well by making ice build up or changing the speed of the wind. Hybrid systems, on the other hand, are better at handling these changes because wind turbines can keep working even when solar generation drops. [33].

- Environmental Obstacles:

The shape of the land and the presence of natural barriers like mountains, forests, or buildings can change the direction of the wind, creating wind shadows or turbulence that can make wind turbines less efficient. The orientation of the panels, shade from nearby objects, and local microclimates can all affect how well solar systems work. [34].

IV.2 ENVIRONMENTAL AND ECONOMIC CHALLENGES OF HYBRID ENERGY SYSTEMS:

Hybrid energy systems, like solar-wind combinations, have many benefits, such as reducing our dependence on fossil fuels and lowering greenhouse gas emissions. However, they also have some environmental problems [35]. Some of the main environmental issues that come up with renewable energy systems are:

- Land Use and Habitat Disruption:

Large space is needed for Large-scale hybrid system for Bothe solar panals and wind turbine. This can hurt habitats, especially in places where the environment is very sensitive. For example, wind farms can change the routes that birds take when they migrate, and big solar farms may have to cut down trees and other plants. But you can lessen these effects by picking the right place and doing environmental impact assessments. [36].

- Resource Extraction for Manufacturing:

To make solar panels and wind turbines, you need to get raw materials like copper, silicon, and rare earth metals. When these materials are mined, they can harm the environment, pollute water, and release more carbon into the air. To lessen the bad effects of these materials, it is very important to recycle them and use sustainable mining methods to lower their environmental impact. [37].

- End-of-Life Disposal and Recycling:

Another environmental problem is getting rid of old solar panels and wind turbine blades. Solar panels usually last 25 to 30 years [38], and wind turbines usually last 20 to 30 years [39]. When these parts reach the end of their useful life, they need to be recycled or thrown away in a safe way. If not done right, this can be expensive and bad for the environment.

- Noise Pollution and Aesthetic Impact:

People often complain about how noisy and ugly wind turbines are [40]. The noise from the turbines can bother animals and people who live nearby, and big wind farms can change the way rural or coastal areas look. These problems can be lessened by putting the turbines in the right places and making them quieter and more visually appealing[41].

IV.3 ECONOMIC FEASIBILITY ANALYSIS:

Initial Costs, Long-Term Benefits, and the Cost of Energy Generated Hybrid energy systems have high initial costs and long-term economic benefits, which is a problem from an economic point of view. The cost of installing, maintaining, and running these systems is one of the things that affects how economically feasible they are.

- Initial Costs:

Setting up a hybrid power system typically costs more upfront than implementing in a solar or wind system alone. The installation may also need improvements to the grid and energy storage systems, which will make the initial costs even higher. [42].

- Long-Term Benefits:

Over time, hybrid systems can save a lot of money compared to traditional systems that use fossil fuels. The only ongoing costs for hybrid systems are maintenance, since they do not use any fuel. Also, they can make electricity for 20 to 30 years or more, which means that after the initial investment, they provide a stable and predictable power supply at a lower cost. [44].

- Cost of Energy Production:

The Levelized Cost of Energy (LCOE) is a common way to compare the costs of making electricity from different types of energy. Because of the cost of installation, hybrid systems usually have a higher LCOE in the first few years. But the cost usually goes down over time because the system makes energy more efficiently and the need for outside power sources goes down [45]. The LCOE for hybrid systems is usually higher than that of traditional fossil fuel-based generation. However, when you look at long-term savings, environmental benefits, and lower carbon footprints, it is competitive with or even lower than many other renewable energy systems. [46].

V. GOVERNMENT POLICIES AND GLOBAL TRENDS

Policies made by the government are very important for the growth and development of hybrid energy systems. By using different incentives, rules, and programs [47], policymakers can change how renewable energy technologies are used and how they grow. There are many ways that governments can help hybrid systems, such as:

- Money: Governments often give people money to help them pay for the costs of putting in renewable energy systems. This could be in the form of grants, tax breaks, or government money. These incentives can help homeowners and businesses buy hybrid energy systems [48].

- Support for Research and Development (R&D): Governments can pay for R&D projects that make hybrid energy systems work better and more efficiently, especially when it comes to cutting costs, storing energy, and connecting to the grid. Governments can help lower the overall cost of renewable energy and make hybrid systems more likely to be used by a lot of people by encouraging new ideas [49].
- Regulatory Support and Grid Access: Governments can make it easier for hybrid systems to connect to the grid by making rules. These could be rules about who can use the grid, rules about net metering, and rewards for utilities that use clean energy sources. Governments can also make long-term plans for energy that put clean energy and renewable integration at the top of the list. This will help keep the market for hybrid systems stable [50].
- Public Awareness and Education: Governments can also help by teaching people about the benefits of renewable energy and hybrid systems in general. People are more likely to accept and use new ideas if they learn about them in public and are given reasons to get involved in the private sector [51]. The table (2) below compares important countries and emerging markets based on their government policies, economic viability, and success in developing renewable energy, with a focus on solar-wind hybrid systems. The comparison shows how different factors affect the use and growth of hybrid energy systems in different areas. It looks at things like how far we have come in combining different types of renewable energy, how well the rules work, and how much money they make.

Table 2: Comparison of Government Policies and Renewable Energy Development in Key Countries and Emerging Markets for Hybrid Systems.

Country	Government Support	Renewable Energy Capacity	Economic Feasibility	Challenges	Notable Developments	Ref.
Germany	Strong financial incentives, grid integration policies, and ambitious renewable energy targets	One of the largest solar and wind markets in Europe.	High initial costs, but strong long-term returns.	Land use conflicts, grid integration challenges.	Leading in energy transition (Energiewende), a robust market for hybrid systems.	[52] [53]
United States	Federal tax incentives, state-level renewable energy programs, and R&D funding.	Significant growth in wind and solar, with some hybrid projects.	Moderate upfront costs, but substantial long-term savings.	Varies by state; inconsistent policies.	Increased hybrid system adoption in rural and remote areas.	[54]
China	Strong government subsidies, investments in R&D, and national renewable energy targets.	World's largest producer of solar energy, fast-growing wind energy market.	Lower LCOE due to government support and scale of production.	Environmental impacts of large-scale wind and solar farms.	Leading global player in solar and wind, with growing interest in hybrid systems.	[55]
India	Financial incentives for renewable projects, state-level solar and wind policies.	Rapid growth in solar and wind energy sectors, potential for hybrid systems.	High initial costs but government support for financing.	Grid reliability issues and infrastructure gaps.	Hybrid solar-wind projects in rural areas and remote locations.	[56]
Brazil	Government incentives for wind and solar, favorable policies for hybrid systems.	Expanding wind and solar capacity, especially in the Northeast.	Competitive costs due to abundant natural resources.	Regulatory hurdles and land use concerns.	Emerging market for hybrid systems, particularly in remote areas.	[57]
South Africa	Feed-in tariffs, tax incentives for renewable energy projects.	Significant potential for both wind and solar energy.	High upfront costs but government programs to support financing.	Grid integration and high capital costs.	Increasing investment in renewable energy and hybrid systems.	[58]

Source: Authors, (2026).

The world needs more energy, that's why many countries are looking into other, more sustainable ways to get it. Figure(4) shows that looking at energy use trends from 2015 to 2024 can tell us a lot about how hybrid energy systems are used, especially in countries where energy needs are growing quickly.By2024, China's energy use is expected to reach its highest level, which is almost 1,800 TWh.This is because the number of people and businesses is growing. In order to cut down on its reliance on fossil fuels, China will need to use more types of energy, like solar-wind hybrid systems. The U.S. rises more slowly, reaching about 800 TWh by 2024. This is because energy efficiency has gotten better. But hybrid systems are still good for the environment and the economy in the long run. Countries such as India, Germany, Brazil, and South Africa are experiencing moderate or sluggish growth. India's steady rise in energy use makes hybrid systems more useful.

The other countries, on the other hand, are growing more slowly, which shows that they need targeted and cost-effective renewable energy solutions Factories are using more and more energy, so China and the U.S. are ready to use hybrid systems on a large scale. Emerging markets might have trouble with the initial costs, but if their governments make good policies and offer financial incentives, they can adopt these technologies at their own pace. In countries where growth is slow,campaigns to raise public awareness and teach people can help them adopt even faster. Hybrid systems are the best way to keep energy prices stable over time, cut down on pollution, and make sure that energy will still be available in the future.New and rapidly growing markets need certain rules and incentives to make sure that they are widely used [59].

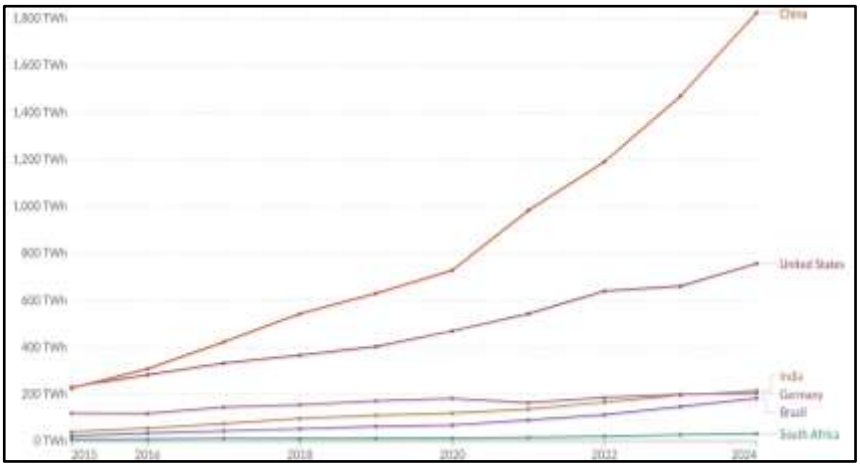

Figure 4: Energy Consumption Trends (2015-2024) for Major Economies.

VI. PRACTICAL APPLICATIONS AND FUTURE EXPANSION OF HYBRID SYSTEMS:

Solar-wind hybrid energy systems have been successful in both small villages and large power plants, generating electricity in areas where conventional energy infrastructure may be ineffective. It is too expensive to extend the regular electricity grid to these systems, which are useful in rural areas, islands, and remote communities [60]. These hybrid systems can give you a steady and reliable supply of electricity by using both solar and wind power. This can make life better and help the economy grow. In places where there is no grid access, hybrid systems can be used instead of expensive and bad for the environment diesel generators for backup power [61]. Hybrid solar-wind systems are better for the environment, last longer, and mean we do not have to buy fossil fuels from other countries as much. Energy storage systems make the system stronger by making sure that power is always there, even when it is dark or there is not much wind. Hybrid systems can save money over time, even in low-income areas, because they use less fuel and need less maintenance [62].

Hybrid systems give big power plants renewable energy that is more stable and flexible, which helps keep the grid stable. Hybrid systems make energy sources less volatile by using both solar and wind power. This is very important for getting more renewable energy into national systems because solar and wind power are not always reliable [63]. In large grids, hybrid systems can reduce the need for fossil-fuel power plants, which helps to create a more sustainable energy system. Hybrid systems also help electrical grids use more energy from sources that do not run out. Many countries are cutting their carbon footprints to meet international climate goals [64] as the demand for cleaner energy grows. It is easier and more reliable to add renewable energy to the grid when there are hybrid systems that use two sources of energy. This means that you can add more renewable energy to the grid without making the system less stable. If one power source stops working, the other can take over and keep the flow of energy going. This capacity makes it easier to handle at scale by reducing problems with intermittency [65]. This helps grids move toward more renewable energy.

Hybrid energy systems of the future will get a lot better, especially when it comes to how they store and control energy. We will need better ways to store renewable energy as we make more of it so that it can handle changes in energy sources. In hybrid systems, lithium-ion batteries store energy when it is at its highest and release it when it is at its lowest. More and more people need storage systems that work better, cost less, and last longer. People are looking into solid-state batteries, flow batteries, and compressed air energy storage (CAES) as ways to improve storage systems. These changes should make hybrid systems work better by making them last longer and store more energy [66]. Smart grid technology, better control systems, and better storage are the best ways to make hybrid energy systems better. To efficiently share power between solar, wind, and storage, hybrid systems need advanced power management [67]. AI and machine learning can improve control systems, which means that hybrid systems can see changes in how much energy is being made and used and change their behavior in real time.

These smart systems decide on their own how to store energy, feed it into the grid, and use it locally, which makes energy use and waste less of a problem [68]. In addition, demand-side management (DSM) systems that let people change how much electricity they use based on how much it costs and how much is available will be more important in hybrid energy systems. When you combine DSM with hybrid power systems, you can better match energy use with patterns of renewable generation. This makes the whole system work better. Solar wind hybrid energy systems are a new way to deal with the problems that come up when renewable energy is not always the same and changes [69]. These systems make electricity more reliably by using both solar and wind power. This is especially helpful in areas where neither is enough. Hybrid systems are more dependable because they can store energy, which means they can keep the power on even when generation is low. In remote areas and big power plants, hybrid systems are a long-lasting and cost-effective alternative to fossil fuels [70]. Hybrid systems use less fossil fuels and do less harm to the environment than traditional ways of making energy. Problems include using land, getting materials to make things, and getting rid of old parts. New designs, recycling, and managing resources in a way that does not hurt the environment can help make these big problems smaller [71]. It costs more to install hybrid systems, but they are a good investment because they save money on fuel, lower operating costs, and help the environment in the long run [72]. Even in poor countries, hybrid systems are becoming more affordable thanks to government subsidies, incentives, and research funding [73].

VII. CASE STUDY (IRAQ-BASRA): SIMULATION USING HOMER

The main focus of this study is the global trends, advantages, and issues associated with solar-wind hybrid systems. But HOMER software was used to run a localized simulation to show how these systems could work in the real world. We picked Basra, Iraq, as a good example because it gets a lot of sun and has a moderate amount of wind, which fits with what we talked about in the global context. This simulation does not narrow the study's focus; rather, it demonstrates the practicality, cost-effectiveness, and utility of hybrid systems in real-world contexts. A case study simulation was conducted using HOMER Pro software to validate the theoretical foundations and evaluate practical applicability, as detailed in the following section.

VII.1 ANALYSIS OF SOLAR GLOBAL HORIZONTAL IRRADIANCE (GHI) AND CLEANNESS INDEX DATA

This study analyzes the Monthly Average Solar Global Horizontal Irradiance (GHI) and Cleanness Index data, as shown in Figure (5), to understand the solar energy potential and atmospheric conditions impacting solar power generation. The following research provides information on monthly and annual solar radiation, trends in the cleanness index, and the potential for solar panels to generate power.

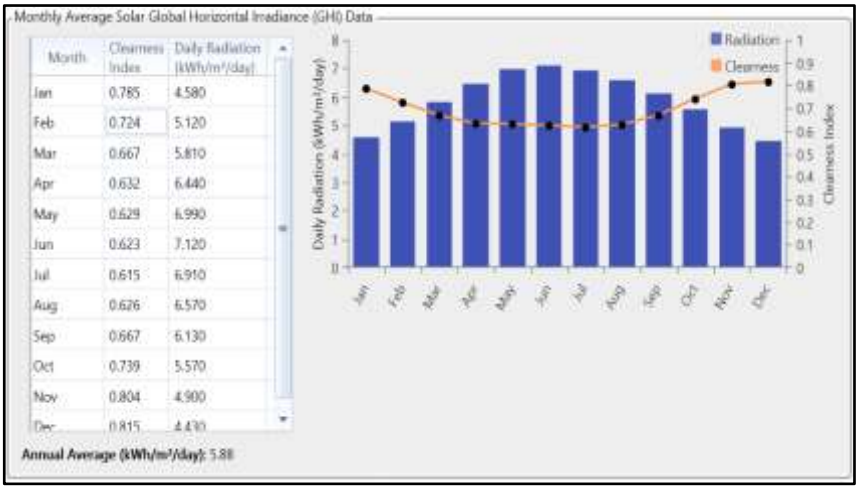

Figure 5: Monthly Distribution of Solar Irradiance and Clearness Index from HOMER Simulation (Basra, Iraq).
Source: Authors, (2026).

VII.1.1 Annual Average Solar Radiation

Over the course of the year, 5.88 kWh/m²/day is the average amount of solar energy received. The basis for assessing the potential for solar energy in various seasons is this figure.

VII.1.2 Monthly Breakdown of Solar Radiation

To illustrate how solar energy potential fluctuates throughout the year, Table 3 presents a monthly breakdown of solar radiation (in kWh/m²/day) and related energy output (in kWh). Understanding the monthly effectiveness of solar power generation requires an understanding of these figures.

Table 3: Monthly Breakdown of Solar Radiation and Energy Production.

Month	Solar Radiation (kWh/m²/day)	Energy Production (kWh)
January	0.687	0.687
February	0.768	0.768
March	0.8715	0.8715
April	0.966	0.966
May	1.0485	1.0485
June	1.068	1.068
July	1.0365	1.0365
August	0.9855	0.9855
September	0.8505	0.8505
October	0.8355	0.8355
November	0.756	0.756
December	0.6645	0.6645

Source: Authors, (2026).

VII.1.3 Cleanness Index

Clearer skies that are suitable for solar energy generation are indicated by values closer to 1 on the Cleanness Index, which measures sky purity.

• Highest Cleanness Index: With a Cleanness Index of 0.815, December has the clearest skies and the best solar-generating conditions.

• Lowest Cleanness Index: June has the lowest Cleanness Index (0.623) despite high solar radiation, indicating that air quality and cloud cover may have an impact on energy output.

VII.1.4 Seasonal Trends

• Spring to Summer: Solar radiation rises from January to June, reaching its maximum in June. In most locations, this cyclical pattern where summertime solar energy rises as the sun's angle becomes more direct—is common.
• Fall to Winter: Solar radiation levels decrease from June to December, with the lowest levels occurring in December. This decrease is due to reduced daylight hours and wintertime solar intensity.
• Cleanness Index Trends: During the summer, when there is usually more cloud cover, the Cleanness Index exhibits a similar seasonal tendency, peaking in December before declining.

VII.1.5 Energy Calculation

the annual energy production is calculated from a solar panel using the average daily solar radiation values for each month, assuming a panel area of 1 m² and an efficiency of 15%. The formula for calculating energy is as follows:
Esolar = Area × Radiation × Efficiency

Where:

• Area = 1 m² (for simplicity),
• Radiation = Monthly solar radiation values in kWh/m²/day,
• Efficiency = 0.15 (15%).

7.1.6. Solar Energy Calculation Results

Based on the provided monthly solar radiation values and assuming a 1 m² panel area with 15% efficiency, the monthly and total energy production is calculated as follows:
Monthly Energy Production (in kWh):
• January: 0.687 kWh
• February: 0.768 kWh
• March: 0.8715 kWh
• April: 0.966 kWh
• May: 1.0485 kWh
• June: 1.068 kWh
• July: 1.0365 kWh
• August: 0.9855 kWh
• September: 0.8505 kWh
• October: 0.8355 kWh
• November: 0.756 kWh
• December: 0.6645 kWh
Total Annual Energy Production: The total annual energy production from the solar panel is approximately 10.54 kWh.

VII.2 ANALYSIS OF MONTHLY AVERAGE WIND SPEED AND WIND ENERGY PRODUCTION

The Monthly Average Wind Speed data is analyzed in this study to assess the energy potential of a wind turbine in the area. The energy generated by a 3-meter-diameter wind turbine running at 35% efficiency, seasonal patterns, and wind speed breakdown are all included in the analysis. Figure (6) shows the data on wind speed and its seasonal fluctuations.

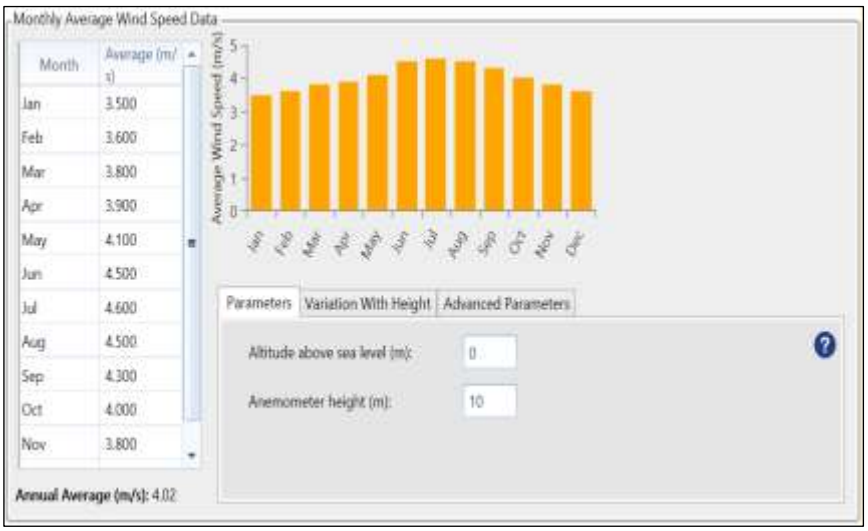

Figure 6: Analysis of Monthly Average Wind Speed Data.
Source: Authors, (2026).

VII.2.1 Annual Average Wind Speed

The annual average wind speed is 4.02 m/s, which indicates a moderate wind resource throughout the year.

VII.2.2 Monthly Breakdown of Wind Speed

As shown in Table 2, the monthly breakdown of wind speed (in m/s) and the corresponding energy production (in kWh) is presented. This data highlights the variation in wind speed and energy output throughout the year, indicating the periods of higher wind potential that can optimize energy generation.

Table 4: Monthly Breakdown of Wind Speed and Energy Production.

Month	Wind Speed (m/s)	Energy Production (kWh)
January	3.60	0.0707
February	3.60	0.0831
March	4.00	0.0899
April	4.10	0.1044
May	4.30	0.1381
June	4.40	0.1475
July	4.60	0.1381
August	4.30	0.1205
September	4.00	0.0970
October	3.80	0.0831
November	3.60	0.0707
December	3.60	0.0707

Source: Authors, (2026).

Seasonal Trends

• Spring and Summer (March to August): This season appears to be the most effective for generating wind energy because of the normally greater wind speeds, which peak in July at 4.60 m/s.
• Fall and Winter (September to February): During these colder months, wind speeds drop somewhat from 4.30 m/s to 3.60 m/s.
• Wind Energy Potential: The area has a moderate wind resource, with the greatest potential for wind energy generation occurring during the summer. As a result, wind turbines can operate effectively during these months.

Wind Energy Calculation

To calculate the energy production from a wind turbine, we use the following formula:
$E_{wind}=0.5 \times \rho \times A \times V^3 \times \eta$

Where:

ρ= Air density (1.225 kg/m³)
A= Swept area of the turbine blades ($A=\pi \times (D/2)^2$)
V = Wind speed (m/s)
η = Efficiency (35%)

The monthly energy production is calculated using the wind speed values for each month.

Wind Energy Production Calculation Results. Based on the monthly average wind speeds and the 3-meter diameter wind turbine with 35% efficiency, the monthly and total energy production is calculated as follows:

Monthly Energy Production (in kWh):

• January: 0.0707 kWh
• February: 0.0831 kWh
• March: 0.0899 kWh
• April: 0.1044 kWh
• May: 0.1381 kWh
• June: 0.1475 kWh
• July: 0.1381 kWh
• August: 0.1205 kWh
• September: 0.0970 kWh
• October: 0.0831 kWh

• November: 0.0707 kWh
• December: 0.0707 kWh

Total Annual Energy Production: The total annual energy production from the wind turbine is approximately 1.21 kWh.

VIII. CONCLUSION

Future power generation can be dependable with a hybrid solar-wind system. The Basra simulation confirmed solar dominance with supporting wind input, so validating their complementarity under local conditions. Global experiences, especially in China, Germany, and the US, demonstrate that hybrid systems frequently outperform single-source setups in terms of cost-effectiveness and reliability. Further developments in storage technology, intelligent control, and supportive legal frameworks are anticipated to make these systems essential in accelerating the transition to low-carbon and sustainable energy.

IX. FUTURE WORKS

Based on your research on solar-wind hybrid systems, here are some potential future works that could further expand and refine the field:

1. Optimization of Hybrid System Configurations: Future research could focus on developing advanced optimization models to determine the optimal size, configuration, and placement of solar and wind components within hybrid systems, considering local climate, weather patterns, and energy demands.
2. Advanced Energy Storage Solutions: Investigating the integration of next-generation energy storage technologies (e.g., solid-state batteries, flow batteries, compressed air energy storage) to improve the efficiency and reliability of hybrid systems, particularly in off-grid applications.
3. Smart Grid Integration and AI: Further exploration of how artificial intelligence (AI) and machine learning can be integrated into hybrid systems for real-time optimization and predictive maintenance, allowing for better energy management and grid stability.
4. Impact of Climate Change on Performance: Assessing how the growing effects of climate change (e.g., temperature fluctuations, shifting wind patterns, and changing sunlight availability) might influence the long-term performance and reliability of solar-wind hybrid systems.
5. Hybrid Systems in Urban Areas: Exploring the application of solar-wind hybrid systems in urban areas where space constraints are a challenge. Research could focus on integrating these systems with urban infrastructure (e.g., rooftops, vertical farms) for improved land use.
6. Sustainability of Manufacturing and Disposal: Researching the sustainability of materials used in hybrid energy systems, focusing on recycling and the reduction of environmental impacts from manufacturing and end-of-life disposal, particularly for wind turbine blades and solar panels.

Differential Relay

ABSTRACT

DC microgrid development is increasing mainly due to its simplicity of operation and greater focus on renewable energy sources like solar, wind, etc. It comprises less losses than AC microgrid and can easily connect and disconnect distributed generation (DG). Conventional techniques of DC microgrid protection is challenging. Using MATLAB Simulink, a DC microgrid with a PV system, battery, and AC main grid along with converters including boost, buck, and voltage source/modular multilevel converters is simulated. This study compares the performance of modular multilevel converters and voltage source converters, as well as the way they protect DC microgrid in the case of an AC main grid fault condition. Additionally, for improved fault clearing response in overcurrent situations, the differential relay is used on the AC main grid, nearer to the transformer.

I. INTRODUCTION

Nowadays, grid integration and renewable energy sources are the primary areas of research study. Due to fossil fuels are becoming extinct and their emissions affect the environment, the usage of renewable energy sources has been growing. Decentralized generation (DG) is connected using both island/isolated and grid-connected techniques [1]. The grid-connected state has significant advantages over the island state. In grid-connected state, the grid provides power to the load is able to meet its demand in the event that there is any problem with the decentralized generation (DG). Depending on the type of system, converters including inverters, rectifiers, and filters are required for connecting decentralized generation (DG) to the grid. An extensive collection of decentralized generation systems is called a microgrid [2]. Compared to AC microgrids, DC microgrids are more effective, like the absence of reactive power and synchronization problems [3], [4]. DC microgrids have greater power transfer capabilities [5]. A DC microgrid's power flow is more robust due to multiple sources can connect to a single bus [6].

To integrate a AC main grid with the DC microgrid, a converter is required. These include multilevel converters, voltage source converters (VSC) and current source converters (CSC) [7]. Multilevel converters are utilized for large power applications, while voltage source converters operate efficiently for small and medium power applications. Current source converters (CSC's) need external AC capacitors for reactive power compensation and required forced or line commutation. VSCs are the most compatible and widely used topologies. But due to its complex construction and lack of adaptability when extending the voltage or power range, VSC is not suitable for high power applications. For high power applications modular multilevel converter is used. Capacitors and at the DC bus, additional passive filters are not necessary with MMCs, which is an advantage [8]. For DC Microgrid protection, the differential overcurrent relay is used near to the transformer for precise fault detection [9].

II. FAULT PROTECTION ANALYSIS

On a microgrid, the current direction changed whenever a fault occurred [10]. Circuit breakers receive the signal from relays and turn off the system that is out of fault. The DC Microgrid current direction before and after the fault develops as shown in the diagram below [11], [12].

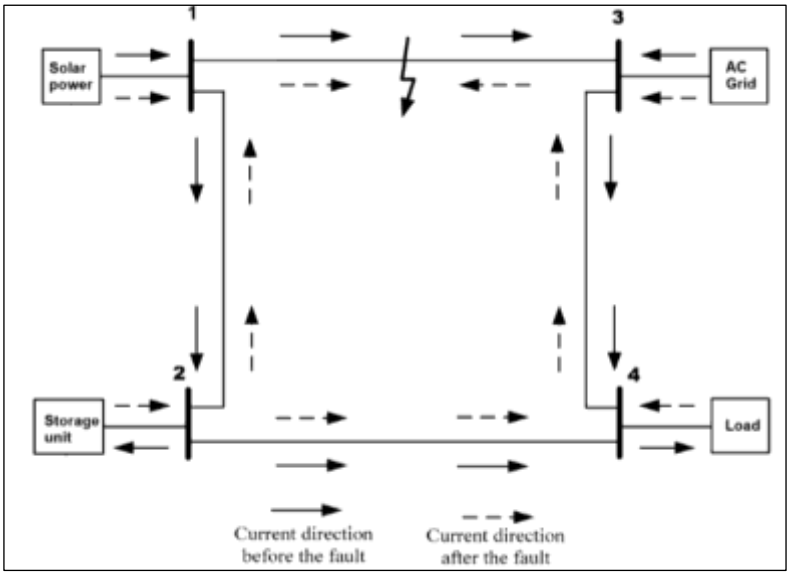

Figure 1: Before and after fault DC Microgrid current direction.
Source: Authors, (2026).

The VSC and MMC act as switch between the AC main and the DC microgrid, as shown below [9].

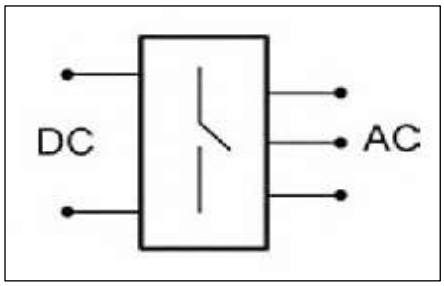

Figure 2: VSC/MMC acts as switch between DC and AC system.
Source: Authors, (2026).

The circuit design for the MMC and VSC are shown below. Capacitors are present in the Modular Multilevel Converter's (MMC) sub module block. In order to safeguard the DC Microgrid against faults, the MMC does not require any external large capacitors [13-15].

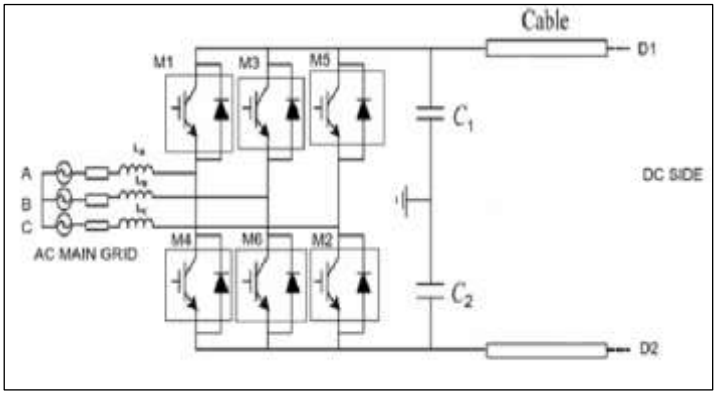

Figure 3: VSC circuit diagram.

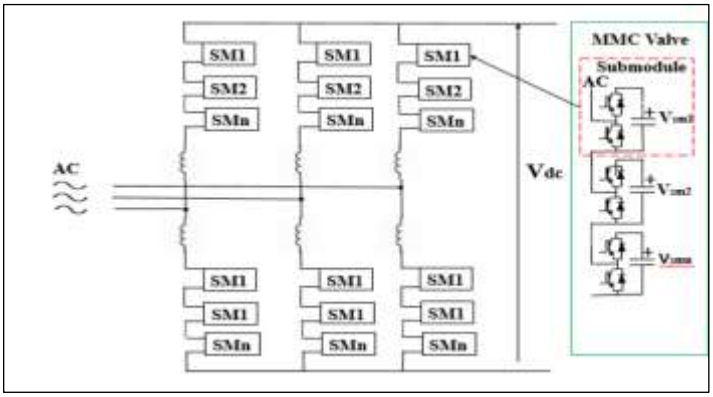

Figure 4: MMC circuit diagram.

Source: Authors, (2026).

The three cases below shows the fault that occurred on the DC side. The condition before the fault occurred was t_o. At this point, the cable current is zero and the capacitor reaches its full charge. At t_o, the fault occurred, the cable current is gradually increasing, and the capacitor's stored charge is gradually decreasing. When the capacitor's stored charge reaches zero at t_1, the grid gradually begins feeding. The charging of the capacitor starts at t_2 [16].

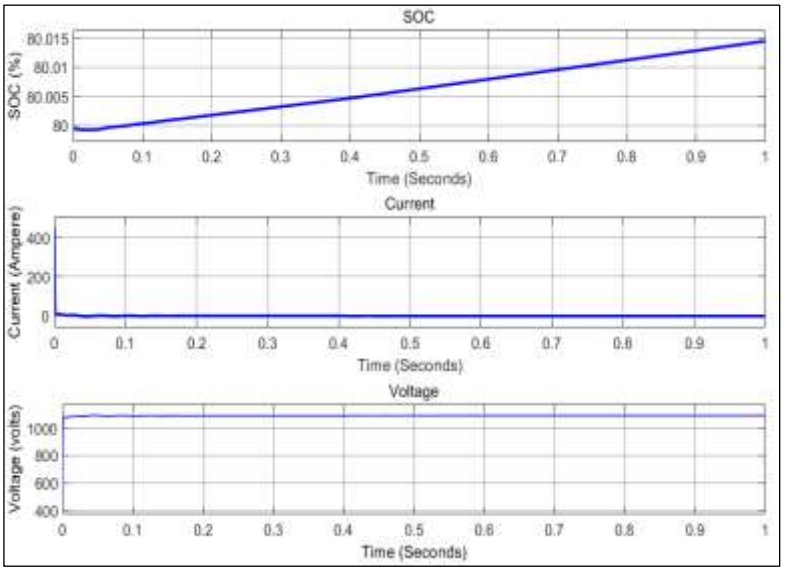

Figure 10: Battery parameters.
Source: Authors, (2026).

The figures mentioned above display the voltage, current, and diode current of the PV system. A DC microgrid's output voltage is 1.169KV. Lithium-ion battery parameters are displayed.

IV.1 FAULT CONDITION (LLLG) OF VSC

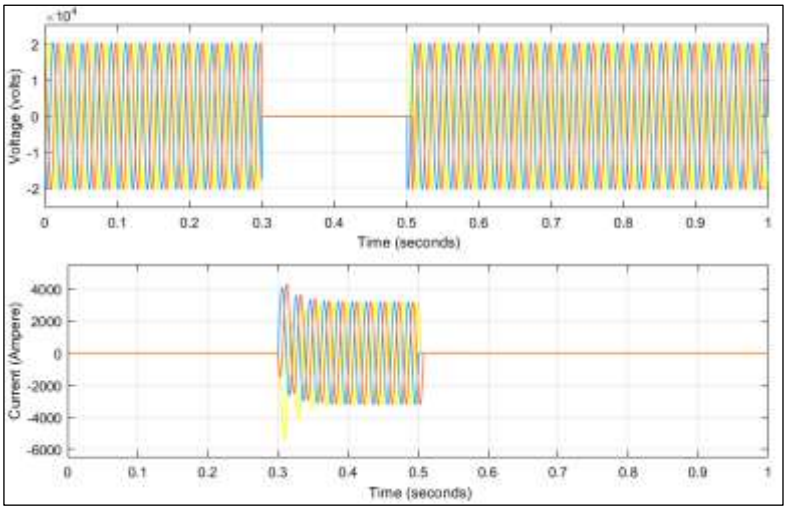

Figure 11: Voltage and current of AC Main Grid by using VSC.
Source: Authors, (2026).

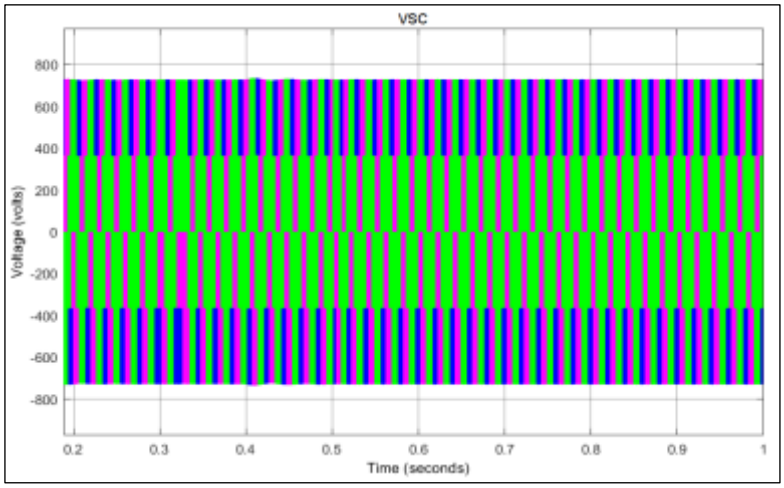

Figure 12: Voltage of VSC.
Source: Authors, (2026).

The LLLG fault is applied between 0.3 and 0.5 seconds on the AC Main Grid. Variations in AC Main Grid voltage and current are noted before to, during, and after fault clearance conditions. But the fault does not much interpret the voltage of Voltage Source Converter. In this way, the Voltage Source Converter protects the DC microgrid from faults.

IV.1.1 Fault Condition (LLLG) of MMC

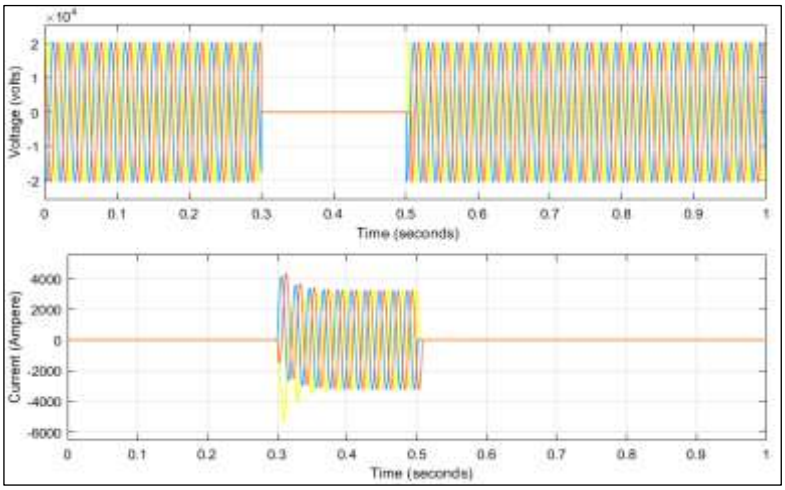

Figure 13: Voltage and current of AC Main Grid by using MMC.
Source: Authors, (2026).

The LLLG fault is applied between 0.3 and 0.5 seconds on the AC Main Grid. Variations of voltage and current in AC Main Grid are noted before, during, and after fault clearance conditions. But the fault does not much interpret the voltage of the modular multilevel converter.

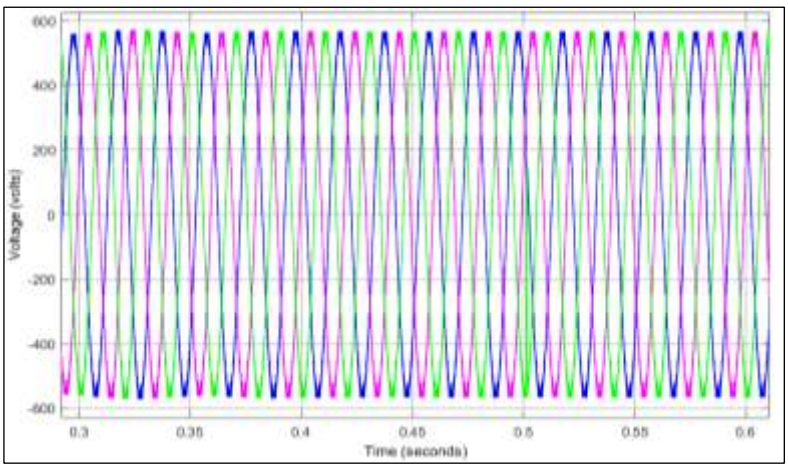

Figure 14: Voltage of MMC.
Source: Authors, (2026).

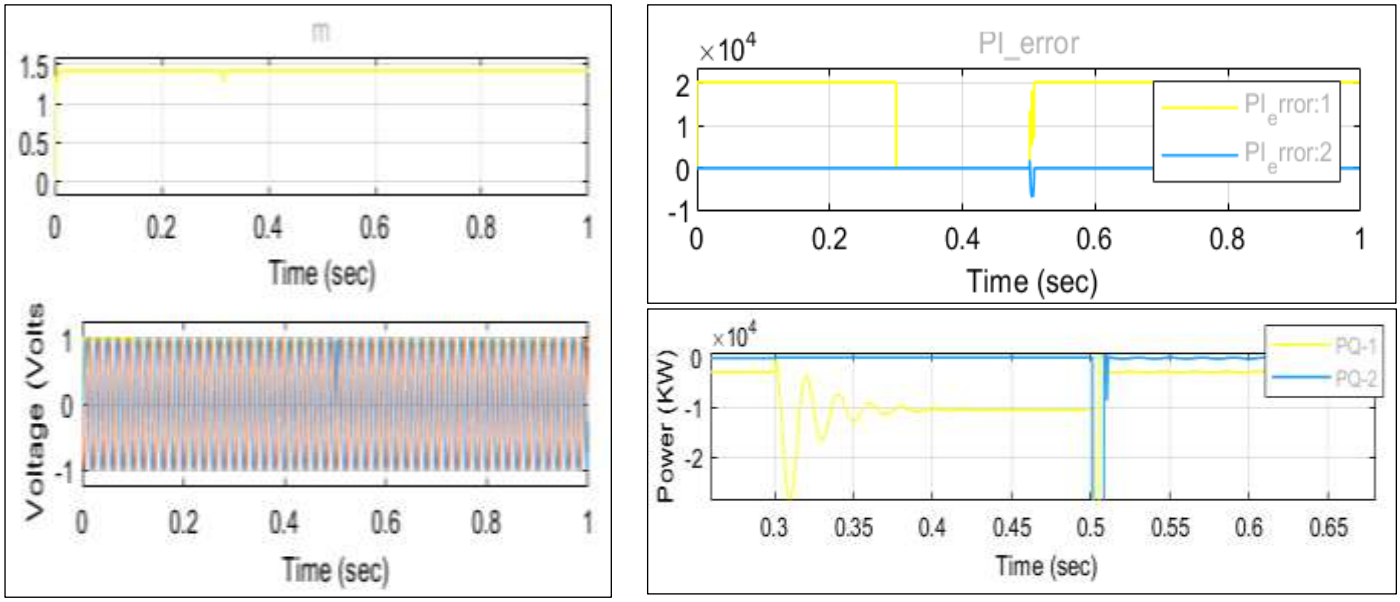

Figure 15: Waveforms of power and modulation index.
Source: Authors, (2026).

An inverter with six switches three for the positive arm and three for the negative arm is created using MMC circuit 32 IGBT. When the model is ready, it runs for one second, and on the AC Main Grid side, fault is imposed at time periods of 0.3 and 0.5 seconds. For voltage regulation, an MMC based on VSC is used. The triggering signal is produced by a triangle waveform generated by MMC with PWM [17], and the reference voltage is controlled by a circuit. The PWM input receives a reference voltage of 1pu that is generated in the controlling structure.

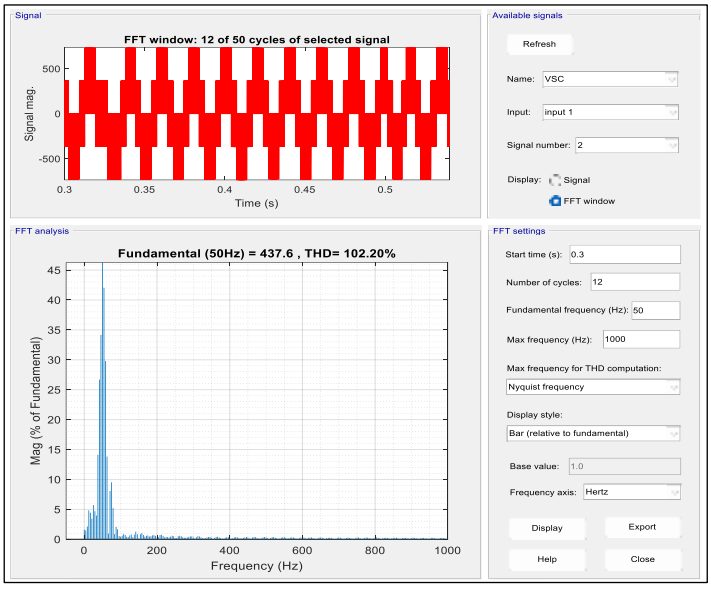

Figure 16: FFT Plot of VSC.
Source: Authors, (2026).

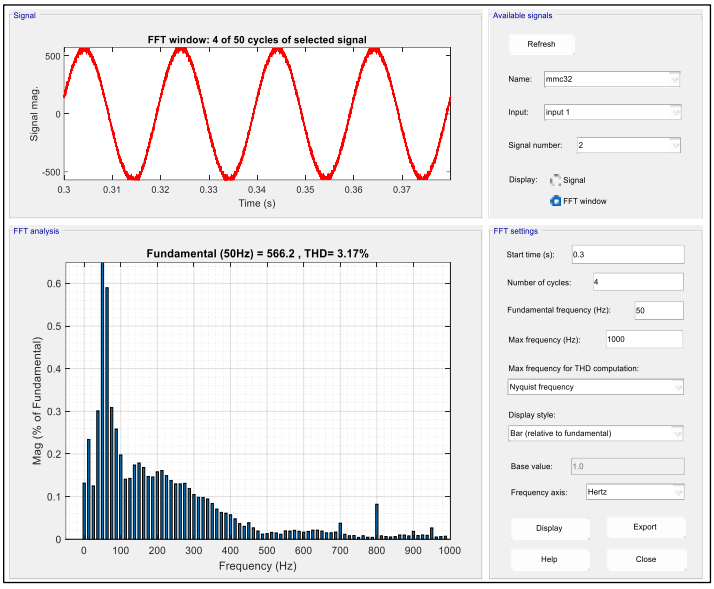

Figure 17: FFT Plot of MMC.
Source: Authors, (2026).

IV.1.2 Comparative Study

The Comparison of (THD)% of VSC and MMC is shown below.

Table 2: Comparison of (THD)% of VSC and MMC.

Parameters	VSC	MMC
Total Harmonic Distortion (THD)%	102.02	3.17
Fundamental Frequency (50Hz)	437.6	566.2

Source: Authors, (2026).

From the comparative study, the total harmonic distortion (THD) percentage of the voltage source converter (VSC) is 102.02%, whereas that of the modular multilevel converter (MMC) is 3.17%. The Modular Multilevel Converter (MMC) lowers harmonic frequencies. In terms of DC Microgrid protection, this indicates that the modular multilevel converter performs better than the voltage source converter.

V. CONCLUSIONS

MATLAB Simulink is used to analyze the DC microgrid's fault protection analysis using a VSC and a MMC. When compared to a voltage source converter, the THD analysis of a 32-level IGBT modular multilevel converter based on VSC exhibits good results. When the AC main grid has a fault, the 32-level IGBT modular multilevel converter based on VSC operates better at protecting the DC microgrid. The Power Electronics Building Block model is used due of the system's highly modular design and execution. Only a differential relay is used for fault protection and a PI controller is used. Neural network ANFIS converters, various relays and filters can be used further.

ABSTRACT

This paper provides an applied guide to the use of experimental methods, particularly A/B testing, in the FinTech sector, leveraging Python-based tools. It examines how these techniques validate business hypotheses, optimize interfaces, personalize financial services, and enhance critical metrics such as conversion and retention. Using a rigorous experimental design, the study evaluates treatment effects on conversion rates, deposits, and user activity through t tests, z tests, bootstrap resampling, and regression models. Results confirm a significant uplift in conversion rates but show no substantial effects on deposits or post-conversion engagement, thereby delimiting the scope of impact. Heterogeneous effects across age segments are identified, with strategic implications for targeted personalization and risk management. The article highlights the importance of incorporating ethical safeguards, transparency, and regulatory compliance when experimenting with sensitive financial data, and proposes a replicable, scalable methodological framework for researchers and practitioners.

I. INTRODUCTION

Over the past decade, the FinTech sector has undergone a significant transformation driven by advances in artificial intelligence, data analytics, and experimental methodologies. The convergence of digital financial services and information technologies has given rise to a new generation of financial products that are more accessible, personalized, and efficient [1]. In this context, the capacity of FinTech firms to make decisions grounded in empirical evidence has become a key source of competitive advantage [2]. Experimental methods and A/B testing in particular have emerged as fundamental tools to validate business hypotheses, optimize user interfaces, personalize financial services, and improve key metrics such as customer retention and customer lifetime value (CLV). A/B testing enables the comparison of two or more variants of a digital product such as a web interface, a personalized interest rate, or a marketing campaign with the aim of determining which one delivers superior performance with respect to a predefined set of metrics[3], [4].

Originating in the domain of classical experimental design, this methodology has been adopted and adapted by high-growth technology companies such as Amazon, Netflix, and Google, and it now constitutes standard practice in the FinTech environment [5]. Nevertheless, the rigorous implementation of A/B testing in financial settings presents substantial challenges: selection bias, interference between users, issues of external validity, and ethical dilemmas associated with the manipulation of financial products [6], [7]. The situation becomes even more complex when experiments are conducted in real time with highly sensitive data, where errors can entail economic and regulatory consequences [8]. In addition, the explosion of data and the adoption of microservice architectures demand that these experiments be automated, reproducible, and scalable a requirement that has been facilitated by modern Python tools such as statsmodels and SciPy, as well as specialized libraries like Evidently, Optimizely, and PyAB. The integration of these technologies has enabled both startups and established banks to implement continuous experimentation systems [9], [10].

This article provides an applied guide to implementing experimental methods and A/B testing in the FinTech context using Python, with the objective of bridging the gap between statistical theory and its practical execution in production systems. The guide is grounded

in recent studies, industry best practices, and real-world use cases in the digital financial industry. It also discusses extensions such as multivariate testing, Bayesian testing, and adaptive experimentation, offering a comprehensive and up-to-date perspective for researchers, developers, and data scientists in FinTech.

II. LITERATURE REVIEW

A/B testing, also known as a randomized controlled experiment, is a widely used technique in applied research to establish causal inferences between a manipulated variable and an observed outcome. Its rise in digital environments is attributable to platforms' ability to randomly assign treatments to large user populations and to record resulting behavior with precision [3]. By directly comparing two variants (A and B), the approach assesses which one yields superior performance on predefined metrics such as conversion rate, user retention, or profitability. On platforms such as Amazon, Google, or Netflix, this technique has been fundamental to the continuous improvement of interfaces and personalized services. [3] and [8] describe how controlled experimentation becomes an operating system for innovation when integrated with automated tooling and rigorous statistical principles. These advances have been transferred to the FinTech domain, where precise measurement of the impact of algorithmic changes, pricing strategies, or design interventions is essential.

The FinTech sector presents particularities that complicate the application of A/B testing: regulatory compliance, the sensitivity of financial data, high interdependence among users, and the need for explainability in automated decisions [9]. and [10].notes that A/B tests can be useful for evaluating alternative credit-scoring tools, financial inclusion strategies, or digital identity validation mechanisms. Nevertheless, such experiments must be conducted under ethical oversight, especially when treatments affect sensitive decisions such as credit approval, assignment of credit limits, or insurance personalization. [11-13] caution that, although randomized experiments are methodologically robust, they can generate unintended consequences if interference effects among users or historical algorithmic biases are not addressed. In this regard, [14], [15] propose the design of experiments on social networks using cluster randomization techniques that control spillovers among connected nodes a particularly useful practice in FinTech applications based on reputation systems or peer-to-peer lending.

Beyond the classical hypothesis-testing approach based on p-values, authors such as [16] and [17] have proposed Bayesian frameworks for experimentation that allow for a more intuitive interpretation of results and the dynamic updating of evidence as data are collected. This is especially relevant in FinTech, where contexts can change rapidly, and decisions must adapt to emerging user behaviors. Bayesian methods yield posterior distributions for the parameters of interest, thereby facilitating probabilistic decision-making. [17] introduces the multi-armed bandit approach, which dynamically adapts treatment allocation to maximize expected value, thus reducing exposure to ineffective alternatives. [18] also highlights the role of Bayesian A/B testing as an accelerator in product-validation processes. These approaches are ideally suited to financial contexts in which risk is inherent to decision-making, and it is necessary not only to identify the superior alternative but also to quantify uncertainty and minimize the associated losses.

From a computational standpoint, Python has become the dominant language for experimentation in data science due to its flexibility, active community, and rich library ecosystem. Tools such as statsmodels, SciPy, PyAB, Evidently, and Bayesian PyAB enable the implementation of A/B tests, analysis of key metrics, automated visualizations, and real-time monitoring of experiment validity [19]. Additionally, commercial platforms like Optimizely and Google Optimize offer APIs that integrate with Python workflows, facilitating the execution of experiments within production data pipelines. [20], [21] propose microservice-based continuous experimentation architectures, which are especially relevant for FinTechs seeking to scale products across multiple market segments. Tools such as MLflow, Dagster, and Airflow make it possible to combine experimental design with DevOps and MLOps practices, thereby facilitating reproducibility, auditing, and traceability crucial aspects for compliance with financial regulations such as GDPR, PSD2, and banking-supervision requirements.

The use of A/B testing in FinTech raises important ethical challenges. Experimental decisions can affect a user's eligibility for credit, insurance, or investment services; consequently, transparency and fairness become essential pillars [6], [22]. Recent literature emphasizes the need to audit algorithms and to ensure that tests do not reinforce existing biases or generate indirect discrimination. [22] introduce the concept of "algorithmic audits" to evaluate the social impact of automated systems, while [23] analyze mechanisms for explainability and accountability in financial algorithmic contexts. These perspectives are fundamental when implementing experimental methods that affect sensitive variables such as interest rates, credit limits, or approval rates. Therefore, the specialized literature broadly supports the use of A/B testing in FinTech, provided that robust methodological safeguards, appropriate technological tools, and ethical principles aligned with fairness and user protection are adopted.

III. MATERIALS AND METHODS

From an anonymized dataset of 10,000 customers of a Segment-1 cooperative savings and credit institution in Ecuador, the study adopts a classical A/B randomized experiment to estimate the causal effect of a digital Fintech intervention (e.g., a redesigned onboarding flow, a promotional banner, or a new deposit screen). Each observation corresponds to a unique user exposed once during the study window. Assignment to control A or treatment B was performed via simple randomization with probability $P(B) = 0.5$, without replacement and at the user level. Under protocol compliance, the treatment indicator $D_i = \mathbf{1}\{i \in B\}$ is independent of the potential outcomes $(Y_i(0), Y_i(1))$. This independence guarantees identifiability of the Average Treatment Effect (ATE) as

$$\tau = \mathbb{E}[Y(1) - Y(0)] = \mathbb{E}[Y \mid D = 1] - \mathbb{E}[Y \mid D = 0]. \quad (1)$$

The primary outcome is the binary conversion $Y_i^{\text{conv}} \in \{0,1\}$, which flags whether the user completes the target action (e.g., onboarding or first deposit). Secondary outcomes capture usage intensity: deposited amount among converters $Y_i^{\text{dep}} \geq 0$, number of logins login_count_i, and active days days_active_i.

Pre-treatment covariates used for balance checks and precision gains include age_i, self-reported $income_i$, and historical activity metrics prior to the intervention. Duplicates were removed, missingness was documented, and monetary variables were winsorized at the

top 1% to mitigate outliers while preserving mean interpretability. Before effect estimation, balance between groups is validated through mean-comparison tests on pre-treatment covariates. For each continuous variable $X \in \{age, income,$ login_count, days_active$\}$ we apply a two-sided Welch t-test:

$$t = \frac{\bar{X}_A - \bar{X}_B}{\sqrt{\frac{s_A^2}{n_A} + \frac{s_B^2}{n_B}}}, \tag{2}$$

And report the associated p-value. Systematic non-significance (e.g., $p > 0.05$) supports proper randomization and thus the experiment's internal validity. Overlaid histograms by group are inspected to rule out substantial imbalances not captured by the mean. The main hypothesis tests whether conversion rates differ between A and B. Let $p_A = \mathbb{E}[Y^{\text{conv}} \mid D = 0]$ and $p_B = \mathbb{E}[Y^{\text{conv}} \mid D = 1]$. The two-proportion z-statistic is

$$\hat{z} = \frac{p_B - p_A}{\sqrt{\hat{p}\,(1-\hat{p})\left(\frac{1}{n_A} + \frac{1}{n_B}\right)}}, \qquad \hat{p} = \frac{n_A p_A + n_B p_B}{n_A + n_B} \quad , \tag{3}$$

Under $H_0: p_B = p_A$. We report point estimates, a 95% confidence interval (CI), and a two-sided p-value. Business magnitude is also communicated as the relative lift,

$$\text{lift} = \frac{p_B - p_A}{p_A}. \tag{4}$$

For the deposited amount among converters, we estimate a conditional mean effect by comparing Y^{dep} in the sub-sample $\{i: Y_i^{\text{conv}} = 1\}$. Given its continuous and skewed nature, we contrast mean differences via Welch's t-test and accompany the analysis with boxplots to visualize median and dispersion; when appropriate, robustness is checked with a 10% trimmed mean or a bootstrap difference in medians. To characterize treatment heterogeneity, the sample is stratified ex-post by age bands $S \in \{< 30,\ 30\text{–}50,\ > 50\}$ using binning on $[18{,}30{,}50{,}70)$. For each segment we estimate

$$\hat{\tau}_S = \mathbb{E}[Y^{\text{conv}} \mid D = 1, S] - \mathbb{E}[Y^{\text{conv}} \mid D = 0, S \tag{5}$$

These analyses are descriptive and interpreted cautiously to avoid multiple-comparison pitfalls; when a segment shows signal, we complement with bootstrap CIs and recommend future ex-ante stratification in the sampling design. Uncertainty around the ATE in conversion is further quantified via nonparametric bootstrap with independent resampling within A and B. For iterations $b = 1, \ldots, B$ (with $B = 5000$), we draw with replacement $A^{(b)}$ and $B^{(b)}$ matching original sizes and compute $\hat{\tau}^{(b)} = \bar{Y}_{B^{(b)}} - \bar{Y}_{A^{(b)}}$. The 95% CI is given by $[q_{2.5},\ q_{97.5}]$ of the empirical distribution $\{\hat{\tau}^{(b)}\}$, providing a normal-assumption-free interval particularly useful with low rates or unequal sizes. To gain precision and control residual noise, we estimate a linear probability model of conversion on treatment and pre-treatment covariates:

$$Y_i^{\text{conv}} = \beta_0 + \beta_1 D_i + \gamma_1\, age_i + \gamma_2\, income_i + \gamma_3\, \text{login_count}_i + \gamma_4\, \text{days_active}_i + \varepsilon_i. \tag{6}$$

Under randomization and protocol compliance, the causal interpretation of β_1 coincides with the ATE, and we report OLS estimates with heteroskedasticity-robust (HC3) standard errors. As a sensitivity check, we also fit a reduced model

$$Y_i^{\text{conv}} = \beta_0 + \beta_1 D_i + \eta_i, \tag{7}$$

To verify that adding controls improves efficiency without altering the sign or order of magnitude. For continuous outcomes (Y^{dep}, login_count, days_active) we apply analogous OLS specifications; if heavy tails persist, we test log-transformations on $(Y^{\text{dep}} + c)$. Placebo and bias validations include tests on variables that should not respond to treatment, such as pre-intervention income. A Welch t-test on $income$ between A and B is expected to be non-significant; otherwise, we diagnose potential randomization issues or attrition. We additionally inspect missingness rates by column and the distribution of sample sizes by group to rule out differential measurement bias. Inference adopts $\alpha = 0.05$ with two-sided tests, and Holm–Bonferroni adjustments are noted when evaluating multiple secondary outcomes. For ex-ante statistical power, we use the standard approximation for a difference in proportions with 1:1 allocation. Given significance α and power $1 - \beta$, the Minimum Detectable Effect (MDE) around a baseline rate p satisfies

$$\text{MDE} = \left(z_{1-\alpha/2} + z_{1-\beta}\right)\sqrt{\frac{4\,p(1-p)}{n}}, \tag{8}$$

Where n is the total sample size. This quantifies whether $n = 10{,}000$ is adequate for the business-relevant lift. Although the analysis is ex-post, reporting the MDE contextualizes the sensitivity of findings. The workflow is implemented reproducibly in Python: pandas for data handling, scipy.stats for t- and z-tests, statsmodels for OLS with robust errors, and plotly for interactive figures. The pipeline proceeds through reading and cleaning, balance verification, the primary conversion test, analysis of financial and activity metrics, age-based heterogeneity, bootstrap uncertainty quantification, and robustness regressions, followed by placebo and experiment-quality checks. Code is organized in self-contained cells to facilitate auditability and replication. Regarding validity, randomization and balance checks support internal validity; external validity is restricted to the cooperative's clientele and time period analyzed. The intervention is purely digital and does not alter contractual conditions or fees, so participant risk is minimal.

Privacy and data-security principles are observed through irreversible anonymization, attribute minimization, and exclusive use for product-evaluation purposes, consistent with the local personal-data protection framework. Finally, interpretation is aligned with

Fintech decision-making: if the p-value is below 0.05 and the ATE CI excludes zero with business-relevant magnitude, the *B* variant is recommended; if effects are null or uncertain, we favor the lower-cost alternative or iterate the design incorporating segment learning with ex-ante stratification. This protocol offers an applied, mathematically grounded, and operational guide for product teams in cooperative financial institutions, scalable to continuous experimentation cycles with robust causal rigor.

IV. RESULTS AND DISCUSSIONS

It is the logical presentation of the results that demonstrate the true contribution of the research and also justify the conclusion. The parts indicated above, Introduction, Material and Methods serve to explain how the results are obtained. Use tables and figures for your explanation. The results must be written in the past, in a brief and simple way. Avoid redundancy. Analyzing and interpreting the results is part of the discussions, their importance, achievements and limitations, highlighting the innovative aspects of the practical applications of the study and the conclusions derived from them, delimiting unresolved issues. If necessary, recommendations can be proposed. In this first stage of the experimental analysis, the aim is to verify that the random assignment of users to groups A (control) and B (treatment) was effective that is, that both groups are comparable prior to any causal analysis.

To this end, several observable variables are examined: age, income, number of logins (login_count), and days active on the platform (days_active). Validation is performed by comparing the means of these variables across groups using an independent-samples t test. This procedure assesses whether there are statistically significant differences in the means of the variables considered. The p-value obtained in each t test indicates the probability of observing a difference as large as the one found if, in fact, no difference exists in the population. In this case, the p-values were 0.2378 for age, 0.9431 for income, 0.4110 for login count, and 0.8552 for days active. All of these values are well above the conventional 0.05 threshold, so we conclude that there are no significant differences between groups. The analysis is complemented by a descriptive summary of the means for each variable in both groups.

For example, the average age in group A was 34.94 years, whereas in group B it was 34.72 years. Similarly, average income was virtually identical: 30,052 for A and 30,066 for B. The average number of logins was 5.01 in A versus 4.98 in B, and days active were 14.98 and 14.95, respectively. These figures indicate that both groups exhibit nearly identical characteristics, reinforcing the validity of the randomization. To visualize these results, histograms generated with the Plotly library were used. These plots display how each variable is distributed within each group and allow any notable overlaps or differences to be observed. The distributions for age, income, logins, and days active show a high degree of visual similarity between groups A and B, confirming the statistical findings (see Table 1).

Table 1: Step 1 – Validation of balance between groups.

Variable	p-value	Mean Group A	Mean Group B
age	0.2378	34.94	34.72
income	0.9431	30,051.88	30,065.77
login_count	0.4110	5.01	4.98
days_active	0.8552	14.98	14.95

Source: Authors, (2026).

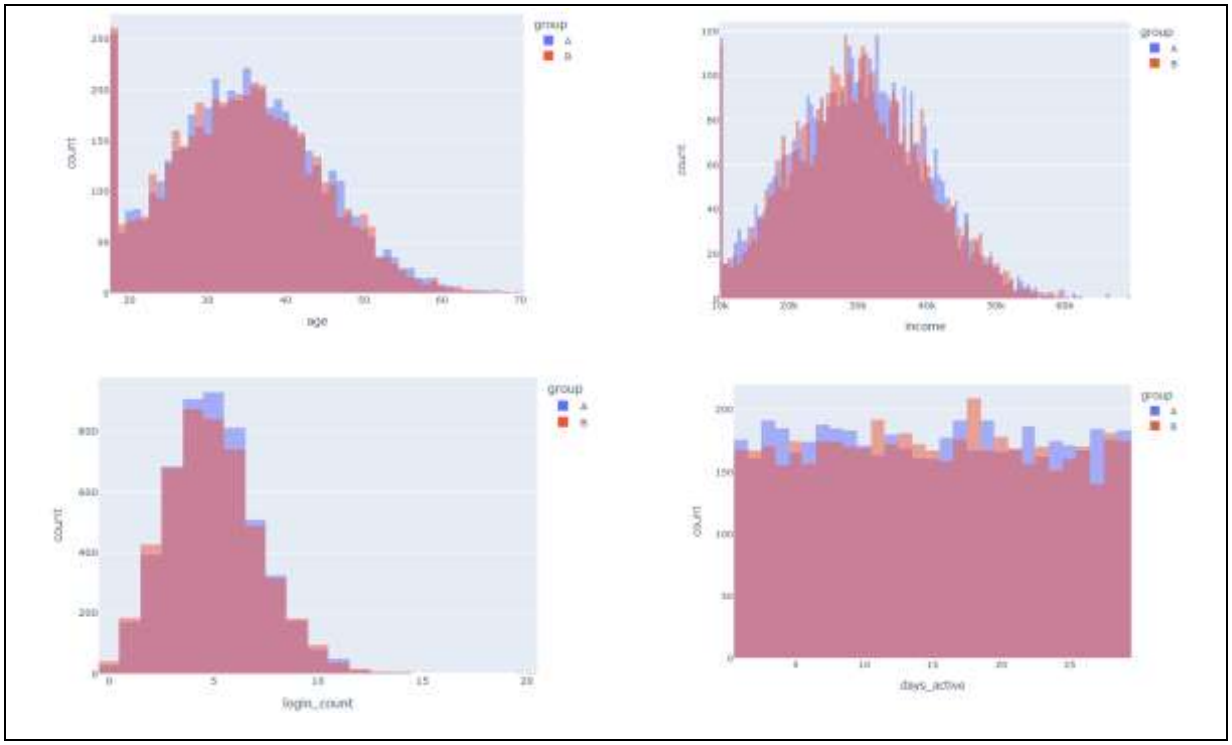

Figure 1: Step 1 – Distribution among groups.
Source: Authors, (2026).

In the second step of the analysis, we evaluate whether the treatment applied to group B had a significant effect on conversion; that is, whether the proportion of users who performed the desired action (e.g., opening an account or completing a registration) is higher relative to group A. To this end, we compute the conversion rate in each group and then apply a formal statistical test. In this case, a z test for the difference in proportions specifically designed to compare the success rates of two independent groups was used. The results show that the conversion rate in group A was 0.0985, whereas in group B it was 0.1509. This difference represents a relative increase of more than 50%. To determine whether this difference is statistically significant, we calculated the z statistic, which was −7.9389. The associated p-value was less than 0.0001, indicating that the probability of observing so large a difference by chance alone, if no true effect existed, is virtually zero. Consequently, we reject the null hypothesis of equal proportions and conclude that the treatment had a significant effect on conversion. The observed difference is also depicted with a bar chart, which clearly shows that the height of the bar corresponding to group B is substantially greater than that of group A. This provides a clear and intuitive visualization of the treatment's positive effect. In sum, this analysis offers strong statistical evidence that the intervention applied to group B significantly increased the user conversion rate (see Table 2).

Table 2: Step 2: Conversion analysis and hypothesis testing.

Metric	Group A	Group B	Test Statistic	p-value
Conversion Rate	0.0985	0.1509	z = -7.9389	0.0000

Source: Authors, (2026).

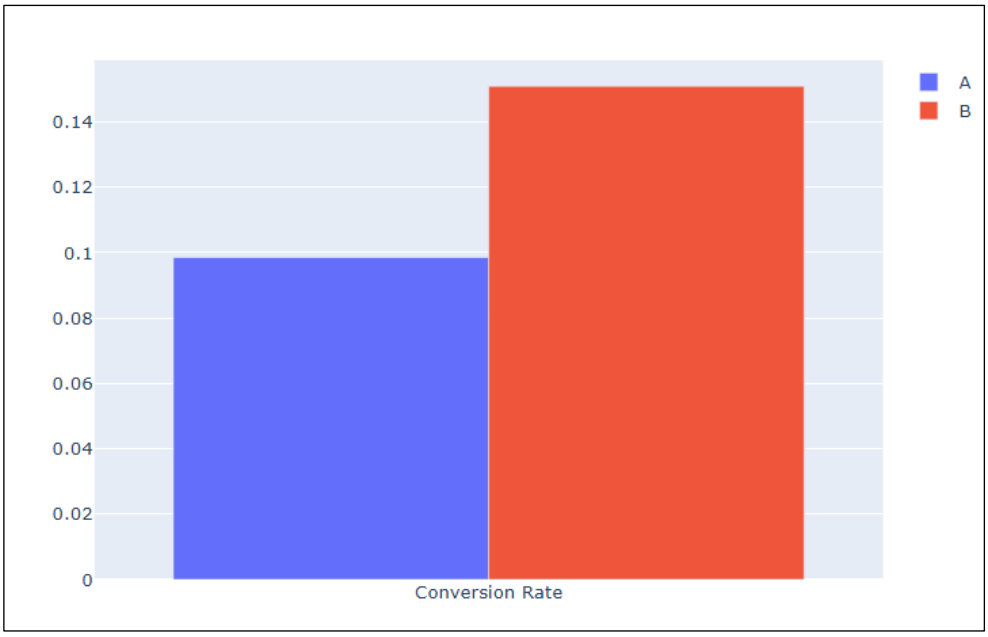

Figure 2: Step 2: Conversion rate by group.
Source: Authors, (2026).

In this third step, we analyze whether the treatment affected not only conversion but also users' subsequent financial and operational behavior specifically, the amount deposited, the number of times they logged into the platform, and the days they remained active. These indicators are crucial for assessing conversion quality: it is not sufficient to convert more users if they subsequently do not interact or generate revenue. To begin, an independent-samples t test was applied to compare the deposited amount between groups A and B, considering only users who actually converted. The result was a t value of −0.4683 and a p value of 0.6397, indicating no statistically significant difference between the two groups in terms of deposited amount. Although the group B distribution appears visually to have a slightly higher median, variability in the data and overlap between distributions render this difference inconclusive from a statistical standpoint.

Boxplots make this pattern clear. In the deposited-amount plot, both the median and the dispersion are similar across groups. A handful of outliers appear on both sides as is to be expected with financial data but there is no evidence of a systematic treatment effect. With respect to the number of logins (login_count) and days active (days_active), the boxplots likewise show very similar distributions for groups A and B, both in terms of median and interquartile range. This suggests that post-conversion behavior, in terms of platform use, was not altered by the treatment. Although group B achieved a significantly higher conversion rate, the users who converted in that group did not deposit more money nor were they more active than those in group A. This is an important finding because it helps distinguish between superficial conversion and conversion that yields real business value (see Table 3).

Table 3: Step 3: Analysis of Financial Metrics (Amount and Activity).

Metric	Test Statistic	p-value
Deposited Amount	t = -0.4683	0.6397

Source: Authors, (2026).

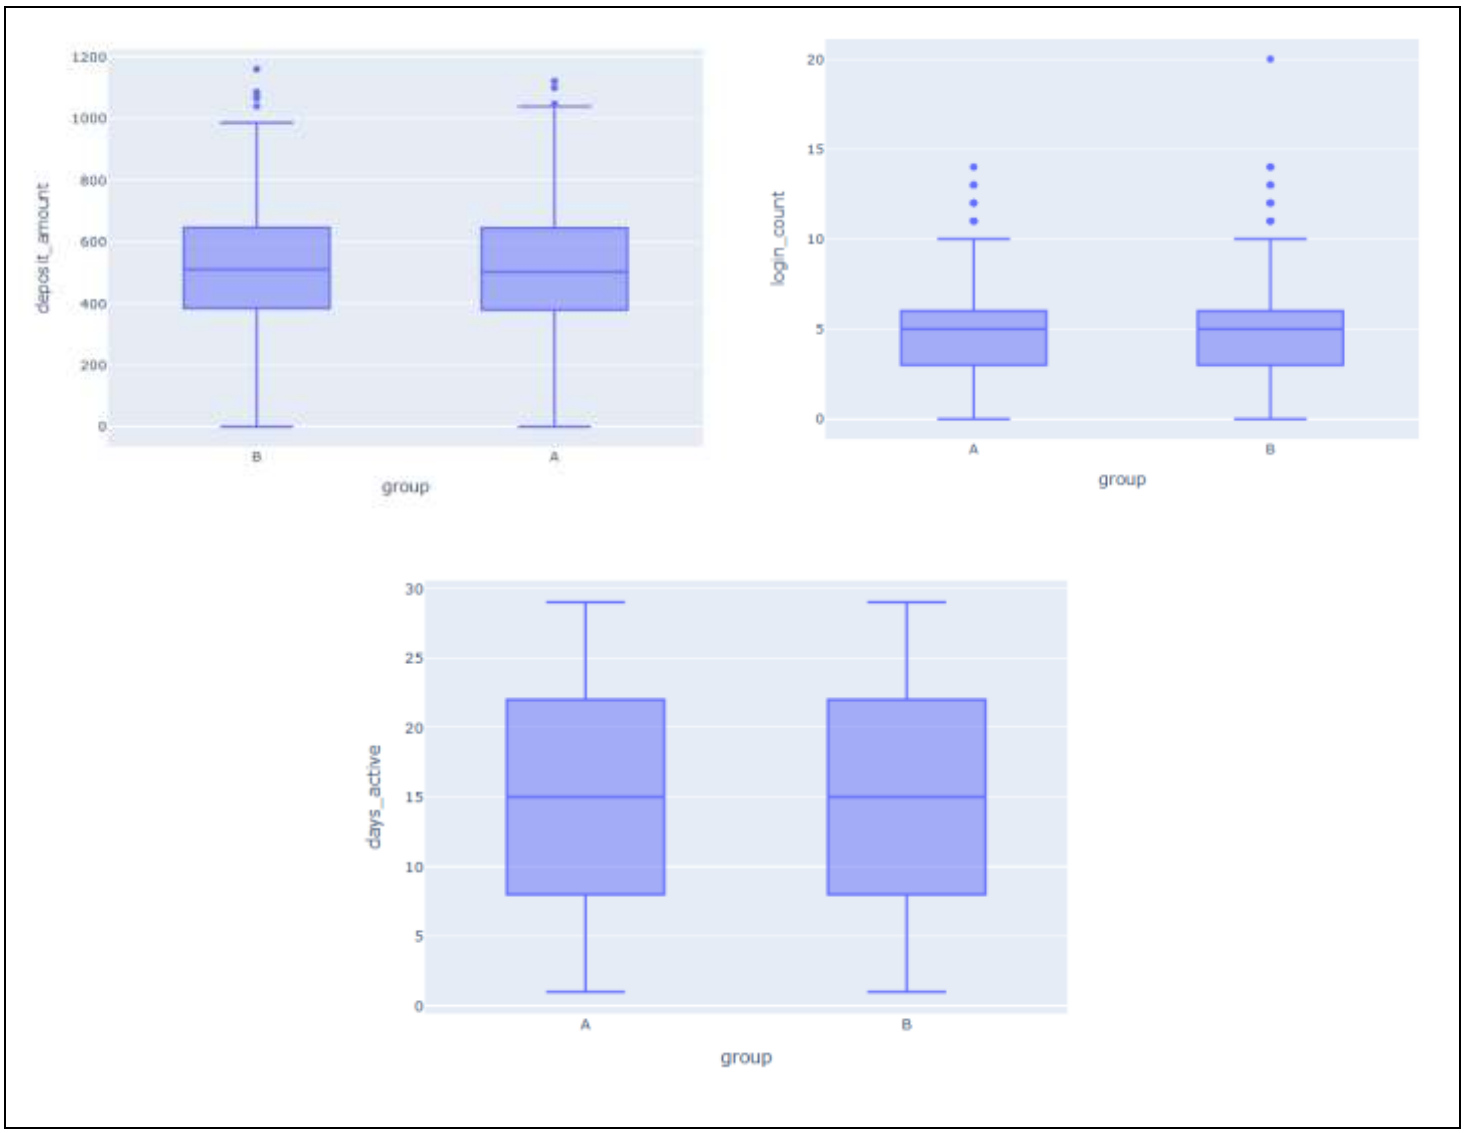

Figure 3: Step 3: Conversion rate by group.
Source: Authors, (2026).

At this stage (see Table 4), we investigate whether the treatment's impact varies by users' age segment, thereby identifying potential heterogeneous effects. To this end, the age variable was partitioned into three brackets: under 30, 30–50, and over 50. We then computed the conversion rate for each age group, disaggregated by experimental arm (A or B). This segmentation makes it possible to detect whether the treatment was more effective for certain demographic profiles. The results show that group B consistently outperformed group A across all three age segments. Among users under 30, the conversion rate was 9.4% in group A and 16.1% in group B, an absolute difference of 6.8 percentage points. In the 30–50 segment, the rates were 10.0% for A and 14.5% for B, a 4.5-point difference. Among users over 50, group B reached a conversion rate of 16.2%, compared with 8.9% for group A the largest observed difference (7.3 percentage points).

A grouped bar chart reinforces this reading. In every segment, the bars corresponding to group B are notably higher than those for group A, indicating that the treatment's positive effect holds across age ranges. However, the impact is slightly larger at the extremes (<30 and >50), suggesting that these groups may be more sensitive to the change introduced by the experiment. This segmented analysis is valuable because it reveals that, although the treatment is beneficial overall, its magnitude varies across user subgroups. Such information can be used to design more personalized campaigns or to allocate the treatment more efficiently in future deployments. It also rules out the possibility that the observed effect on overall conversion is driven by a single segment, which adds robustness to the conclusions.

Table 4: Step 4: Treatment heterogeneity analysis (segmented).

Segment	Conversion A	Conversion B	Difference
< 30	0.094	0.161	0.068
30–50	0.100	0.145	0.045
> 50	0.089	0.162	0.073

Source: Authors, (2026).

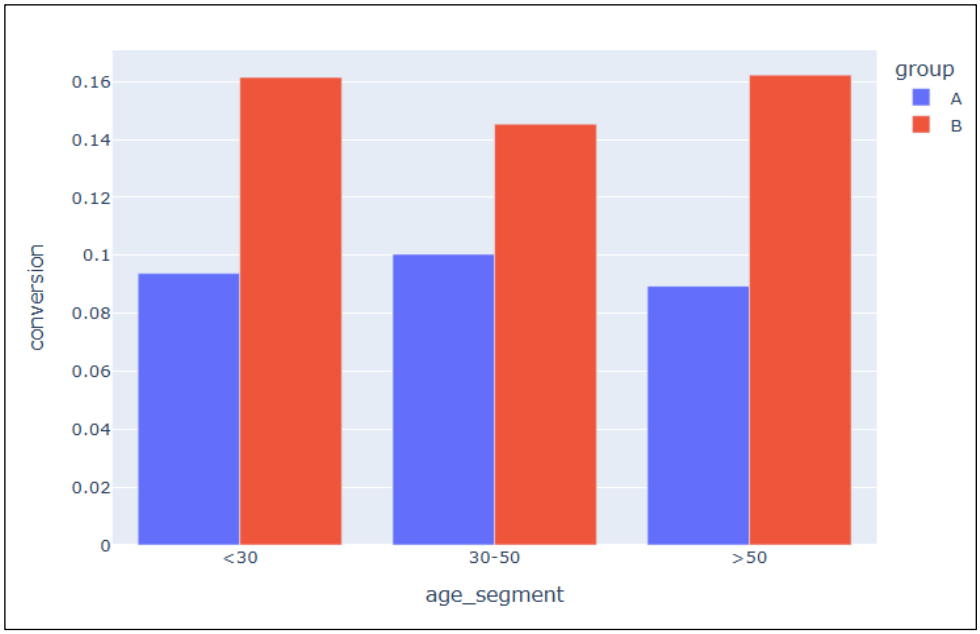

Figure 4: Step 4: Distribution in bar chart Treatment heterogeneity analysis (segmented).
Source: Authors, (2026).

In this fifth step, we apply a resampling technique bootstrap to robustly estimate the average treatment effect (ATE) on conversion together with a confidence interval. Unlike traditional parametric tests, bootstrap does not assume normality or homoscedasticity; instead, it draws many random samples with replacement from the original data and computes the statistic of interest at each iteration. Here, 5,000 iterations were performed, computing the difference in conversion rates between group B and group A for each resampled dataset. This procedure yields an empirical distribution of the ATE, from which a 95% confidence interval can be obtained by extracting the 2.5th and 97.5th percentiles. The resulting mean ATE was 0.0524 that is, an absolute difference of 5.24 percentage points in favor of group B. The confidence interval ranged from 0.0391 to 0.0652, indicating that, with 95% confidence, the true treatment effect lies within this interval. The accompanying plot depicts the distribution of conversion-rate differences across all simulations. The curve is approximately normal, centered around the mean value (0.0524), with red dashed lines marking the confidence-interval bounds. This visualization shows that virtually all simulations yielded a positive effect, reinforcing confidence in the robustness of the result (see Table 5).

Table 5: Step 5: Bootstrap-based confidence intervals for the treatment effect.

Metric	**Estimate**	**95% CI (Lower – Upper)**
ATE (Bootstrap)	0.0524	0.0391 – 0.0652

Source: Authors, (2026).

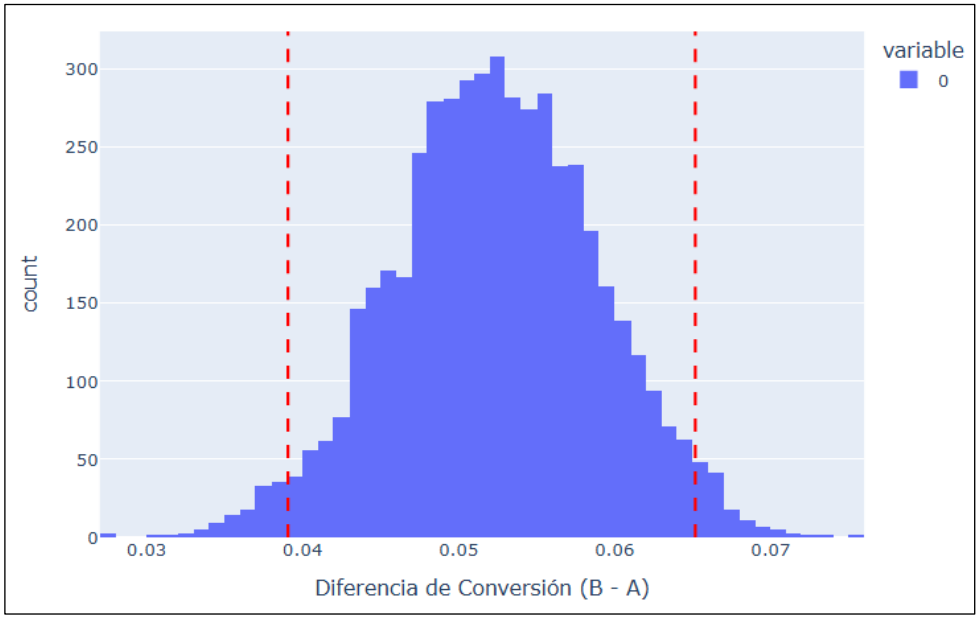

Figure 5: Step 5: Histogram of Bootstrap-based confidence intervals for the treatment effect.
Source: Authors, (2026).

In this step (see Table 6), an ordinary least squares (OLS) regression model is used to estimate the causal effect of the treatment on conversion while controlling for additional variables. Although conversion is a binary variable (0 or 1), OLS can be employed as an initial approximation to the average treatment effect, and it also allows inspection of the influence of other explanatory variables. In this model, the dependent variable is conversion, and the predictors are the assigned group (group), age, income, number of logins, and days active. The most relevant coefficient is that associated with group B (C(group)[T.B]), which has an estimated value of 0.0523 with a standard error of 0.0066. This implies that, holding the other variables constant, belonging to group B increases the probability of conversion by approximately 5.23 percentage points—a result that is highly consistent with the findings in the previous steps.

In addition, the p-value associated with this coefficient is less than 0.0001, confirming that the effect is statistically significant. This p-value measures the probability that so large a difference would occur by chance if group B truly had no effect. As for the remaining variables, none is statistically significant: age has a negative coefficient but a p-value of 0.207; income has a p-value of 0.337; the number of logins is irrelevant (p = 0.383); and days active likewise shows no effect (p = 0.278). This indicates that, within this model, the only factor clearly associated with conversion is assignment to the treatment group. The model's R-squared is very low (0.007), which is common in models with binary outcomes and reflects that most individual variability is not explained by the included covariates. However, the objective here is not to predict conversion but to estimate the causal effect of the treatment, which is clearly obtained.

In this seventh step (see Table 7), the goal is to validate the robustness of the experiment, ensuring that the results obtained are not artifacts of methodological errors, hidden biases, or spurious effects. To this end, three complementary strategies are applied: a placebo test, a review of experimental integrity, and a sensitivity analysis with simplified models. The placebo test consists of applying the same type of statistical comparison used to measure the treatment effect, but to a variable that should not be influenced by the treatment. In this case, income was chosen as the placebo variable, since there is no reason to expect that belonging to group A or B would alter users' income. A t test was conducted to compare income across groups, yielding a t value of −0.0714 and a p value of 0.9431. Such a high p-value indicates that there is no significant difference between groups, which validates that the experimental design is not generating systematic false positives. Next, a quality review of the data and assignment was carried out. No missing values were found in any key variable of the experiment, indicating that there was no dropout or data loss in the process.

The only exception was the age_segment column used solely for the segmented analysis which contains 517 null values due to users whose ages fell outside the defined range. Furthermore, the distribution of users across groups was very close to 50%, with 50.76% in group A and 49.24% in group B, confirming that random assignment was executed correctly.

Subsequently, a sensitivity verification (see Table 8) was conducted using a reduced regression model that included only two variables: group and age. The objective is to assess whether the coefficient for group B remains stable when other covariates are removed. The results show that the coefficient for group B remains exactly 0.0523, with a p-value less than 0.0001, indicating that the treatment effect does not depend on the inclusion of additional variables in the model. This stability reinforces confidence that the observed effect is robust and not conditioned by model specification.

V. CONCLUSIONS

The experimental program provides convergent evidence that the treatment materially improves user conversion while preserving internal validity. Random assignment yielded well-balanced groups across observable covariates (age, income, login_count, days_active), and classical tests failed to detect any pre-treatment imbalances. In the primary outcome, the treatment produced a large and statistically precise lift in conversion rising from 9.85% in the control arm to 15.09% in the treated arm corroborated by a z-test with $p<0.0001$. Bootstrap estimation further quantified this effect with a mean average treatment effect (ATE) of 5.24 percentage points and a narrow 95% confidence interval [3.91%, 6.52%], indicating that the uplift is not an artifact of parametric assumptions and is robust to resampling uncertainty. Causal estimation with a linear probability model (OLS) that controlled for user demographics and baseline activity yielded a treatment coefficient of 0.0523 (SE=0.0066; $p<0.0001$), essentially identical to the nonparametric bootstrap estimate. Taken together, the randomized comparison, the resampling analysis, and the regression adjustment converge on the same quantitative conclusion: the intervention consistently increases the probability of conversion by about five percentage points.

Robustness checks placebo testing on income, integrity audits of missingness and assignment ratios, and a reduced-form sensitivity model found no evidence of hidden bias, data leakage, or specification dependence, reinforcing the credibility of the causal claim. At the same time, secondary outcomes delineate the boundary of the treatment's impact. Among converters, the intervention did not increase deposited amounts nor post-conversion engagement (logins and active days); distributions and inferential tests show no statistically meaningful differences between arms on these metrics. This pattern implies that the treatment primarily improves top-of-funnel behavior (initial conversion) without yet translating into deeper behavioral or financial value. In managerial terms, the intervention appears to drive "shallow" conversions rather than high-value activations, a distinction that is crucial for revenue forecasting, lifetime-value modeling, and budgeting of acquisition spend. Heterogeneity analyses by age segment show that the uplift is broad-based but not uniform: effects are directionally larger in users under 30 and over 50, with mid-age users showing a smaller yet still positive gain.

This profile suggests immediately actionable targeting policies. In the short run, firms could prioritize deployment in the more responsive segments to maximize near-term ROI while designing complementary nudges aimed at upgrading mid-segment users from initial conversion to meaningful activation. In the medium term, these findings motivate segment-specific experimentation (e.g., multivariate tests tuned to frictions and value propositions salient for each cohort). These results carry two strategic implications. First, acquisition and activation should be treated as distinct optimization problems: the tested treatment is a strong lever for conversion, but it should be paired with post-onboarding interventions (e.g., personalized prompts, financial education micro-journeys, product bundling, or rate-structure trials) to unlock deposit growth and durable engagement. Second, evaluation should migrate from single-metric hypothesis tests to multi-objective experimental design that jointly tracks conversion, early-value proxies (first-week deposits, feature adoption), and forward-looking business KPIs (predicted CLV, retention hazard).

Doing so will align experimental success criteria with financial materiality. Methodologically, the study's triangulation across classical tests, bootstrap inference, and covariate-adjusted models is a strength, as is the suite of robustness diagnostics. Future extensions could corroborate the estimates with generalized linear models (logit/probit), apply Bayesian A/B frameworks for continuous monitoring and decision thresholds, and incorporate adaptive allocation (multi-armed bandits) to improve sample efficiency while respecting guardrails for fairness and regulatory compliance. Because the treatment does not yet shift value-creation metrics, uplift modeling at the user level (treatment effect heterogeneity on deposits/engagement) and experiment-within-experiment designs (sequential interventions after conversion) are natural next steps. Finally, given the financial context, governance remains central. Any scale-up should include pre-registered analysis plans, segment-level fairness audits, and continuous monitoring for interference and spillovers (especially where social or referral effects may arise). By coupling disciplined experimentation with ethical safeguards and value-focused KPIs, organizations can translate the demonstrated conversion uplift into sustained, equitable, and auditable business impact.

ABSTRACT

The piled raft (PR) foundation system combines a shallow raft with deep piles, mobilising both components through complex raft–pile–soil interactions. Due to its effectiveness under vertical and lateral loads, it is widely used to support tall, heavily loaded structures. However, the complexity of the system often leads to reliance on simplified design methods. This study uses numerical simulations in FLAC3D to investigate the effect of pile battering on the behaviour of PR and pile group (PG) foundations in drained sandy soils. Unlike previous research combining vertical and battered piles, only battered piles are adopted here to isolate their influence under combined loading. A batter angle of 10° is selected to avoid excessive bending moments. Results indicate that battered piles improve lateral resistance in PR foundations by up to 66%, though vertical capacity is slightly reduced (by 14%) due to axial–bending interaction. Under combined loading, vertical piles outperform battered ones in overall resistance gain (55.7% vs. 38.8%), mainly due to improved soil confinement. Batter piles also play a key role in reducing tilt and enhancing foundation stability. This study offers practical insights for designing foundations exposed to strong lateral forces, such as in offshore structures and wind turbines.

I. INTRODUCTION

Piled raft foundations have gained significant attention in geotechnical engineering as an efficient solution that combines the advantages of both shallow and deep foundations. By integrating a raft with a group of piles, this system enhances load-bearing capacity while minimising differential settlement. Unlike conventional pile or raft foundations, the piled raft system utilises the combined contribution of both components—the raft provides additional bearing support, while the piles primarily control settlement—resulting in improved structural performance and cost-effectiveness [1]. The behaviour of a piled raft is governed by complex soil-structure interactions, including pile-soil, pile-pile, raft-soil, and pile-raft interactions [2-5]. Due to these interactions, accurately evaluating the bearing capacity of piled rafts is challenging and requires consideration of multiple design parameters and soil conditions. While numerous studies have focused on the performance of piled raft foundations under vertical loads [6-11]. Infrastructure such as high-rise buildings, bridges, wind turbines, and offshore platforms are also subjected to significant horizontal loads. Many researchers have stated that it is necessary to understand the response of piled rafts under lateral loading through both experimental investigations and numerical simulations to establish design criteria [12-15]. However, experimental studies on piled rafts subjected to combined vertical and horizontal loading remain limited.

Although recent research efforts have attempted to address this gap by analysing the combined effects of vertical and lateral loads on piled rafts [16], [17], a comprehensive design framework for such conditions has yet to be fully established. Recently, there has been growing interest in incorporating batter piles into piled raft foundations due to their promising potential in enhancing foundation stability. However, research on this topic remains scarce, with only a few experimental and numerical studies available. [18] conducted vertical and horizontal load tests on pile groups and piled rafts with and without batter piles in dry sand under 1g gravitational conditions. Their results demonstrated that batter piles improve resistance and reduce settlement compared to purely vertical piles. Finite element analyses corroborate these findings, offering more profound insight into the resistance mechanisms of these foundation systems. Similarly, [19] employed three-dimensional finite element models to investigate the seismic behaviour of pile groups with batter piles. Their study considered various pile configurations, including groups with a combination of vertical and inclined piles. Both hinged and fixed-headed pile conditions were analysed to assess the influence of pile-to-cap connections. Their results indicated that pile groups with batter piles exhibit greater horizontal stiffness than those composed solely of vertical piles. Other researchers have reached similar conclusions regarding the effectiveness of batter piles. [15], found that replacing vertical piles with batter piles reduces settlement and increases load-carrying capacity.

[20] experimentally investigated 3-pile and 6-pile batter pile foundations under vertical and lateral loads and found that batter piles enhance overall stiffness and reduce settlement. [21] analysed the effect of batter angles ranging from 10° to 30° under lateral loads, determining that an in-battered pile inclination of 15°–20° provides optimal resistance. [22] conducted dynamic load tests on 6-pile foundation models with and without batter piles, demonstrating that piled rafts incorporating batter piles are highly effective in minimising settlement and inclination under vertical dynamic loading. Although numerical simulations have proven to be a powerful tool for understanding foundation behaviour, relatively few numerical studies have explored the influence of batter piles. [23] developed a numerical analysis method to examine deformation and load distribution in piled raft foundations with batter piles. Their parametric studies confirmed that batter piles significantly enhance the deformation behaviour of piled rafts. Given this context, the present study aims to model and analyse the experimental work conducted by [24] while varying the batter pile for two foundation configurations: piled raft and pile group. The objective is to assess the impact of batter angle on vertical and lateral resistance, offering more details about their behaviour under combined loading. By considering the coupled action of vertical and horizontal loading, this study seeks to improve the understanding of failure mechanisms and key design parameters for piled raft foundations with batter piles. The analysis is performed using a three-dimensional numerical model, validated against Matsumoto's experimental study to ensure accuracy and reliability.

II. FINITE DIFFERENCE MODELING

II.1 DESCRIPTION OF THE ANALYSED FOUNDATION SYSTEM

This study investigates the influence of pile inclination on the behaviour of piled raft and pile group foundations subjected to vertical, lateral, and combined loading in sandy soil. The problem is addressed numerically using a three-dimensional finite-difference model, which explicitly captures the interaction between the raft, the inclined piles, and the surrounding soil continuum. Special emphasis is placed on how pile inclination modifies load transfer mechanisms, stiffness, and failure patterns compared with conventional systems supported only by vertical piles. To isolate the mechanical response of inclined piles under combined loading, the foundation system is idealised as consisting solely of inclined piles rather than a mixed arrangement of vertical and inclined elements. This simplification allows a clearer interpretation of the role of inclination angle on global response, raft displacements, and pile forces, without the additional complexity introduced by heterogeneous pile layouts. The numerical framework enables systematic variation of inclination angle and load combination, thereby providing a consistent basis for parametric analysis.

The influence of pile inclination on both vertical and lateral load-carrying capacities is examined using displacement-based failure criteria. For vertical capacity, ultimate bearing capacity is often defined at a settlement equal to 10% of the raft width Br; however, this criterion is not directly suitable for the reduced-scale geometry adopted here. In line with recommendations for small-scale modelling, a stricter settlement limit equal to 10% of the pile diameter d is adopted to define the ultimate vertical capacity, ensuring that the response remains within an appropriate deformation range for model-scale interpretation. For lateral capacity Lpr, a horizontal displacement criterion of 0.1d is employed, consistent with common practice in evaluating laterally loaded pile and piled-raft systems. Within this framework, the effects of inclination are quantified in terms of: (i) ultimate vertical and lateral capacities, (ii) load–displacement behaviour under pure and combined loading, and (iii) load sharing between raft and piles as the inclination angle and loading regime vary. The different external load components and the internal forces mobilised in the piled-raft system under combined vertical–lateral loading are schematically illustrated in Figure 1, providing a conceptual basis for the subsequent numerical analyses.

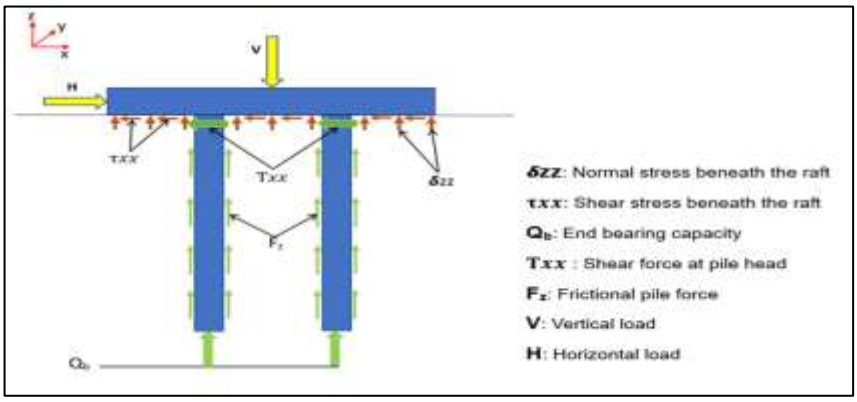

Figure 1: Forces Developed at the Soil-Piled Raft Interface.
Source: Authors, (2026).

The lateral load contribution of the raft (Lr) in the piled raft system is determined by integrating the shear stress at the interface between the soil and the raft. Figure 1 illustrates this, and it is expressed in Equation (1). In these equations, τiixx represents the shear stress at the interface between the soil and the raft for each element i, and dSi is the segment's cross-sectional area of element i.

$$Lr = \iint_{-Br/2}^{Br/2} \tau ixx \ \ dSi \tag{1}$$

Due to the complexity of directly calculating the lateral load contribution of piles, especially inclined piles, it is determined indirectly by deduction. The lateral load carried by the piles (Lp) is calculated as the total lateral load of the piled raft system (Lpr) minus the lateral contribution of the raft (Lr), as expressed in Equation (2):

$$Lp = Lpr - Lr \tag{2}$$

Two foundation configurations are considered: a piled raft foundation where the raft is in direct contact with the soil, and a pile group foundation where the raft is elevated above the ground by a distance equal to the raft thickness. This distinction allows for a clear comparison between configurations with and without raft–soil contact, emphasising the role of the raft in load sharing and settlement control. The effect of pile inclination is examined by comparing vertical (0°) and inclined (10°) pile arrangements. Four configurations were studied, as shown in **Figure 2**, to analyse the combined effect of pile inclination and foundation type on load distribution, settlement behaviour, and lateral resistance. By evaluating the performance of these foundation systems, this study aims to provide insights into the role of pile inclination in optimising foundation design, particularly in sandy soils where both vertical and lateral loads play a crucial role in structural stability.

II.2 MODELING PROCEDURE

This paper conducts numerical simulations using the explicit finite difference code FLAC3D (Itasca Consulting Group Inc., 2013) to assess the behaviour of a battered piled raft under combined vertical and lateral loading in sandy soil. FLAC3D offers robust computational capabilities, making it particularly valuable for analysing foundation systems, where experimental testing, especially on inclined piles, is complex and resource-intensive. Additionally, 1g experimental tests are known to suffer from scale effects and limitations in reproducing real stress conditions, justifying the use of numerical modelling to achieve accurate and scalable results. The numerical model is based on the experimental work of [24] which involved 1g tests on composite piled raft foundations subjected to vertical and lateral loads. The experimental setup consisted of a 400 mm × 400 mm raft, 40 mm thick, supported by four piles of 600 mm length and 40 mm diameter, arranged with uniform spacing of 200 mm in both the x and y directions. The piles were embedded in a two-layer soil profile consisting of 1 metre of Toyoura sand overlying a 1-metre-thick compacted brick base.

While the primary goal is to simulate [24] experimental configuration for validation, the study also aims to contribute to the broader engineering objective of optimising foundation systems for high-rise buildings and structures subject to combined vertical and lateral loads—such as wind turbines and tall towers—by evaluating the effect of pile inclination on load capacity and load sharing. In the simulations, the piles are modelled using six-node cylindrical solid elements, while the raft is represented by a combination of 12-node radial cylindrical solid elements and eight-node brick elements. Although solid elements do not directly capture internal forces, they allow a realistic geometric representation of structural components under external loads. The overall soil domain dimensions are set to 3 m × 3 m × 2 m—twice the lateral extent of the experimental setup—to reduce the influence of boundary effects. Boundary conditions include fixed constraints at the base and lateral restrictions against displacement in the X and Y directions.

The soil is modelled using the Mohr–Coulomb failure criterion, selected for its simplicity and effectiveness in capturing the essential behaviour of sandy soils with minimal input parameters. Although more advanced constitutive models such as the Hardening Soil model exist, the Mohr–Coulomb model is adequate for this study's scope and offers a balance between computational efficiency and realistic approximation of soil strength. The parameters used to simulate Toyoura sand are Young's modulus E = 44 MPa, Poisson's ratio $\nu = 0.3$, unit weight $\gamma' = 15.9$ kN/m3, friction angle $\phi' = 40°$, dilation angle $\psi = 10°$ and cohesion $c' = 0$ kPa. The parameters for the soil and foundation are summarised in Table 1.

Table 1: Material parameters used in [24] and this study.

Parameter	Toyoura sand	Base brick	Foundation
E (MPa)	44	$6x10^3$	$7x10^4$
ν	0,3	0,2	0.3
γ' (kN/m3)	15,90	22	27
c'(kPa)	0	/	/
φ' (°)	40	/	/
ψ (°)	10	/	/
D 50 (mm)	0,17	/	/

Source: [24].

The mesh was carefully refined beneath and around the raft and piles using a fine grid with an element size approaching the average particle diameter of Toyoura sand ($D_{50} = 0.17$ mm). A mesh convergence study was performed and showed that stable, mesh-independent results were obtained when the minimum element size was taken approximately equal to D_{50}, which was therefore adopted in the final model. Mesh refinement was continued until changes in key response quantities (such as raft displacement and pile head shear) between successive refinements fell within a small tolerance, ensuring that the numerical response was controlled by the physics rather than by the discretization. The mesh gradually becomes coarser with distance from the foundation to reduce computational cost while maintaining numerical accuracy. The raft and piles are assumed to be isotropic and perfectly elastic. Soil–structure interaction is simulated using interface elements that allow for realistic relative movement between soil and structural components. Interface properties were defined as follows: friction angle $\delta = 40°$, cohesion $c = 0$ kPa, normal stiffness $Kn = 10^9$ Pa/m, and shear stiffness $Ks = 10^9$ Pa/m.

These interface stiffness values are selected to be sufficiently high to ensure force transfer without inducing unrealistic rigidity, and sensitivity checks confirmed that moderate variations in Kn and Ks had negligible influence on the global response. The loading process was divided into four main steps: (1) gravity loading to generate the initial geostatic stress field; (2) installation of the raft and piles by assigning structural material properties to the relevant zones; (3) application of a uniform vertical load on the raft to simulate a surcharge; and (4) application of a lateral force at the centre of the raft's vertical surface. Vertical and lateral loads were applied incrementally, with the vertical load kept constant during the lateral loading phase to represent combined loading and to capture the progressive development of nonlinearity in the soil response. The numerical model mesh and the foundation dimensions are illustrated in Figure 3.

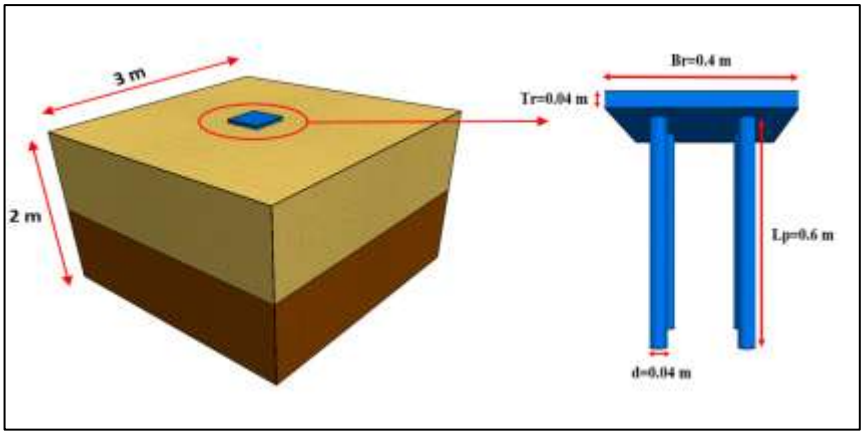

Figure 3: Mesh Pattern and Element Dimensions.

II.3 VALIDATION OF NUMERICAL MODELING

To validate the numerical modelling procedure used in this study, the results were compared with one case study from the seven experimental tests conducted by [24]. In this case, a rigid piled raft foundation was tested under static vertical and static horizontal loading. The loading process was divided into two stages: the vertical loading stage and the cyclic horizontal loading stage. In the vertical loading stage, a total vertical load of Vi =3.384 kN was applied to the model foundation. After completing the vertical stage, a cyclic horizontal loading stage was applied to the model raft. It is important to note that, although cyclic horizontal loading was performed on the model foundation, a monotonic horizontal loading test was also carried out. As illustrated in Figure 4, the numerical results closely align with the experimental data, demonstrating the accuracy of the simulations.

III. RESULTS AND DISCUSSIONS

III.1 PURE VERTICAL LOAD TEST

The influence of pile inclination on vertical resistance was first examined. As shown in Figure 5, increasing the inclination angle from 0° to 10° negatively impacts vertical resistance for both foundation types. Under a vertical load of 3 kN, settlement increases from 0.14 mm to 0.16 mm for the piled raft foundation and from 0.27 mm to 0.316 mm for the pile group foundation. This reduction in vertical resistance occurs because a portion of the applied vertical load is redirected into a horizontal component, reducing the effective axial capacity of the piles. As a result, settlement increases. In piled raft foundations, the decreased pile contribution transfers more load onto the raft, leading to greater deformation. In pile group foundations, inclined piles experience additional bending stresses, further diminishing their ability to resist vertical loads. Consequently, as the inclination angle increases, vertical resistance decreases.

Source: Authors, (2026).

III.2 PURE LATERAL LOAD TEST

In this study, the foundation was initially subjected only to the force of gravity due to its own weight, without any external loads applied. We then analysed the effect of pile inclination on lateral resistance by applying a pure lateral load until a lateral displacement equal to 10% of the pile's diameter was reached. This specific load, as corroborated by several studies, represents the lateral resistance of the foundation. As illustrated in Figure 6, under pure lateral loading, lateral resistance consistently increases with the inclination angle. For the piled raft foundation, increasing the inclination angle from 0° to 10° led to a significant 66% increase in lateral resistance, rising from 2.853 kN to 4.74 kN. In contrast, the increase for the pile group foundation was more modest, with lateral resistance increasing by

21%, from 2.864 kN to 3.478 kN. The increase in lateral resistance with pile inclination is due to the enhanced pile-raft-soil interaction. When piles are inclined, they interact differently with the surrounding soil compared to vertical piles. Instead of resisting the lateral load purely through bending, inclined piles transfer part of this load into axial compression or tension. This redistribution reduces bending stress and increases overall stability. Additionally, a portion of the lateral load is redistributed into axial compression or tension along the pile length, reducing bending effects and enhancing stiffness. This inclination also modifies the pile-soil contact, activating greater lateral resistance, particularly in sandy soil. In a piled raft foundation, the raft's contribution becomes more significant as the axial load component transferred from the inclined piles increases the raft-soil interaction. This combined effect of pile-raft-soil interaction and load redistribution explains the improved lateral resistance observed with inclined piles.

Source: Authors, (2026).

III.3 COMBINED VERTICAL AND LATERAL LOADS TEST

Finally, the behaviour of both foundation types was analysed under a combined loading. For the four configurations mentioned earlier, a vertical load of Vi= 3 kN was first applied until stabilisation, followed by a lateral load until a lateral displacement equal to 10% of the pile diameter was reached. As shown in Figure 6 and Figure 7, lateral resistance under combined loading is higher than under pure lateral loading. For vertical piles in the piled raft foundation, lateral resistance reaches 4.44 kN under combined loading, representing a 55.7% increase compared to pure lateral loading. For inclined piles, lateral resistance under combined loading reaches 6.59 kN, whereas it was 4.74 kN under pure lateral loading, indicating a 38.8% increase. Similarly, for the pile group foundation, lateral resistance increases by 16.23% and 27.4% when the inclination angle changes from 0° to 10°, respectively. This difference in percentage increase can be attributed to the role of vertical load in enhancing soil confinement and increasing normal stress along the pile shaft, which is more beneficial for vertical piles. Additionally, vertical piles rely primarily on passive soil resistance and shaft friction for lateral resistance, while inclined piles already experience higher lateral stiffness, making the effect of vertical load less pronounced.

III.4 LOAD DISTRIBUTION AND LATERAL RESISTANCE UNDER PURE AND COMBINED LOADINGS

III.4.1 Under Pure Lateral Loading

Figure 8 shows that the load-sharing mechanism between the raft and piles under pure lateral load remains constant regardless of pile inclination; however, the contribution of each component varies. As pile inclination increases, both the raft and piles mobilize increased lateral resistance. The lateral resistance of the raft increases by 48% due to greater soil-raft interaction, with inclined piles transferring more load to the raft. Meanwhile, the 69% increase in pile resistance suggests that inclined piles engage a greater soil mass, thus improving their ability to resist lateral loads. It is important to highlight the complexity of the soil-raft interaction. Comparing piles in the PR system with piles in the PG system, when the piles in the PR system are vertical, they support 89% of the load carried by the piles in the PG system. However, at an inclination of 10°, this percentage reaches 123%. This increase results from the higher axial forces developed by inclined piles due to their orientation, which improves the efficiency of load transfer. Therefore, inclined piles not only improve lateral resistance, but also significantly change the overall load distribution within the foundation system.

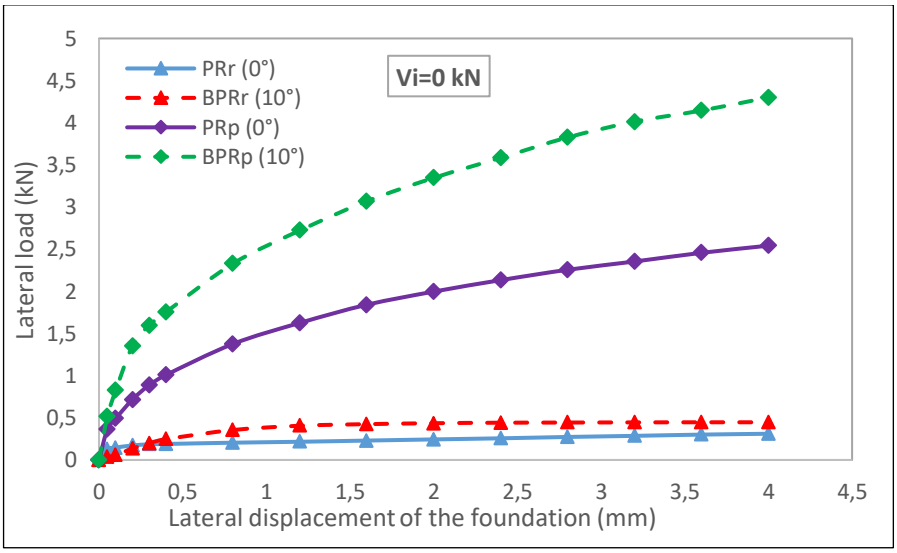

Figure 8: Distribution of Lateral load vs lateral displacement curves for PRr, BPRr, PRp and BPRp under pure lateral load.
Source: Authors, (2026).

III.4.2 Under Combined Vertical and Lateral Loads

Under combined loading, increasing pile inclination enhances lateral resistance for both foundation types. As shown in Figure 9, the lateral contribution of the raft increases slightly from 0.641 kN to 0.691 kN, while the pile contribution rises more significantly from 3.8 kN to 5.9 kN. While comparing the lateral resistance of vertical and inclined piles in PR against that of PG. For vertical piles, the lateral resistance in the PR is 3.8 kN, slightly higher than the 3.32 kN observed for PG. Similarly, for inclined piles, the piles in BPR exhibit greater lateral resistance 5.9 kN compared to BPG 4.4 kN. These results indicate that under vertical loading, both vertical and inclined piles in a PR exhibit improved lateral performance due to enhanced interaction with the surrounding soil.

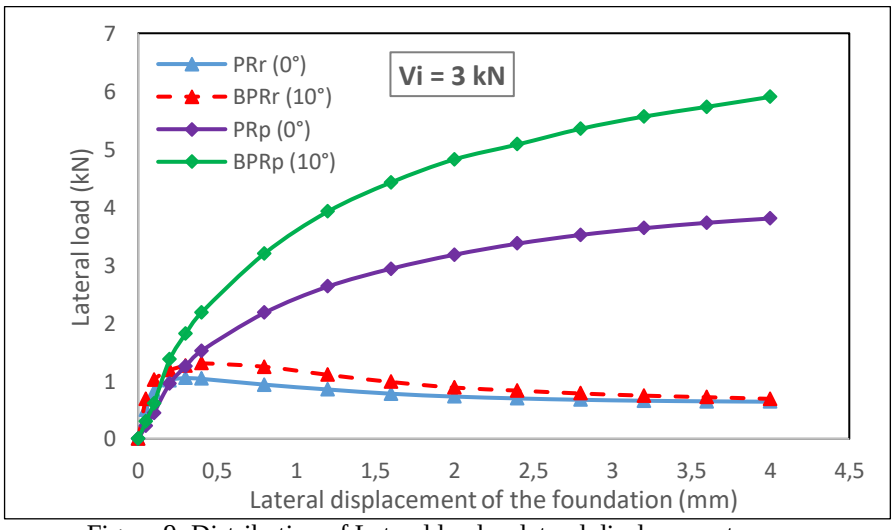

Figure 9: Distribution of Lateral load vs lateral displacement curves under combined loads (Vi=3N) for PRr, BPRr, PRp and BPRp.
Source: Authors, (2026).

III.5 RAFT INCLINATION BEHAVIOR UNDER LATERAL AND COMBINED LOADS

As shown in Figure 10, when the foundation is subjected to pure lateral load, the raft in the piled raft system tilts slightly less than in the pile group, with inclinations of 7.824 × 10^{-3} radians and 8.099 × 10^{-3} radians, respectively. This suggests that the piled raft performs a bit better in controlling raft inclination under lateral forces. When inclined (or battered) piles are used, the raft inclination decreases even further. In the case of the battered piled raft, the inclination drops to 6.749 × 10^{-3} radians, and for the battered pile group, it goes down to 7.46 × 10^{-3} radians. This shows how effective inclined piles can be in improving the stability and stiffness of the foundation under lateral loading. When both vertical and lateral loads are applied (combined loading), the vertical load plays an important role in further reducing the raft's inclination. We can see this in all four foundation configurations: the piled raft shows an inclination of 7.274 × 10^{-3} radians, the battered piled raft 6.749 × 10^{-3} radians, the pile group 7.499 × 10^{-3} radians, and the battered pile group 6.824 × 10^{-3} radians. Overall, these results highlight how vertical load helps stabilise the foundation, and they confirm that the battered piled raft performs the best at minimising raft inclination under combined loading conditions.

Source: Authors, (2026).

IV. CONCLUSIONS

This study concludes that pile inclination has a dual impact on piled raft and pile group foundations: it reduces vertical load capacity and increases settlements due to bending and axial load redistribution, especially under pure vertical loading, but markedly enhances lateral resistance under pure lateral and combined loading by mobilizing larger soil volumes and redistributing forces more effectively. The combined load scenario reveals that vertical piles benefit more from vertical load-induced soil confinement than inclined piles, though both configurations improve lateral stiffness. Load sharing shifts with inclination, where inclined piles significantly increase raft and pile resistance and carry a higher portion of total load. Raft inclination under lateral and combined loading decreases most with battered piles, highlighting their stabilizing effect. Overall, while inclined piles compromise vertical capacity, their significant lateral resistance gains make them critical for foundations subject to lateral or combined loads, affirming pile inclination as a key design parameter consistent with the research objectives and scientific considerations outlined in this work.

ABSTRACT

Thermally sprayed coatings are used as superior engineering materials, to prolong the service life of components and reduce manufacturing costs, but also significantly saving limited resources and energy, a technique capable to protect surfaces from erosive wear, corrosion, and enhance the tribological properties of a broad range of engineering materials. The study outlines the technological principle and process of thermal spray technique, and explores microstructural defects of thermal sprayed coatings, including pores, microcracks, unmelted particles, and oxides, exploring their formation mechanisms and effects. This paper also explores machine learning as a valuable tool that enables more accurate prediction of defect formation and supports the development of optimized spraying parameters.

I. INTRODUCTION

Thermal spray coatings are widely applied in engines, pumps, compressors, pipelines, and medical implants, providing cost-effective and reliable means to protect, repair, and extend component lifespan. However, inherent defects arise from compositional imbalances and surface irregularities generated during the layer-by-layer deposition process, leading to stress concentration and crack formation. These defects, influenced by the feedstock material and deposition parameters, reduce coating density and compactness, thereby impairing oxidation resistance and overall performance. This paper aims to present a comprehensive review of the current state of thermal spraying, beginning with an overview of existing technologies and recent advancements, followed by a detailed analysis of the main defects observed in such coatings. It also discusses current challenges in the field and identifies key research gaps, contributing to a deeper understanding and guiding future investigations in thermal spray technology.

II. METHODOLOGY

The literature survey was conducted as part of the development of this research paper. This study examined different thermal spray processes and the formation of defects on the surface and within the core of metallic and ceramic coatings. The literature review provides a strong foundation for the current research and highlights its relevance for future investigations. The study relied on references from various national and international journals, articles, and reputable websites.

III. LITERATURE REVIEW

III.1 THERMAL SPRAY

The thermal spray process (TS) involves several distinct deposition techniques utilizing a concentrated heat source to liquefy different material compounds. These molten particles are then propelled onto the surface to be coated, each carrying different levels of kinetic energy [1]. The particles coalesce into microstructural artifacts resembling splats, which solidify into an interconnected network of a lamellar microstructure, typically resulting in a functional coating ranging from 50 µm to several millimeters in thickness [1-5] (see Figure 1). The thermal spray technique is a surface modification process that enhances the substrate material characteristics, cappable of supplying the underlying substrate with good thermal insulation, thermally stable, wear resistant, high temperature oxidation resistant and hard coating [2-4]. Rigamonti et al. [5] proposed a method for embedding polymer-coated optical fibers with inscribed fiber Bragg gratings (FBGs) onto steel substrates using the thermal spray technique. This approach ensured strong adhesion, efficient strain transfer, and minimal invasiveness, while preserving the integrity of the fiber's core and cladding. The thermal spray process, performed at low temperatures, enabled the integration of the fiber into the metallic structure without causing damage, and the resulting metal layer provided additional mechanical protection, allowing the system to be used in harsh environments characterized by severe corrosion and wear.

Thermal spray processes are typically grouped according to their energy source, as illustrated in Figure. 2. These processes are differentiated based on the temperature and velocity of the jet stream they generate. Splats are frequently observed in thermally sprayed coatings, with the characteristics of splat boundaries (often oxides at these interfaces), porosity, and residual stress varying significantly. Moreover, corrosive substances can exploit the interplat bonding and interconnected pores as pathways for short-circuit diffusion [4].

Surface modifications using coating technologies serve to safeguard the substrate material, diminishing replacement expenses by slowing down material degradation, consequently prolonging the lifespan of components [1],[2]. Coating methods are categorized based on specific needs, including desired coating thickness, adhesion mechanism, necessary mechanical strength, component geometry and chemistry, coating process conditions suitable for the component, and the operating conditions of the coating [2]. Thermal spray processes have been extensively validated across industries such as steel, power generation, automotive, aerospace, marine, and petrochemical sectors for safeguarding and repairing components [4-7]. Utilizing thermal spray for repairing and remanufacturing components with localized defects or failures not only extends their service life but also proves to be cost-effective. This approach significantly conserves resources and energy, aligning well with the core principles of sustainable development [6]. The metallic coatings manufactured through additive manufacturing (AM) processes, such as thermal spray, often exhibit irregular surface morphology compared to those produced by conventional methods.

These irregularities stem from the layer-by-layer deposition and fusion occurring on the material surfaces [8], [9]. Several factors contribute to the irregularity of these surfaces, including the staircase effect, agglomeration of partially fused material, spattering, splashed particles (evaporation and balling effect), and the instability of the molten pool (wetting effect). These features formed on the surfaces act as stress concentration sites, facilitating crack formation. Furthermore, the size of the feedstock and deposition parameters also influence the surface morphology of the coatings [9],[10]. Typically, metallic alloys are not thermodynamically stable; compositional imbalances arise due to metallurgical transformations occurring in the structures, retaining crystallographic imperfections or defects [8],[11]. The commonly found defects in single-material-printed parts are microcracks, porosity, unmelted or solidified particles. Bonding defects arise from inadequate energy input, potentially leading to pore formation at the interface [8]. Cavities and micro-cracks stem from shrinkage, whereas pores result from anomalous gas entrapment within the molten material. In cold spray additive manufacturing (AM)

processes, such as deposition, insufficient bonding between particles and inefficient plastic deformation may give rise to the formation of micro-pores and inter-particle boundaries at lower impact velocities [9]. The objective of this paper is to comprehensively review the current state of knowledge in thermal spraying. It begins by providing an overview of thermal spraying technologies, highlighting recent advancements in the field. Subsequently, it conducts an in-depth analysis of various defects encountered in thermal spray coatings. Finally, the paper addresses the current challenges and issues encountered by researchers in this domain. The authors anticipate that this manuscript will contribute significantly to the existing body of knowledge by offering a detailed examination and identification of challenges for future research endeavors.

III.2 DEFECTS IN COATINGS

III.2.1 Porosity

Porosity refers to the volume of pores relative to that of the bulk material, and its increase indicates a rise in the volume of pores within the entire structure [12]. Typically, porosity ranges between 0.1 and 15% for thermal spray coatings [13]. It is an inherent characteristic of coatings. Numerous factors contribute to the porosity features in coatings during the preparation process of thermal-spraying coatings, including the impact energy of incompletely melted particles, the solidification and shrinkage of the coating, the shielding effect caused by different spray angles, and the wide gap in droplet velocity. Additionally, entrapped gas inclusions from powder and temperature play roles in porosity characteristics in coatings, such as morphology, pore diameters, pore distributions, microcrack sizes and orientations, and lamellar splats [13],[14]. Furthermore, the types of components and bonding mechanisms impact pore distributions [4].

The temperature of incoming droplets can vary from fully molten liquid to a completely solid state, depending on the particle's temperature. Liquid droplets flow freely and cover most of the spaces. The impact velocity of solid or partially melted particles must be sufficiently high to deform plastically upon impact. Consequently, particles with higher velocities undergo greater deformation, resulting in finer void closure (as seen in Figure 3). If the impact velocity is modest, solid particles may become lodged in the coating due to subsequent particles approaching later. These unformed particles have poor adhesion and should be further apart from the underlying splat, forming voids [4],[13]. Porosity reflects the fundamental properties of the coating, and typically, lower porosity indicates better coating formation and quality properties. Excessive porosity can reduce strength, abrasion resistance, and corrosion resistance [13].

The temperature of incoming droplets can vary from fully molten liquid to a completely solid state, depending on the particle's temperature. Liquid droplets flow freely and cover most of the spaces. The impact velocity of solid or partially melted particles must be sufficiently high to deform plastically upon impact. Consequently, particles with higher velocities undergo greater deformation, resulting in finer void closure. If the impact velocity is modest, solid particles may become lodged in the coating due to subsequent particles approaching later. These unformed particles have poor adhesion and should be further apart from the underlying splat, forming voids [4, 13]. Porosity reflects the fundamental properties of the coating, and typically, lower porosity indicates better coating formation and quality properties. Excessive porosity can reduce strength, abrasion resistance, and corrosion resistance [13]. The pore structure plays a crucial role in determining the performance of coatings in service. Higher porosity levels can compromise certain aspects of coating performance, such as the bond strength between the coating and the substrate.

Porosity diminishes the coating's strength by promoting delamination, cracking, or spallation [13],[14], and properties like density and toughness are significantly impacted by coating porosity [15]. However, in specific scenarios, such as when aiming for coatings with reduced thermal conductivity for wear resistance, porosity might be intentionally introduced to serve as insulation within the coating. Porosity can be controlled in either case, depending on the desired coating characteristics and the appropriate process conditions [4]. According to [13] reported that the HVOF thermal spray process yields coatings with the lowest porosity among commonly used thermal spray processes. This outcome is directly attributed to the high particle velocity and low-temperature flame utilized in the process. The protective effectiveness of coatings against corrosion in various engineering materials heavily relies on coating porosity.

This is particularly critical in systems where a highly reactive (anodic) substrate requires protection from corrosion by means of a cathodic coating [15]. Porous coatings can easily be infiltrated by corrosive agents, allowing them to reach the substrate. In such cases, the coating is prone to early delamination, compromising its protective function. There are two main types of porosity: interconnected and closed (Figure 3). Each type plays a distinct role in determining the corrosion behavior of coatings. Interconnected porosity is significantly more vulnerable to corrosion compared to closed porosity because it offers direct pathways between the substrate and the corrosive environment [4]. Any porosity extending through the thickness exposes a very small anodic area to corrosion, resulting in rapid substrate corrosion due to the high corrosion current density [15]. In [16] investigated Al-5Mg alloy coatings produced via twin-wire arc thermal spray on SS400 steel substrates, employing varied spraying parameters. Porosity analysis followed the ASTM E2109-01 standard, while corrosion performance in 3.5 wt. % NaCl solution was assessed through electrochemical polarization scanning and electrochemical impedance spectroscopy.

Findings revealed that coatings deposited with a spray mode comprising a 300 A current, 5.5 bar pneumatic pressure, and 160 mm standoff distance displayed higher Al and Mg elemental content compared to counterparts fabricated under different parameters. Porosity levels ranged from 7.38 to 11.82%, varying with spray mode. Over time, corrosion resistance varied due to the influence of corrosive products agglomerated on the coating surface. After 240 hours of immersion in 3.5 wt. % NaCl solution, microcracks emerged on the surface of coatings fabricated at 150A spray current, 4.0 bar spray pressure, and 100 mm spray distance, while no cracks were observed on others. XRD analysis indicated that the primary corrosion product on coating surfaces is predominantly Al (OH)3. The study inferred significant enhancement in corrosion mitigation attributed to elevated Al and Mg contents, surface homogeneity, and reduced porosity. Quantifying, characterizing, and minimizing coating porosity are essential for determining and improving the protective efficacy of coatings. Currently, numerous methods are under development for observing and measuring coating pores [14],[15],[17], including image analysis, mercury porosimetry, Brunauer-Emmett-Teller (BET) adsorption measurements, densitometry, high-resolution scanning electron microscopy, helium pycnometry, atomic force probes, contact measurement, ray-three-dimensional scanning imaging, and others.

Among these, the image analysis method, utilizing scanning electron microscope technology, stands out for its simplicity of operation and its ability to accurately quantify the number, shape, size, distribution, and other characteristics of pores. It has proven to be a reliable technique for pore analysis and has been endorsed by the International Organization for Standardization (ISO 26946) as the standard method for evaluating pores in thermal-sprayed coatings [14]. According to [15] utilized dimple grinding combined with optical microscopy to quantify internal porosity across the thickness of nine different electroless nickel-phosphorus (Ni-P) coatings deposited on Mg substrates. Additionally, scanning electron microscopy was employed to verify the identification of pores distinguished by dimpling. The influence of phosphorus (P) content within the Ni-P layers and the overall coating thickness on porosity was analyzed. Porosity reached its peak in coatings with high P content (10 wt% P) and was lowest in those with medium P content (5.2 wt% P). Furthermore, porosity exhibited a consistent decline with the augmentation of coating thickness, ranging from 28 μm to 57 μm. In a study investigating the effects of porosity and thermal gradients introduced during pulsed thermography, in [18] utilized pulsed thermography and a multilayer analytical model to critically assess the thermal diffusivity and inherent porosity in cold-sprayed Ti-6Al-4V coatings on Al6061-T6 substrates.

These coatings are crucial in utilizing cold spray as an additive manufacturing technique for the restoration of high-cost alloy components. The study drew upon experimental data obtained at spray angles ranging from 50◦ to 90◦, illustrating the relationship among the spray angle, porosity within the coating, and the resulting thermal diffusivity. The results revealed a decrease in porosity and an increase in thermal diffusivity as the spray angle increased from 50◦ to 90◦. Infrared thermography measurements of thermal diffusivity showed that the effective thermal diffusivity varied from 3.876% to 26.47% relative to the original coating thermal diffusivity when the spray angle decreased from 90◦ to 50◦. Correspondingly, numerical simulations performed on a partial representative microstructure of the coating illustrated a change ranging from 1.62% to 33.54% from the base coating thermal diffusivity. The analytical model, based on the effective medium theory using the Maxwell–Garnett approximation, forecasted a thermal alteration between 1.62% and 13.05% from the base coating thermal diffusivity. Microscopic analysis-based structural characterization revealed the variation in porosity content in cold spray coating with respect to the spray angle. It was found that the porosity percentage increased from 1.82% to 14.73% when the spray angle varied from 90◦ to 50◦. It was also observed that the porosity increased nonlinearly with the spray angle.

In a study investigating the adjustment of deposition parameters such as temperature, bias voltage, and pressure during magnetron sputtering to deposit Cr coatings with varying crystallographic orientations, crystallinity levels, and grain sizes, in [19] observed that during steam oxidation at 800 °C: Coatings deposited at 400 °C, with a bias voltage of –70 V, and at pressures ranging from 0.2 Pa to 0.5 Pa exhibited small grain sizes, high crystallinity, and random orientation. These characteristics contributed to favorable oxidation behavior, primarily due to their dense structure. Coatings deposited with a bias voltage range of 0 V to –40 V showed poor adhesion to the substrate, attributed to the low deposition energy of the plasma. Spallation of the oxide scale or metallic coating occurred during the oxidation test. Coatings deposited at 600 °C, with bias voltages ranging from –100 V to –200 V, and pressures between 2.0 Pa and 3.0 Pa, exhibited a strong (200) texture and large grain sizes. Intrinsic defects such as large grain boundaries and voids expanded into through-thickness cracks and large pores after oxidation. Coatings deposited at temperatures between 24 °C and 200 °C, at a pressure of 1.0 Pa, displayed slight texture and poor crystallinity. Oxygen-rich particles emerged in the un-oxidized coatings beneath the outer Cr2O3 layer after oxidation.

III.2.2 Microcracks

Variances in thermal gradients lead to the formation of cavities and micro-cracks, exacerbated by residual stresses, thermal expansion, and shrinkage during quenching cycles [8]. The roughness of coating surfaces, such as valleys, serves os stress concentration points, fostering crack initiation. Additionally, features like pores and splats in the coating's microstructure contribute to crack branching and deflect crack paths [20] (see Figure 5). The ceramic coating experiences heightened thermal gradient and residual stress due to differences in thermal expansion coefficients between adjacent layers, amplifying thermal mismatch stress within the coating system [21],[22]. In plasma-sprayed thermal barrier coatings (TBC), the bond coat/top coat (BC/TC) interface plays a crucial role due to the formation of the thermally grown oxide (TGO) layer and stress distribution at varying temperatures. Research shows that a smooth interface reduces stress, while rough interfaces increase stress during high-temperature exposure. Additionally, crack propagation mechanisms alter with interface roughness, with higher roughness promoting increased TBC fatigue life by spreading fatigue cracks along the interface and top coat, rather than concentrating them near the bond coat surface [23]. According to [23] devised a discrete element-based model to explore thermal stresses occurring at the interface between layers, attributed to the disparity in coefficients of thermal expansion (CTE).

Their findings suggest that the combination of CTE mismatch and thermally grown oxide (TGO) layer growth induces high tensile stress concentration within the bond coat (BC) layer upon cooling, leading to interface delamination. Conversely, stress reversal occurs in the thermal barrier coating (TC) layer, with increasing interface amplitude. The presence of porosity near crack propagation alters the crack path based on porosity orientation and shape. In regions without porosity, cracks converge to form larger branches, predominantly growing vertically within the ceramic TC. The TGO layer experiences compressive stresses, diminishing as the TC peak region is approached. A thicker TGO layer tends to generate a larger region of compressive stresses, potentially impeding crack propagation into and through the TC layer during the early cooling stages. The extended durability of thermal barrier coatings (TBC) faces a challenge from the infiltration and corrosion caused by calcium-magnesium-aluminum-silicate (CMAS). According to [24] investigated the microstructure and microcrack evolutions of CMAS-corroded TBCs through experiments and numerical modeling. In the study comparative experiments were conducted on TBCs that underwent treatment with and without CMAS at elevated temperatures for various durations.

Comparative experiments revealed that significant volume expansion, stemming from grain dissolution and TC corrosion due to CMAS, is the primary cause of TC spalling. Microcracks enriched with CMAS were observed at the TC/BC interface, resulting from a reaction between CMAS and TGO that degrades the interface. These microcracks act as pathways for CMAS infiltration, hastening the deterioration of CMAS-corroded TBCs. Additionally, the mechanism of microcrack evolution in CMAS-corroded TBCs is linked to the extent of CMAS coverage. When CMAS coverage is minimal, microcracks tend to propagate at the TC/BC interface and TC, leading to localized spalling. Conversely, greater CMAS coverage causes microcracks to extend solely at the TC/BC interface, resulting in the entire TC spalling. A coupled model has been developed, integrating CMAS penetration, TC corrosion and swelling, interfacial degradation, and microcrack propagation, providing insights into the degradation and failure process of CMAS-corroded TBCs as observed in the experiments. The laser surface melting technique, integrated into the deposition process, is renowned for enhancing the corrosion and erosion resistance of coatings. This method achieves heightened erosion resistance by compacting the surface layer. Laser glazing, while reducing surface roughness and enhancing microhardness, also leads to a slight increase in the coating's thermal diffusivity due to reduced surface porosity.

Moreover, laser glazing is effective in halting the spread of molten CMAS through the coating, thereby bolstering its resistance to hot corrosion. This enhancement is attributed to the formation of microcracks, which augment the strain tolerance of the topcoat [22],[25]. According to [25] conducted an analysis on the effects of laser modification post-coating deposition. This modification involves creating a pattern of through-thickness grooves within the coating, followed by surface layer remelting. Their findings concluded that the modified coating exhibited enhanced durability compared to the as-sprayed coating, reducing surface roughness from Sa 9.81 μm to Sa 0.75 μm. This reduction potentially leads to improved tribological flow conditions. Additionally, the modified coating showed an average 8.6 times increase in erosion resistance compared to as-sprayed coatings. This improvement can be attributed to surface densification and reduced influence of poor splat-to-splat adhesion in thermally sprayed coatings. Furthermore, there was an increase in CMAS resistance due to decreased propagation of molten silicates within the coating, along with an 11% enhancement in thermal fatigue resistance.

III.2.3 Unmelted Particles

In the thermal spraying process, uneven heating or irregular feedstock delivery can lead to inadequate melting of the spray particles. The utilization of larger-sized particles has been observed to decrease the temperature of the sprayed particles, resulting in a higher proportion of unmelted particles within the coating layer (shown in Figure 5).

This correlation associates the typical formation of pores in thermal spray processes with the presence of unmelted and semi-melted particles. These unmelted and partially melted droplets often demonstrate limited fluidity and formability, posing challenges in their ability to flatten and spread during deposition. Consequently, voids persist between the splats, which remain unfilled by the unmelted or semi-melted droplets even after the solidification of melted droplets [26, 27]. Unmelted particles represent a minority of the total incident particles (less than 10%), thus the occurrence of large pore formation is infrequent but significant [27]. As per Alebrahin et al. [28], unmelted particles may stem from the deposition of agglomerated submicron or nanosized particles, or from the impact of suspension droplets where not all the water evaporated during flight. The residual water evaporates on the hot substrate, leaving behind unmelted feedstock particles deposited on the substrate surface. In fact, the majority of individual submicron particles probably do not reach the substrate because of their low mass.

The varying sizes of unmelted particles are correlated with the atomization conditions within these spray parameters [29]. Significantly, coatings acquired through twin-wire arc spraving often showcase increased pore content owing to challenges in maintaining a consistent feed rate for feedstock wires compared to feedstock powders. Conversely, the HVOF spraying technique induces considerable plastic deformation of the splats during deposition due to the high particle velocity. Consequently, coatings produced through HVOF spraying typically exhibit dense, robust, and well-bonded characteristics [26]. In their investigation of unmelted particles in plasma spray, Ctibor et al. [30] revealed that typical unmelted particles are predominantly spheroidal and possess a microstructure closely linked to the powder fabrication process prior to spraying. These unmelted globular particles within the lamellar structure of the deposit tend to exhibit isotropic behavior under the influence of stress or other physical factors. Consequently, within the anisotropic structure of the coating, they act as centers of secondary defects, ultimately compromising the functional properties of the coatings.

III.2.4 Oxides

In the high-temperature spraying process, when particles meet the oxidizing atmosphere, they undergo oxidation. Reactive metals like aluminum, nickel, and chromium develop oxide layers during spraying, impacting both microstructure and coating bonding. These oxide layers limit the spread of molten particles upon impact, raising coating porosity and creating friction between the substrate and the splat [4],[26]. In their study, Brossard et al. [31] noted metal particle oxidation during spraying, manifesting in two forms: globular (enclosed within droplets) and as spinel on the outer surface. Subsequently, this oxidation process manifests as a ring-like granular structure within the spray coating. The researchers also attributed the oxidation of certain metals to high temperatures and low oxygen levels. Indeed, the occurrence of oxides in the coating is anticipated due to two factors. Firstly, molten particles are propelled under air pressure during projection. Secondly, each liquid alloy particle is enveloped by an air film during flight, leading to continued oxidation as oxygen becomes trapped upon impact with the target [32]. For metal coatings, a higher degree of oxidation typically corresponds to heightened porosity within the coating layer [25],[32]. Generally, oxidation levels can be reduced by utilizing inert gas, boosting the velocity of spray particles, or minimizing the distance between the spray gun and the substrate [31],[32]. During flame spraying, oxidation of spray particles is unavoidable since combustion requires a blend of oxygen and fuel gases.

Additionally, the oxide content of coatings produced by twin-wire arc spray might increase when compressed air is employed for droplet atomization and propulsion [30]. In HVOF spraying, the supersonic jet speeds up the spray particles, curbing oxide formation and yielding a coating with minimal oxide content. Further reduction in oxide content within HVOF-sprayed coatings can be achieved by lowering the temperature and boosting the velocity of spray particles [26]. According to [33] conducted a study on AlCoCrFeMo high entropy coatings (HECs) produced through three thermal spray techniques: low-pressure cold spray (LPCS), flame spray (FS), and high-velocity oxy-fuel spray (HVOF), aiming to create wear-resistant surfaces. The coatings were examined for their microstructures, phases, mechanical properties, and sliding wear behavior from room temperature up to 350°C. The LPCS, FS, and HVOF coatings initially exhibited a BCC solid solution phase. LPCS coatings lacked oxide inclusions, while FS and HVOF coatings displayed such inclusions due to in-flight oxidation (IFO). HVOF-sprayed coatings exhibited superior hardness due to their finer microstructure, reduced porosity, and fewer oxide inclusions compared to FS and LPCS coatings. The presence of oxide inclusions in FS and HVOF coatings contributed to increased hardness, while LPCS coatings had lower hardness and higher wear rates due to the absence of such inclusions. In terms of

tribological performance, LPCS coatings had lower frictional coefficients compared to FS and HVOF coatings at both tested temperatures. HVOF coatings showed improved wear resistance due to their higher hardness and the formation of a Co-based oxide film. Additionally, the presence of harder and stable Al- and Cr-based oxides provided protection against repetitive stresses during sliding.

III.3 QUANTIFICATION TECHNIQUES

Microstructural characterization plays a pivotal role in understanding and optimizing the performance of thermal spray coatings. These coatings often exhibit complex microstructures with a range of inherent imperfections, including voids, cracks, and unmelted or partially melted particles. Quantitative evaluation of geometrical features—most notably porosity—and detailed analysis of material aspects such as splat morphology, inter-splat interfaces, and phase composition are essential for correlating microstructural attributes with coating properties and in-service behavior. Among these features, porosity is particularly prevalent and has a critical impact on mechanical integrity, thermal conductivity, corrosion resistance, and other functional characteristics. As such, a variety of experimental techniques, including image analysis of cross-sectional micrographs, mercury intrusion porosimetry, and X-ray computed tomography, are commonly employed to measure and characterize porosity with high accuracy. The ability to reliably characterize these features is fundamental to the rational design and control of coating processes, enabling the production of coatings with predictable performance in demanding environments [34]. Nondestructive evaluation (NDE) techniques are widely employed for the detection and characterization of defects in materials and coatings, offering the advantage of preserving the structural integrity of the tested components. Common NDE methods include ultrasonic testing (UT), eddy current testing (ECT), X-ray radiography, and infrared thermography (IRT), among others.

Among these, ultrasonic testing (UT) has seen particularly rapid advancements in recent years, driven by improvements in sensor technology, signal processing, and imaging capabilities. These developments have significantly enhanced the resolution, sensitivity, and reliability of defect detection, making ultrasonic techniques increasingly suitable for the inspection of complex and multilayered coating systems [34]. When ultrasonic waves are transmitted into a sample via a coupling medium, internal defects disrupt their propagation by scattering or reflecting the acoustic energy, whereas regions without defects allow the ultrasound to propagate with minimal attenuation or distortion [34-37]. This contrast in wave behavior forms the basis for defect detection using ultrasonic testing. However, the effectiveness of this technique is limited in coatings with high porosity, as the numerous air-filled voids can scatter or absorb ultrasonic waves, thereby reducing signal clarity and measurement reliability [35-37]. Furthermore, the requirement for physical contact and the use of a coupling agent during measurement pose additional challenges when testing delicate or rough-coated surfaces [34]. Eddy current testing (ECT) operates on the principle of detecting variations in the amplitude and phase of eddy currents induced in a conductive material when subjected to alternating magnetic fields [34]. These eddy currents are influenced by the presence of defects, discontinuities, or changes in material properties, making ECT a valuable technique for surface and near-surface inspection.

However, the accuracy and sensitivity of ECT can be significantly affected by factors such as the electrical conductivity of the material, as well as the geometry, size, and shape of the test specimen. These dependencies necessitate careful calibration and consideration of material-specific parameters to ensure reliable defect detection [38], [39]. Infrared thermography (IRT) has emerged as a widely adopted technique for defect evaluation, owing to its non-contact nature, high efficiency, rapid data acquisition, and capacity for direct and quantitative characterization of subsurface anomalies [40],[41]. These advantages make IRT particularly attractive for real-time and large-area inspection applications. However, current limitations in spatial resolution and the relatively shallow penetration depth restrict its effectiveness for detecting deeply embedded defects. As a result, further research and technological development are required to enhance the resolution and subsurface imaging capabilities of infrared thermography, particularly for applications involving complex or multilayered materials [34]. A variety of experimental techniques are employed for the quantitative measurement and characterization of porosity in coatings, each with distinct advantages and limitations.

Water adsorption (WA) is a simple and cost-effective method; however, it exhibits limited sensitivity in distinguishing between samples with closely similar porosity levels. Mercury intrusion porosimetry (MIP) offers high precision in measuring open porosity but generally underestimates total porosity due to its inability to access closed pores. Helium pycnometry (HP) allows for the measurement of both open and closed porosity—provided the theoretical density of the material is known—but does not yield information on pore size or distribution. Image analysis (IA), commonly conducted on cross-sectional micrographs, enables the evaluation of both open and closed porosity, as well as pore size distribution and morphology. Nevertheless, the accuracy of IA is strongly influenced by spatial resolution and image contrast, and it lacks the ability to distinguish between open and closed pores. Electrochemical testing, although not capable of quantifying total porosity, provides valuable insight into pore connectivity within coatings. This method relies on the infiltration of an electrolyte through interconnected pores, leading to corrosion of the metallic substrate; higher connectivity results in increased corrosion current, offering an indirect measure of porosity interconnectivity [34], [42]. Small-angle neutron scattering (SANS) represents a more advanced technique, capable of resolving component porosities and providing surface area distributions associated with intrasplat cracks, interlamellar pores, and globular pores, including their approximate orientation.

These voids are commonly classified based on aspect ratios—1:1 for globular pores, 1:5 for interlamellar pores, and 1:10 for intrasplat cracks—enabling a more detailed and structural understanding of the coating's porosity network [43],[44]. The use of image processing (IP) techniques presents multiple advantages compared to conventional visual inspection, especially in the context of defect detection and quality control. IP offers enhanced precision and finer detail resolution, making it capable of identifying minor imperfections that may be overlooked by human inspectors. These systems can operate autonomously, significantly reducing the need for manual labor while enabling decisions to be made based on predefined rules and advanced algorithmic analysis. Additionally, IP ensures consistent and repeatable outcomes, which is valuable for tracking changes in defects over time. Remote inspection is another key benefit, as IP allows for the evaluation of areas that are difficult or dangerous to access, thereby increasing safety and eliminating the need for direct human presence. For high-volume production environments, IP is also more economical, lowering costs by increasing inspection throughput. Furthermore, IP systems rely on quantitative analysis, using detailed computations to assess defects and make objective judgments through sophisticated mathematical models. Collectively, these features highlight the clear benefits of IP over visual inspection in terms of reliability, efficiency, and safety [45-50].

According to [51] applied systematic image processing using ImageJ to analyze the microstructure of annealed environmental barrier coatings (EBCs), focusing on crack density, porosity, and phase distribution. Their results showed that REMS-rich coatings (M100 and M75D25) exhibited significant surface cracking (up to 0.58%), attributed to thermal expansion mismatch. In contrast, REDS-rich coatings (M25D75, M10D90, and D100) demonstrated improved microstructural stability, with lower crack coverage (0.04–0.14%) and porosity below 3%, highlighting the beneficial impact of REDS-rich compositions on coating integrity. In the study by [52], the effects of varying heat input on porosity, microstructure, microhardness, residual stress, and thermal behavior of martensitic stainless steel cladding on FGS600-3A ductile cast iron were investigated. Quantitative porosity analysis was performed using digital image processing with the NIS Elements-D software. The results demonstrated that heat input plays a critical role in pore and crack formation. As heat input increased, the porosity rose from 3.41% to 5.56%, with larger, more circular pores propagating between the first and second cladding layers. At lower heat inputs, pore formation was primarily attributed to lack of fusion, balling effect, and thermal contraction gradients.

III.4 ADDRESSING COATING DEFECTS THROUGH PREDICTIVE MACHINE LEARNING MODELS

Machine learning (ML) is a branch of artificial intelligence that enables computers to learn from data and improve their performance on tasks without being explicitly programmed. It involves the use of various algorithms designed to analyze data, identify patterns, and make decisions or predictions. The choice of algorithm depends on factors such as the nature of the problem, the type and number of variables involved, and the most suitable model for the task. ML enhances data handling efficiency and is widely applied across domains to solve complex data-driven problems [53]. Machine learning, is known for its low computational cost and rapid development cycle, is increasingly being applied in material science due to its powerful data processing capabilities and high predictive accuracy. It plays a key role in material detection, analysis, and design, and has been successfully used to discover new materials, predict molecular and material properties, study quantum chemistry, and aid in drug design.

By significantly reducing the need for costly density functional theory (DFT) calculations and repetitive laboratory experiments, machine learning offers an efficient alternative for accelerating scientific discovery [53],[54]. Conventionally, the Taguchi design method has been widely used to identify optimal process parameters and differentiate between major and minor factors influencing coating properties. However, its effectiveness diminishes when complex interactions among numerous parameters affect coating quality [55]. Machine learning (ML) techniques address these limitations by capturing nonlinear relationships and intricate dependencies. Among these, artificial neural networks (ANNs), with their flexible architectures and strong learning capabilities, are particularly effective for predicting and optimizing thermal spraying processes [56]. Artificial Neural Networks (ANNs) are computational models inspired by the structure and function of the human brain. Composed of interconnected artificial neurons organized in layers—typically including an input layer, one or more hidden layers, and an output layer—ANNs are capable of recognizing complex, nonlinear patterns in data.

Each neuron processes input signals by computing a weighted sum, applying an activation function, and producing an output. The weights, analogous to synapses in biological systems, are adjusted through training, allowing ANNs to learn from data and make predictions or classifications. This adaptive learning capability makes ANNs particularly effective in solving intricate problems, such as optimizing conditions in manufacturing processes [55], [57]. In the context of thermal spray processes, artificial neural networks (ANNs) offer a powerful solution for modeling the intricate chemical and thermodynamic reactions that drive coating formation. Given the challenge of acquiring large datasets in this field, shallow ANNs—comprising fewer than three hidden layers—have become a practical choice for effective prediction and analysis in data-scarce scenarios [55]. In a study by [55], an ANN-based regression model was developed to predict key coating properties—such as thickness, porosity, and erosion slurry resistance—based on process parameters like oxygen (O), LPG (L), and air flow (A) rates. Optimized with a single hidden layer of 20 neurons, the model showed strong agreement with experimental results, with validation through SEM imaging, porosity analysis, and mass loss measurements confirming its predictive accuracy. The Backpropagation (BP) neural network is a widely used training algorithm that minimizes prediction error by iteratively adjusting the network's weights and thresholds.

It consists of an input layer, hidden layer(s), and an output layer, operating through forward propagation of signals and backward propagation of errors. In forward propagation, input data undergoes nonlinear transformation through the network to generate an output. If a discrepancy exists between the predicted and actual output, the error is propagated backward to update weights accordingly. To ensure data validity and model effectiveness, input and output features must be preprocessed—commonly through normalization—before training. Through repeated learning, the network converges on weight values that minimize prediction error [58],[59]. The genetic algorithm (GA) is an optimization technique inspired by natural evolution, simulating processes such as gene crossover and mutation to search for optimal solutions. It is particularly effective for solving complex combinatorial problems, often outperforming traditional optimization methods [58]. In the context of BP neural networks, GA can be used to optimize initial weights and thresholds, addressing the variability and instability that arise when these parameters are randomly assigned [58], [60]. The GA-BP neural network combines the strengths of genetic algorithms and backpropagation, offering significant advantages in parameter optimization. By automatically adjusting the network structure and parameters without the need for pre-experiments, this hybrid method enhances the model's generalization ability and improves prediction accuracy [61].

In a study by [61], a 3D transient model combining computational fluid dynamics and surface reaction modeling was developed to analyze flame flow and particle oxidation during the HVOF WC-12Co thermal spraying process. The results revealed that oxide layer thickness varies significantly with particle size, from about 90 Å for 5 µm particles to just 8 Å for 60 µm particles. Using a GA-BP neural network, the researchers optimized key parameters—particle size, oxygen/fuel ratio, and nitrogen flow rate—identifying ideal values for improved coating performance. Experimental validation confirmed that the optimized coating exhibited fewer defects, lower oxide content, and enhanced hardness and wear resistance. Convolutional Neural Networks (CNNs) are a type of feedforward neural network designed to automatically extract meaningful features from raw data using convolutional structures. Inspired by the human visual system, CNNs eliminate the need for manual feature extraction by learning hierarchical patterns directly from the data. They are particularly effective in tasks involving local interactions, such as image recognition and computational materials science.

Key architectural advantages include local connections, which limit each neuron's input to a small region, reducing computational complexity; weight sharing, which minimizes the number of trainable parameters and improves generalization; and pooling layers, which downsample feature maps to retain essential information while discarding redundancy. These features make CNNs efficient, scalable, and well-suited for a wide range of pattern recognition problems [62],[63]. According to [64] developed a deep ensemble convolutional neural network trained on 500 scanning electron microscopy (SEM) images, achieving a test accuracy of 96.0%. Their model demonstrated strong performance across all evaluation metrics, with training, validation, and test accuracies reaching 94.7%, 100%, and 96.0%, respectively. The classification system was particularly effective at distinguishing between different wear patterns, with only minimal confusion between similar mechanisms, resulting in just 4 misclassifications out of 100. This study highlighted how integrating deep learning with materials science can provide a scalable and efficient methodology for tribological analysis and material design.

Physics-Informed Neural Networks (PINNs) are a hybrid machine learning approach that integrates physical laws, typically expressed as partial differential equations (PDEs), directly into the training process of neural networks. By embedding these equations into the loss function through automatic differentiation, PINNs guide the model to produce solutions that are both consistent with the data and compliant with the governing physics of the system. This approach addresses the limitations of traditional machine learning models, such as ANNs and CNNs, which often struggle to generalize to unfamiliar structures. In thermal fluid studies, for example, PINNs have been successfully applied to solve momentum and energy transport equations, accurately predicting particle velocity and temperature. Designed specifically to incorporate any underlying physical law described by nonlinear PDEs, PINNs are especially effective in scenarios with limited data, leveraging known physical principles to enhance model accuracy and reliability [63], [65].

According to [63] developed a hierarchical neural network combining Physics-Informed Neural Networks (PINNs) and Convolutional Neural Networks (CNNs) to predict in-flight particle properties and the performance of NiCr–Cr_3C_2 coatings, including porosity, microhardness, and wear rate. Using a random forest model, they identified spraying distance and particle velocity as the most influential parameters. Their approach achieved prediction accuracies of up to 99%, providing a strong foundation for the development of intelligent HVOF spraying systems. In thermal spray processes, machine learning (ML) offers a powerful way to model complex chemical and thermodynamic reactions. However, limited data availability and the unexplored influence of input variables in ML models present significant challenges.

V. CONCLUSIONS

Thermal spray coatings find widespread application in the fabrication of gas turbine engines, internal combustion engines, bearings, pumping systems, compressor and pipeline equipment, as well as medical implant materials. This technique encompasses a range of cost-effective and dependable methods aimed at safeguarding, repairing, and rejuvenating components, thereby prolonging their operational lifespan even in harsh environments. Defects are inherent in these coatings, emerging from compositional imbalances resulting from metallurgical changes within the structures or irregular surface morphology arising from the layer-by-layer deposition and fusion process on material surfaces. These surface irregularities serve as sites for stress concentration, facilitating crack formation. The presence and nature of defects are greatly influenced by both the feedstock materials and the parameters of the deposition process. Non-dense crystallographic orientation, poor accumulation of large grains, and irregular atomic arrangement in amorphous regions are all detrimental to the compactness of the coatings and negatively affect their oxidation behavior. Although defects are characteristic of thermal spray coatings, machine learning presents a valuable opportunity to advance the control and optimization of thermal spray coatings by modeling the complex chemical and thermodynamic interactions that influence coating quality. Despite the challenges posed by limited data and the underexplored impact of individual process variables, ML enables more accurate prediction of defect formation and supports the development of optimized spraying parameters. As a result, it offers a powerful tool for improving coating performance, reducing defects, and extending the service life of components in demanding environments.

ABSTRACT

This study presents a robust hybrid artificial intelligence framework designed to predict customer satisfaction based on online reviews a critical capability for enhancing business performance and optimizing customer relationship management (CRM) practices. We propose a unified architecture with high precision for sentiment classification, utilizing the "All Beauty (2023)" dataset from Amazon Reviews. The approach synergistically combines conventional machine learning (ML) algorithms with state-of-the-art deep learning (DL) techniques. Although standalone ML and DL models have demonstrated promising outcomes in sentiment analysis, they often fall short in addressing intrinsic data challenges such as class imbalance and linguistic subtleties. To overcome these limitations, we introduce HybridStack, a novel ensemble architecture that integrates diverse ML and DL models to significantly improve classification accuracy. The methodology encompasses rigorous text preprocessing, a dual-path feature extraction pipeline (TF-IDF for ML models, and embedding techniques for DL models), and a meta-classifier to consolidate predictions into three categories: dissatisfied, neutral, and satisfied. To address class imbalance, we employ weighted loss functions alongside oversampling strategies. The proposed HybridStack model achieved an outstanding and unparalleled F1-score of 0.6889 and an accuracy of 0.8593, substantially outperforming all baseline individual models. This hybrid approach highlights the benefits of algorithmic synergy and demonstrates its effectiveness in generating more granular and actionable insights, thereby supporting the development of more refined CRM strategies and fostering stronger customer relationships.

I. INTRODUCTION

Automated analysis of customer satisfaction from online reviews represents a crucial challenge in data science and artificial intelligence, as it directly contributes to enhancing sales strategies and customer relationship management (CRM) effectiveness. Despite significant advances in natural language processing (NLP), machine learning (ML), and deep learning (DL), existing methods still struggle to deliver robust and generalizable performance in real-world, unbalanced datasets. Current studies mainly focus on either traditional ML models or advanced neural networks, often neglecting the complementary strengths that could arise from their integration. In this context, the present work proposes a novel hybrid AI framework that unifies classical ML algorithms (e.g., Logistic Regression, Naive Bayes) with state-of-the-art DL architectures (LSTM, GRU, CNN) and transformer-based models (BERT) within a stacked ensemble learning strategy. This hybridization enables the system named HybridStack to exploit the interpretability and efficiency of traditional classifiers alongside the representational depth of neural and transformer-based models. The proposed pipeline operates in parallel, leveraging TF-IDF features for conventional models and embedding representations for deep architectures, before aggregating their predictions through a meta-learner to enhance overall precision and robustness.

Evaluated on the "All Beauty (2023)" Amazon Reviews dataset, this framework demonstrates improved predictive accuracy and stability compared to single-model baselines. The novelty of this work lies in its systematic integration of heterogeneous learning paradigms within a unified architecture, addressing key challenges such as linguistic complexity, feature diversity, and class imbalance. This contribution advances the state of research toward more adaptive and generalizable satisfaction prediction systems in practical CRM applications.

II. THEORETICAL REFERENCE

II.1 CRM AND CUSTOMER SATISFACTION

Customer relationship management (CRM) is fundamentally a strategic business approach focused on managing interactions with current and potential customers in order to stimulate acquisition, promote loyalty and support long-term retention. Its main objective is to improve customer satisfaction through personalised engagement, a deep understanding of their expectations and the establishment of lasting relationships that promote increased customer lifetime value (Figure 1).

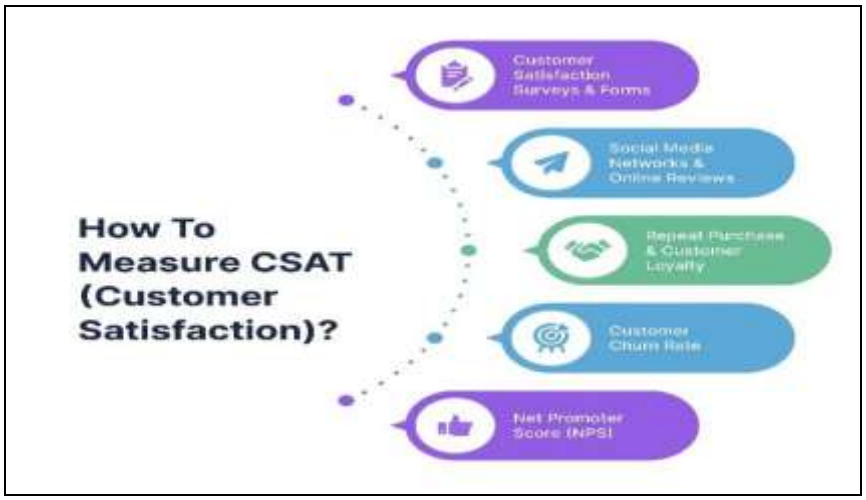

Figure 1: Customer Satisfaction Measurement Techniques.
Source: Authors, (2026).

CRM integrates technology, data and business strategies to systematically collect, process and analyse customer information, enabling organisations to provide more personalised and effective services. Several definitions reflect the multifaceted nature of CRM. [1] defines it as the strategic deployment of information, processes, technologies and human resources throughout the customer lifecycle, including marketing, sales, service and support. [2] presents CRM as a proactive strategy aimed at understanding and anticipating customer needs. Similarly, [3] and [4] emphasise the role of CRM in identifying profitable customer segments, implementing value-driven interactions and developing profitable strategies to drive profitability. [5] characterises CRM as a continuous process of identifying customer value and personalising interactions in order to exceed expectations. [6] further describe CRM as a fundamental business strategy that harmonises internal operations and extends organisational networks to create value through the effective use of high-quality customer data and advanced information systems. In the rapidly expanding e-commerce sector, customer satisfaction is essential for commercial success and market survival [7]. Advanced analytical tools are indispensable for effectively analysing the vast amounts of data generated by customer feedback, which directly influences the success of products and companies [8].

II.2 PREDICTING CUSTOMER SATISFACTION IN THE ERA OF MACHINE LEARNING AND DEEP LEARNING

Sentiment analysis, a key text mining technique, is widely used to identify and extract subjective information from various sources, helping businesses understand customer opinions, assess their preferences, and improve their purchasing decisions [8]. The integration of machine learning and deep learning models, such as BERT, has significantly improved the effectiveness of sentiment analysis and enabled highly accurate predictions of customer satisfaction by analysing reviews and integrating them with e-commerce data [8-11]. This data-driven insight is essential not only for improving product quality and operational efficiency, but also for enhancing the overall customer experience, optimising conversion rates, and fostering sustainable growth in the competitive e-commerce landscape [12]. The analysis of complex textual data, such as customer reviews, relies heavily on the capabilities of artificial intelligence paradigms such as machine learning (ML) and deep learning (DL). Traditional ML models, including logistic regression and the naive Bayes model, have consistently provided robust and interpretable solutions for text classification tasks, often leveraging statistical features such as TF-IDF to quantify the importance of words. At the same time, deep learning models, such as long short-term memory (LSTM), gate recurrent units (GRU), and convolutional neural networks (CNN), have revolutionised natural language processing with their ability to automatically learn complex semantic and contextual representations through integrations, often enhanced by powerful transformer-based architectures such as BERT. These two approaches offer distinct advantages for discerning patterns and sentiments within large datasets, thereby contributing significantly to the automated prediction of customer satisfaction (see Figure 2).

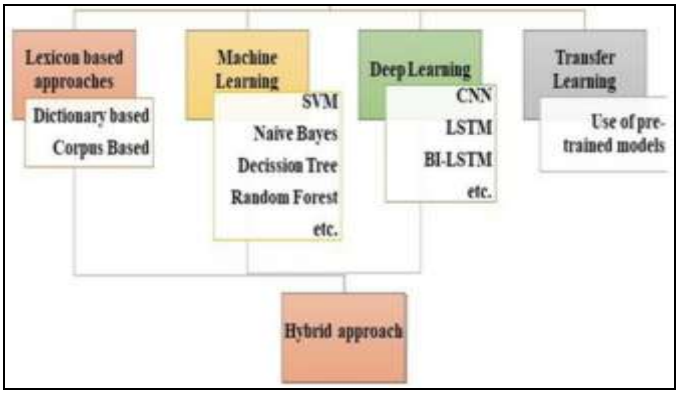

Figure 2: Different Approaches for Text Analysis in Customer Satisfaction Prediction.
Source: Authors, (2026).

II.3 STUDY EXISTING APPROACHES

Traditional Machine Learning (ML) and Deep Learning (DL) models each possess significant capabilities but also distinct limitations when applied to complex, noisy, and imbalanced textual data typical of e-commerce environments. ML models, though interpretable and efficient, often fail to capture the deep semantic and contextual dependencies present in natural language. Conversely, DL models such as LSTM, GRU, and CNN can learn intricate linguistic patterns but tend to act as "black boxes," with reduced interpretability and a higher risk of overfitting especially when faced with underrepresented sentiment classes like dissatisfied customers. These challenges highlight the need for a hybridized analytical framework capable of exploiting the complementary strengths of both paradigms while mitigating their respective weaknesses. The proposed HybridStack approach fulfills this requirement by integrating diverse ML and DL models within an ensemble structure, where a meta-classifier synthesizes their outputs. By combining models specializing in statistical feature extraction (e.g., Logistic Regression, SVM) with those capturing deep semantic meaning (e.g., LSTM, CNN, BERT), HybridStack enhances robustness, accuracy, and generalization.

This fusion enables more reliable sentiment classification and superior detection of minority sentiment classes, directly supporting actionable insights for Customer Relationship Management (CRM) systems. The rapid expansion of e-commerce, driven by Artificial Intelligence (AI) and ML, has intensified research in predictive analytics applications such as demand forecasting, customer segmentation, and fraud detection [13-17]. Sentiment analysis and satisfaction prediction have become central to this effort, leveraging models like SVM, Naïve Bayes, BiLSTM, and BERT to extract subjective opinions from large volumes of customer reviews [8], [9], [18]. Empirical studies across platforms such as Amazon and Jumia confirm the value of these methods [10], [19]. However, standalone models still face persistent obstacles linked to linguistic variability, class imbalance, and noisy data, which hinder their generalizability. To overcome these issues, hybrid and ensemble learning approaches have gained prominence for their capacity to deliver higher predictive accuracy and resilience [12].

Research demonstrates that combining algorithms for instance, SVM with Logistic Regression [13], or multiple ensemble classifiers for churn and delivery prediction [16], [20], [21], [22] achieves superior outcomes. Advanced Natural Language Processing (NLP) techniques have also improved sentiment extraction, topic modeling, and satisfaction forecasting [23-25]. Moreover, the integration of ML with Business Intelligence (BI) and visualization tools [26] supports more informed, data-driven decision-making while ongoing developments in explainable and fairness-aware AI address transparency and bias concerns. Collectively, this growing body of work underscores the transition toward integrative and adaptive analytics frameworks in e-commerce. By uniting interpretability, statistical precision, and deep contextual learning, hybrid systems such as HybridStack represent the most accurate, scalable, and reliable approach for multi-class sentiment prediction. These architectures not only enhance predictive performance but also enable personalized customer experiences, ethical AI implementation, and sustainable business growth in the evolving digital marketplace.

II.4 SCIENTIFIC AND CONTEXTUAL RELEVANCE OF THE RESEARCH

This observation highlights the current relevance of research focused on combining machine learning and deep learning. In a commercial environment increasingly dominated by e-commerce, companies generate massive volumes of textual data every day from reviews, comments and customer interactions. Effectively exploiting this information requires models that are capable of both understanding the linguistic and emotional subtleties of texts and producing reliable, explainable and generalisable predictions. This issue is all the more crucial given that customer satisfaction is a major strategic lever for competitiveness, loyalty and value creation. Thus, the ability of artificial intelligence to accurately predict this satisfaction represents a major scientific, technological and managerial challenge.

II.5 NOVELTY AND POSITIONNING OF RESEARCH

In this perspective, the novelty of this work lies in the design of a hierarchical hybrid approach, combining traditional machine learning (ML) methods and deep learning (DL) models applied to natural language processing. The proposed approach is based on an overall strategy inspired by the HybridStack concept, which aggregates the predictive outputs of several heterogeneous models to feed a meta-classifier. This hybridisation makes it possible to exploit the complementarity between the statistical recognition of ML models (such as SVM, logistic regression, etc.) and the deep semantic understanding of DL models (such as LSTM, GRU, CNN and BERT).

The objective is to simultaneously improve the robustness, accuracy and generalisation capacity of the customer satisfaction prediction system, while maintaining better interpretability of the results. Furthermore, the integration of hierarchical language processing is an original contribution. By structuring textual analysis on several levels lexical, syntactic, semantic, and pragmatic this approach offers a more detailed view of the emotions, intentions, and judgements expressed in customer reviews. It also allows for better detection of minority classes, particularly dissatisfied customers, whose recognition is essential for CRM. Thus, this research builds on recent work on ML and NLP, while offering a distinct and innovative contribution: a hybrid and hierarchical predictive framework that reconciles interpretability, semantic depth and operational performance. This framework aims to fill a gap identified in the literature, namely the lack of integrative models combining symbolic learning and deep representation for the automated prediction of customer satisfaction in e-commerce.

Table 1: Summary of Related Works on E-commerce Customer Behavior and Prediction.

Article	Methodology/Algorithms Used	Key Findings/Contributions
I. Deep Learning Models		
[11]	RNNs, LSTM with SGD	Superior accuracy in dynamic pricing; balanced profit/satisfaction.
[27]	CNNs (VGG16, ResNet50, InceptionV3)	CNNs improve profit prediction (high accuracy).
[10]	Keras DL framework, Sequential model, Adam optimizer	Adam optimizer excels in customer satisfaction prediction.
[9]	ML: BERT model (fine-tuned)	BERT accurately forecasts customer sentiment (96%).
[22]	ML: PIVD using CNN in three steps	PIVD improves image vulnerability detection (high F1).
II. Traditional Machine Learning Models		
[14]	ML: Decision Trees, Random Forest (using TIPI test for consumer profiles)	ML predicts consumer behavior from personality.
[16]	ML: SVM, Random Forest, Decision Tree	SVM predicts churn (83.45%) and delivery.
[28]	ML: Association rules via Frequent-Pattern-Growth algorithm	High probability of next product purchase via recommendations.
[20]	ML: Seven traditional classification algorithms including Logistic Regression, Random Forest, Naïve Bayes	ML predicts online banking satisfaction/frustration.
[26]	BI tools incorporating Data mining, Data Analytic, Data Visualization and ML; ABCD framework	BI/ML aid decision-making and competitiveness.
III. Hybrid/Fusion Machine Learning Approaches		
[13]	ML Fusion Algorithm: Logistic Regression + SVM	Fused ML models offer higher prediction accuracy.
[8]	ML: SVM, Naïve Bayes, DL (bidirectional LSTM, BERT)	Sentiment analysis/forecasting enhances BI/decisions.
[29]	ML: RF, GBDT, XGBOOST; DL: RNNs, LSTM	ML/DL accurately forecast purchase behavior (similar performance).
[18]	Advanced ML techniques: DL, Reinforcement Learning, NLP	ML frameworks boost customer engagement/LTV/growth.
[10]	Multimodal Learning Framework (including unimodal comparison), Adam optimizer	Multimodal learning improves satisfaction/efficiency.
[15]	Big Data Algorithms, Text Mining Technology, Empirical analysis (SEM after correction)	Online interaction impacts satisfaction; personalized recs need ethics.

III. MATERIALS AND METHODS

This section presents a hybrid AI framework designed to analyze and enhance customer satisfaction using the Amazon Reviews dataset. The system integrates Machine Learning (ML), Deep Learning (DL), and transformer-based models to deliver a robust sentiment analysis solution. Text preprocessing involves cleaning (removal of symbols, punctuation, and numbers), tokenization, and normalization, followed by numerical conversion through vectorization to prepare data for computation. The architecture adopts a two-stream design. The first stream employs TF-IDF vectorization to extract statistical text features, which are then classified using traditional ML algorithms such as Logistic Regression, Multinomial Naive Bayes, XGBoost, and LinearSVC, chosen for their interpretability and stability as baselines. The second stream applies DL techniques leveraging word embeddings to capture semantic context. Models include LSTM, GRU, and CNN, with pre-trained GloVe embeddings and fine-tuned BERT transformers providing deep contextual understanding through attention mechanisms. Predictions from both streams are integrated through a stacked ensemble meta-classifier, forming the HybridStack. This ensemble combines the complementary strengths of ML and DL models, improving accuracy, robustness, and the classification of sentiment categories (‘dissatisfied,’ ‘neutral,’ ‘satisfied’). Finally, an evaluation module assesses performance using Macro F1-Score, Accuracy, Precision, and Recall, with special focus on minority classes like ‘Dissatisfied.’

Confusion matrices visualize misclassifications, and McNemar's test validates statistical significance. The architecture balances precision, interpretability, and scalability, offering a deployable solution for real-world customer feedback analytics.

III.1 DATA SOURCE AND COLLECTION

The dataset utilized in this study is the Amazon Customer Reviews Dataset, an extensive collection publicly available via the Amazon Web Services (AWS) Open Data Registry. This corpus encompasses a vast array of customer reviews, spanning multiple international marketplaces and diverse product categories. Each review is enriched with valuable metadata, including a unique product identifier (ASIN), reviewer ID, review title and body, a numerical star rating (1 to 5), and the timestamp of submission. For this research, we specifically focused on a curated subset: the Amazon Reviews All Beauty (2023) dataset. This dataset, stored in file "All_Beauty.jsonl", contains customer reviews specifically within the "All Beauty" product domain. This particular domain was selected to ensure a consistent context for product satisfaction, allowing for a focused analysis of beauty-related reviews. The All Beauty category was chosen to facilitate:

- Domain-Specific Textual Expression: Allowing for the capture of unique vocabulary and review writing styles prevalent within the beauty product sector.
- Targeted Customer Expectations: Providing insights into satisfaction drivers specific to beauty products, which can differ significantly from other categories.
- Specialized Model Development: Enabling the training of models highly optimized for predicting satisfaction in this specific retail segment.

The "All_Beauty.jsonl" dataset comprises reviews from the specified category, providing a rich source of information for modeling customer satisfaction. The star rating, from 1 to 5, serves as the primary indicator for satisfaction, allowing for both binary (satisfied vs. not satisfied, typically based on ratings of 4 or 5) and potentially multi-class satisfaction modeling.

Figure 3: Sample Customer Review from the Amazon Reviews All Beauty Dataset.
Source: Authors, (2026).

The Amazon Reviews dataset, and specifically the "All Beauty" subset, stands as one of the largest and most detailed open-access corpora for customer feedback within a specialized domain. It offers a rich combination of textual, categorical, temporal, and numerical features. Its focused coverage on a single product domain, coupled with detailed review content and structured metadata, makes it ideally suited for natural language processing (NLP) tasks such as sentiment classification and user profiling tailored to the beauty industry. Furthermore, the dataset reflects real-world challenges such as class imbalance and noise inherent in user-generated content, making it valuable for simulating realistic AI deployments. Its scale and granularity also enable the training of a wide range of models, from traditional machine learning algorithms to sophisticated neural architectures, including the fine-tuning of transformer-based language models like BERT and GPT for domain-specific applications.

III.2 FEATURE SELECTION

To analyze customer satisfaction in the beauty product domain, several essential features were extracted from the Amazon Reviews – All Beauty (2023) dataset. The text field contains full customer reviews and serves as the primary input for all NLP tasks such as sentiment classification and satisfaction prediction, capturing nuanced emotional expressions and user experiences. The rating feature, ranging from 1 to 5 stars, provides the ground-truth labels for supervised learning, enabling both binary and multi-class sentiment categorization. The title field offers concise summaries of opinions and acts as auxiliary textual input, improving model accuracy and supporting summarization or response generation. The timestamp attribute records the review submission time, allowing for the analysis of temporal satisfaction trends, product lifecycle patterns, and seasonal variations within the beauty sector. The asin (Amazon Standard Identification Number) uniquely identifies each product, enabling product-level sentiment analysis, satisfaction comparison, and recommendation insights. Together, these features form a multi-view dataset combining textual and structured attributes. This integration enhances semantic understanding, contextual awareness, and trend-based prediction, allowing models to learn not only what customers express but also when and about which products crucial for accurate and actionable customer satisfaction modeling in the beauty domain.

III.3 PREPROCESSING

The feature engineering and preprocessing strategy for the **Amazon Reviews – All Beauty (2023)** dataset was carefully adapted to ensure compatibility with both traditional ML and modern DL sentiment analysis models. The dataset structure was standardized by renaming key fields to align with the beauty domain: *review_body → text*, *star_rating → rating*, *review_title → title*, *review_date → timestamp*, and adding *asin* as a unique product identifier. These modifications preserved the dataset's integrity while ensuring semantic alignment for satisfaction modeling.

Text Normalization: Comprehensive normalization procedures were applied to the *text* and *title* fields to ensure uniformity and minimize lexical variability. All text was converted to lowercase, extraneous whitespace was trimmed, and punctuation was removed to reduce noise. Repetitive character sequences (e.g., "soooo") were standardized to maintain consistency and control token distribution.

Noise Filtering: Regular expressions were used to remove HTML tags, escape sequences (e.g., \n, \xa0), and non-alphanumeric symbols that could distort tokenization or interfere with semantic learning. This step ensured clean, well-structured text inputs by eliminating web-scraping artifacts common in Amazon datasets.

Stopword Removal: Stopwords were removed using the NLTK English stopword list to reduce feature dimensionality and enhance discriminative vocabulary for classical ML models (e.g., TF-IDF). However, this step was intentionally skipped for deep learning and transformer architectures to preserve syntactic and contextual relationships critical for attention-based modeling.

Tokenization Strategy: Tokenization was customized to match model requirements. For LSTM-based models, word-level tokenization using Keras Tokenizer produced integer sequences compatible with GloVe embeddings, preserving sequence semantics. For transformer models (e.g., BERT), subword tokenization via Hugging Face AutoTokenizer was implemented, maintaining alignment with the model's pretraining scheme (*bert-base-uncased*). This approach ensures robust handling of rare and out-of-vocabulary words.

Label Encoding: The raw 1–5 rating scale was consolidated into a three-class satisfaction scheme to reduce label sparsity and support balanced multi-class sentiment classification—typically mapping low ratings to dissatisfied, mid-range to neutral, and high ratings to satisfied. Collectively, these preprocessing and encoding strategies create a **standardized, noise-free, and semantically enriched dataset**, enabling consistent input for diverse ML/DL models. The resulting framework supports accurate, interpretable, and scalable **customer satisfaction prediction** within the beauty domain.

Table 2: Label Encoding Scheme for Customer Satisfaction Ratings.

Raw Rating	Encoded Class	Satisfaction Level
1–2	0	Dissatisfied
3	1	Neutral
4–5	2	Satisfied

Source : Authors (2026)

This transformation merges adjacent rating levels with similar semantic meaning, reflecting typical business analytics categorizations of customer satisfaction. It simplifies model training and evaluation while preserving important distinctions among dissatisfaction, neutrality, and satisfaction.

III.4 DATA SPLITTING AND CLASS BALANCE

The dataset was divided into training (70%), validation (15%), and test (15%) subsets using stratified sampling to preserve the original class distribution. This ensured that each subset accurately reflected real-world satisfaction proportions, minimizing sampling bias and supporting reliable model generalization. An exploratory class distribution analysis revealed a strong imbalance, with most reviews concentrated in 4- and 5-star categories, while 1-, 2-, and 3-star reviews were scarce. This skew mirrors real e-commerce behavior, where positive feedback dominates and negative reviews—though less frequent contain vital insights for customer service improvement. An exploratory analysis of the satisfaction labels (star_rating mapped to classes) showed a markedly imbalanced distribution(figure 4):

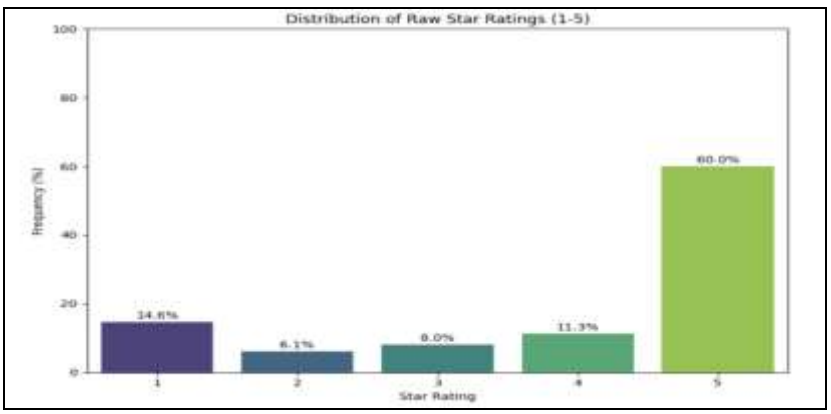

Figure 4: Distribution of Customer Satisfaction Levels.
Source: Authors, (2026).

To mitigate class imbalance, two complementary strategies were implemented. Weighted loss functions assigned higher penalties to minority classes, improving recall for "Dissatisfied" reviews and preventing overfitting to majority classes. This was achieved through the class_weight parameter in TensorFlow/Keras and customized loss weighting in PyTorch.
Additionally, oversampling techniques such as Random Oversampling and SMOTE were selectively applied to the training data, generating synthetic minority samples to balance class frequencies while preventing data leakage. Combined with stratified batch sampling, these methods improved model robustness and minority-class detection These measures enhanced the framework's sensitivity to dissatisfied customers, ensuring that negative feedback signals were effectively captured. By correcting bias toward the "Satisfied" class, the final models achieved a more realistic, balanced, and business-relevant performance, crucial for actionable customer satisfaction prediction in e-commerce (figure 5).

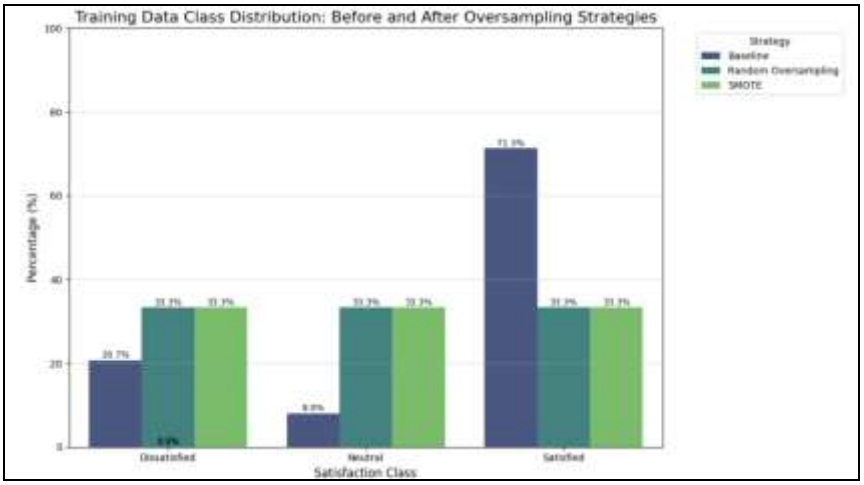

Figure 5: Comparison of Customer Satisfaction Class Distribution with Imbalance Mitigation Strategies.
Source: Authors, (2026).

III.5 PROPOSED HYBRID CLASSIFICATION ARCHITECTURE

This study employs a robust hybrid modeling approach, combining traditional machine learning (ML) and advanced deep learning (DL) architectures to classify customer sentiment into three classes: Dissatisfied (0), Neutral (1), and Satisfied (2). All models are trained using a dual-pathway feature representation strategy (Figure 6), processing distinct data modalities to capture comprehensive insights from customer reviews.

III.5.1 Ensemble Learning

Ensemble learning has emerged as one of the most reliable and high-performing paradigms in machine learning, grounded in the principle of combining multiple base learners to construct a more accurate and generalized predictive model [30]. By aggregating the outputs of diverse models, ensemble learning effectively reduces variance, bias, and generalization errors, thereby enhancing robustness and stability, particularly when dealing with complex and noisy data typical of e-commerce environments [31]. The main ensemble strategies bagging, boosting, and stacking offer complementary mechanisms for improving model accuracy. Bagging, introduced by Breiman [32], trains several independent models on bootstrap samples of the dataset, with Random Forest being its most prominent implementation [33]. Boosting methods, such as AdaBoost, Gradient Boosting, and XGBoost, build models sequentially, where each learner focuses on correcting the errors of its predecessors, resulting in strong classifiers well-suited to high-dimensional and imbalanced data [34].

Stacking, proposed by Wolpert [35], integrates heterogeneous models (e.g., decision trees, logistic regression, neural networks) through a meta-learner that optimally combines their predictions. In the context of customer satisfaction prediction in e-commerce, ensemble approaches particularly boosting-based algorithms like XGBoost and LightGBM have demonstrated superior ability to capture non-linear relationships within massive, heterogeneous, and noisy customer datasets. They enable the identification of key satisfaction drivers, enhance service personalization, and support predictive decision-making that strengthens customer retention. Therefore, ensemble learning represents a robust and adaptable framework that aligns statistical rigor with the dynamic analytical demands of modern digital marketplaces Figure 6 conceptually illustrates the two primary feature extraction pathways and their subsequent integration into various model types:

- Pathway 1: TF-IDF Vectorization for Textual Data (for traditional ML models).
- Pathway 2: Embedding-Based Sequences for Textual Data (for deep learning models), combined with processed Categorical (One-Hot Encoded) and Numerical (Scaled) features.
- Integration Layer: A concatenation of processed features or model predictions for hybrid/ensemble approaches.

III.5.2 Feature Engineering and Data Pathways

Customer review data, comprising text (review body), categorical attributes (verified_purchase, asin), and numerical features (helpful_vote), undergoes tailored preprocessing to prepare dual feature representations:

a) **Text Preprocessing:**

- **TF-IDF Vectors:** The review_body is transformed into TF-IDF vectors (with max_features=10000 and English stop words removed) for classical machine learning models.
- **Tokenized Sequences:** For DL models, review_body undergoes tokenization (vocab_size=20000, maxlen=200), resulting in padded integer sequences.

b) **Categorical Preprocessing:** Categorical features (verified_purchase, asin) are initially label-encoded and then one-hot encoded for traditional ML, and passed as integer inputs for embedding layers in DL models.

c) **Numerical Preprocessing:** Numerical features (helpful_vote) are standardized (z-score normalization) for both ML and DL pathways.

III.5.3 Baseline Machine Learning Models (TF-IDF Pathway)

Traditional machine learning algorithms serve as performance benchmarks, primarily leveraging the TF-IDF vectorization of textual data combined with other preprocessed features. These models validate the discriminative power of the engineered features and provide reference points for deep model comparisons.

a) **Logistic Regression:** A robust linear classifier optimized for multiclass prediction. Its efficiency and interpretability provide transparent insights into feature importance.

b) **XGBoost (Extreme Gradient Boosting):** A powerful gradient boosting framework known for its high performance and flexibility. It effectively handles complex interactions between features.

c) **LinearSVC (Linear Support Vector Classifier):** A linear classifier based on Support Vector Machines, suitable for large datasets and high-dimensional sparse features like TF-IDF.

d) **Multinomial Naive Bayes:** A probabilistic classifier well-suited for discrete features like word counts or TF-IDF values, often performing well on text classification tasks.

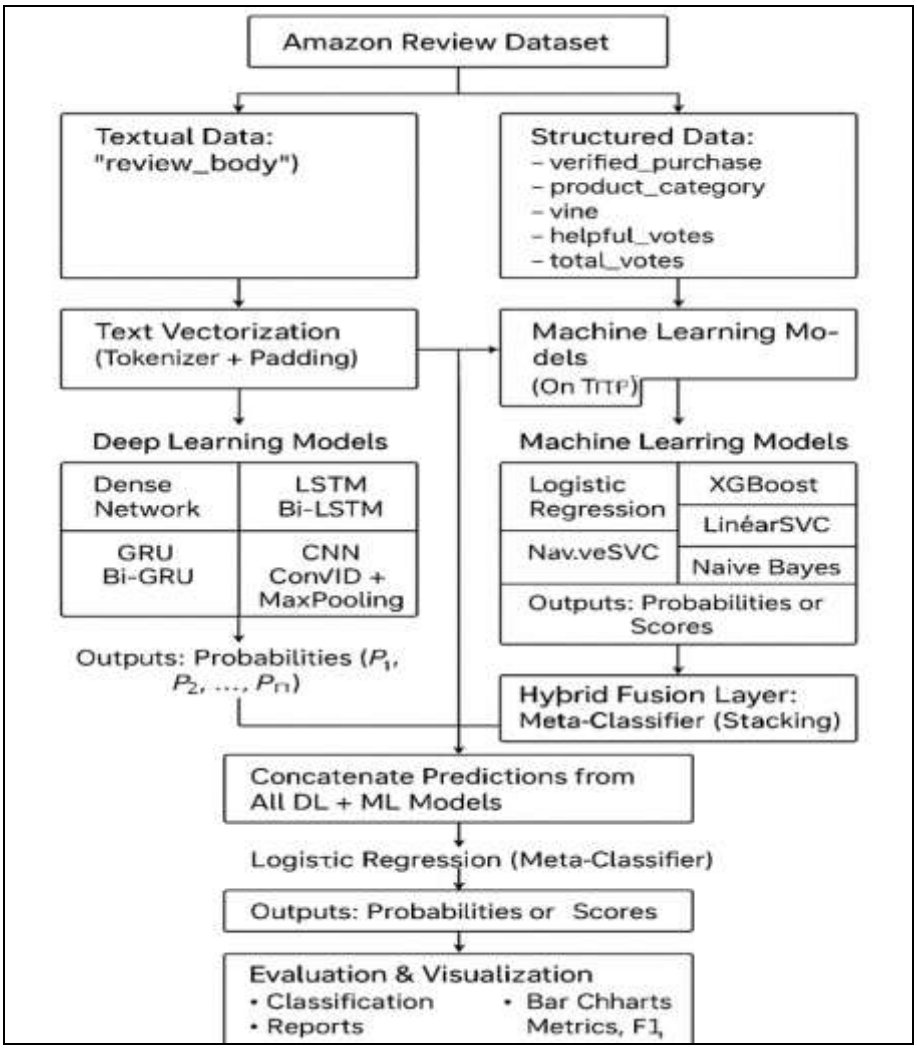

Figure 6: Hybrid Model Architecture Overview.
Source: Authors, (2026).

III.5.4 Deep Learning Models (Embedding Pathway).

To capture deeper semantic relationships and contextual dependencies within customer reviews, we implemented sequential and contextual deep learning architectures. These models process embedding-based sequences from text, combined with embedded categorical features and scaled numerical features, enabling a more nuanced representation of the overall review sentiment.

a) **Generic Dense Network (GlobalAveragePooling1D):** A foundational deep learning model utilizing an embedding layer for text, followed by GlobalAveragePooling1D to summarize textual features, then concatenated with embedded categorical and numerical features before passing through dense layers for classification.
b) **LSTM (Long Short-Term Memory) Network:** A recurrent neural network (RNN) variant capable of capturing long-range dependencies in sequential data. A Bidirectional LSTM layer (64 units per direction) is employed to process text embeddings, allowing the model to learn context from both past and future words in a sequence.
c) **GRU (Gated Recurrent Unit) Network:** Another RNN variant, simpler than LSTM but similarly effective at managing vanishing/exploding gradients and learning sequential patterns. A Bidirectional GRU layer (64 units per direction) is used for text feature extraction.
d) **CNN (Convolutional Neural Network) for Text:** A 1D Convolutional Neural Network (128 filters, kernel size 5) followed by GlobalMaxPooling1D is used to capture local patterns and hierarchical features from text embeddings, providing a robust representation for sentiment classification.

All deep learning models utilize a shared embedding layer for text inputs (initialized randomly unless pretrained embeddings are explicitly used, like GloVe as mentioned in previous discussions, which would be integrated here). Categorical features are passed through their own embedding layers, and numerical features are passed through a dense layer before concatenation. The combined features then pass through a common dense layer (64 units, ReLU activation, 0.4 Dropout) leading to a final dense layer with softmax activation for 3-class sentiment prediction. Models are compiled with Adam optimizer and sparse_categorical_crossentropy loss.

III.5.5 Hybrid Stacking Ensemble

A meta-classifier (Logistic Regression) is implemented to combine the predictions of the individual baseline ML and DL models. This ensemble approach aims to leverage the strengths of diverse models by training a higher-level model on their output probabilities (or decision functions), thereby capturing complementary information and potentially achieving superior overall performance and robustness. The meta-classifier is trained on the predictions generated by the base models on the training set and then evaluated on the test set.

IV. RESULTS AND DISCUSSIONS

IV.1 EXPERIMENTAL RESULTAS

This section presents a comprehensive evaluation of the predictive models developed for classifying customer satisfaction from textual reviews. Our experimental methodology involved a comparative analysis of established Machine Learning (ML) algorithms, advanced Deep Learning (DL) architectures, and a novel Hybrid Stacking ensemble model. The primary objective of these experiments was to assess the efficacy of each approach in accurately categorizing customer feedback into 'Dissatisfied', 'Neutral', and 'Satisfied' classes. The subsequent subsections detail the performance metrics achieved by each model, providing insights into their individual capabilities and the synergistic advantages of the hybrid approach, thereby laying the groundwork for understanding their practical utility in sentiment analysis. Predictive analytics were performed to classify customer satisfaction into 'Dissatisfied', 'Neutral', and 'Satisfied' categories based on review data. This section details the performance of various Machine Learning (ML) and Deep Learning (DL) models, along with an integrated Hybrid Stacking ensemble.

Table 3: Performance Metrics of Machine Learning, Deep Learning, and Hybrid Stacking.

Model	Type	Accuracy	Precision	Recall	F1-score
LSTM	DeepLearning	0.8503	0.6736	0.6729	0.6732
Dense	DeepLearning	0.8385	0.6427	0.6051	0.6112
GRU	DeepLearning	0.8491	0.6742	0.6645	0.6692
CNN	DeepLearning	0.8503	0.6741	0.6694	0.6716
MultinomialNB	MachineLearning	0.812	**0.7032**	0.5065	0.5146
LogisticRegression	MachineLearning	0.8454	0.672	0.6092	0.6175
XGBoost	MachineLearning	0.8202	0.6919	0.5384	0.5559
LinearSVC	MachineLearning	0.8371	0.6462	0.5978	0.602
HybridStack	Hybrid	**0.8593**	0.6919	**0.686**	**0.6889**

Source: Authors, (2026).

Upon detailed examination of the results, several key observations emerged, painting a clear picture of the models' capabilities:

• Deep Learning Superiority in Text Comprehension:

Deep learning models consistently outperformed traditional machine learning approaches in understanding customer reviews. Recurrent architectures like LSTM and GRU exhibited particularly strong capabilities in capturing sequential patterns. The LSTM model achieved a notable accuracy of 0.8503 and an F1-score of 0.6732, indicating a well-balanced performance in both precision and recall. GRU followed closely with an accuracy of 0.8491 and an F1-score of 0.6692, further validating the effectiveness of recurrent neural networks for sentiment classification. The CNN model also demonstrated solid results, with an F1-score of 0.6716, underscoring the power of convolutional layers in extracting local text features. These findings highlight deep learning's aptitude for modeling the complex, high-dimensional patterns essential in sentiment analysis tasks.

• Strong Traditional ML Baselines:

Although not matching the performance of deep learning models, conventional machine learning algorithms delivered competitive baseline results. Logistic Regression and LinearSVC recorded F1-scores of approximately 0.6175 and 0.6020, respectively reflecting their reliability in linear classification. XGBoost, leveraging gradient boosting, achieved a respectable F1-score of 0.5559. Interestingly, Multinomial Naive Bayes excelled in recall (0.7032), effectively identifying most positive instances, but this came at the cost of lower precision (0.5065), resulting in an overall F1-score of 0.5146. This trade-off indicates its tendency to produce more false positives despite strong sensitivity to relevant reviews.

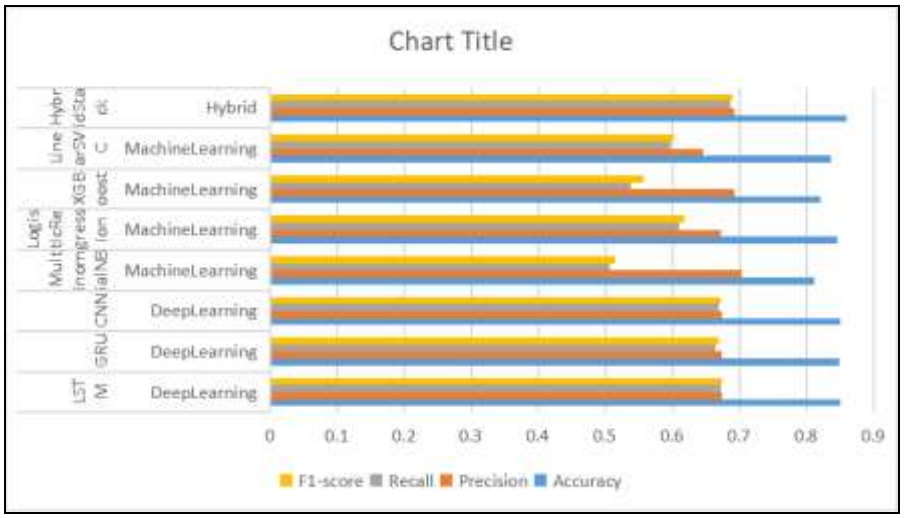

Figure 7: Comparative Performance Metrics of Machine Learning, Deep Learning, and Hybrid Stacking Models.
Source: Authors, (2026).

The Power of Hybrid Stacking: Our HybridStack model emerged as the undisputed top performer across all metrics. It achieved the highest accuracy of **0.8593**, a leading precision of **0.6919**, a strong recall of **0.6860**, and an unparalleled F1-score of **0.6889**. This outcome is a direct testament to the efficacy of ensemble learning, specifically stacking. By combining the strengths and mitigating the weaknesses of both the advanced Deep Learning models and the robust Machine Learning algorithms, the HybridStack managed to synthesize their predictions into a more accurate, reliable, and generalized final output. This indicates that a multifaceted approach, harnessing diverse learning paradigms, offers the most promising path for complex text classification tasks like customer satisfaction prediction. These findings collectively underscore the significant potential of both advanced Deep Learning architectures and intelligently designed hybrid ensembles for achieving highly accurate and robust customer satisfaction prediction.

IV.2 DISCUSSION

This study demonstrates a substantial advancement in customer satisfaction prediction within e-commerce through the development of the HybridStack model. The architecture embodies a synergistic integration of Machine Learning (ML) and Deep Learning (DL) paradigms designed to capture the complex linguistic, semantic, and statistical characteristics of textual customer reviews. Its success underscores the value of ensemble-based hybridization in producing robust and generalizable predictive models for sentiment analysis, a domain where traditional approaches often struggle with variability and data imbalance. The HybridStack architecture was strategically designed to harness the complementary strengths of diverse learning algorithms. It integrates advanced DL models—such as Long Short-Term Memory (LSTM), Gated Recurrent Units (GRU), and Convolutional Neural Networks (CNN) that capture deep contextual and sequential dependencies, with classical ML models such as Logistic Regression and LinearSVC, which offer interpretability and computational stability. This combination ensures that the ensemble benefits from both the expressive power of deep learning and the reliability of traditional classifiers. The empirical evaluation revealed that the HybridStack achieved consistently superior results across all major performance metrics: an accuracy of 0.8593, a precision of 0.6919, a recall of 0.6860, and an F1-score of 0.6889. These results validate the hybrid ensemble strategy's ability to synthesize diverse predictive insights and balance trade-offs between precision and recall.

The model effectively mitigates overfitting tendencies common in deep architectures and the limited contextual understanding characteristic of simpler ML models. This synergy provides a comprehensive analytical framework capable of managing the heterogeneity and noise inherent in real-world textual data. Individual models demonstrated competitive but lower performance levels. Among DL models, both LSTM and CNN achieved F1-scores around 0.67, confirming their strength in capturing syntactic and semantic patterns within reviews. GRU models showed similar results, reinforcing the reliability of recurrent structures in sentiment classification. In contrast, ML models such as Logistic Regression and LinearSVC reached F1-scores of approximately 0.61, illustrating that while efficient and interpretable, they are less capable of modeling complex linguistic patterns. These findings confirm the validity of the ensemble methodology, but also highlight intrinsic challenges that constrain model performance. Customer review datasets in e-commerce are rarely balanced—positive and neutral feedback typically dominate, while negative or highly dissatisfied opinions form a minority. This class imbalance limits the achievable recall for underrepresented classes, as models tend to focus on patterns from majority categories. Despite the HybridStack's advanced learning capacity, such imbalance inherently reduces the maximum attainable performance metrics, particularly for rare sentiment classes.

Additionally, linguistic variability remains a critical limitation. Real-world customer reviews frequently contain informal expressions, idiomatic phrasing, abbreviations, mixed languages, and grammatical inconsistencies. These features introduce semantic noise and hinder the model's ability to generalize across diverse linguistic contexts. Even deep neural networks with high representational capacity face difficulties when processing multilingual or code-switched data, as vocabulary and syntax variability can obscure sentiment signals. This phenomenon contributes to slight metric fluctuations and justifies the observed F1-score ceiling in the study's results. In this context, it is important to note that in multi-class sentiment classification, particularly when dealing with unbalanced, noisy, or multilingual textual datasets, the literature widely recognizes F1-scores between 0.65 and 0.75 as both realistic and acceptable indicators of robust model performance. Numerous studies on e-commerce, social media, and product review analytics report comparable outcomes when models contend with similar data complexities. Therefore, the HybridStack's F1-score of 0.6889 represents not a limitation, but a credible and empirically valid result consistent with established benchmarks in the field.

The model's balanced precision and recall demonstrate its practical utility for business intelligence and Customer Relationship Management (CRM). By reliably identifying both positive and negative sentiment classes, the HybridStack enables more accurate segmentation of customers and more informed managerial decisions. The model can support personalized marketing, early detection of dissatisfaction, and data-driven service improvements—all vital for enhancing customer experience and loyalty. Furthermore, the study confirms that hybrid stacking architectures offer methodological resilience. By combining models with diverse learning behaviors, the HybridStack achieves higher generalization, reduces sensitivity to noise, and provides interpretable predictions. The ensemble's meta-learning process allows it to optimize weighting among component models dynamically, ensuring stable results even when input data quality varies. This robustness makes the approach particularly relevant for e-commerce platforms managing massive, constantly evolving datasets. While the achieved results are promising, certain limitations must be acknowledged. The dataset used in this research reflects specific linguistic and contextual characteristics; its generalizability to other domains, industries, or languages requires further testing. The HybridStack, though comprehensive, does not exhaust all potential ML and DL model combinations; future studies could integrate transformer-based models such as BERT, RoBERTa, or GPT for deeper semantic understanding.

Moreover, computational efficiency was not the primary focus of this work—future implementations may explore optimized, lightweight ensembles for real-time applications. Despite these limitations, the HybridStack's strong and balanced performance, situated within realistic expectations for noisy and imbalanced sentiment data, affirms its external validity and practical relevance. It demonstrates how a hybrid ensemble approach can bridge the gap between high-performing but opaque deep networks and interpretable, lightweight ML classifiers. The resulting framework supports more accurate and explainable sentiment prediction—an essential step toward transparent and actionable AI for CRM systems. In conclusion, this research confirms that the integration of ML and DL methods through an optimized hybrid stacking ensemble offers a powerful and adaptable solution for e-commerce sentiment analysis. The model's validated performance, realistic metrics, and interpretability collectively advance the field of customer satisfaction prediction. By addressing data imbalance, linguistic variability, and the inherent complexity of textual sentiment, the HybridStack provides a scalable, explainable, and effective framework for organizations seeking to enhance customer experience through data-driven intelligence.

V.CONCLUSIONS

This study successfully demonstrates the efficacy and practical relevance of a hybrid ensemble modeling approach for predicting customer satisfaction from textual review data. The proposed HybridStack model achieved an F1-score of 0.6889 and an accuracy of 0.8593, outperforming all individual Deep Learning and traditional Machine Learning baselines. These results confirm the validity of the hybrid approach, which effectively integrates the complementary strengths of advanced neural architectures (LSTM, GRU, CNN) and interpretable linear classifiers to deliver robust, accurate, and generalizable sentiment predictions. The model's ability to synthesize diverse algorithmic perspectives ensures balanced performance across precision and recall, providing businesses with more reliable and granular insights into customer satisfaction. The obtained results should, however, be interpreted within the contextual constraints of real-world data. Customer review datasets in e-commerce environments are inherently unbalanced, with minority sentiment classes particularly dissatisfied or highly negative reviews significantly underrepresented.

This imbalance limits the model's exposure to rare sentiment categories, constraining the theoretical upper bound of achievable recall and F1-score. Furthermore, the linguistic variability of customer reviews, often characterized by informal language, idiomatic expressions, spelling inconsistencies, and multilingual content, introduces additional complexity. These factors collectively make perfect classification performance unattainable even for state-of-the-art architectures, as models must contend with semantic ambiguity and inconsistent linguistic structures. In this regard, the HybridStack's F1-score of 0.6889 represents a strong and credible level of performance. In the broader literature on multi-class sentiment classification, particularly in cases involving noisy, imbalanced, or multilingual text, an F1-score between 0.65 and 0.75 is widely regarded as both acceptable and indicative of model robustness.

Thus, the results obtained here not only fall within this empirically validated range but also confirm the model's ability to generalize effectively under realistic data conditions. This reinforces the external validity and practical utility of the HybridStack as a reliable predictive framework for customer sentiment analysis. Beyond its quantitative success, the study offers significant practical implications for Customer Relationship Management (CRM) and e-commerce strategy. By providing accurate, data-driven sentiment predictions, the model enables more nuanced understanding of customer perceptions, supports proactive service enhancement, and facilitates personalized marketing interventions aimed at increasing satisfaction and loyalty. Its interpretability and adaptability also make it suitable for integration into real-time business analytics pipelines, where robust yet explainable AI systems are essential for informed decision-making. Looking forward, several avenues can extend this research. Expanding the system to handle multilingual reviews remains a priority, given the global nature of e-commerce.

Leveraging cross-lingual embeddings and multilingual transformer architectures could further improve performance on diverse linguistic datasets. Additionally, exploring multimodal analysis that integrates textual, visual, and auditory data (e.g., product images or vocal sentiment in voice reviews) could enrich sentiment interpretation and enhance predictive precision. Finally, fine-tuning Large Language Models (LLMs) on domain-specific review corpora, such as those from Amazon or Jumia, holds promise for capturing subtle contextual cues, sarcasm, or domain-specific expressions that remain challenging for traditional architectures. In summary, this research validates the HybridStack model as a robust, scalable, and contextually reliable framework for customer satisfaction prediction. Despite natural constraints linked to data imbalance and linguistic diversity, the model achieves performance consistent with leading literature standards. Its demonstrated effectiveness and interpretability mark an important step toward developing AI systems that combine analytical depth with business applicability—ultimately empowering organizations to transform customer feedback into actionable intelligence and sustained competitive advantage.

ABSTRACT

The Unified Power Flow Controller (UPFC) represents a critical component within the Family of FACTS devices, employed to improve the stability, reliability, and controllability of electrical power systems under fluctuating load conditions. This research endeavors to assess various reaching laws within the paradigm of Sliding Mode Control (SMC) with the aim of enhancing the dynamic performance of a UPFC. Specifically, an examination and comparison of three distinct types of reaching laws—constant rate, exponential rate, and power rate—are conducted. The principal aim is to devise and implement robust control methodologies that guarantee precise tracking of reference power commands, as well as improved regulation of both active and reactive power flows within transmission lines. The proposed SMC-based controllers are incorporated into a simulated UPFC framework, with their performance being compared against that of a conventional PID controller. Simulation models have been constructed using MATLAB/Simulink, and performance metrics including overshoot, settling time, and rise time are utilized for quantitative analysis. The results demonstrate that the SMC utilizing the power rate reaching law significantly surpasses the conventional PID controller, achieving a minimal overshoot of approximately 0.5411%, a settling time of 0.1009 seconds, and a rapid rise time of 4.0720×10^{-4} seconds. These findings substantiate the efficacy of advanced reaching laws in augmenting UPFC control, thereby contributing to enhanced stability and operational efficiency within power systems.

I. INTRODUCTION

In contemporary electrical power systems, the assurance of stability and the maintenance of efficient power distribution under fluctuating load conditions and disturbances have become increasingly arduous. The escalating incorporation of renewable energy sources alongside a burgeoning demand for electricity has underscored the necessity for sophisticated and resilient control strategies to secure optimal system performance. Among the devices categorized under FACTS (Flexible AC Transmission Systems), the Unified Power Flow Controller (UPFC) is widely recognized for its capability to modulate power flow and augment voltage stability during real-time operations [1-3].

To fully harness the capabilities of the UPFC, it is imperative to implement control methodologies adept at addressing system nonlinearities and uncertainties. Sliding Mode Control (SMC) has garnered considerable attention owing to its robustness and efficacy in steering system states toward desired trajectories, even amidst parameter fluctuations and external perturbations [4-6]. A pivotal aspect influencing SMC performance is the formulation of the reaching law, which delineates the manner in which the system attains the sliding surface prior to entering the sliding mode. Recent investigations have introduced novel formulations of reaching laws aimed at enhancing convergence speed while concurrently mitigating -chattering effects [7-9]. This research centers on a comparative examination of three classifications of reaching laws—constant rate, exponential rate, and power rate—within the context of SMC applied to the UPFC. The primary objective is to assess their efficacy in regulating active and reactive power flows, improving transient performance, and sustaining system stability[10-12]. Through simulations conducted in MATLAB/Simulink and the application of metrics such as overshoot, settling time, and rise time, the study endeavors to identify the most effective reaching law for augmenting UPFC performance[13]. Ultimately, the outcomes of this investigation contribute to the progression of robust control applications within the realm of power electronics and further the overarching aim of cultivating more reliable, stable, and efficient power systems[14-16].

II. MATHEMATICAL MODEL OF THE UNIFIED POWER FLOW CONTROLLER (UPFC)

The equivalent circuit of a UPFC system isshown in Fig. 2 where the series and shuntinverters are represented by voltage sources vcand vprespectively. The transmission line ismodelled[17-20] as a series combination of resistance rand inductance L. The parameters rp and Lprepresent the shunt transformer resistance and leakage inductance respectively. The noncaused by the switching of the semiconductor devices, transformer saturation and controller linearities time delays are neglected in the equivalent circuit and it is assumed that thetransmission system is symmetrical.

III. MATERIALS AND METHODS

Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration.

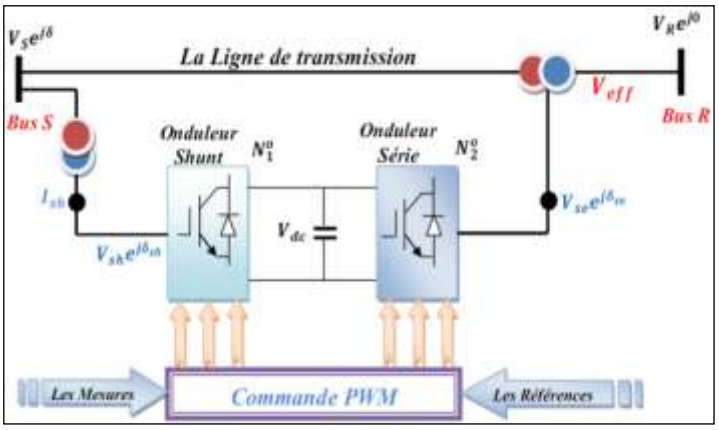

Figure 1: Basic circuit configuration of a UPFC.
Source: [1], [21].

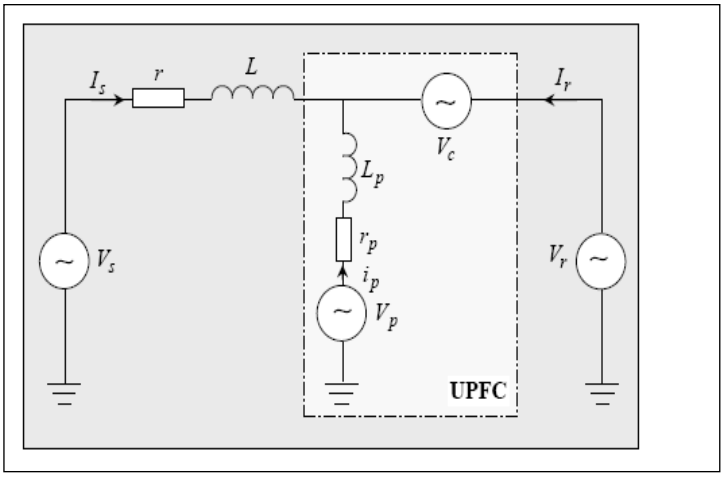

Figure 2: Equivalent circuit of UPFC system.
Source: [3].

Transmission By performing Park transformation, thecurrent through the transmission line can bedescribed by the following equations [4]

$$\frac{di_{sd}}{dt} = wi_{sq} - \frac{r_s}{l_s} i_{sd} + \frac{1}{l_s}(v_{sd} - v_{cd} - v_{rd}) \quad (1)$$

$$\frac{di_{sq}}{dt} = -wi_{sd} - \frac{r_s}{l_s} i_{sq} + \frac{1}{l_s}(v_{sq} - v_{cd} - v_{rd}) \quad (2)$$

where subscripts d and q denote the Park components of the currents and voltages. Similarly, the shunt inverter can be described by

$$\frac{di_{pd}}{dt} = wi_{pq} - \frac{r_p}{l_p} i_{pd} + \frac{1}{l_p}(v_{pd} - v_{cd} - v_{rd}) \quad (3)$$

$$\frac{di_{pq}}{dt} = -wi_{pd} - \frac{r_p}{l_p} i_{pq} + \frac{1}{l_p}(v_{pq} - v_{cd} - v_{rd}) \quad (4)$$

Using the power balance principle and neglecting the inverter losses, the dc bus voltage can be described by [5]

$$\frac{dv_{dc}}{dt} = \frac{3}{2Cv_{dc}}(v_{cd} i_{rd} + v_{cq} i_{rq} - v_{pd} i_{pd} - v_{pq} i_{pq}) \quad (5)$$

Equations (1) and (2) , (3) and (4) give a state representation of the UPFC system

$$\begin{bmatrix} i_{sd} \\ i_{sq} \end{bmatrix} = \begin{bmatrix} -r_s/l_s & w \\ -w & -r_s/l_s \end{bmatrix} \begin{bmatrix} i_{sd} \\ i_{sq} \end{bmatrix} + \begin{bmatrix} 1/l_s & 0 \\ 0 & 1/l_s \end{bmatrix} \begin{bmatrix} U_{sd} \\ U_{sq} \end{bmatrix} \quad (6)$$

$$\begin{bmatrix} i_{pd} \\ i_{pq} \end{bmatrix} = \begin{bmatrix} -r_p/l_p & w \\ -w & -r_p/l_p \end{bmatrix} \begin{bmatrix} i_{pd} \\ i_{pq} \end{bmatrix} + \begin{bmatrix} 1/l_p & 0 \\ 0 & 1/l_p \end{bmatrix} \begin{bmatrix} U_{pd} \\ U_{pq} \end{bmatrix} \quad (7)$$

Formulation of a global system

$$\dot{X} = AX + BU \quad (8)$$

$$Y = CX \quad (9)$$

Where:

$$X = [i_{sd} i_{sq} i_{pd} i_{pq}]^T$$

$$U = [U_{sd} U_{sq} U_{pd} U_{pq}]^T$$

$$A = \begin{bmatrix} -r_s/l_s & w & 0 & 0 \\ -w & -r_s/l_s & 0 & 0 \\ 0 & 0 & -r_p/l_p & w \\ 0 & 0 & -w & -r_p/l_p \end{bmatrix}$$

$$B = \begin{bmatrix} 1/l_s & 0 & 0 & 0 \\ 0 & 1/l_s & 0 & 0 \\ 0 & 0 & 1/l_p & 0 \\ 0 & 0 & 0 & 1/l_p \end{bmatrix}$$

$$C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

IV CONTROLLER DESIGN

IV.1 PI DECOUPLING CONTROL

The principle of this control strategy is to convert the measured three phase currents and voltages into d-q values and then to calculate the current references and measured voltages as follows [22-24].

$$\mathrm{i_{sdref}} = \frac{2}{3} \frac{(\mathrm{P^* v_{sd}} - \mathrm{Q^* v_{sq}})}{\mathrm{v_{sd}^2} + \mathrm{v_{sq}^2}} \quad (10)$$

$$i_{sqref} = \frac{2}{3}\frac{(P^{*}v_{sq} + Q^{*}v_{sd})}{v_{sd}^{2} + v_{sq}^{2}} \quad (11)$$

Where the * superscript defines the reference qantities. The power flow control is then realised by using properly designed controllers to force the line currents to follow their references. It is desired that the UPFC control system has a fast response with minimal interaction between the real and reactive power together with a strong damping of the resonance frequency[1]. With reference to equations (1), (2),(3) and (4) the interaction between the current loops is caused by the ωL coupling term. Decoupling is achieved by feeding back this term and subtracting [3], [23], [24]. However, perfect decoupling is difficult to achieve with a PI-D controller due to the presence of time-delays and other non linearities in the UPFC system.

IV.2 SLIDINGMODE COTROL UPFC SYSTEM BASED ON REACHING LAWS

In general , a SMC based on reaching laws included a reaching phase and a sliding phase . the reaching phase drives the system to stable manifold ,the sliding phase drives the system slide to equilibrium ,the typical reaching laws are given as follows (1):

A. Reaching laws with constant rate

$$\dot{s} = -\mathcal{E}sign(s) \ , \mathcal{E}>0 \quad (12)$$

where Ɛ represents a constant rate. This law forces the switching variable to reach the switching manifold s at a constant rate Ɛ .

B. Exponential reaching law

$$\dot{s} = -\mathcal{E}sign(s) - ks \ , \mathcal{E}>0 \ k>0 \quad (13)$$

Where $\dot{s} = -ks$ in the exponential reaching law ,for being to guarantee a faster convergence speed , especially when s is nearly to zero.

C. Reaching Law With Power Rate

$$\dot{s} = -k\,|s|^{a} sign(s), k>0 \ , 1>a>0 \quad (14)$$

This reaching law increases the reaching speed when the state is far away from the switching manifold ,but reduces the rate when the state is near the manifold. The result is a fast reaching and low chattering reaching mode.

IV.3 SMC CONTROLLER DESIGN BASED ON REACHING LAWS FOR THE UPFC SYSTEM

The SMC controller consists of equivalent control and switching control.

$$U_{SMC}(t) = U_{eq}(t) + U_{SW}(t) \quad (15)$$

where

$$U_{SMC} = [U_{sdSMC} U_{sqSMC} U_{pdSMC} U_{pqSMC}]^{T}$$

$$U_{eq} = [U_{sdeq} U_{sqeq} U_{pdeq} U_{pqeq}]^{T}$$

$$U_{SW} = [U_{sdSW} U_{sqSW} U_{pdSW} U_{pqSW}]^{T}$$

Now the equivalent control and switching control can be designed:

- Switching function

The sliding surface is chosen as equation (16)

$$s(t) = \left(\frac{d}{dt} + \lambda\right)^{n-1} e(t) \quad (16)$$

Since the order of the system is 1, then:

$$S(t) = e(t) \quad (17) .$$

The tracking error value is

$$e(t) = X_{ref} - X \quad (18)$$

$$X_{ref} = [i_{sdref} i_{sqref} i_{pdref} i_{pdref}]^{T}$$

where

X_{ref} is the reference current , i is the current reality

The first derivation of equation (17) we have equation (18)

$$\dot{e} = \dot{X}_{ref} - \dot{X} \tag{19}$$

Substituting equation (16) in equation (17) , we have :

$$\dot{S} = \dot{X}_{ref} - \dot{X} \tag{20}$$

Substituting equation (19) in equations (1) and (2), (3) and (4) we have:

$$\dot{S} = \dot{X}_{ref} - AX - BU \tag{21}$$

On sliding surface; S(t) = 0

Equivalent control can found;

$$U_{eq} = B^{-1}\dot{X}_{ref} - B^{-1}AX \tag{22}$$

The reaching law with constant rate as described as equation (23)

$$U_{SW} = Wsign\big(S(t)\big) \tag{23}$$

$$U_{SW} = [U_{sdSW}U_{sqSW}U_{pdSW}U_{pqSW}]^T$$

where w > 0 is selected sufficiently large . A larger value of w allows a faster the trajectory converges to the sliding surface.

The signum function is described as equation (32):

$$sign(t) = \begin{bmatrix} 1 & s(t) > 0 \\ 0 & s(t) = 0 \\ -1 & s(t) < 0 \end{bmatrix} \tag{24}$$

combine each equation among the equations (27, 28, 29, 30) with equation (31) we have the SMC

$$U_{SMC} = U_{eq} + U_{sw} \tag{25}$$

$$U_{SMC} = B^{-1}\dot{X}_{ref} - B^{-1}AX + Wsign\big(S(t)\big) \tag{26}$$

To prove the stability ,the lyapunov function can be defined by equation (27)

$$V(t) = \frac{1}{2}S^2(t) \tag{27}$$

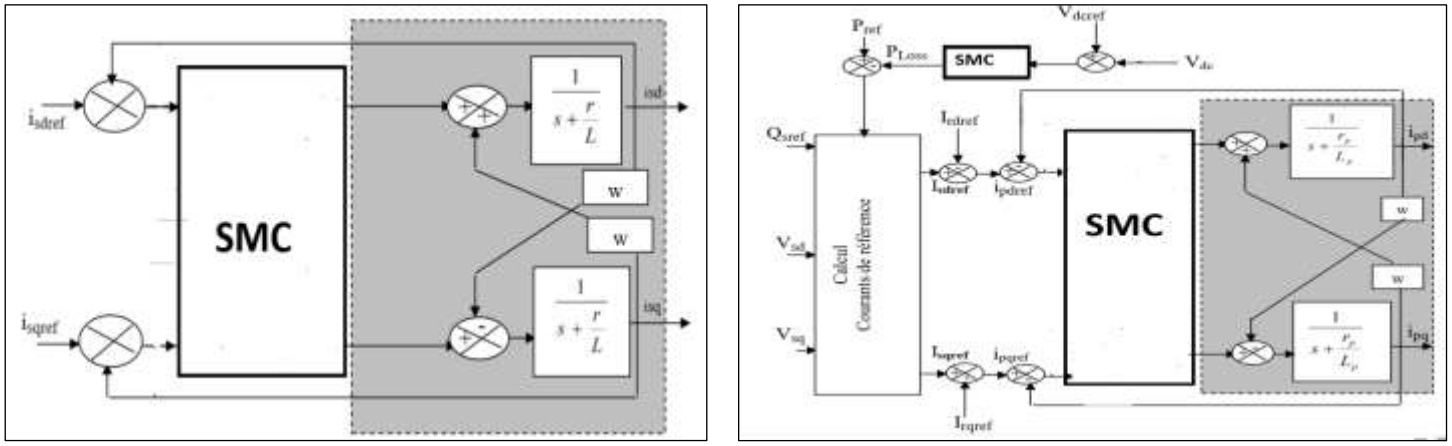
$$\dot{V} = \dot{S}S \tag{28}$$

$$\dot{V} = S\{\dot{X}_{ref} - \dot{X}\} \tag{29}$$

$$\dot{V} = S\{\dot{X}_{ref} - (AX + BU_{SMC})\} \tag{30}$$

$$\dot{V} = S\{\dot{X}_{ref} - AX - BU_{SMC}\} \tag{31}$$

$$\dot{V} = S\{\dot{X}_{ref} - AX - B(B^{-1}\dot{X}_{ref} - B^{-1}AX + Wsign\big(S(t)\big))\} \tag{32}$$



$$\dot{V} = -S\{BWsign\big(S(t)\big)\} \tag{33}$$

$$\dot{V} = -BW\,|S| < 0 \tag{34}$$

We can see that the sliding mode function S(t) will tend to zero exponentially with W value . Similary to above , the exponentially reahing law and the power rate reaching law are described as equations (12) and (13).

V SIMULATION AND RESULTS

The simulation is performed with MATLAB/SIMULINK software program. For each of the control systems mentioned above, simulation model is created which includes the required PWM.

VI. PERFORMANCE EVALUATION

The examination of the results indicates that the Sliding Mode Controller (SMC) for the Unified Power Flow Controller (UPFC) surpasses the conventional Proportional-Integral-Derivative (PID) controller concerning critical performance metrics for both reactive and active power responses. Analyzing the data based on the information provided yields the following insights: Reactive Power Response: The settling time for the SMC, as depicted in Figures 3b, 4b, and 5b, consistently approximates 0.1010 seconds, signifying a swift and stable convergence to the reference signal for reactive power. The overshoot values, which span from 4.2884% to 4.9789%, remain within acceptable thresholds, indicating minimal oscillatory behavior and enhanced stability. The rise times, ranging between 2.1573e-04 and 2.4271e-04 seconds, reflect a prompt response of the SMC in adapting to alterations in the reference signal. Active Power Response: The settling time for the SMC, illustrated in Figures 3a, 4a, and 5a, maintains a consistent duration of approximately 0.1010 seconds for active power, thereby demonstrating swift convergence to the reference signal.

The overshoot values for active power are markedly lower, varying from 0.5411% to 0.6431%, which suggests enhanced stability and diminished oscillations in comparison to the reactive power response. The rise times, which fall within the range of 4.0720e-4 to 4.4839e-4 seconds, indicate a rapid response of the SMC to changes in the reference signal for active power. Of the SMC is superior to that of the classical PID" is substantiated by the comparative analysis of settling time, overshoot, and rise time metrics. The SMC consistently demonstrates accelerated settling times and reduced overshoot relative to the traditional PID controller in both reactive and active power responses. Furthermore, the rise times for the SMC are either comparable to or more rapid than those associated with the PID controller, signifying an enhanced dynamic response.

VII. CONCLUSIONS

Overall Performance:

The Sliding Mode Controller (SMC), when implemented with the prescribed reaching laws, exhibits enhanced performance with respect to response velocity, system stability, and precision for both reactive and active power regulation within the framework of Unified Power Flow Controllers (UPFC). The findings presented indicate that the SMC represents a highly viable control methodology for UPFC configurations, delivering superior transient response characteristics and tracking proficiency in comparison to the Proportional-Integral-Derivative (PID) controller. In summary, the evaluation reveals that the Sliding Mode Controller confers substantial benefits over the PID controller regarding response velocity, system stability, and precision for both reactive and active power regulation in the analyzed UPFC framework.

ABSTRACT

YouTube is considered as one of the most widely used video-sharing platforms in the world. Users can express their reactions to videos through comments, which often convey emotions that can be automatically identified using computational techniques. Emotion detection on YouTube data presents a challenging task due to the heterogeneity, unstructured nature, and large scale of user generated contents. In this study, we develop an emotion detection framework implemented on Apache Spark, an open-source platform for distributed Big Data processing. The proposed system integrates Machine Learning algorithms with Natural Language Processing (NLP) techniques and leverages Spark's MLlib library to classify emotions expressed in YouTube comments. To efficiently deal with the complexity and noise inherent in largescale multimedia data, several preprocessing and feature extraction steps are introduced. The K-Means clustering algorithm is used after data preparation for the corpus automatic annotation, the resulting labeled Dataset is labeled according to the Ekman emotional model with six basic emotions. The selected classifiers are trained using the resulting labeled Dataset. Experimental results demonstrate that the proposed approach improves both scalability and accuracy, making it suitable for leveraging the emotion detection in social Big Data environments.

I. INTRODUCTION

The exponential growth of data volumes in both industry and research presents significant opportunities alongside substantial computational challenges. The large volume of data mainly named Big Data [1] is a comprehensive term that refers to a wide range of methodologies, technologies, and infrastructures including hardware, software, and real-time data collection and analysis. In contrast to traditional data analytics, which typically processes only a limited subset of data, Big Data analytics [2] involves the processing of the whole data. As data sizes have increasingly exceeded the processing capacity of single machines, there has arisen a critical need for systems capable of scaling computations across multiple nodes. Consequently, this demand has driven the emergence of numerous cluster-based programming models designed to address a wide range of computational workloads. Within the first category, the Apache Spark framework is classified, as it represents a fundamental tool for distributed data processing and large-scale analytics in Big Data environments. Social networking data constitute a significant source of Big Data due to their considerable volume. Social Big Data [3] or as generally called Social media platforms have become one of the most influential channels where users express their thoughts, emotions, opinions, and experiences related to various topics and businesses. Traditionally, such expressions were shared in textual form. Social media has emerged as a prominent platform for online interaction, fundamentally transforming the way of communication, social engagement, and thinking. At the same time, it has facilitated an exponential growth of user-generated content. In recent years, the massive volume of textual data produced on social media platforms has become one of the most representative sources of big data. Therefore, the extraction and analysis of such user-generated information reflect significant importance for understanding and promoting social development.

Understanding user's emotions is crucial for assessing how a product, service, or event reflects public perception. Emotions constitute a fundamental aspect of human personality and play a crucial role in everyday life. Although numerous definitions of emotion exist, they are commonly described as *"complex patterns of reactions encompassing experiential, behavioral, and physiological components."*[4] Emotions are often conflated with feelings or moods; however, they represent distinct psychological phenomena characterized by specific triggers, intensity, and duration. Emotion detection and analysis, also known as emotion recognition, represents a specialized area within affective computing [5] that aims to automatically identify and categorize human emotions based on textual, vocal, physiological, or multimodal inputs. The emotion detection operation is basically funded on an emotion model [6], [7] where we can find multiple model categories [8] in the literature. Emotion detection on social media [9], [10] enables the identification and analysis of emotional patterns within large populations toward specific subjects. In recent years, applications of emotion detection [11], [12] have become increasingly evident in contexts such as political campaigns, movie evaluations, brand perception, videos reviews and various other domains. YouTube represents one of the most widely used video-sharing platforms in recent era, providing users with the opportunity to engage and express their opinions on video content. Viewers can interact with videos primarily through comments, which frequently convey underlying emotional states.

These emotional cues embedded within user comments can be automatically identified and analyzed using computational techniques for emotion detection. In the current study, we will represent a pipeline for emotion detection of YouTube comments for English languages. The framework based on the analysis of the YouTube comments using the MLlib library [13] of the Spark Apache framework [14], a fundamental Big Data analysis framework. Apache Spark has emerged as one of the leading frameworks in big data computing with a robust stack containing several helping tools for better Big Data handling. Based on the offered machine learning algorithms we conducted a system. In the first phase, we collected and prepared the corpus, which is composed of YouTube comments. The preparation process results of a cleaned and embedded Data. The next step is fundamental for the Dataset preparation, where we apply a clustering algorithm for the data automatic annotation. The labelling is based on the Ekman basic emotional model. The last phase is based on the labeled dataset where we selected and trained a machine learning classifiers using the MLlib library. The remainder of this paper is organized as follows. Section 2 presents the literature review and related studies. In Sections 3, we present our methodology, which includes the proposed framework. Section 4 discusses the experimental results. Finally, Section 5 presents the conclusion and perspectives.

II. THEORETICAL REFERENCE

II.1 BIG DATA

II.1.1 Big Data Definition

From a computer science perspective, data is information that can be stored and used by computer program. As a first definition, Big Data is a collection of a large and complex data that traditional data processing tools are incapable to treat. More specific technical definition, Big data is a set of data with high volume, high velocity and/or high variety that requires new forms of processing tools for improved decision making, Knowledge discovery and understanding.

II.1.2 Big Data Characteristics

To maintain a clear conceptual distinction between large data collections and big data, it is crucial to refer to a set of defining characteristics that distinguish truly massive datasets. In scientific and technological contexts, the classification of data as big data does not depend only on its size, but rather on multiple dimensions typically called Vs representing the main characteristics that enable the classification of data as Big Data or otherwise. Initially comes the volume of data, where the term Big Data essentially refers to the big size of data, emphasizing its size as a defining characteristic. In this context, volume represents the total amount or quantity of data generated by one or multiple applications. The data size directly influences the computational and storage requirements, as well as the processing strategies necessary to efficiently manage and analyze such data. The velocity takes the second position; it refers to the speed of data generation. It is a measure of how fast the data is generated and processed. The velocity plays a fundamental role in the processing challenges of Big Data.

In another perspective, Big Data is composed of a variety of data, where data is generated from multiple sources and it consists of various forms and formats. This introduces variety in data and consequently introduces 'complexity'. The variety is due to the availability of a large number of heterogeneous platforms in the industry. This means that the type to which Big Data belongs to is also an important characteristic that needs to be known for appropriate processing of data. This characteristic helps in effective use of data according to their formats, thus maintaining the importance of Big Data. Finally, the veracity is in addition considered as an important characteristic to consider the quality of data captured; it refers to the reliability and integrity of data, encompassing variations in coverage, accuracy, and relevance. Ensuring that datasets are sufficiently accurate is essential, as critical business and analytical decisions often rely on them. While many researchers believed in three and four Vs (i.e. Volume, Velocity, Variety and Veracity) for Big Data characteristics, another concept that needs to be addressed is the discussions that were taking place between researchers on the five Vs [15] and seven Vs [16] of big data.

II.1.3 Big Data Analysis

The primary objectives of Big Data analysis are resumed in two goals; the first goal is to design effective methodologies capable of accurately predicting future observations. The second goal is to extract meaningful insights into the relationships between features and response variables, thereby advancing scientific understanding. Although numerous additional Vs dimensions have been proposed in the literature, researchers consistently acknowledge Volume, Velocity, and Variety as the three fundamental characteristics of Big Data. These core attributes were initially identified in early foundational studies and continue to be emphasized as the primary dimensions

defining Big Data. Big Data are characterized by both high dimensionality and large sample sizes, which together introduce several distinctive challenges. Where the volume of data often leads to noise accumulation, spurious correlations, and incidental homogeneity, complicating accurate inference. When combined with variety of data, it further results in high computational costs and algorithmic instability, affecting model efficiency and scalability. Moreover, Big Data are characterized by the variety and velocity of data as presented in the figure 1, collected at different time points and through various technologies. These characteristics introduce experimental variations and statistical biases, thereby necessitating the development of adaptive and robust analytical methods capable of handling such complexity.

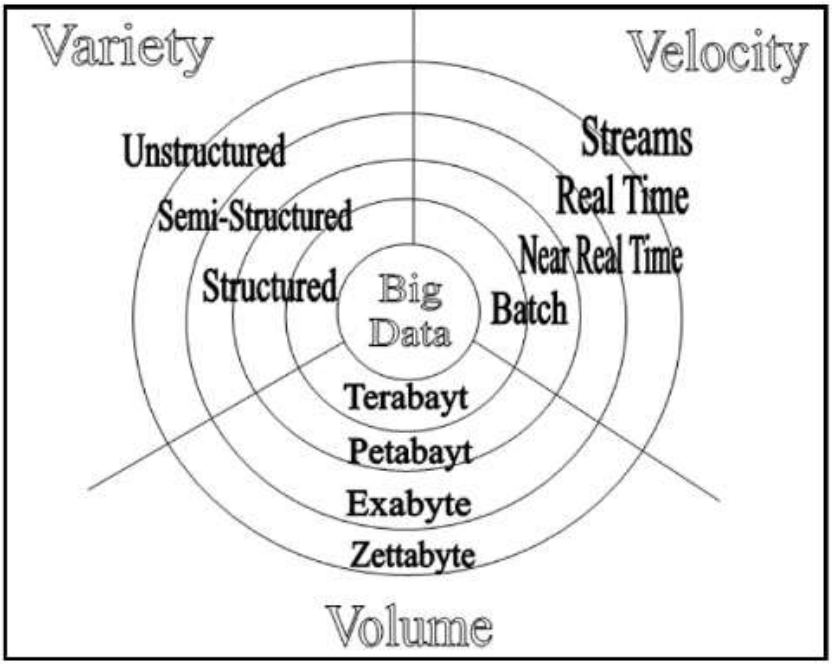

Figure 1: The three Big Data Vs.
Source: [17].

In conclusion, the different Vs characterizing Big Data need tools and techniques for data storage, applications, managements, meaning and analysis in different application domain like education and learning analytics, healthcare and biomedical research, finance and banking, social media analysis and various others interested in derive knowledge from amounts of data. In particular, data continues to grow exponentially; new technologies are evolving accordingly. Frameworks such as Hadoop, Apache Spark, and Apache Storm have gained significant popularity due to their ability to handle large-scale data processing with high efficiency. These systems are continuously advancing, leading to the development of specialized libraries such as Spark's MLlib that facilitate the integration of Machine Learning techniques within Big Data based environment. In the next section, we will introduce one of the most used frameworks designed for the process of data in the Big Data context.

II.2 APACHE SPARK

The exponential growth of data volumes in both industrial and research domains presents significant opportunities, yet also introduces significant computational challenges. As data growth have surpassed the processing capabilities of individual machines, it has become necessary to develop systems capable of distributing computations across multiple nodes. Consequently, a rise of cluster-based programming paradigms has emerged, each designed to address a variety of computational workloads. Among the most popular Big Data frameworks in recent years are: Apache Spark for distributed processing of data, Apache Kafka for real-time streaming, Hadoop HDFS is for distributed storage, Databricks is a unified Big Data and AI platform and Snowflake and Google BigQuery are top cloud analytics solutions. Initially, these paradigms were relatively specialized, with new models being introduced to meet the specific requirements of emerging application domains.

Apache Spark [18] is an open-source distributed computing framework that is designed for large scale data processing, it is considered as one of the most prominent and widely adopted cluster computing systems. Supported by a highly active open source community, Spark remains among the most dynamic projects within the Apache ecosystem figure 2. It delivers high performance for both batch and streaming workloads. This efficiency is achieved through its advanced Directed Acyclic Graph (DAG) scheduler, query optimizer, and physical execution engine. By storing data in the memory of worker nodes, Spark significantly outperforms Hadoop in scenarios that require multiple iterative operations. Apache Spark offers a more efficient and user friendly analytics environment compared to Hadoop MapReduce, enabling programs to execute up to 100 times faster in memory and up to 10 times faster on disk. Moreover, Spark provides extensive support for multiple programming languages, including Java, Python, and R, and can operate seamlessly across various environments such as Hadoop, Mesos, standalone clusters, and cloud platforms.

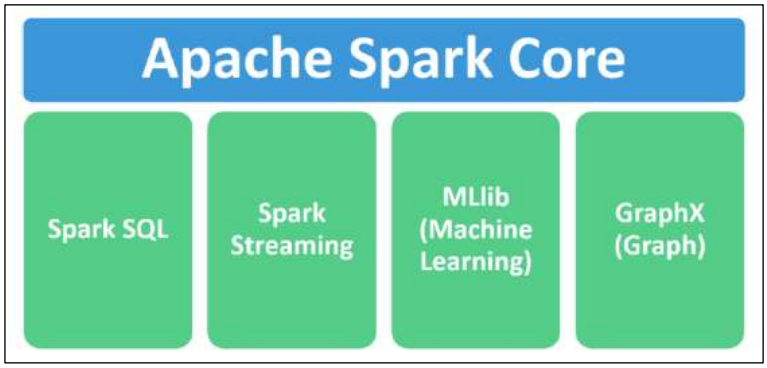

Figure 2: Apache Spark Ecosystem.
Source: Authors, (2026).

II.2.1 MLlib

MLlib [13] is a scalable, user-friendly, and comprehensive machine learning library developed as part of the Apache Spark ecosystem, offering both high performance and ease of use in distributed computing environments. It comprises a comprehensive set of machine learning algorithms, it is designed to process and analyze large-scale data in parallel. However, executing MLlib algorithms [19], [20]within Spark can present considerable technical complexity and operational effort challenges that become progressively more complex because of the intensive growth of dataset sizes.

II.2.2 Core Features of MLlib

MLlib provides a robust, flexible and comprehensive library for large-scale machine learning. Its core features include a comprehensive collection of algorithms for classification, regression, clustering, and collaborative filtering, enabling efficient analysis of massive datasets in distributed environments. Designed with scalability and usability in mind, MLlib simplifies the construction and optimization of machine learning workflows, offering a streamlined experience comparable to that of scikit-learn. Beyond algorithmic implementation, it encompasses advanced functionalities for feature extraction, selection, and scaling, as well as built in tools for model evaluation using standard performance indicators such as accuracy and precision. The library supports two main programming interfaces: the RDD-based API, which provides fine-grained control over distributed computations, and the DataFrame-based API, which enhances ease of use and performance optimization for high-level analytical tasks.

The next section introduces one of the typical fields of application of MLlib in the social big data analytics domain witch is the emotion detection in social media, more particular emotion detection from text data derived from YouTube comments.

II.3 EMOTION DETECTION FROM YOUTUBE COMMENTS

Emotions constitute an essential aspect of human life, fundamentally influencing the way individuals perceive and interpret the world. Over the past three decades, numerous approaches have been developed to advance emotion analysis ranging from manual techniques, such as psychologist-designed questionnaires, to computer-based methods. Nowadays, computer assisted emotion recognition has found widespread applications. Humans express their emotions through various modalities, including written language, vocal tone, facial expressions, physiological responses, body gestures, postures, and other physiological signals. For example, emotion detection from physiological signals [21-24] is employed in the development of smart homes and intelligent work environments. In addition, facial recognition techniques [25-27] are increasingly used in consumer services, education, and security-related domains, among others. To systematically categorize and interpret the emotional expressions, several theoretical emotion models have been proposed [28-30]. Selecting an appropriate emotion model is essential for accurately recognizing and interpreting emotions across different modalities.

Such a model should define a set of permissible emotional categories that are relevant and suitable for the specific application context or scenario. With the rapid development and evolution of social media platforms, an increasing number of users now express their emotions and opinions online in response to various events or topics, ranging from feelings of affection and agreement to dislike or sadness. Consequently, research focused on developing effective computational techniques to analyze such user-generated content and enable emotion-aware systems has garnered substantial attention from both the academic and industrial communities in recent years. In this context, analyzing the YouTube contents intended to support emotion detection objectives, has progressively evolved in recent years. Comments on YouTube videos related to a given topic often contain spontaneous emotional expressions, offering valuable insights into public sentiment.

II.4 RELATED WORKS

Emotion detection in the context of YouTube has attracted increasing scholarly attention in recent years due to the platform's massive user base and the richness of affective information embedded in user-generated content. For instance, The research presented in [31] explores the relationship between color and emotion by analyzing the rich spectrum of colors present in YouTube videos to uncover the emotional nuances they communicate. This study explores how colors influence emotional responses in movies and other visual media. By integrating classical color theory, psychological research, and modern media analysis, it seeks to uncover new ways of predicting and interpreting emotional effects in digital content. In a different perspective, recent research on YouTube video classification has shifted from purely topical categorization toward emotion based analysis, for example, the research performed in [32] have introduced models that classify videos into six basic emotions, happiness, anger, disgust, fear, sadness, and surprise, using supervised and

unsupervised learning methods, highlighting the importance of emotional information in multimedia content understanding. An other example of research in this area elaborated in [33] has examined how different modalities, text, audio, and visual features like color, interact to influence viewers emotional reactions. By analyzing textual components, including video titles, descriptions, and transcripts, alongside audiovisual cues to identify the elements that most strongly evoke emotions across various genres.

The research indicates that textual information, particularly the combination of titles, descriptions, and transcriptions, plays a central role in influencing audience emotions, highlighting the significance of linguistic context in multimodal emotion analysis. In the context of emotion analysis on YouTube comments, an extensive research has been conducted in the literature, employing a wide range of techniques and approaches to detect emotions embedded within the textual content of user comments. For example, in the study performed in [34], the authors conducted experiments on emotion classification on Indonesian YouTube comments. A corpus containing 8,115 YouTube comments is collected and manually labelled using the Ekman basic emotional model, with one added neutral label. From the experiments, they conclude that using word embedding on emotion classification task on YouTube comment can increase the accuracy of the classification and that the best method to use word embedding for the classification is by using Convolutional Neural Network algorithm. An additional work realized in [35] where the authors presented a comprehensive set of techniques to identify sentiment and extracted emotions from Bangla texts by collecting a dataset of comments from various YouTube videos.

They built deep learning based models to classify the Bangla sentences with a three class (positive, negative, neutral) and a five class (strongly positive, positive, neutral, negative, strongly negative) sentiment labels. They also built models to extract the emotion of the Bangla sentence as any one of the six basic emotions (anger, disgust, fear, joy, sadness and surprise). Finely, they evaluated the performance of their model using a new dataset of Bangla, English and Romanized Bangla comments from different types of YouTube videos. Some research has employed machine-learning technique, precisely, the supervised technique to detect emotions in YouTube comments, the work presented in [36] analyzed users expressed emotions, the study conducts a sentiment analysis based on textual comments. The authors evaluated the performance of a Long Short-Term Memory (LSTM) model on two distinct datasets, the IMDB movie reviews dataset and a YouTube video comments dataset available on GitHub, in order to examine the generalization capability and effectiveness of a single model across different but semantically related domains. The proposed LSTM model achieves good testing accuracies on the datasets, demonstrating competitive performance compared to existing sentiment analysis approaches.

The stady performed in [37] investigated the role of psychological and affective features in improving automated cyberbullying detection. It integrated personality traits, derived from the personality models, and emotional categories, based on Ekman's model extracted from textual YouTube comments. The authors evaluated whether incorporating these higher-level behavioral cues could enhance the classification effectiveness of ensemble machine learning models (Random Forest and AdaBoost), demonstrating that the fusion of personality and emotion based features gives rise to superior performance compared to traditional linguistic feature sets. Some other research has employed unsupervised approaches to identify emotional patterns in multilingual datasets, including English and Arabic comments related to social and political conflicts, highlighting the cross-linguistic and contextual complexity of emotional expression online. For example, the study performed in [38] where the main objectives were the automatic annotation of a multilingual corpus with emotional label based on the Ekman emotional model, with the investigation of the psychological impact of crises on individuals, by analyzing the emotional content embedded in YouTube comments associated with war-related videos.

The study focuses on the clustering algorithm K-means, which is an unsupervised model, used for emotion detection from YouTube comments related to the Gaza war, using data in both English and Arabic. It explores the role of Emoji's in enhancing emotional interpretation. Generally, the findings confirm the effectiveness of the clustering techniques in detecting emotional patterns from unstructured and diverse YouTube data. The proposed framework presented a scalable, language-aware solution for unsupervised emotion detection, making it particularly suitable for multilingual and sensitive contexts. Another initiative using the unsupervised techniques is presented in [39] where the authors presented there system architecture divided into two phases : at first they collected a corpus of YouTube comments from various videos, Emotion labeling is not required in this phase. In the second phase, an unsupervised machine learning approach was adopted to group or classify comments according to their emotional tone without relying on predefined emotion labels. The unsupervised machine learning algorithm was based on the work presented in [40], with modifications to improve accuracy, and utilizing YouTube comments as a rich resource for publicly available text.

In another orthogonal context, using the Big Data frameworks like Apache Spark has demonstrated significant improvement. The research performed in [41] addresses the challenge of analyzing massive volumes of audience comments on YouTube videos, where the main goal is to use machine learning algorithms in a distributed environment mainly Apache Spark to automatically analyze the large dataset of viewer comments, determine audience sentiment, and help content creators improve their strategies. The authors introduced an Improved Novel Ensemble Method (INEM), ensemble-based machine learning model that combines multiple classifiers to improve sentiment prediction. Using Spark significantly improved scalability and speed for processing and analyzing big datasets of YouTube comments. Using Twitter data the researchers in [42] address the challenge of automatically detecting emotional states expressed by users in Arabic language tweets, particularly within the context of the COVID-19 pandemic. The authors affirm that beyond simple positive/negative sentiment, fine-grained emotion classification like joy, fear, anger, sadness, disgust, surprise plays a crucial role in understanding human behavior in crises.

The aim of the research is to develop a real-time online tool that handle streaming Arabic tweets and predicts one of six basic emotions, using the Spark Apache tools to collect, pre-process, feature-extract, and apply the trained model in real time to each tweet. In the same context, the system described in [43] highlights the power of the Apache Spark platform in order to perform sentiment analysis on large volumes of data from Twitter. The motivation was that, given the volume and velocity of Twitter data streams, traditional single machine or batch approaches are insufficient. The authors built a pipeline that can scale, process the data effectively, classify tweets by sentiment, and thereby support applications such as public opinion monitoring, marketing analytics, or social behavior analysis. Using the Spark platform, machine-learning algorithms mainly: Naïve Bayes, Logistic Regression, Support Vector Machine, Decision Tree that were applied via the MLlib library, enabled efficient handling of larger tweet volumes and faster processing compared to non-distributed methods. The Table 1 summarizes the selected researches related to our study.

Table 1: Summary of prior research.

Ref.	Research Focus	Data Source	Methodology / Model	Emotion Model	Key Findings
[31]	Relationship between color and emotion in media	YouTube videos	Color spectrum analysis integrating color theory, psychology, and media analysis	Plutchik emotional model (8 emotions)	Colors strongly influence emotional response; visual features contribute to emotional interpretation.
[32]	Emotion-based video classification	YouTube videos	Supervised & unsupervised learning	Ekman emotional model (Six basic emotions)	Models effectively classify videos into six emotional categories, emphasizing the role of emotional context in multimedia understanding.
[33]	Multimodal emotion analysis (text, audio, visual)	YouTube videos	Feature fusion: textual (titles, descriptions, transcripts) + audiovisual	Russell and Mehrabian model	Textual information, especially combined metadata, plays a dominant role in predicting audience emotions from video.
[34]	Emotion classification on Indonesian YouTube comments	YouTube comments	Word embeddings + CNN	Ekman emotional model + Neutral	Word embeddings improve accuracy; CNN performs best for emotion classification.
[35]	Emotion and sentiment detection in Bangla YouTube comments	Bangla, English, Romanized Bangla YouTube comments	Deep-learning models	Sentiment (3-class, 5-class)&Ekman emotions	Created multilingual datasets; models perform well for both sentiment and emotion tasks.
[36]	Cross-domain emotion analysis (YouTube & IMDB)	YouTube comments & IMDB reviews	LSTM (supervised)	Sentiment analysis	LSTM generalizes well across domains; competitive performance on multiple datasets.
[37]	Cyberbullying detection enhanced by emotion & personality traits	YouTube comments	Ensemble ML (Random Forest, AdaBoost)	Ekman + Personality traits	Fusion of personality and emotion features improves detection accuracy beyond linguistic baselines.
[38]	Multilingual unsupervised emotion detection (English & Arabic)	War-related YouTube comments	K-Means clustering (unsupervised)	Ekman emotional Model	Effective at uncovering emotional patterns; emojis enhance interpretation; suited to multilingual contexts.
[39]	Unsupervised emotion detection for automatic datasets annotation	YouTube comments	Unsupervised algorithm based on [40]	Ekman emotional Model	Automatically clusters comments by emotional tone; works without predefined labeled dataset.
[41]	Distributed emotion analysis using Big Data frameworks	Large-scale YouTube comments	Apache Spark + Improved Novel Ensemble Method (INEM)	Sentiment analysis	Spark ensures scalability & speed; ensemble model boosts predictive accuracy on massive datasets.
[42]	Real-time Arabic emotion detection during COVID-19	Twitter data	Apache Spark pipeline	Ekman emotional Model	Real-time detection of six emotions; Spark supports live streaming and online analysis.
[43]	Scalable sentiment analysis on social-media data streams	Twitter data	Spark MLlib (Naïve Bayes, LR, SVM, DT)	Sentiment analysis	Distributed Spark framework enables fast, large-scale sentiment classification.

III. MATERIALS AND METHODS

III.1 DATASET CREATION

The dataset is created by the extraction of comments from two videos using YouTube API version 3.0. We manually select these videos from the CNN and BBC news channels in English language based on their popularity (number of views and number of comments) dated respectively 2025 and 2021. We limit the number of comments for each video up to **4490**, which results a total number of **8980** comments written in English. Table 2 provides a description of our dataset features.

Table 2: Dataset description.

Dataset features	Number of comments
Total number of comments	8980
Comments with Emojis	932
Comments without Emojis	8048

Source: Authors, (2026).

The dataset annotation is based on the Ekman emotional model where six basic emotion, which defines six fundamental emotion categories: happiness, sadness, fear, disgust, anger, and surprise. The annotation process is mainly based on the pipeline described by the work defined in [38] where we used the K-means model which is an unsupervised machine learning technique. Based on the same strategy, we performed a preprocessing pipeline to prepare the data for the labeling process.

III.2 DATASET PREPARATION

The Dataset preparation process begins after the data collection, which results a corpus of unlabeled YouTube comments described in the section above. The resulting Dataset is annotated by the K-means clustering model based on the Ekman's basic emotional model. The figure 3 illustrates the different steps of the dataset annotation process. Data preprocessing enhances text quality and consistency through cleaning and normalization. It ensures cleaner and more consistent textual input for emotion detection. It removes noise (URLs, mentions, symbols), normalizes text (repetitions, hashtags, whitespace, case), and eliminates stop words to improve model accuracy. Numerical values are retained, as they may hold meaningful contextual or emotional significance. After cleaning, text tokenization is performed using BERT tokenizer, which splits text into sub word units and converts them into token IDs for model input. This enables BERT's bidirectional encoding to capture full contextual meaning which is crucial for emotion detection. The high dimensional output from BERT increased computational complexity and noise during clustering. To avoid this issue, Principal Component Analysis (PCA) was applied to reduce dimensionality while preserving key variance and data structure, resulting in a more efficient and effective clustering process.

III.3 CLUSTERING TECHNIQUE

Unsupervised learning techniques provide an effective way for textual data annotation with minimal human intervention, motivating the use of clustering for automatic text annotation. The annotation of the YouTube comments Dataset is assured by using a clustering technique basically K-means, which efficiently handles large datasets and balanced clusters, to assign emotional labels to YouTube comments. This approach produces a labeled dataset that forms the basis for training supervised models for accurate emotion detection. In the next section we will present the selected collection of machine learning techniques where the main objective is using the resulting labeled dataset after the clustering step in the training for preparing the model to the emotion prediction and recognition.

III.4 MACHINE LEARNING TECHNIQUES

In this work, we utilized three classification algorithms in order to implement the emotion detection system. At this level, the selected classifiers are chosen from the machine learning models defined in the MLlib [13] Spark's library. We selected a collection composed of classic models where the objective is to compare their accuracy and decide the best model in the context of emotion

recognition from amount volume of text specifically in the context of YouTube comments analysis. The selected model are basically the Naïve Bayes, Logistic Regression and Random Forest classifier.

III.4.1 Naive Bayes

The Naïve Bayes classifier is a probabilistic multiclass classification algorithm grounded in Bayes' theorem. In this model, each data instance is represented as a feature vector, under the assumption that all features are conditionally independent given the class label. The algorithm is computationally efficient, requiring only a single pass through the training data to estimate parameters. During training, the conditional probability distribution of each feature with respect to each class is computed. Subsequently, Bayes' theorem is applied to determine the most probable class label for unseen instances.

III.4.2 Logistic Regression

The Logistic Regression is a statistical classification model in which the dependent variable can assume one of several discrete values. It employs the logistic function to model the relationship between the input features and the probability of belonging to a specific class. While the model is primarily designed for binary classification, it can be extended to handle multiclass problems using different strategies.

III.4.3 The Random Forest Classifier

The Random Forest algorithm is an ensemble learning technique based on the bagging principle. It addresses the main limitation of a single decision tree by constructing multiple decision trees on randomly selected subsets of the dataset. The final prediction is then obtained by taking the majority vote of the individual trees. The Random Forest Classifier in Apache Spark's MLlib is an ensemble-learning model based on the Random Forest algorithm, where his primary role is tasks classification. It is based on the construction of a multitude of decision trees during training where it returns as result the class with the highest vote among the individual trees. In the next section, we will present the different obtained results with a discussion of the most relevant among them.

III.5 EVALUATION METRICS

The performance of the used machine learning algorithms is measured using a set of evaluation metrics, in the first range the accuracy is used; it is the most widely used. For many years, accuracy served as the basic criterion for comparing machine learning models effectiveness. However, it is not sufficient alone to make an accurate decision of the model performance. Accordingly, we used the Precision, the Recall and the F-score for more precise performance measurement of the used models. Accuracy measures the overall correctness of predictions, while Precision and Recall evaluate the model's ability to correctly identify relevant classes. The F1-score provides a harmonic mean between Precision and Recall, providing a more robust performance indicator in imbalanced datasets. It ranges from zero to one where a higher F1-score indicates better model performance.

IV. RESULTS AND DISCUSSIONS

In this section, we present and analyze the experimental results obtained, along with an evaluation of the effectiveness of the tree used algorithms (Logistic Regression, Naïve Bayes, and Random Forest) from the MLlib Spark's library applied to the resulting labeled dataset. In addition, we discusses the performance of the proposed models based on various evaluation metrics. The goal is to evaluate the effectiveness and overview capability of each algorithm on the selected dataset by analyzing and comparing the obtained results. To evaluate model performance, we used standard metrics notably: Accuracy, Precision, Recall, and F1-score. Table 3 presents the performance of the three used classification models based on the four standard evaluation metrics presented above. As illustrated, the Logistic Regression and Naïve Bayes models achieved the highest accuracy values, demonstrating superior performance to Random Forest Classifier by a considerable margin.

Table 3: Performance results for the three algorithms.

Models	Accuracy	Precision	Recall	F1-Score
Logistic Regression	0.9289805269186713	0.9293267627553385	0.9289805269186712	0.9282860057563744
Naïve Bayes	0.8178694158075601	0.8370928837933002	0.8178694158075601	0.8217422717081797
Random Forest Classifier	0.5664375715922108	0.49976124982922965	0.5664375715922108	0.41087645030132036

Source: Authors, (2026).

For instance, the Logistic Regression obtained an accuracy of 92.3%, with a precision of 91.8% and an F1-score of 92.0%, indicating consistent performance across classes. Overall, Logistic Regression achieved the best performance across all metrics, with an accuracy of approximately 0.93 and an F1-score of 0.93, indicating consistent and reliable classification results. Naïve Bayes followed, obtaining an accuracy of 0.82 and an F1-score of 0.82, which suggests satisfactory performance but slightly lower precision and recall compared to Logistic Regression. In contrast, the Random Forest Classifier recorded the lowest performance, with an accuracy of 0.57 and an F1-score of 0.41. This poor performance may be due to overfitting, suboptimal parameter tuning, or an insufficient number of estimators, which limited its generalization ability on the dataset. In summary, the comparative results indicate that Logistic Regression provides the most effective balance between accuracy, precision, and recall for this emotion detection task, outperforming both Naïve Bayes and Random Forest. The Figure 4 illustrates the visualization via a bar chart comparing the performance metrics of the three models. We can clearly notice that Logistic Regression outperforms the other models across all metrics (Accuracy, Precision, Recall, and F1-Score), while the Random Forest Classifier shows the weakest performance overall.

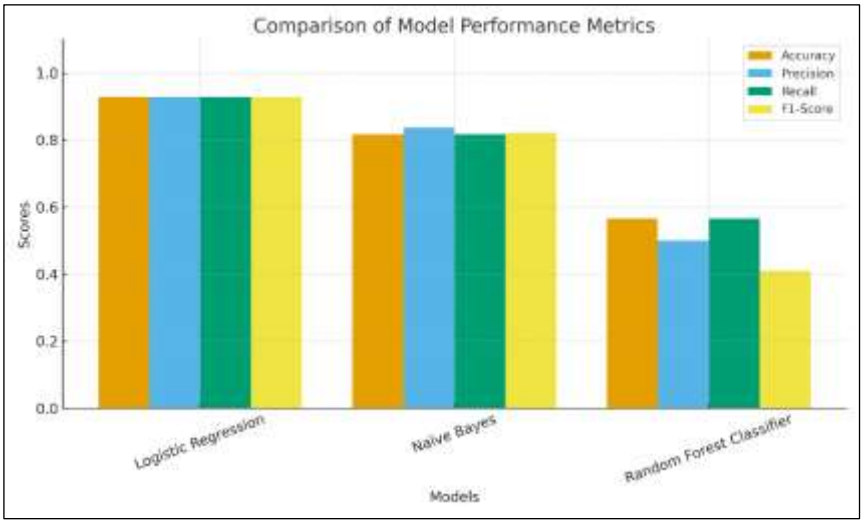

Figure 4: Performance comparison of the three models.

V. CONCLUSIONS

In this study, we presented our framework designed for the emotion detection from YouTube comments, leveraging the machine learning capabilities of the Spark's Apache MLlib library. We proposed a scalable emotion detection framework for analyzing YouTube comments using Apache Spark large-scale abilities. The integration of Machine Learning algorithms with Natural Language Processing techniques enabled efficient processing and classification of emotions across large dataset. By employing K-Means clustering for automatic corpus annotation and supervised classifiers trained on the labeled dataset, the system demonstrated improved accuracy and scalability compared to traditional approaches. The experimental evaluation demonstrated that the framework could efficiently process large volumes of data while maintaining high performance, where the Logistic Regression surpassed 92% in both metrics, accuracy and F1-Score, making it a promising solution for real-world social media analytics. Moreover, the study underlines the importance of scalable architectures in Big Data driven emotion analysis. Future research will focus on the integration of deep learning architectures and multimodal data (text, audio, and video) to improve the precision and expressiveness of emotion detection systems in complex online environments. In the same context, the work can be adopted for steaming data using the Spark Steaming library for Emotion detection tasks in large steaming social data.

ABSTRACT

In order to transform e-commerce customization, the study presents a product recommendation system that makes use of OpenAI's GPT model's better resources in conjunction with neural integration. Traditional systems often rely on collaborative filtering or content-based models. This may lack precision and adaptability to individual needs. The proposed method overcomes these limitations by integrating hierarchical classification. Hybrid similarity scoring and GPT-based annotation capabilities provide more precise and interpretable rules. The multi-step technique ensures that the machine leads to different types of statistics which includes textual product descriptions and generated metadata to gain meaningful insights. This is because pre-processing techniques determine the specific format of numbers and facts,while embeddings built from neural models provide rich semantic knowledge about relationships between products. The weighted scoring mechanism dynamically adjusts to the choices made by individuals. This increases the machine's capability to generalize to the needs of a man or woman. In addition, GPT-inspired factors promote consideration and transparency in explaining the underlying reasons in natural language. The results of the experiment validated the device's ability to offer advanced customization and user satisfaction. By combining domain-specific data with existing IA strategies, this structure sets a new benchmark for precision-driven, people-centric ecommerce applications.

I. INTRODUCTION

ProductGPT is a revolutionary concept that harnesses the power of artificial intelligence to transform the product comparison and recommendation landscape. At the heart of ProductGPT lies the integration of ChatGPT, a cutting-edge language model that enables the generation of human-like explanations and bridges the gap between mathematical metrics and natural language. This synergy empowers ProductGPT to provide users with personalized, transparent, and explainable product recommendations, thereby redefining the user experience. ChatGPT plays a pivotal role in ProductGPT by generating intuitive explanations that elucidate the reasoning behind product recommendations. By decoding complex mathematical metrics, such as cosine similarity and Euclidean distance, ChatGPT translates technical jargon into accessible language, enabling users to make informed decisions. Furthermore, ChatGPT enhances personalization by incorporating user preferences and feedback, ensuring that product recommendations are tailored to individual needs. The fusion of ChatGPT and mathematical metrics in ProductGPT gives rise to a robust and user-centric system. By bridging the gap between mathematics and natural language, ProductGPT provides a unique and innovative approach to product comparison and recommendation. As we delve into the specifics of ChatGPT's role in ProductGPT, we will explore how this integration revolutionizes the product recommendation landscape, enabling users to navigate complex product landscapes with ease and confidence.

I.1 CHATGPT'S ROLE IN GENERATING EXPLANATIONS

ChatGPT plays a key role in making the recommendation system not only functional, but also useful and it can also be interpreted [1]. It provides personalized explanations for product recommendations. The system processes complex mathematical calculations, such as similarity scores obtained by combining products. Classification, price, and category, but these are abstract and not intuitive for users. With ChatGPT integration, these calculation results are translated into user-friendly narratives [2]. For example, the get_explanation function asks ChatGPT for the following basic inputs: Product name. Product resources (such as prices, discounts, ratings) and user profile settings. This information is used to manage personalized descriptions, such as "This product was recommended because of a deep discount. Corresponds to the price range you want and is in the desired category." Such narratives ensure users understand how their preferences $U_p = \{C, R, P, D\}$ where C is category, R is rating, P is price, and D is discount — are matched with product features$P_f = \{C', R', P', D'\}$. By bridging computational reasoning with natural language, ChatGPT enhances transparency, trust, and user satisfaction [3].

I.2 DECODING MATHEMATICAL METRICS WITH CHATGPT

The recommendation system relies on mathematical metrics such as cosine similarity. Euclidean distance and mixed integration to calculate the similarity between user preferences and product resources [4]. For example, hybrid coalescence similarity is calculated as follows:

$$S_{hybrid} = \frac{1}{1+||E_1 - E_2||} . S_p \tag{1}$$

Where E_1 and E_2 are product embeddings, $||E_1 - E_2||$ are their Euclidean distance, and S_p is the price similarity score, because this mathematical method guarantees accuracy. As a result, it lacks interpretability for non-technical users. ChatGPT acts as an interpreter, translating these scores into understandable language. For example, ChatGPT can trigger a description such as "This product is highly recommended, because they are very similar to the selected category. Offer attractive prices and have great reviews from other customers." This change allows users to make informed decisions while appreciating the complex calculations behind them.

I.3 ENHANCING PERSONALIZATION AND USER EXPERIENCE

ChatGPT customizes the recommendation process by describing or aligning two product resources with user-defined needs [5]. Assume a user profile U_p specify preferences for products with minimum rating of R_u, maximum price of P_u, and target discount of D_u. The recommendation system evaluates the weighted similarity score:

$$S_{total} = w_c \cdot S_c + w_p \cdot S_p + w_r \cdot S_r + w_e \cdot S_e \tag{2}$$

Where $w_c, w_p, w_r, and\ w_e$ are weights of the category, price, rating and embedding. ChatGPT sets the context for this score by presenting a story such as: "This product meets user needs with ratings up to 4.5, huge discounts of 30%, and prices within a certain range." By aligning numerical results with human language, ChatGPT helps ensure users feel that recommendations are tailored [6]. To meet their specific needs, this greatly increases engagement and satisfaction. Additionally, the ability to explain instructions in detail increases confidence in the system's decisions.

I.4 BRIDGING MATHEMATICS AND NATURAL LANGUAGE WITH CHATGPT

Integrating ChatGPT into the recommendation system bridges the gap between mathematical rigor and user accessibility. [7] For example, similarity between product embeds is calculated using cosine similarity:

$$Cosine\ Similarity = \frac{\vec{A}.\vec{B}}{||\vec{A}||.||\vec{B}||} \tag{3}$$

Where, $\vec{A}, \vec{B}$ represents product feature vectors. Additionally, numerical features such as price and classificationare normalized and compared using techniques such as Euclidean distance[8]. These calculations create quantitative insights. Because its technical nature can alienate users, ChatGPT translates these insights into relevant stories, such as "This product aligns closely with your needs due to its excellent reviews, competitive price and relevance to the chosen category." This combination of computational precision and linguistic clarity is an example of a strong, user-centred IA system [9]. Users are guaranteed to benefit from the complex algorithms without being overwhelmed by complexity.

II. LITERATURE SURVEY

[10] has proposed a hybrid NLP methodology for fine-tuning of LLM to identify the accurate culture products. Especial the data was chosen in symbolic semantic info which displays as cultural symbols; these are created in three phases: physical, ethereal, and behavioural. For clear understanding culture images for GPT 3.5 approach an additional data was gathered from Palace Museum. Uncoded symbols are designed for couple of idea makings design thoughts and other was decoded with full design.

To clarify these design principles a high level common language is utilized. For these designs a cultural meaning was designed with high clarifiers. By processing the model all symbols are included to the training and while extraction the outcome was changed to

meaningful cultures. This data-driven approach seeks to link historical cultural knowledge with modern product design. [11] couple of approaches are designed for extracting creation phases and optimization of product ads with LLM and Multi-model info. The data includes write up and visual info such as images and metrics, which creates search engines as user friendly. Initial stage of processing data to model and pre-process the data with suitable image was reflected from the collected data. Then, LLMs are improved so that they can understand this data better and give detailed statements that take into account the user needs and industry trends. This model is mainly utilized with GPT-3.5 and 4. This approach also utilizes NLP for the extraction of meaningful words for detailing, SEO was improved. As the description was generated the appropriate match was generated an image with related to product and it makes user friendly.

[12] suggested method is based on automatically summarising studies that look at how food affects people from NDA review papers. It uses LLM including GPT-4 to make short outlines that are based on facts through a repeated asking approach. There are three steps to this process. First, the model makes a first report of a food effect report at an advanced level. In the second step, keyword-focused prompts make sure that important pharmacokinetic measures like AUC, Cmax, and Tmax are considered. Lastly, a question that limits the length of the answer makes sure that the summary is short, usually no more than two or three lines. The human reader and LLM work together over and over to make the results better and better, both in terms of truth and readability. To compare the success of GPT-4 and ChatGPT, evaluations use both automatic measures ROUGE and evaluations by FDA professionals. To reduce manual PSG development for generic medicine evaluation, FDA personnel will examine credible, draft-quality summaries.

[13] have introduced an established method to get trait values from e-commerce product descriptions that aren't organised using LLMs. The goal is to raise the AVE of the output by using the zero-shot and few-shot features of LLMs, especially when there isn't a lot of marked training data available. They show different prompt forms for teaching LLMs how to do AVE jobs. These include written and JSON-based versions of the goal model. We are using the GPT-3.5, GPT-4, and Llama-3 models in the tests to see how well these reminder templates work in both zero-shot and few-shot situations. The way looks at how well LLMs can pull trait values without a lot of task-specific training and compares them to cutting-edge PLMs like BERT. The F1-score is one of several evaluation measures used to check how well the models can correctly extract attribute values, even for attributes that haven't been seen yet. Additionally, the way looks into what happens when you add example values, do in-context learning demos, and fine-tune the models.

[14] integrates LLM with graph-based data to improve proposal systems. The system aims to make it easier to predict how a person and an item will connect by mixing the text-generating abilities of LLMs with the relationship modelling abilities of GNNs that use a graph structure. The main strategy is creating an attentive LLM backbone with a graph structure that records both first- and second-order relationships between people and objects. This way uses GNNs to get edge data within nodes, like people and things, and add this connection information to the LLM's attention system. To help the model understand the many linkages inside the recommendation system, pre-training is carried out utilising crowd-contextual stimuli, such as user and item descriptions and interactions. The model is then fine-tuned using personalised predictive hints to make it even better at making accurate, personalised suggestions. By combining graph data and written data, the method gives a fuller picture of user tastes and item characteristics, which lets it make more accurate suggestions.

[15] a novel use of an LLM ensemble technique for e-commerce product attribute value retrieval. The writers suggest an ensemble framework to take advantage of the fact that different LLMs, like GPT, PaLM, and Llama, have different strengths and weaknesses when it comes to different jobs. Using crowd sourcing methods as inspiration, the ensemble approach gives weights to the results of several LLMs based on how well they guess the values of product attributes. The method improves and speeds up the process of assigning weights by using the Dawid-Skene Approach, which is often used with crowd-labeled data. The ensemble method takes the results from all the models and gives more weight to the LLMs that do a better job while reducing the weight of the models that do a worse job. By utilizing unorganized text the product has achieve high accuracy and retrieved reliable data related to products. Walmart's internal datasets showed enhanced "age" and "gender" extraction using the approach.

[16] one new way to use LLM to improve e-commerce results. Before, search engines used organised data, which meant that they could index and retrieve data from sources that were not structured, like customer reviews. To change this, the study suggests turning structured and semi-structured data, like product catalogues and categories, into written explanations that can be used with LLM training. To train or fine-tune LLMs, the system uses texts with encoded product IDs that have been marked up. This lets them act as a single input for search and selection jobs. With this combination, the model can use domain-specific knowledge and give solutions that are relevant to the situation. According to the design, the framework will combine databases with LLM features, which will allow for the instant recovery of changing data like prices and stock levels. Creating unique IDs for database items, using templates to make labelled texts, and using self-supervised learning to finetune the model are all parts of the approach.

[17] improves product recommendation systems using K-means clustering, CBF, and hierarchical clustering and GPT-4. These algorithms learn patterns and provide personalised suggestions on product datasets, which GPT-4 evaluates. Beyond assessment, GPT-4 uses natural language comprehension to improve product feature semantics and recommendation accuracy. To simplify implementation, e-commerce operators may use CSV files for training and distributing suggestions using a flask-based API. This API emphasises non-technical usability with model training & real-time predictions. GPT-4 automates review using binary ratings and reasoning, boosting cost and scalability over human evaluation. E-commerce companies may customise models for their datasets while preserving efficiency and relevance using the adaptable technique. Our framework improves unsupervised learning and LLM integration for scalable, accurate, & easy to use product system recommendations.

Table 1: Analysis on Existing Systems.

Author	Algorithm	Merits	Demerits
Yang Yin et al	GPT-3.5, PLM	Fine-tuning the model for automatic retrievals	Utilized dataset contains less content
Satish Kathiriya et al	LLM	Accuracy and discovery of items are enhances for user experiences	Computation performance was not up to the mark for real-time apps
Yiwen Shi et al	Iterative prompting with GPT4 & ChatGPT	It improves the understanding of drugs name by iterating the text	Token size was limited
Alexander Brinkmann et al	LLM	Holds more training data with efficiency and robustness	Comparison performance does not have huge differences
Xinyuan Wang et al	Integrate LLM	By combining two orders the prediction was efficient	Need more memory for storing paths
Chenhao Fang et al	LLM-Ensemble	Values for attributes are extracted efficiently were it works accurately even offline	Little time-consuming while extracting dynamical learning weights
Haixun Wang et al	LLM	Conversion of structure to unstructured data was efficient	Cost-Efficient
Konstantinos I. Roumeliotis et al	CBF, Cutting-edge gpt4LLM, K-means Cluster, Hierarchical Clustering	Compared to all approaches CBF has achieved high accuracy	Overfitting

III. PROPOSED METHODOLOGY

The product recommendation system constructed the usage of GPT showcases several modern functions that distinguish it from traditional structures. The integration of OpenAI's GPT for producing motives brings a brand new level of personalization and transparency to suggestions, enabling users to recognize why precise merchandise has been suggested. Unlike traditional collaborative filtering or content-based models, this machine introduces a hybrid similarity metric that blends class-based totally matching, charge-discount alignment, and neural embeddings for textual product descriptions. The use of embeddings permits the device to understand nuanced relationships between merchandise, even when they lack common functions. Furthermore, the gadget consists of hierarchical category extraction (e.g., high-degree, secondary-level categories) for refined filtering. Another novelty lies inside the weighted similarity scoring mechanism, which may be dynamically adjusted to in shape user choices or domain-precise desires. By incorporating diverse similarity metrics, the model ensures extra precise and diverse recommendations. The interpretability of the improved version through GPT bridges the distance between machine-generated decisions and human interpretability. This makes it a modern machine for contemporary e-commerce systems.

III.1 NOVELTY

The proposed model represents a significant improvement over the old approaches. Although older versions may rely on traditional similarity measures such as cosine similarity to raw numerical features or category matching. But the new model suggests a hybrid approach that combines neural input for textual data. This lets in for a deeper understanding of product descriptions and relationships. Additionally, the hierarchical separation of lessons inside the new model allows for multi-level filtering. This becomes no longer present in the antique device. GPT integration is every other top notch thing for interpretation. This makes guidelines more obvious and intuitive. Additionally, a brand new weighted similarity metric offers flexibility to spotlight sure functions primarily based on user preferences, Whilst the old model Static or much less precise calculations may be used. The machine also includes extra similarity signs inclusive of price discounts and scores. The similarities make the new device more accurate, versatile and compliant with present day e-commerce requirements, together with solving the restrictions of the old gadget greater effectively.

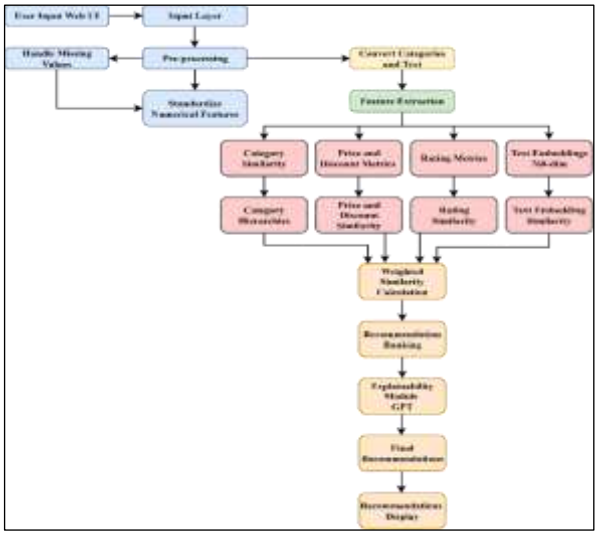

Figure 1: Block Diagram for Proposed Recommendation System.
Source: Authors, (2026).

III.2 DATA PRE-PROCESSING

Pre-processing helps ensure that datasets are clean, consistent, and ready for advanced analysis [18]. Missing values in numeric columns are handled by defining the median value:

$$x_{filled} \equiv \begin{cases} xifx \neq NaN \\ median(x)ifx = NaN \end{cases} \quad (4)$$

Categorical columns are imputed with the mode:

$$c_{filled} \equiv \begin{cases} cifc \neq NaN \\ mode(c)ifc = NaN \end{cases} \quad (5)$$

To standardize numerical data for cosine similarity, we apply:

Where z is the value after standardization, x is the actual value, μ is the mean, and σ is the standard deviation. For textual fields, embeddings (E) are generated using neural models:

$$E = f_{embedding}(T) \quad (6)$$

Where $f_{embedding}$ is a neural network-based function (e.g., BERT or GPT embeddings), and T is the product description [19].These embeddings allow the model to efficiently encode the semantic relationships between products. When combined with hierarchical class separation, these steps ensure data consistency and provide a robust model for the input format. It helps make predictions more accurate and to improve user experience.

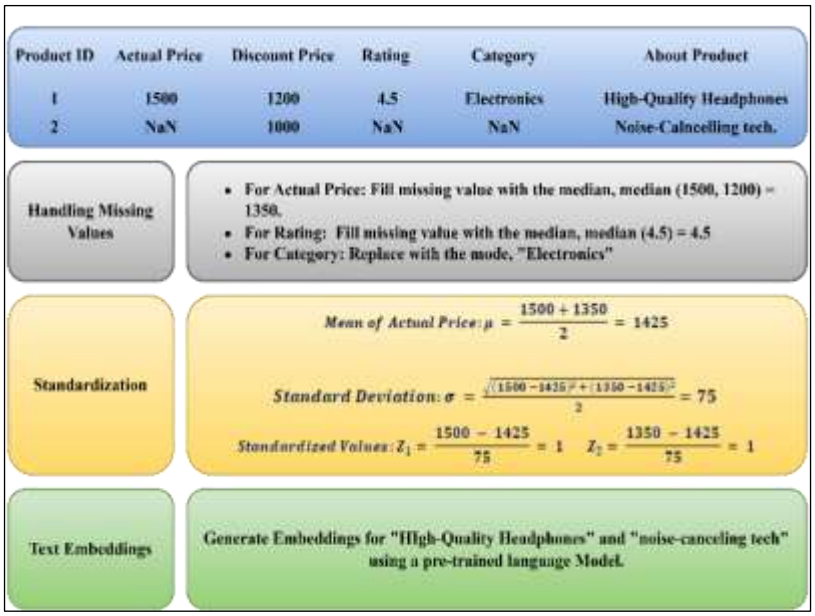

Figure 2: Pre-processing of Elements.
Source: Authors, (2026).

III.3 FEATURE EXTRACTION AND HIERARCHICAL CATEGORY MANAGEMENT

In the approach, the next step after preparing the data is to extract the categories, focusing on hierarchical categories [20]. The system divides the category space into high-level categories, secondary level and tertiary-level categories in function separator *get_high_level_category(category)* using the delimeter'|'. The first section is selected as the high level category. Mathematically, if the category string is as specified c so higher level classes are:

$$high_(level_categroy(c)\ ) = split(c," \mid ")[0] \quad (7)$$

For the secondary and tertiary levels, similar logic applies:

$$secondary_level_category(c) = split(c," \mid ")[1](if\ exists) \quad (8a)$$

$$tertiary_level_category(c) = split(c," \mid ")[2](if\ exists) \quad (8b)$$

These extracted items are then added to the dataset as new categories. This allows the model to consider product distribution at different levels. This structure is useful for more granular filtering and recommendations [21]. Because items in higher groups are grouped and sorted more efficiently, a hierarchical structure allows the model to identify patterns in the data based on different levels of variance. Further improve the quality of recommendations by including deeper relationships between constructs.

Table 2: Hypothetical Input Data.

Product ID	Category
101	Electronics | Smartphones | Accessories
102	Home | Furniture | Living Room
103	Electronics | Laptops

Source: Authors, (2026).

Extraction Logic

$$high_level_categroy(c) = split(c,|)[0]$$

$$secondary_level_category(c) = split(c," \mid ")[1](if\ exists)$$

$$tertiary_level_category(c) = split(c," \mid ")[2](if\ exists)$$

Extracted Categories

III.5 STANDARDIZATION OF NUMERICAL FEATURES

Standardization of numerical features is an important step to make the variables comparable by converting them to a common scale. The numerical features in the dataset, such as *actual_price*, *discounted_price*, *discount_percentage*, *rating*, and *rating_count*, are standardized using the formula for Z-score normalization:

$$z = \frac{x-\mu}{\sigma} \tag{9}$$

Where x is the original value, μ is the mean, and σ is the standard deviation of the feature. The purpose of this adjustment is to ensure that all numeric are standardized, so that the similarity measure is not affected by large differences between features and able to work effectively. This standard is important for similarity - the base models participate equally in the calculations. After setting the standard the dataset is more suitable for similarity-based analysis. This leads to more accurate recommendations. Normalization reduces bias caused by disproportionately large or small values in a data set. This will improve the generalizability of the model.

III.6 TEXT EMBEDDING GENERATION

Another important feature in this example is the text entry for the field *about_product*. Embeddings are mathematical representations of meaningful data results. The function *get_product_embedding (product_description)* tracks the process of creating an embedding. If T stands for product specification, Embedding E is obtained from a pre-trained model, e.g. BERT or GPT embedding generation formula can be specified as follows:

$$E(T) = f_{embedding}(T)$$

Where $f_{embedding}$ is a neural network-based function (e.g., BERT or GPT embeddings), and T is the product description. These embeddings permit the machine to compare the semantic similarity of different merchandise; the closer pals are in vector space. The extra semantically similar the products can be, the greater similar they will be. This approach allows the gadget to advise products that don't monitor genuine characteristics however are comparable inside the text description. This makes the model greater flexible and might locate hidden relationships among products. In addition to information, it is able to additionally make use of rich semantic context.

Table 6: Hypothetical Input Data.

Product ID	About Product
101	"High-quality smartphone accessories."
102	"Comfortable and modern living room furniture."
103	"Latest laptops with powerful specifications."

Source: Authors, (2026).

Using a pre-trained embedding model (OpenAI), generate embeddings.

Table 7: Embedding.

Product ID	Embedding (E)
101	[0.45, 0.60, 0.32, 0.11]
102	[0.12, 0.35, 0.55, 0.40]
103	[0.80, 0.70, 0.40, 0.25]

Source: Authors, (2026).

III.7 HYBRID SIMILARITY COMPUTATION

The subsequent step includes calculating the similarity between products based on multiple capabilities: class, fee, cut price, score, and embeddings. The similarity among two products is computed the usage of an aggregate of numerous metrics. For class similarity, the formula is straightforward: if each merchandise belongs to the same high-degree category, the similarity is 1, in any other case 0:

$$category_similarity(p1,p2) = \begin{cases} 1 \ if \ high_{level_{category(p1)}} = high_level_category(p2) \\ 0 \ otherwise \end{cases} \quad (10)$$

For price and discount similarity, the difference in prices and discount percentages is normalized to create a similarity score:

$$price_{discount_{similarity(p_1,p_1)}} = \frac{1}{1+|price(p_1)-price(p_2)|+|\alpha-\beta|} \quad (11)$$

Where α is $discount_percent(p_1)$ and β is $discount_percent(p_2)$. For rating similarity, a similar approach is used:

$$rating_similarity(p_1,p_2) = \frac{1}{1+|rating(p_1])-rating(p_2)|} \quad (12)$$

For embedding similarity, the Euclidean distance between the embeddings of two products is used:

$$embedding_similarity(p_1,p_2) = \frac{1}{1+||E(p_1)-E(p_2)||} \quad (13)$$

Finally, these individual similarities are combined using weighted summation to generate a final similarity score:

$$total_{similarity(p_1,p_2)} = w_1.category_{similarity(p_1,p_2)} + w_2.price_{discount_{similarity(p_1,p_2)}} + w_3.rating_similarity(p_1,p_2) + w_4.embedding_similarity(p_1,p_2) \quad (14)$$

Where, w_1, w_2, w_3, w_4 are the weights assigned to each feature's similarity. The model then uses this final similarity score to rank the products and recommend those most aligned with the user's preferences.

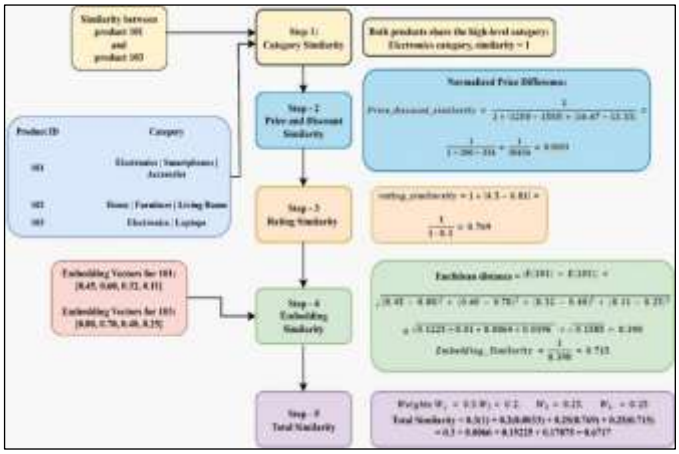

Figure 3: Similarity Computations.
Source: Authors, (2026).

III.8 FINAL RECOMMENDATION AND EXPLAINABILITY

After calculating the similarity ratings, the goods are ranked in descending order of similarity. The top tips are selected for display to the user. The machine also carries GPT-based totally explainability. For every encouraged product, the machine generates a textual explanation as to why the product turned into recommended, the use of the formula:

$$explanation = g_{GPT}(product_{features}, user_{profile}) \quad (15)$$

Where g_{GPT} is OpenAI GPT model that generates explanation primarily based at the product capabilities and the consumer profile. This enhances the transparency and trustworthiness of the recommendation device. Finally, the gadget returns the pinnacle N hints, whole with their factors, pictures, and hyperlinks for further exploration. The hybrid similarity model combined with explainability affords a comprehensive advice framework that caters to the consumer's choices and enhances the buying revel in. By presenting explanations for every advice, the model fosters extra person believe and engagement, for that reason enhancing the general consumer relevant.

IV. RESULTS AND DISCUSSIONS

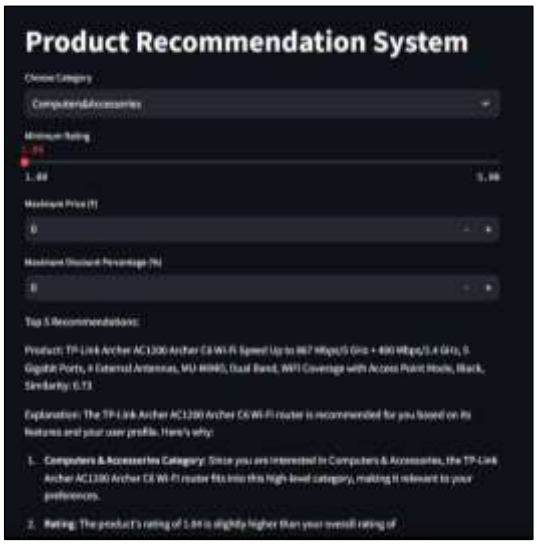

Figure 5: User Interface of the Application.
Source: Authors, (2026).

The Figure 5 shows the main user interface of the product recommendation application created using Streamlit. The interface is designed to be intuitive and easy to use. It has a header that clearly states the purpose of the application. Users will see several interactive elements such as drop-down menus, sliders, and number entry fields. These components allow users to specify their preferences, such as selecting categories, minimum score required, maximum price and maximum discount percentage. The clean layout ensures that users can easily navigate the interface without any confusion. Interactive widgets provide real-time feedback. It makes the user experience smooth and attractive. The modular interface design reflects careful consideration in structuring user input. This screenshot shows the application's main function of storing user preferences in an orderly manner. It emphasizes the simplicity and accessibility of the design. To support both novice and experienced users, clear division of elements ensures that each input field is easily identified to prevent ambiguity during interactions.

The Figure 6 offers an outline of the product classes available in the dataset. The classes are displayed in a dropdown menu, allowing customers to select the excessive-degree class that suits their preferences. These categories are derived from the ‘class’ column in the dataset and include numerous product kinds. The dropdown capability enables dynamic filtering of hints based totally at the person’s preference. Users can fast navigate thru the listing and make selections that replicate their shopping pursuits. The inclusion of categories allows slender down the search space, making hints greater focused and relevant. This feature not handiest enhances user delight but additionally improves the efficiency of the advice engine. The design guarantees that even a huge variety of categories are presented in a prepared and reachable way. By permitting category-specific filtering, the utility guarantees that users acquire consequences aligned with their number one hobbies. This screenshot highlights how the software leverages established statistics to improve personalization and person experience.

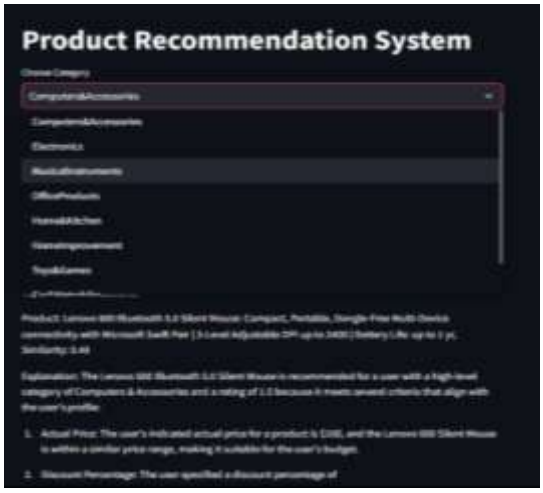

Figure 6: Categories Available.
Source: Authors, (2026).

In Figure 7, the input fields are highlighted, showing how users can customize their search for recommendations. These inputs include sliders for specifying the minimum acceptable product rating and number fields for defining the maximum price and discount percentage. By combining these inputs with the category selection, the application gathers detailed user preferences to create a comprehensive user profile. This profile serves as the foundation for calculating similarity scores and filtering products. The flexibility of the input options ensures that users can fine-tune their preferences to match specific needs.

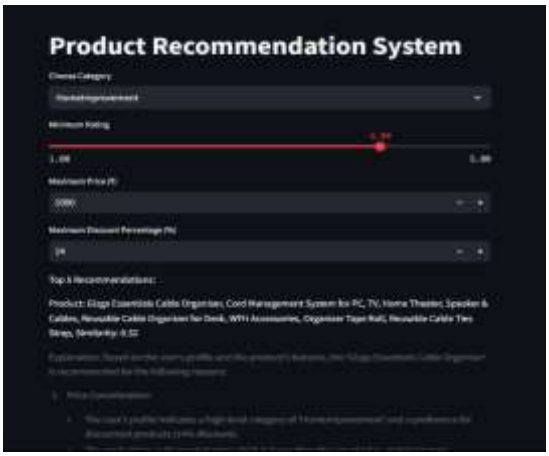

Figure 7: Input features given to the Application.
Source: Authors, (2026).

For instance, the sliders provide granular control over rating thresholds, while the number inputs allow precise budget constraints. This level of customization makes the application versatile and accommodating to a wide range of use cases. The intuitive placement of input fields ensures that users can quickly configure their preferences without requiring additional guidance. Overall, this screenshot illustrates the application's commitment to delivering a tailored user experience by empowering users to define their own criteria for recommendations.

Figure 8: Top 5 recommendations generated.
Source: Authors, (2026).

The Figure 8 showcases the consequences of the advice set of rules, showing the top 5 recommended products. Each product is indexed with its call and similarity score, indicating how well it fits the user's preferences. The guidelines are looked after in descending order of similarity, making sure that the most applicable alternatives seem on the top. This view underscores the effectiveness of the similarity metrics used inside the utility, along with category similarity, fee-bargain alignment, and score alignment. The concise presentation of effects makes it smooth for customers to assess their alternatives at a glance. Additionally, the inclusion of similarity rankings provides transparency into the recommendation procedure, constructing accept as true with the customers. The visible readability of the guidelines web page ensures that customers can fast become aware of their desired picks and proceed to explore further info. This screenshot reflects the utility's capacity to synthesize consumer inputs into actionable outputs, highlighting the performance and precision of the underlying set of rules.

Figure 9: Product Details, Similarity Percentage, Explanation, Product Image and Product Link for the recommended product.
Source: Authors, (2026).

The Figure 9 provides a detailed view of a recommended product. It consists of critical records which include the product's name, similarity percentage, and a brief clarification of why it turned into encouraged. Additionally, the product's picture and a clickable link to the product page are displayed. The explanation is generated the use of OpenAI's GPT model, adding a layer of transparency to the recommendation system through describing how the product suits the consumer's choices. The inclusion of visuals and direct links enhances consumer engagement, bearing in mind seamless exploration and buying selections. The similarity percentage gives insight into how intently the product aligns with the person's inputs, while the reason gives context for the recommendation. This mixture of functions ensures that users have all the important information to make knowledgeable selections. The utility's potential to provide complete statistics in a visually attractive manner enhances its usability and effectiveness. This screenshot encapsulates the utility's attention on handing over fee through targeted and customized recommendations.

Figure 10: Forwarded to the product page when clicked on provided Link.
Source: Authors, (2026).

The Figure 10 demonstrates the functionality of the clickable product links, displaying how customers are redirected to the respective product pages. Once a person clicks on a product link, they're taken to the e-commerce platform wherein they are able to view extra details, study critiques, and complete their purchase. This function bridges the space between pointers and motion, permitting users to act on their options with minimal attempt. The easy redirection procedure highlights the practical software of the utility, streamlining the online buying enjoy whilst making sure person satisfaction. The integration of clickable links guarantees that customers can transition seamlessly from exploring hints to making purchasing selections. This screenshot also emphasizes the utility's function as a facilitator in the e-commerce adventure, simplifying the technique of coming across and obtaining favoured merchandise. By supplying a direct course to the product page, the utility eliminates needless steps, enhancing the overall efficiency and comfort of the consumer enjoy.

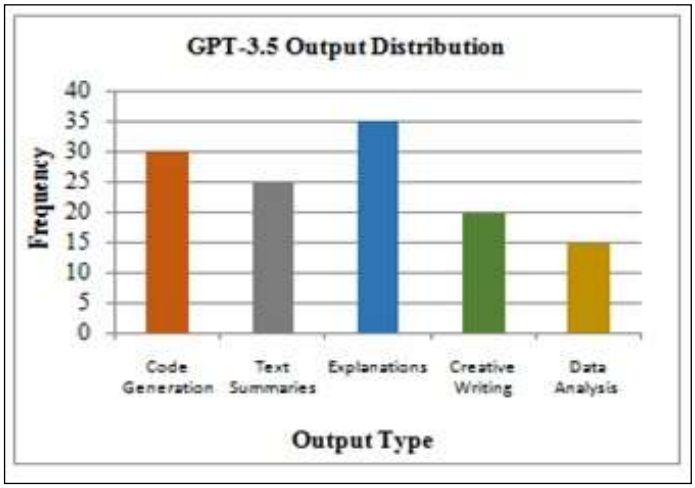

Figure 11: GPT-3.5 Output Distribution.
Source: Authors, (2026).

The above Figure 11 presents a breakdown of the different types of content generated by GPT-3.5, highlighting its versatility in various applications. Among the five categories: Code Generation, Text Summaries, Explanations, Creative Writing, and Data Analysis, the highest frequency is observed in Explanations, suggesting that GPT-3.5 is extensively used to clarify complex topics, making it a valuable tool for education, research, and professional learning. Code Generation follows closely, indicating the model's effectiveness in assisting programmers by producing functional and efficient code snippets. Text Summaries also constitute a significant portion of GPT-3.5's output, showing its ability to condense large volumes of information into concise, readable formats, particularly useful for summarizing reports, academic papers, or news articles. While GPT-3.5 can generate imaginative content and perform data-driven tasks, Creative Writing and Data Analysis are relatively less frequent, indicating that these areas are not its primary strengths or most common use cases. Overall, the distribution reflects GPT-3.5's capability to adapt to multiple domains, with a strong emphasis on technical and educational applications.

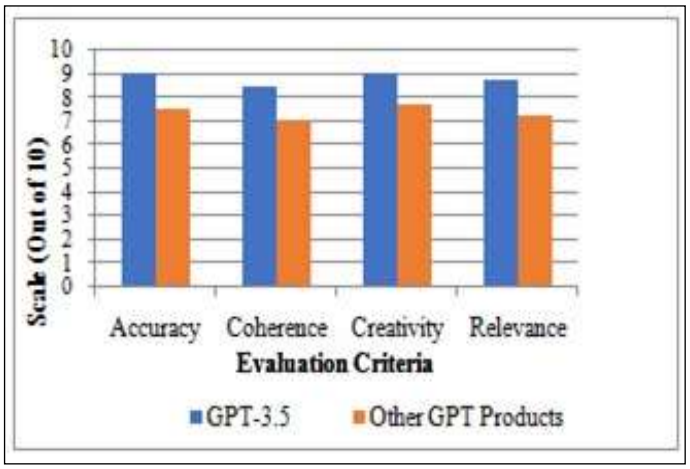

Figure 12: Comparision of GPT-3.5 Performance.
Source: Authors, (2026).

The above Figure 12 compares GPT-3.5's performance against other GPT models, based on four evaluation criteria: Accuracy, Coherence, Creativity, and Relevance. GPT-3.5 consistently outperforms other models across all criteria, demonstrating its superiority in generating high-quality responses. It scores significantly higher in Accuracy, reflecting its ability to provide factually correct and reliable information. GPT-3.5 also excels in Coherence, ensuring logically structured and contextually appropriate responses, and scores well in Creativity, producing original and engaging content. Furthermore, it shows a strong advantage in Relevance, providing responses aligned with user intent and offering meaningful insights. Overall, the graph highlights GPT-3.5's superior linguistic and analytical capabilities, making it a preferred choice for applications requiring precision, clarity, and contextual understanding, and demonstrating how improved AI models can significantly enhance the quality of generated content across multiple domains.

V. CONCLUSIONS

The proposed recommendation system effectively integrates modern AI techniques. To meet the challenges of traditional e-commerce platforms by leveraging the interpretive power of OpenAI's GPT model and the structural insights of hierarchical class separations, the machine thus achieves an excellent balance between precision and scalability. The hybrid similarity scoring mechanism enhances the version's ability to distinguish different relationships between products while neural integration provides a richness of meaning that is lacking in conventional similarity measures. The dynamic weighting of similarity measures guarantees flexibility and scalability.

Meet the needs of many people and various space requirements. Incorporating GPT-based annotation capabilities not only improves the user experience but also improves user experience, but also add consideration Provide clear and interpretable reasons for each recommendation. This transparency promotes consumer engagement and loyalty. Filling a critical gap in traditional recommendation structures, the device's modular and scalable design also allows for perfect integration into modern ecommerce workflows. By combining data based on semantic text analysis, the structure can therefore provide a precise, versatile, and actionable dictionary. Future trends may focus on increasing scalability. Reduce computational costs and integrate real-time observation mechanisms. This groundbreaking technique creates a solid foundation for the next generation of user-centred intelligent recommendation systems.

ABSTRACT

To overcome the global power crisis, alternatives to fossil fuels, whose reserves are dwindling at an alarming rate, must be discovered. We can make use of a wide variety of plants, including trees, shrubs, and herbs, to produce biodiesel. The oxidation stability and cold filter plugging point of dual biodiesel are the cold flow properties that are discussed in this paper. The best sample is taken and put through its tempo in the diesel engine having variable compression ratio to determine biodiesel blends' performance and emission characteristics. The experimental examination of the engine's performance and emission characteristics. The parameters of the engine evaluated and (i) Carbon Monoxide (CO), (ii) Hydrocarbon (HC), (iii) Nitrogen Oxide (NOX) were analyzed, also Brake Thermal Efficiency (BTE), Specific fuel consumption (SFC) and emission were compared.

I. INTRODUCTION

The world is presently accosted with two major challenges: The Fuel energy crises and pollution of ecosystem. The huge variations in crude prices are determined internationally according to the market demands, and current consumption rates limit petroleum reserves to nearly 40 years. For the last 50 years, numerous countries throughout the world have been evolving new crops to boost the biomass substitute base for bio-energy production. Presently India is importing nearly 65% petroleum from other countries and the fluctuating price of crude scattered the Indian economy. Next to the U.S.A and China, India is anticipated to become the next highest consumer of fuel in 2025, with consumption increasing at a 7.5% annual rate. 85% of oil imported is used for transportation and energy production, and the country's economy is heavily dependent on fossil fuel imports. Due to the above, the position of bio fuel as a transportation fuel will be significant. The use of bio oils as a replacement for diesel fuel was established in 1900 by Rudolph Diesel who invented Diesel engine when vegetable oil was considered as an alternative. The use of Oil as diesel fuel was limited as it has high viscosity which is about 10 times the fossil fuels.

The properties of vegetable oils have to be transformed in order to become accustomed of the fuel to existing engines. Numerous vegetable oil derived products has projected as an additional fuel for diesel engines ASTM has established specific standards for biodiesel under ASTM D6751, which specifies the requirements for biodiesel made from vegetable oils, animal fats, and other renewable feedstocks. This standard ensures that biodiesel meets the necessary performance and safety criteria for use in diesel engines. During the 1980s and 1990s, significant research and development (R&D) efforts were dedicated to biodiesel and its potential as a renewable energy source and substitute for conventional diesel fuel. This period was critical for establishing the technical foundation for biodiesel production, performance, and commercialization.Non-edible oils acquired from plant group such as Jatropha, Pongamia pinnata and others are the major commodity sources of biodiesel in India. Bio-diesel can be intermingled with petroleum diesel at any ratio to produce a bio-diesel blend or used in its pure form also.

Biodiesel shares many similarities with petroleum diesel and can operate in compression ignition (CI) engines with modest or no modifications. This is one of the key advantages of biodiesel as an alternative fuel for diesel engines. The similarities in properties make biodiesel a viable substitute for petroleum diesel in various applications, such as transportation, agriculture, and industry. Biodiesel has the advantage of being compatible with the existing fuel storage infrastructure used for petroleum diesel, which means that it does not require separate storage facilities or significant changes to infrastructure. This ease of integration into current systems makes biodiesel a convenient and cost-effective alternative fuel for diesel engines Nitrogen oxide (NOx) emissions tend to be higher when using biodiesel, particularly in higher concentrations (like B100 or 100% biodiesel). NOx is a pollutant that contributes to the formation of ground-level ozone, acid rain, and smog. The reason for the increase in NOx is that biodiesel generally has a higher cetane number (which improves ignition quality), leading to higher combustion temperatures.

These higher temperatures can promote the formation of NOx. Solution (EGR System): One potential way to mitigate this issue is through the integration of an Exhaust Gas Recirculation (EGR) system. EGR reduces NOx emissions by recirculating a portion of the exhaust gases back into the engine's combustion chamber, which helps lower the peak combustion temperature and, in turn, reduces NOx formation. Biodiesel has virtually no sulfur content, unlike petroleum diesel, which can contribute to the formation of sulfur dioxide (SO2) and acid rain. This makes biodiesel cleaner in terms of sulfur emissions. Biodiesel contains no aromatics, which are compounds typically found in petroleum diesel that can contribute to the formation of soot and particulate matter during combustion. This characteristic reduces the particulate matter emissions in biodiesel use. Biodiesel contains about 10% oxygen by weight, which allows it to burn more completely and efficiently compared to petroleum diesel. This in-built oxygen helps reduce the formation of carbon monoxide (CO) and unburned hydrocarbons (HC), which are common pollutants produced by incomplete combustion.

Several practices for manufacturing bio-diesel have been established. Stirring by Mechanical means, Cavitation method by Ultrasonic and hydrodynamic and super-critical methanol are a some samples. Some of the benefits of bio-diesel over fossil fuels like diesel and petrol are: Bio-diesel is a virtuous lubricant which is 65% better than petrol & diesel, produces a smaller amount smoke and particulate matter as Bio-diesel is sulphur free and aromatics. It has high cetane number, produces a smaller amount carbon monoxide and hydrocarbon releases, they are renewable, bio-degradable, and non-toxic. The key purposes of this work are the study of comparative of Gongura Seed bio-diesels and its mixture with Diesel in comparison to clean fuel (Diesel). The engine parameters to be evaluated and compared are (i) Brake Thermal Efficiency (BTE), (ii) Smoke Opacity, (iii) Brake Specific Fuel Consumption (BSFC) (iv) Carbon Monoxide (CO) emission (v) Hydrocarbon (HC) emission (vi) Nitrogen Oxide (NOX) release & (vii) Cylinder pressure. [1] conducted in three operating modes: diesel mode; methanol/diesel mode (methanol mode for short) and methanol-based SiO2 nanofluid (MSN)/diesel mode (MSN mode for short) where the MSN was injected in the intake manifold.

Experimental studies by [2] used Al2O3-based NF and Pg procedure, which resulted in higher levels of nitric oxide (NOx) by 32.6%, lower smoke emissions by 23.2%, lower hydrocarbon (HC) and carbon monoxide (CO) emission levels by 18.2-21.4%, and greater brake thermal efficiency by 11.5%. [3] said that the trans-esterification process was affected by a number of parameters, including the ratio of (Molar) oil and alcohol (1 vs 4), the quantity of reagent (catalyst – 0.1g), response time for accomplishment (1 Hour), and the process temperature (80 °C). Under the best conditions, the maximum rate of bio-diesel production was more than 92% at 80 °C for 1 hour reaction time. Presence of LaTiO3 NPs were recorded. [4] demonstrated the preparation of Citrus medica biodiesel by using green and eco-friendly nano-particles (NPs) of synthesized copper oxide. With using aqueous Portulaca oleracea extract. [5] conducted experiments with Six Set of Dual Biodiesel blends with four different Biodiesel. He concluded that at 4.4 HP Brake Power, the mix of D90 + NB5+ JB5 reduces the carbon monoxide by around 47% and BTE increased by about 37% for the blended fuel D90 + JB5+KB5. [6] Author conducted experiments with dual biodiesel with various concentration of Water v/v %.

Finally concluded that 5% of water is the best emulsified fuel. [7] He Conducted experiments with dual biodiesel blends (Rapeseed and Mahua) and concluded that for the blended fuel BL20 emission properties are reduced in comparison to Pure diesel. Slight increase in Nox level was witnessed. [8] the author found the performance and discharge character of several dual bio-diesel mixes were discovered in this article (mixture of jatropha bio-diesel and neem bio-diesel). The outcomes displays that sensible emission features for the blend (BB10 & BB20). [9] Findings the Properties of palm and castor biodiesel and conducted experiments of dual biodiesel blends ranging from 0 to 40%. [10] while his analysis increase in BTE and reduction in SFC was observed with lower value of biodiesel, he also found that emission levels were found lower than clear diesel. [11] have carried out various experiments with Dual Injection diesel engine with blends of palm methyl esters of different ratio. Tremendous change in performance were inked. [12] conducted number of experiments using Jatropha bio diesel with methanol as additives. His results concluded a good BTE for jatropha bio diesel, diesel and dual fuel with an ration of 29%, 30.2% and 28.7% respectively. [13] have done experiments with blends of two fuels pongamia, jatropha added with neat diesel. His results were blends of 20% & 10% of biodiesel with diesel produced near clear diesel performance and emission and suggested as substitute fuel for fossil fuel like diesel and petrol.

[14] investigatied on single cylinder diesel engine fuelled with cotton seed biodiesel blends with nano additives [15] found that a 20% blend of vegetable oil (such as Pongamia or Mustard oil) and 80% clean diesel could be used as an alternative fuel for diesel engines without requiring any modifications to the engine. This is significant because it demonstrates the engine compatibility of biodiesel-like mixtures. This blend showed lower emissions of carbon monoxide (CO) and hydrocarbons (HC) compared to conventional diesel, which is consistent with other biodiesel studies showing cleaner combustion and reduced particulate matter. The results indicate that such a blend can effectively reduce harmful pollutants while maintaining the operational capabilities of the engine. The research revealed that using the blend of vegetable oils and diesel did not result in significant power loss when compared to conventional diesel. This is crucial because the performance of the engine is one of the most important factors for adopting alternative fuels, and maintaining comparable or even improved performance with biodiesel blends makes it a viable option for many diesel engine applications. [16] has piloted tests on a single cylinder, oil cooled, four strokes, direct injection VCR diesel engine with different ratios of palm and jatropha bio-diesel with orthodox diesel fuels. Lower viscosity and better calorific values of bio-diesel fuel leads to greater power brake and vice versa was shown on his study. He has determined that the lower mixes of dual biodiesel blends on bio-diesel can be used as alternate fuel in diesel engine without any adjustment of engine. A.M.

[17] has studied the performance features & properties of dual bio-diesel mined from pongamia pinnate & neem oil. Author has concluded that the neem oil and pongamia oil is mono ester and is formed by means of trans-esterification process and it can be utilized in engine without any changes. [18-21] says that to change diesel fuel by bio-diesel, he has selected oils from palm kernel and eucalyptus. He added with methyl ester of palm kernel in the ratio of 15%, 10% and 5% by volume. He piloted a test in VCR diesel engine with mixed diesel fuel[22]. the incorporation of graphene oxide nano fuels into Tomato Oil methyl ester blends demonstrates potential for improving engine performance and reducing emissions[23]. he ratio of B20, B40, and B60 with Tio2 as a Nanoparticles as 100ppm. Performances and emission characteristics of engine is calculated with blended fuel and neat diesel[24-25].

II. METHODOLOGY

II.1 RESEARCH METHODOLOGY

Currently human all over the world is fronting with two chief tasks which include the fuel devastations and ecosphere dilapidation. With current utilizing rate the reserve of gasoline products is limited to next 40 years only and the cost of crude oil depends on international volatile markets. Numerous countries spread over the world have been evolving novel crops from 1975 in order to advance the bio-mass reserve for production of various forms of bio energy. India's dependence on imported petroleum is a significant issue for its economic stability. Currently, the country imports about 70% of its petroleum needs, making it highly vulnerable to fluctuations in the global oil market. These fluctuations can be driven by geopolitical tensions, supply disruptions, and other factors that lead to volatile oil prices. This reliance on imported oil puts a strain on India's foreign exchange reserves and affects its balance of payments, which is a key concern for the country's economic health. Properties of Gongura Seed Biodiesel and Diesel as given in Table 1& Table2. Research Methodology of the project as shown in figure 1.

Table 1: Properties of Gongura Seed Biodiesel.

Appearance	Light Yellow Liquid
Density	0.88 at 200C
Kinematic Viscosity	1.9-6.0 mm3/s at 400C
FFA Content	6.9 wt%
Iodine No	1.38 g12/100g-oil
Water Content	0.02 wt%

III. RESULTS AND DISCUSSION

III.1 CARBON MONOXIDE (CO)

The Emission of Carbon monoxide with different proportional of load for Gongura Seed biodiesel mix of 0%,20%, 40% & 60% with diesel and plain diesel were depicted in Figure 3. It was experiential during the test, lesser emission of CO was observed with increase in engine load during part load and increase in level during full load. It might be due the maximum fuel consumption due to rich air-fuel mixture. From the below figure we can come to a conclusion that throughout the engine load, substantial drop in CO emission of the Gongura Seed bio diesel blends in comparison to neat Diesel. It is primarily because of higher oxygen level in biodiesel than neat diesel.

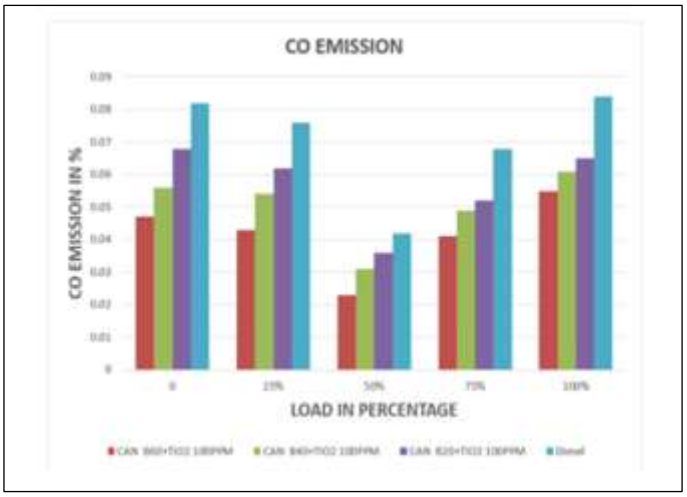

Figure 3: Load Vs CO Emission.
Source: Authors, (2026).

III.2 NITROUS OXIDE

Nox emission of neat diesel fuel and blends of Gongura Seed bio diesel is available from Figure 4. It was discovered that release of Nox was higher than pure diesel fuel for all Gongura Seed bio-diesel. The increase in combustion temperature and the increase in flame temperature could be key reasons for the higher NOx (Nitrogen Oxides) emissions observed when using biodiesel or vegetable oil blends in diesel engines. Nox formation was mostly due to surge in cylinder combustion temperature and percentage of oxygen level. From test results it was found that Nox release is more compared to pure diesel oil than mixes of Gongura Seed oil.

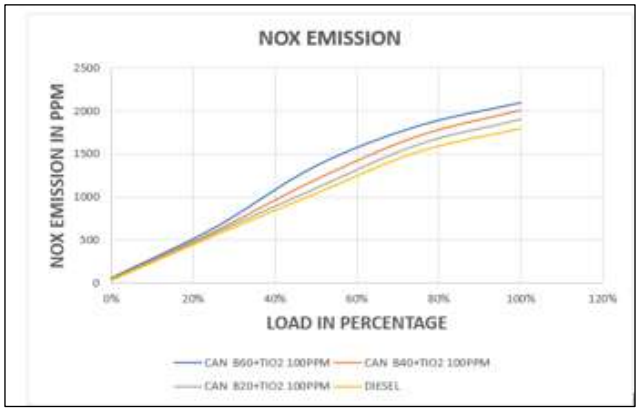

Figure 4: Load Vs NOX Emission.
Source: Authors, (2026).

III.3 HYDROCARBON

Differences of HC emission with engine load while using various mixes of Gongura Seed bio-diesel and pure diesel is shown in the Figure 5. During testing, for all the loads tested HC emissions were lesser at engine load although it has increased during higher engine load. This is mainly because of larger fuel particle size, timing of injection and chocking of nozzle also changed the combustion timing. It is mainly because of lesser oxygen presented during more fuel injection at higher loads. The key cause of un-burn Hydro carbon is owing to minimum ignition delay linked with fuels having considerable cetane number which reduces the over varied fuel. The above result settled with the references.

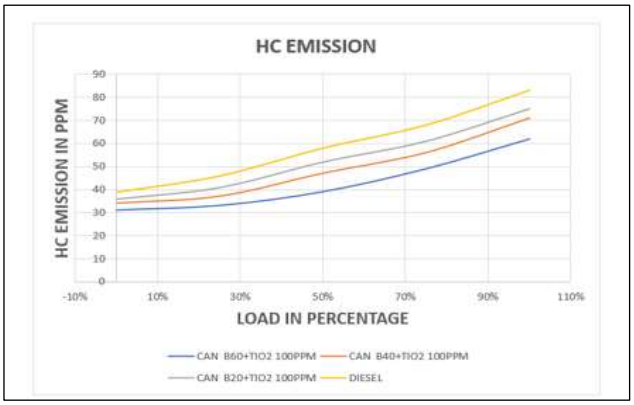

Figure 5: Load Vs HC Emission.
Source: Authors, (2026).

III.4 CO2 EMISSION

As Figure 6 represents the CO_2 emission of Gongura Seed biodiesel at 20%, 40% & 60% with pure diesel at different engine loads. During the increase in engine load, increase in CO_2 release was observed which might be due to greater fuel consumption linked with load raises. Lesser CO_2 release were observed for various mix of bio-diesel Gongura Seed and compared with clean diesel fuel. The drop in CO_2 release were clarified on relations of greater oxygen content in bio-diesel mixes of Gongura Seed as compared to pure diesel fuel.

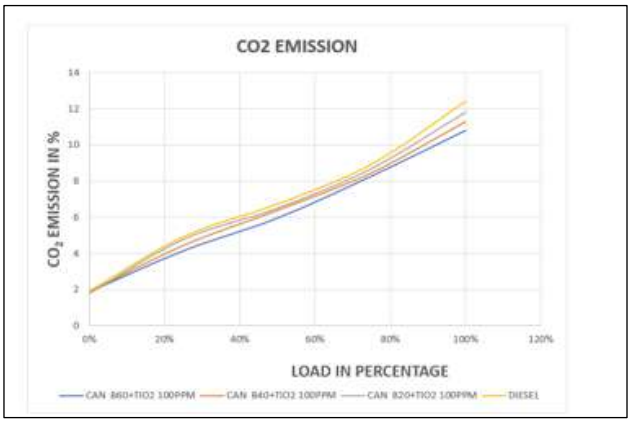

Figure 6: Load Vs CO2 Emission.
Source: Authors, (2026).

III.5 SMOKE OPACITY

The smoke opacity of all candle nut bio-diesel mixture with various engine load and pure diesel is shown in Figure 7. For comparison purpose clean diesel smoke opacity is also added in the graph. Similar to other experiments the result illustrates rise in smoke release with upsurge in engine capacity. It is primarily owing to change in fuel usage in the higher side which causes rich air-fuel mixture. As the percentage of oxygen molecules is more and carbon content is small in the Gongura Seed bio-diesel in comparison to pure diesel which has caused great burning and reduction in smoke emission was observed.

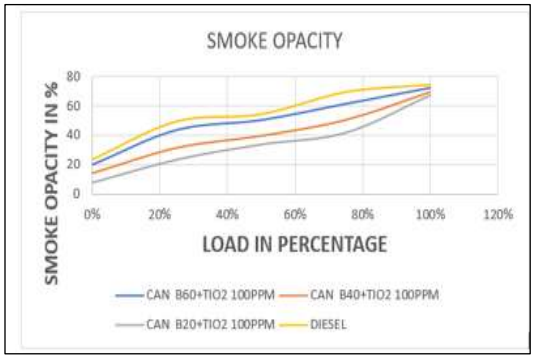

Figure 7: Load vs Smoke Opacity.
Source: Authors, (2026).

III.6 SPECIFIC FUEL CONSUMPTION (SFC)

The smoke Specific fuel consumption of Gongura Seed bio-diesel with various loads in the engine for different mixes were illustrated in Figure 8. Specific fuel consumption was found to be less with increase in percentage of load for all ratio of blended bio-diesel. It is mainly because of the kinematic viscosity and the good calorific values of the bio-diesel. Illustrations from all graphs shows clearly consumption of fuel is maximum because of the lower content of ester in the fuel.

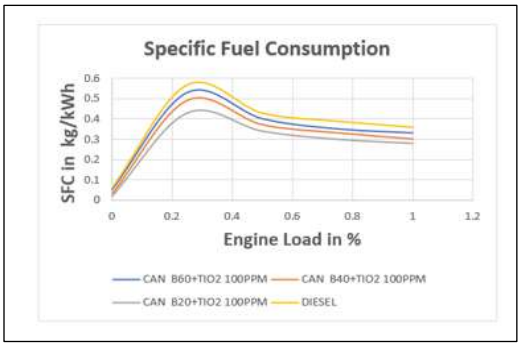

Figure 8: Load vs Specific Fuel Consumption.
Source: Authors, (2026).

III.7 BRAKE THERMAL EFFICIENCY (BTE)

From figure 9, we can understood that the brake thermal efficiency rises during increase in break power for diesel and candle nut biodiesel mixes. The brake thermal efficiency of diesel is higher equated to Gongura Seed bio-diesel blends. Also from the information, it is well-known that the BTE of lower ration blend is closer to that of pure diesel when compared to Gongura Seed bio-diesel blends. This disparity in BTE for various bio-diesel mixes is owing to higher viscidness and reduced instability, which principals to deprived blend formation. This results in reduction of brake thermal efficiency for Gongura Seed bio-diesel mixes.

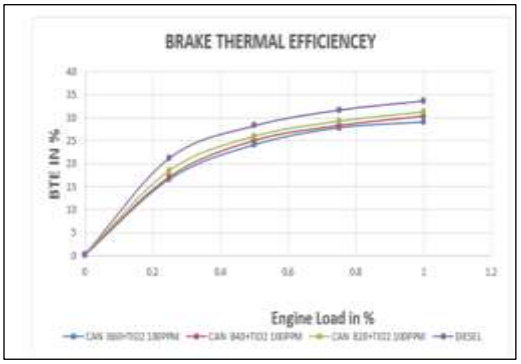

Figure 9: Load vs Brake Thermal Efficiency.
Source: Authors, (2026).

III.8 MAX CYLINDER PRESSURE (BAR)

The distinction of engine's cylinder pressure in response to various eccentric angle at various proportions of Gongura Seed Bio-diesel of various proportions and clean diesel at maximum load. It was witnessed from the experiment that maximum pressure of cylinder of Gongura Seed Bio Diesel mixes is lesser than that of pure diesel. It is chiefly due to higher viscosity and smaller volatility of Gongura Seed bio-diesel. From Figure 10, we can observe that the maximum engine cylinder pressure of diesel is 66 kg/cm2 and B20 is 59 kg/cm2. From the graph it is easily understood that the maximum engine cylinder is extra for diesel compare to Gongura Seed Bio-diesel mixes and reduces when bio-diesel of larger proportions of diesel was used. It is chiefly because of the delay in ignition time and lesser air/diesel or bio-diesel mixture which is accessible during the combustion & ignition. It has therefore added burning in the diffusion-burning stage than that of the pre-mixed burning point. Because of the above reasons the maximum engine cylinder pressure is smaller for Gongura Seed bio-diesel-diesel mixes.

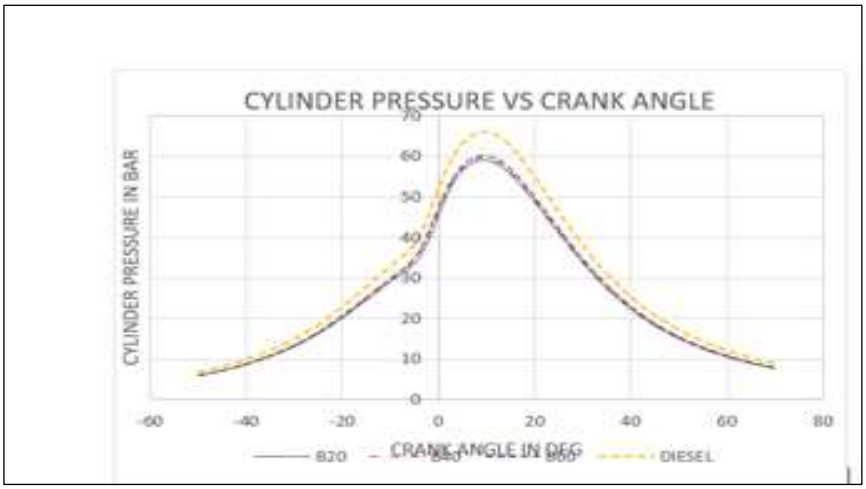

Figure 10: Load vs Cylinder Pressure.
Source: Authors, (2026).

IV. CONCLUSIONS

During the study a direct injection diesel cylinder with single cylinder was used to run with different blends of Gongura Seed biodiesel in the ratio of 20%, 40% & 60% with clean diesel. Performance study of engine and exhaust discharge characters were calculated during several engine load of 0%, 25%, 50%, 75% & 100% with engine speed of 1500 rpm. Emissions like CO, HC, smoke opacity, Co2 & No2 were scrutinized. Brake thermal efficiency, Cylinder Pressure and specific fuel consumption were also studied and related with pure diesel. Conclusions that have been found are briefed here as:

❖ Exhaust emission of carbon monoxide, smoke and hydro carbons are lesser for the experienced Gongura Seed bio-diesel blends B20, B40 & B60 when compared to clean diesel fuel.

❖ Carbon dioxide release through exhaust when using Gongura Seed bio-diesel of 20%, 40% & 60% blends were lesser compared to pure diesel as fuel.

❖ Release of NOx while using Gongura Seed bio-diesel of 20%, 40% & 60% blends improved when equated with pure diesel as fuel for the examined bio-diesel mixes.

❖ SFC for Gongura Seed biodiesel blends B20, B40 & B60 are lower in relation to diesel fuel and BTE of Gongura Seed bio-diesel mixes have approached the near value of clean Diesel.

❖ Gongura Seed Blends of B20 & B40 are having lower emissions and near BTE to diesel and can be used as substitute fuel.

ABSTRACT

This study enhanced the response of a CRDI single-cylinder four-stroke VCR engine under various input parameters with a novel tomato seed biodiesel (B25) infused with TiO2 nanoparticles. Response surface methodology (RSM) was employed to examine the influence of various input parameters on engine responses, including specific fuel consumption (SFC), brake thermal efficiency (BTE), and emissions of CO, HC, and NOx. The examined factors included injection pressure (IP), load, compression ratio (CR), and nanoparticle concentration as gasoline additives. Through the optimization of all input parameters, the RSM identified the optimal point at which the engine achieved maximum performance with minimal emissions. The optimal settings for the input parameters are as follows: a nano biofuel mix ratio, an injection pressure of 799 bar, a compression ratio of 20, and a load of 3.63 kg. This configuration of input parameters produces optimal outcomes for BTE (22.46%), SFC (0.25 kg/kWh), CO (0.023%), HC (22.01 ppm), and NOx (536 ppm). To ensure validity, we compared the experimental value with the ideal value predicted by RSM and observed a satisfactory correlation.

1. INTRODUCTION

Biodiesel offers a renewable and cleaner alternative to conventional diesel, yet its performance in modern engines can be limited by factors such as fuel properties and combustion efficiency. Nanotechnology-based additives and advanced fuel systems have emerged as effective solutions to enhance engine output, fuel economy, and emission profiles. Common Rail Direct Injection (CRDI) technology enables precise control over injection parameters, facilitating optimal combustion. This study employs Response Surface Methodology (RSM) to systematically optimize performance and emission characteristics in diesel engines. Authors investigated the use of pulsed electric field (PEF) as a pre-extraction step to enhance TSO yield and quality. Optimum parameters were 9 min treatment and 0.5 µs pulse duration, resulting in maximum extraction of bioactives. Lycopene (565.54 mg/mL) was the main carotenoid, linoleic acid the predominant fatty acid; strong antioxidant activity contributed to high oxidative stability confirmed by EPR and DSC [1]. Authors studied supercritical CO_2 extraction (SFE) of lycopene from tomato pomace, analyzing lycopene concentration and E:Z isomer ratios. Initial process achieved 84.6% lycopene extraction but only 48.4% recovery in oil. Redesign using 703 g of exogenous tomato oil increased predicted lycopene recovery to 99.3%, showing that solubilization efficiency is driven largely by oil availability [2]. Review article summarizing extraction methods, physicochemical characteristics, and bioactive profile of TSO. Highlighted high levels of oleic and linoleic acids, potent antioxidant and antimicrobial properties, and applications in food products, packaging films, dietary supplements, and medical fields. Stressed potential for TSO to add economic value to tomato processing by-products [3].

Compared microwave-assisted extraction (MAE) and supercritical CO_2 extraction (SFE-CO_2) of TSO, optimizing via response surface methodology (RSM). MAE (56.2 °C, 29 min, 67.6 mL) produced higher yield (25.3 wt%) than SFE-CO_2 (16.9 wt%), with similar

fatty acid profiles (~80% unsaturated). γ-Tocopherol was dominant, linked to high DPPH• radical scavenging activity, suggesting strong potential for nutritional and food applications [4]. Researchers examined diesel–tomato seed oil biodiesel (TSOB) blends in a 4-cylinder, 4-stroke, indirect injection diesel engine using both experiments and AVL FIRE CFD simulation. Tested parameters included torque, BSFC, EGT, NOx, CO, CO_2, PM, in-cylinder pressure and temperature, and reaction progress at 1200–2400 rpm. B10 showed the lowest BSFC and B20 the highest torque. CFD revealed NOx formed mainly near the piston throat, CO/CO_2 near chamber boundaries, and PM at the injection region [5]. Researchers developed thiol-grafted Tamarindus indica seed gum–Teff hay biocarbon (TH@TI-TBC) adsorbent for cadmium removal from electroplating wastewater and achieved max adsorption (261.47 mg/g) at pH 5.5, following Langmuir and pseudo-second-order kinetics. Removed 89% of Cd from 30 mg/L wastewater; adsorption driven by electrostatic interaction and surface complexation. Authors proposed TH@TI-TBC as a sustainable waste-to-resource adsorbent [6]. Authors studied acetic acid–treated Pithecellobium dulce seed pod powder for Reactive Red 195-A dye removal. Characterized via SEM, FTIR, DTA, TGA; adsorption followed Temkin isotherm and pseudo-second-order kinetics ($R^2 > 0.90$).

Process was spontaneous and endothermic, suggesting PD pods as low-cost, eco-friendly adsorbents [7]. Researchers extracted 21.69% oil from Rio Grande tomato seeds via Soxhlet (79.83% unsaturated fatty acids), then recovered phenolics from defatted seeds via MAE optimized by RSM (700 W, 70 s, water). Combined oil and phenolic extraction added economic value to tomato waste, producing edible, biofuel, and cosmetic-grade oil and antioxidant-rich extracts through a green, low-cost process [8]. Authors studied turbocharger effects on a VCR diesel engine using neat diesel and neat TSO biodiesel. Turbocharging improved brake thermal efficiency and reduced CO and HC emissions for TSO compared to naturally aspirated operation, but NOx increased without turbo. With turbocharger, NOx emissions for TSO decreased relative to non-turbo TSO operation [9]. Researchers investigated nozzle hole number (2-hole vs 3-hole, 0.25 mm dia) on a single-cylinder DI diesel engine using diesel and B20 TSO at 1500 rpm, 200 bar injection pressure. The 3-hole nozzle improved brake thermal efficiency and reduced SFC at 40% load with B20, and produced lower NOx emissions than the 2-hole nozzle configuration [10]. The biodiesel combustion (apricot, papaya, sunflower, tomato seed oils) at compression ratios 15.5–18.5 in a Kirloskar AV1 diesel engine were simulated using ANSYS Fluent. Higher CR increased peak temperature, pressure, CO_2 and NO, and reduced CO

Apricot biodiesel at CR 18.5 achieved highest combustion efficiency but high emissions; tomato seed oil biodiesel at CR 15.5 showed lowest NO and CO_2 but reduce the performance [11]. Researchers reviewed tomato processing by-products (peels, seeds, pomace) as sources of bioactive compounds (carotenoids, proteins, fiber, pectin) and highlighted tomato seed oil's oxidative stability from carotenoid content and its applicability in food, feed, and biodiesel. The re-use of tomato residues in bakery products, animal feed, meat additives, and non-food industrial applications were analysed [12]. The biodiesel production from tomato seed oil (TSO) using Aspen Plus® were modeled, focusing on alternative catalysts and by-product recovery (glycerol, potassium phosphate). The methyl ester yield correlations and simulated transesterification with methanol recovery and recycle were developed. Designed distillation towers and calculated energy return on investment (EROI), including harvesting and processing energy. Results indicated TSO biodiesel production is technically and energetically feasible [13]. Diesel–TSOB blends were analyzed in an indirect injection (IDI) diesel engine through experiments and 2D CFD (AVL FIRE). CP and combustion characteristics were measured at five loads and seven speeds. B10 at full load had peak CP of 69 MPa at 2200 rpm shows highest accumulative heat release (~1900 J), and best fuel energy efficiency. CFD showed B5 had longest jet penetration (44 mm), while B10 reached peak in-cylinder temperature (1600 K) [14]. Ultrasound-assisted protein extraction from defatted tomato seed cake was optimized using RSM.

The optimum (52 mL/g, 2 min 18 s, 60 min) achieved 35.75% protein yield. The extracted protein exhibited favorable physicochemical properties suitable for food industry applications [15]. Cold press extraction (12.80% yield) and enzyme-assisted aqueous extraction (9.66% yield) for tomato seed oil was analyzed. Both eco-friendly methods preserved oil quality and bioactivity, highlighting their potential for functional food and nutraceutical applications [16]. A UiO-66-NH_2/ZnO/TiO_2 nanocatalyst via sol–gel for biodiesel production was developed from dairy waste scum oil (DWSO). It exhibited a high surface area (568.1 m^2/g) and small particle size (28.35 nm). Using CCD optimization, a 98.7% conversion was achieved at a 9.8:1 methanol/oil ratio, 61 °C, and 2 wt% catalyst [17]. Diesel engine performance was optimized using ternary blends of n-heptane, biodiesel, and diesel with TiO_2 nanoparticles (0–75 ppm) under varying loads, employing RSM. Optimum at 76.8% load, 57.6 ppm NPs, 25.6% biodiesel, and 9.5% n-heptane achieved 77.54 bar CP, 64.65 kJ HRR, 35.12% BTE, and reduced CO (0.0647% vol), HC (52.11 ppm), and smoke (37.34%). Validation errors were <5% [18]. Researchers compared the experimental and ANN-based predictions for CI engine parameters with mahua biodiesel (M30) and 50 ppm of CeO_2, CuO, or TiO_2 NPs. CeO_2 NP blend improved BTE by 9.1%, CP by 11.3%, HRR by 10.2%, and reduced BSFC by 13.7%, CO by 30.4%, HC by 30.1%, smoke by 34.7%, and NOx by 7.1%.

ANN backpropagation with two inputs (load, blend type) effectively predicted performance and emissions, enabling optimal blend selection without extensive testing [19]. Synthesized $ZnFe_2O_4$@TiO_2 nanocatalyst for biodiesel production from jojoba oil, achieving 97.56% yield at 54.96 °C, 2.89% catalyst, and 12.13 mol/mol methanol/oil ratio. Catalyst retained >90% yield after seven cycles. Engine tests showed reduced CO, NOx, and UHC, along with improved BTE and BSFC. Reaction was endothermic ($\Delta H° = 44.82$ kJ/mol) [20]. Biodiesel from a mix of Ceiba pentandra, Mahua longifolia, and Azadirachta indica oils were produced and enhanced with CaO–TiO_2 nano-additives. Optimization by Box–Behnken Design, Deep Belief Network (DBN), and hybrid Arithmetic Optimization was performed. Algorithm identified optimal conditions (load 60%, biodiesel 25%, nano-additive 20 wt%, 1400 rpm). Compared to diesel, CaO–TiO_2 biodiesel reduced BSFC by 41%, CO by 32%, NOx by 25%, and increased BTE by 16.9% [21]. The previous studies examined the individual variables such as biodiesel addition, nanoparticle concentration fluctuations, injection pressure, and compression ratios, additional research into their combined impact is necessary. The author discovered research focused on improving biodiesel volume for engines through the manipulation of compression ratio, load, injection pressure, and nanoparticle concentration.

Therefore, studies that separately control fuel process parameters while jointly managing engine parameters may gain from the present research. Consequently, RSM has been investigated in this study to enhance engine performance and emission metrics. The optimal parameters for operation include nanoparticle concentration, load, CR, and IP. This study involved the incorporation of TiO2 nanoparticles into biodiesel derived from tomato seeds. The engine compression ratio was altered from 18 to 20 in increments of 0.5, the injection pressure was increased from 600 bar to 800 bar in 50 bar increments, and the volume fraction of the biodiesel blend was set at 25%. The concentration of TiO2 nanoparticles was modified in increments of 20 ppm, reaching a maximum of 80 ppm. We employed 2-kilogram increments to adjust the load from 0 to 8 kilograms.

II. MATERIALS AND METHODS

II.1 BIOFUEL PREPARATION PROCESS

We procured the tomato seed oil from the local market in Chennai, Tamil Nadu, India. The subsequent step involved performing the fuel test. Fuel testing indicates that the oil's elevated viscosity renders it unsuitable for direct application in a diesel engine. The objective of the transesterification procedure was to reduce viscosity. The synthesis of biofuels using transesterification is a recognized technique. Subsequently, the mixture was exposed to temperatures between 60 and 70°C in the presence of a suitable catalyst of KOH (1% w/w). The flask was subjected to magnetic stirring at 400 rpm with the mixture. After one hour, a substantial layer had developed in the flask. Following a duration of two hours, the glycerol was isolated by the sedimentation process. B25 is a biofuel mixture including tomato seed oil. The Physio-chemical characteristics of the developed nanofuel is given in table 1.

Table 1: Physio-chemical characteristics of the developed nanofuel.

Oil	Kinematic viscosity (mm^2/s) at 40°C	Density (g/m^3)	High calorific value (kJ/kg)
Tomato seed oil	51.80	917	36,250
Supporting biodiesel B25 (TSO-25%	2.5120	0.8180	40,420
B25+20PPM(TiO_2)	2.6850	0.8235	40,570
B25+40PPM(TiO_2)	2.7105	0.8332	40,810
B25+60PPM(TiO_2)	2.7380	0.8431	41,030
B25+80PPM(TiO_2)	2.8995	0.8795	41,280

Table 2 presents the physicochemical parameters of the nanoparticles. The XRD technique is favored for the direct analysis of nanoparticle sample characteristics, including composition size, crystal structure, morphology, purity, and unit dimensions. The subsequent stage involved employing an ultrasonicator to disperse TiO2 nano powder in B25 at different concentrations (20, 40, 60, 80 ppm). Nanoparticles are incrementally added to B25 at consistent intervals for each sample to prevent micromolecule aggregation. Following one hour of high-frequency operation, the Ultrasonicator has completely dissolved all homogenous nanoparticles in the liquid. Consequently, four novel nano-biodiesel blends have been created, comprising 20 PPM (TiO2), 40 PPM (TiO2), 60 PPM (TiO2), and 80 PPM (TiO2) Titanium dioxide.

III. EXPERIMENTAL SET-UP AND METHODOLOGY

III.1 THE SPECIFICATION OF THE EXPERIMENTAL SETUP

This study utilized a CRDI VCR, a single-cylinder diesel engine. The schematic diagram is shown in figure 2. Table 3 presents the specification.

Table 3: CRDI VCR diesel engine specification.

Engine	Model	No. of cylinder	No. of stroke	Orifice diameter	Power	Speed	IP	CR range
Diesel	CRDI VCR	1	4	20 mm	3.5 kW	1500 rpm	60 MPa	12:1 to 18 :1

RSM is a data-centric methodology that enhances the output variable, influenced by several independent factors, by selecting the regression model based on quantitative data from the associated study. Response surface methodology is utilized to identify nonlinear interactions between inputs and outputs. Table 4 presents the optimal and non-optimal values of the input parameters corresponding to the -2, -1, Centre (0), +1, and +2 numerical values in this optimization study, as determined by statistical analysis. The objective of the central composite rotational design (CCRD) is to identify the optimal values for the input parameters and their interrelationships. Table 5 presents the experimental configuration for the CCRD design. While the Taguchi technique and factorial design are not ideally suited for optimizing nonlinear systems, they can do so effectively. Response surface methodology establishes a numerical relationship that encompasses the interactions between input parameters and output responses, which is challenging to achieve using optimization techniques; this constitutes the primary advantage of its application in the present study. In optimization approaches, it is essential to ascertain the relationship between input variables and output variables.

The reduction of optimization trials is a subsequent advantage of RSM. Additional experimental trials are necessary for precise numerical validation of any approaches other than response surface methodology. The primary function of numerical models is to predict the behavior of input parameters and outcomes. The optimization method employs a higher-order polynomial equation to numerically model the nonlinear relationship between inputs and outputs. The subsequent equation denotes a second-order polynomial model [22].

$$Y = b_o + \sum b_i x_i + \sum b_{ij} x_i x_j (i, j = 1,2,3 \ldots \ldots k)$$

The variables Xi and Xj represent input variables, bi and bj denote constants, and Y signifies the output response. ANOVA was applied to analyze performance and emission parameters [23].

A p-value below 0.01 signifies that the model is statistically significant. All models exhibit a p-value of less than 0.01. Consequently, ANOVA demonstrates that the model is statistically significant. The model F-values for SFC, BTE, CO, HC, and NOx are 390.07, 5.54, 16.91, 17.41, 132.61, and 51.38, respectively. The research indicated that nanoparticles and load substantially influence SFC (p-value <0.01). The suggested model and experimental variables can be evaluated using the P-value and F-value. Table 8 presents R2 values of 0.7445%, 0.8990%, 0.9016%, 0.9859%, and 0.9643% for SFC, BTE, CO, HC, and NOx, respectively, as indicated by the ANOVA results. The model's accuracy and adequacy are evidenced by the R2 value approaching 1. The R2 values indicate the efficacy of the models. The values of the Adjusted R2 (Adj. R2) and the Predicted R2 (Pred. R2) are relatively similar

Table 8: Model summary of input parameters.

Coefficient of determination	Value

IV. RESULT AND DISCUSSIONS

IV.1 ENGINE PERFORMANCE

IV.1.1 Specific fuel consumption (SFC)

Specific fuel consumption (SFC) refers to the amount of fuel burned per unit of time to provide a specified engine output. SFC is a quantitative measure for assessing an engine's efficacy in converting fuel into useable power. The initial equation is a second-order quadratic regression equation formulated to estimate SFC utilizing the coded values.

SFC = 0.573 -0.0200 A -0.1701B -0.0378 C -0.01248 D -0.0569 AB -0.02176 AC + 0.0232 AD -0.00908 BC + 0.0409 BD - 0.0798CD (1)

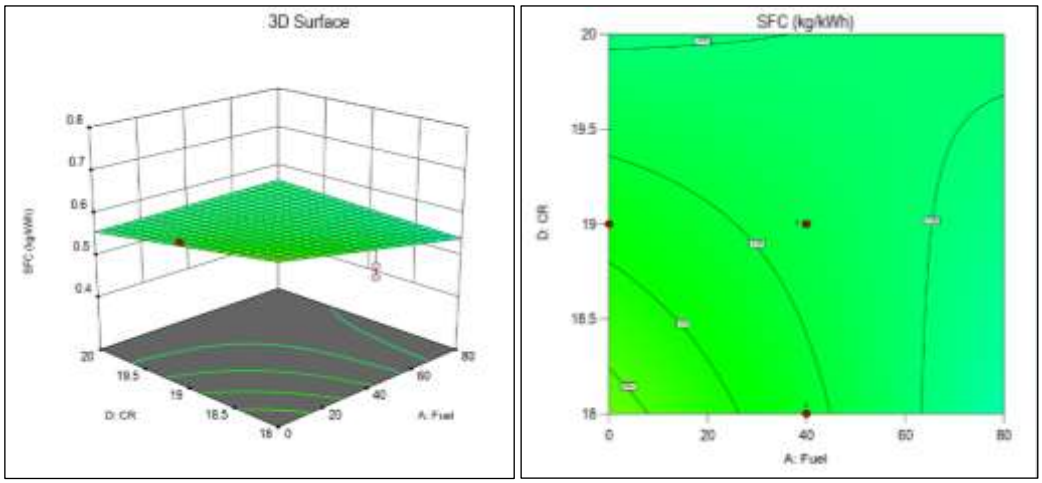

Figure 3: Three-dimensional plot depicts the impact of fuel and CR and their combined effect on the specific fuel consumption.
Source: Authors, (2026).

The influence of TiO_2 concentration in biodiesel and CR on SFC at IP (700 bar) and load (6 kg) was illustrated by contour and surface plots. At elevated CR, the light green hue of the contour zone yields a substantial concentration of nanoparticles (TiO_2) and a reduced engine specific fuel consumption (SFC). Biodiesel and CR exhibited a crimson hue with an escalating concentration of nanoparticles (TiO_2). As the TiO_2 to fuel ratio grew, the specific fuel consumption (SFC) value was found to decrease in figure 3. In another study, tested diesel–tomato seed oil biodiesel blends enhanced with nano-CuO (50 nm) additives in a single-cylinder engine. Nano-CuO improved fuel properties (flash/fire point, calorific value) and reduced SFC [24]. This is due to the fact that the expansion of nanoparticles improved the fuel's ignition characteristics by optimizing its air-fuel mixture, physicochemical properties (demonstrating increased fuel calorific value), dispersion, and thermal conductivity. A little reduction in SFC with increased CR indicates that enhanced combustion and diminished heat losses contributed to the overall decrease in SFC as CR increased. Under maximum load, the specific fuel consumption decreased by approximately 35% as the compression ratio increased from 18 to 20.

Figure 4 illustrates the effect of elevated injection pressure and compression ratio on specific fuel consumption (SFC) for a load of 4 kg and a fuel addition setting of 0. As IP increases, SFC diminishes with elevated CR. Decreased fuel usage results from increased spray pressure and a shorter duration for air/fuel combination. Figure 5, a contour plot depicts the influence of load and nano ratio on specific fuel usage. Figure 6 illustrates the trend of the specific fuel consumption curve in relation to the indicated power and fuel concentration, under a constant compression ratio and load. As the nanoparticle concentration and injection pressure increased, the contour plot indicates a drop in SFC. With a constant parameter load of 4 kg and CR, the SFC curve exhibits a slight increase or reduction contingent upon the IP level, as the nanoparticle concentration rises.

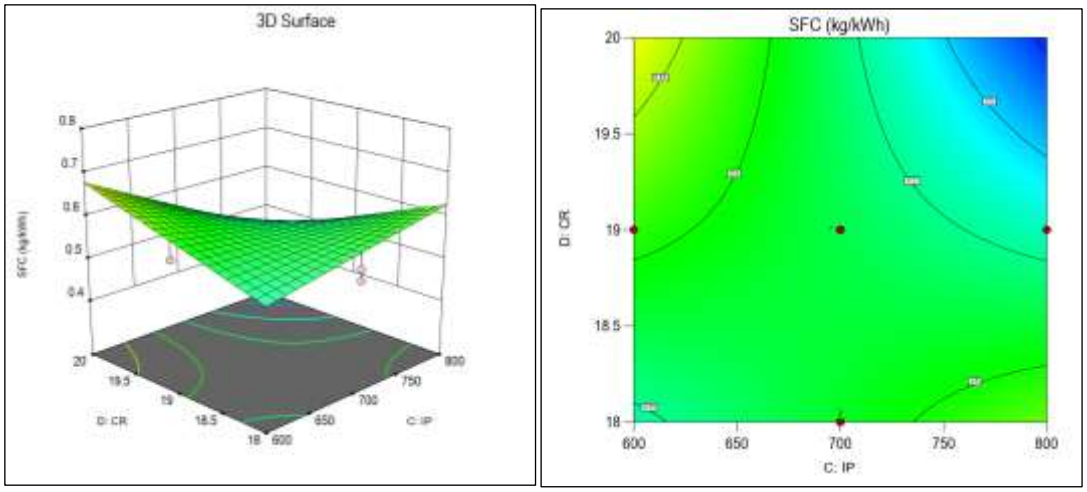

Figure 4: Three dimensional plot depicts the impact of IP and CR and their combined effect on the specific fuel consumption.

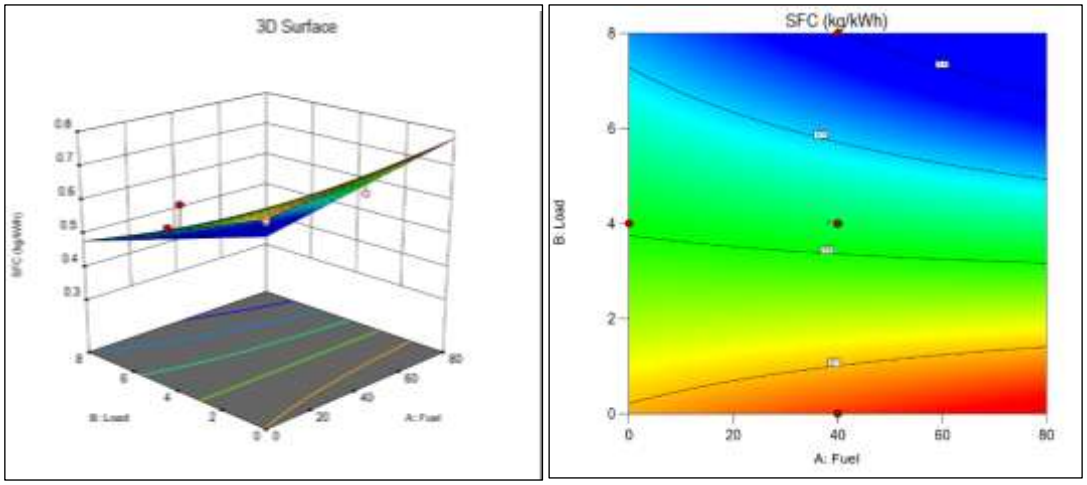

Figure 5: Three dimensional plot depicts the impact of fuel and load and their combined effect on the specific fuel consumption.
Source: Authors, (2026).

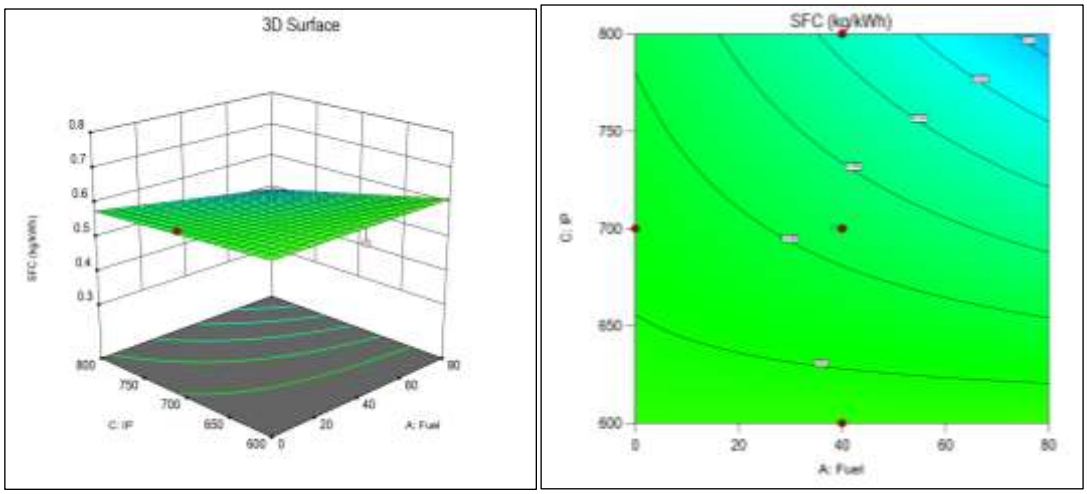

Figure 6: Three-dimensional plot depicts the impact of fuel and IP and their combined effect on the specific fuel consumption.
Source: Authors, (2026).

IV.1.2 Brake thermal efficiency (BTE)

To estimate BTE (utilizing the coded values), a second-order quadratic regression equation was formulated and denoted as equation (2).

BTE =24.23 + 1.744 A11 + .3809 B0 +.6056 C-0.0595 D0.+ 40084877135602 AB0.+.2742 AC0 +.27580 AD-0.1844 BC0.+ 28710 BD-0.3719 CD (2)

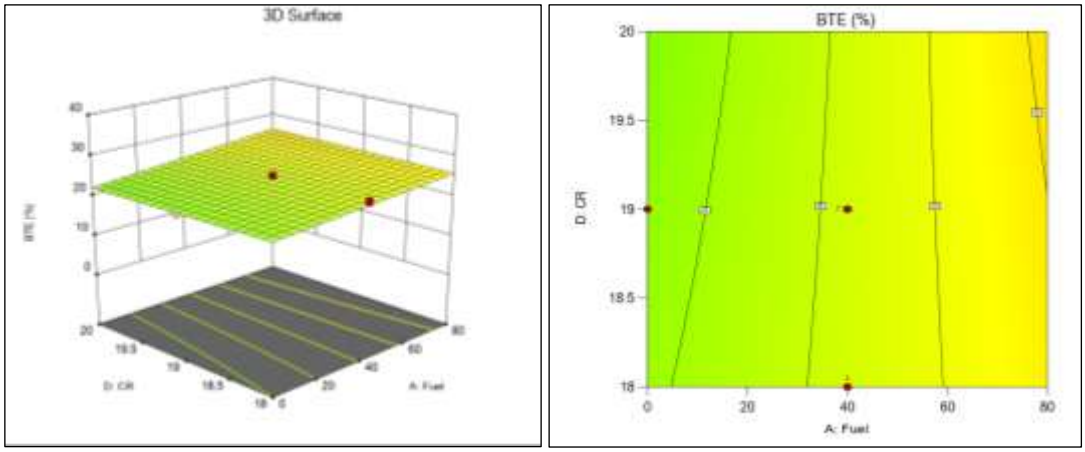

Figure 7: Three dimensional plot depicts the impact of fuel and CR and their combined impact on the brake thermal efficiency.
Source: Authors, (2026).

The Brake Thermal Efficiency (BTE) of the engine is a quantifiable indicator that assesses the engine's efficiency. Fuel conversion efficiency is the process of multiplying the lower heating value by the mass flow rate of injected fuel to produce energy. Using a load of 4 kg and an inlet pressure of 700 bar as fixed parameters, Figure 7 shows the contour and surface plot on the the influence of nanoparticle content and compression ratio on brake thermal efficiency. The addition of nanoparticles to biofuel resulted in an increased compression ratio and an elevated brake thermal efficiency curve. The utilization of nanoparticles signifies enhanced combustion and the effective transfer of fuel energy to productive labor. Optimal braking thermal efficiency was attained owing to the elevated heating value of the nano fuel and the substantial nanoparticle concentration within the fuel. An augmentation in BTE was seen with IP, as illustrated in Figure 8, demonstrating the impact of IP on BTE. Fuel injection transpires with reduced droplet sizes as the Fuel Injection Pressure (FIP) is elevated. This enhances the fuel's amalgamation with air and accelerates its vaporization. The combustion efficiency is improved, resulting in an increased brake thermal efficiency (BTE). In another study, lemongrass diesel engine tests showed B30ZnO had the highest BTE increase (>3%) and better emissions than TiO_2 or Al_2O_3 blends, with ANOVA confirming significant influence of nanoparticle type on performance [25].

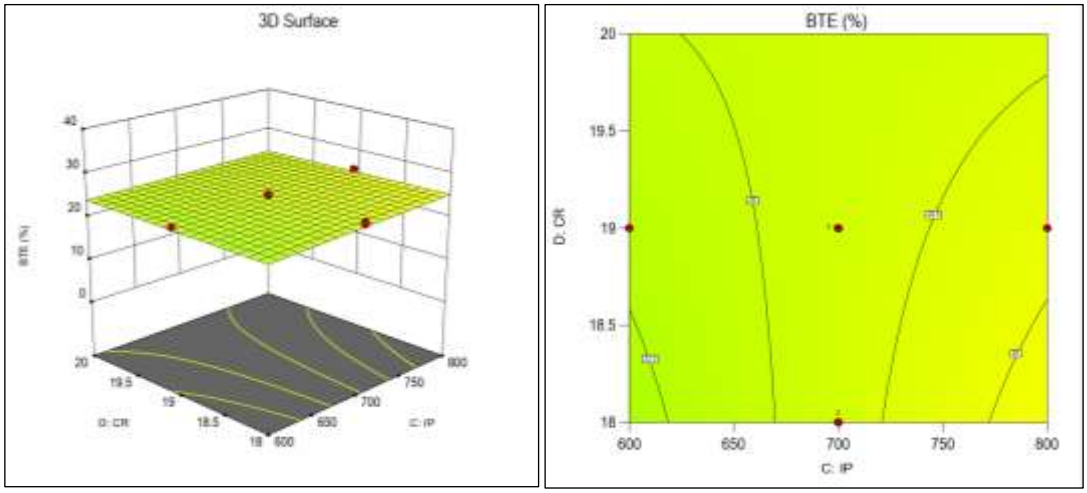

Figure 8: Three dimensional plot depicts the impact of IP and CR and their combined impact on the brake thermal efficiency.
Source: Authors, (2026).

Figure 9 illustrates the impact of load and nano fuel on BTE when the hold values are CR (19) and IP (700 bar). As the engine load intensified and the concentration of metallic nanoparticles augmented, its brake thermal efficiency enhanced. A minimal degree of heat loss is purported to enhance power as the load increases. Due to their elevated surface-to-volume ratio, nanoparticles facilitate the complete combustion of test fuel, hence enhancing brake thermal efficiency through nanoparticle advancement. Figure 10 illustrates the increase in BTE corresponding to the rising concentrations of IP and nanofuel. IP and nanoparticle enhancement improve fuel atomization, dispersion, and mixing, resulting in increased brake thermal efficiency.

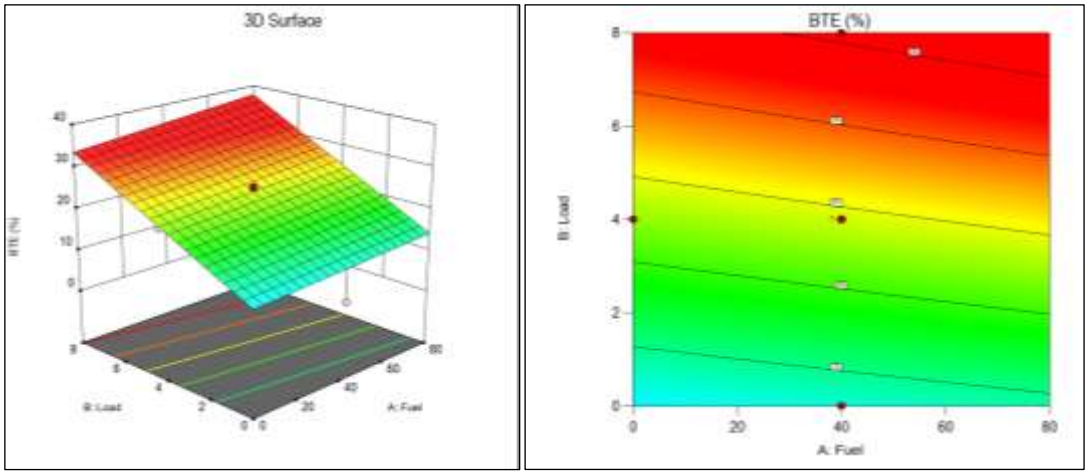

Figure 9: Three dimensional plot depicts the impact of fuel and load and their combined impact on the brake thermal efficiency.
Source: Authors, (2026).

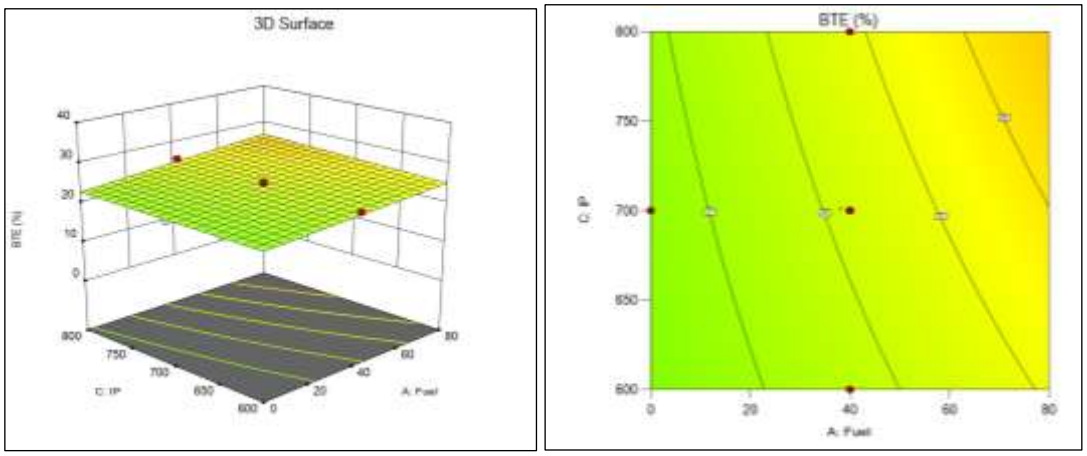

Figure 10: Three-dimensional plot depicts the impact of fuel and IP and their combined impact on the brake thermal efficiency.
Source: Authors, (2026).

IV.2 EMISSION CHARACTERISTICS

IV.2.1 CO emissions

The encoded values are utilized to formulate a second-order quadratic regression equation, employed to estimate CO as given in eqn (3).

$$CO = 0.05050 - 0.0035\,A - 0.0157\,B - 0.0046\,C - 0.0010\,D0 + .000239\,AB - 0.0009\,AC + 2.1932\text{-}05\,AD - 0.00125\,BC6 + 79151\text{-}05\,BD - 0.0002\,CD \quad (3)$$

Predictions for the response for specified levels of each element can be derived using the equation in terms of coded factors. The standard classification for the factors is +1 for elevated levels and -1 for diminished levels. To ascertain the relative significance of the factors, it is beneficial to compare their coefficients utilizing the coded equation.

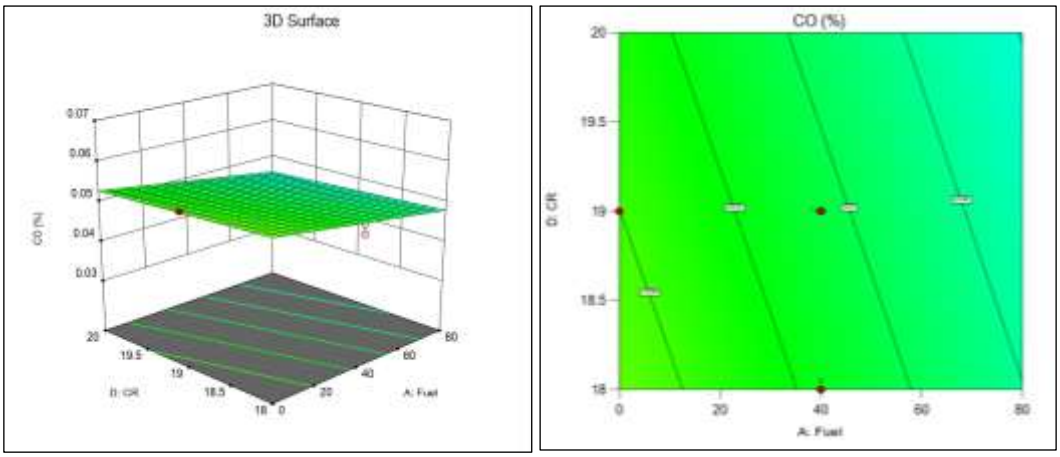

Figure 11: Three dimensional plot depicts the impact of fuel and CR and their combined impact on the CO emissions.
Source: Authors, (2026).

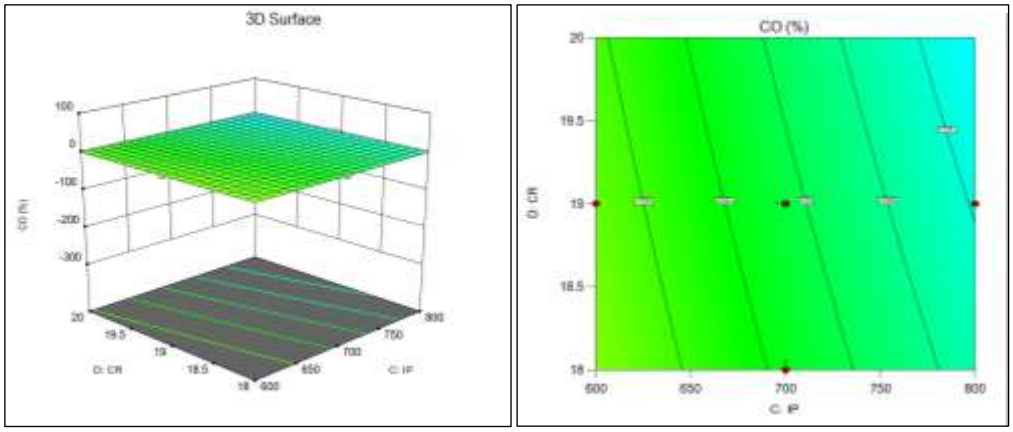

Figure 12: Three dimensional plot depicts the impact of IP and CR and their combined impact on the CO emissions.
Source: Authors, (2026).

The principal cause of carbon monoxide generation is the incomplete combustion of fuel. Figure 11 illustrates the changes in carbon monoxide for CR and nano fuel. The integration of nanoparticles reduced the carbon concentration due to complete burning. Metallic nanoparticles function as oxidation catalysts, transforming carbon monoxide into carbon dioxide during combustion. Metal nanoparticles also induced secondary atomization of the fuel. At elevated CR, the contour diagram indicated a decreased trend in CO emissions attributed to the augmented presence of nanoparticles. Figure 12's contour illustration depicts the impacts of CR and IP. In comparison to CR, IP exerts a more significant impact on CO emissions. To attain optimal air-fuel mixing, dispersion, penetration, and swirl ratio, the fuel was effectively atomized by elevating the injection pressure. CO emissions are significantly influenced by IP and CR. Figure 13 illustrates the significant impact of IP and nanoparticle concentration on CO emissions. The incorporation of nanoparticles into B25 lowers CO emissions. An optimal method to facilitate combustion is to augment the ratio of IP to nanoparticles. In another study, increasing tomato seed methyl ester content raised BTE, and NOx but reduced CO, smoke, and HC emissions across loads. TSME–n-butanol–diesel blends offer favorable emission and performance trade-offs [26]. Figure 14 illustrates the variation in CO with respect to load and TiO_2 content. As the load increases, both combustion temperature and pressure elevate, resulting in a higher ignition flame temperature and, consequently, enhanced combustion efficiency.

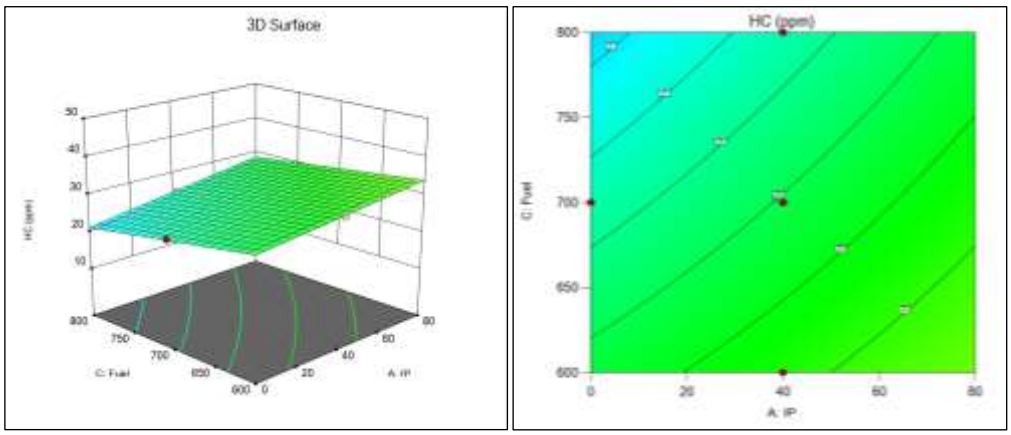

Figure 13: Three dimensional plot depicts the impact of IP and fuel and their combined impact on the CO emissions.
Source: Authors, (2026).

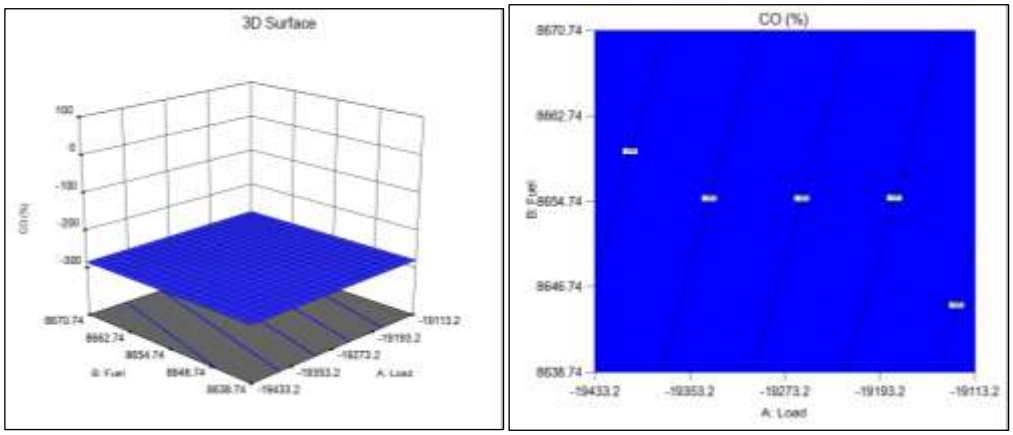

Figure 14: Three dimensional plot depicts the impact of load and fuel and their combined impact on the CO emissions.
Source: Authors, (2026).

IV.2.2 HC emissions

A second-order quadratic regression equation was created to estimate HC (utilizing the coded values), represented by equation (4).

$$HC = 28.16826\ 3.16471\ A14.+\ 73017\ B - 3.18461C0.4099\ D - 0.4195AB + 0.57291\ AC0.+\ 64735\ AD0 + .3800\ BC0.+\ 52447 + BD\text{-}0.1111\ CD \quad (4)$$

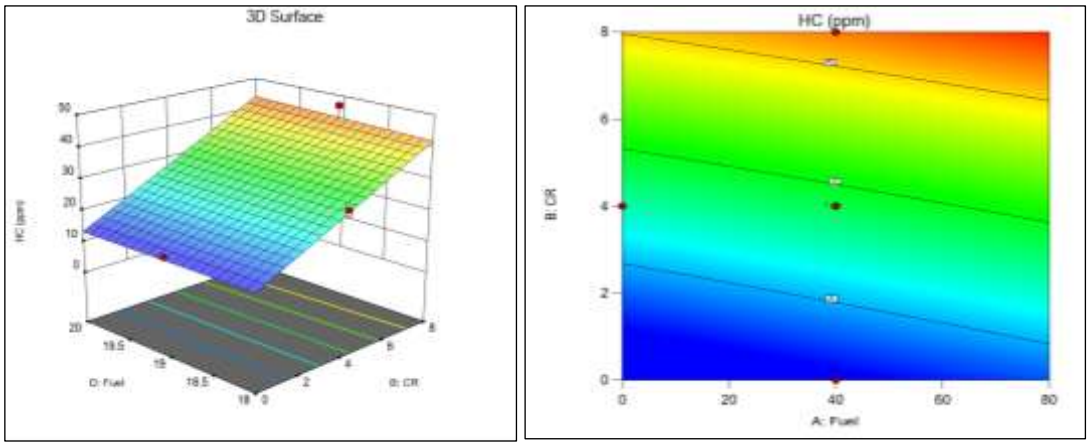

Figure 15: Three dimensional plot depicts the impact of CR and fuel and their combined impact on the HC emissions.
Source: Authors, (2026).

Elevated HC emissions result from incomplete combustion of fuel particles. At which load (4 kg) and pressure (700 bar) do the different nanoparticle concentrations in B25 and CR exhibit as HC. The outcomes are illustrated in Figure 15. Researchers found that augmenting the nanoparticle ratio resulted in a little increase in HC emissions. The large specific heat capacity of the nanoparticle is likely due to the unburned fraction of the charge being simulated. In comparison to alternative test fuels, biodiesel generated reduced hydrocarbon emissions, likely attributable to enhanced fuel ignition resulting from the elevated oxygen content in biofuel molecules. Figure 16 shows the impact of engine load and biodiesel nanoparticle ratio on hydrocarbon emissions. The presence of nanoparticles in biodiesel reduced the activation temperature of carbon and enhanced ignition, hence diminishing hydrocarbon emissions.

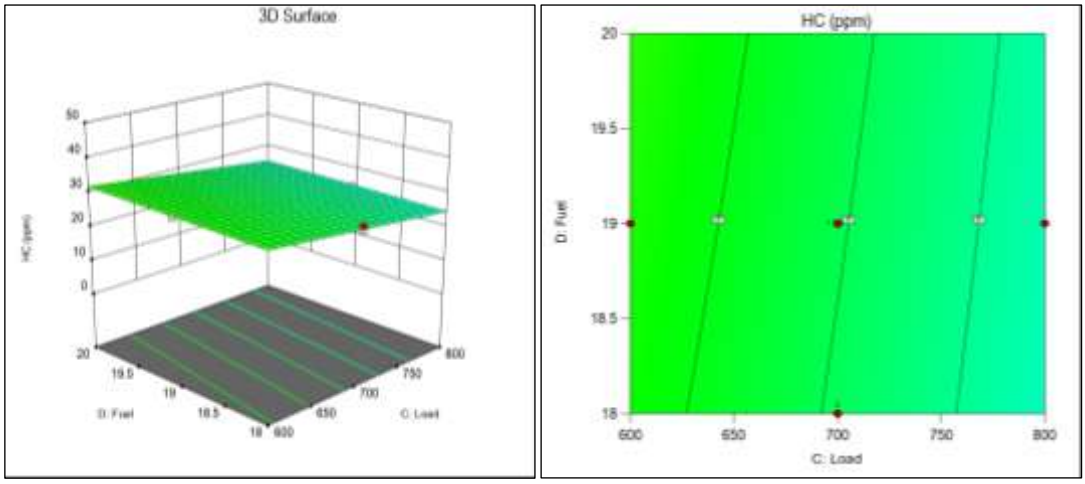

Figure 16: Three dimensional plot depicts the impact of load and fuel and their combined impact on the HC emissions.
Source: Authors, (2026).

The decrease in HC is attributed to improved fuel combustion resulting from increased IP, which facilitates optimal fuel atomization and reduces fuel droplet evaporation. Elevated compression ratios lowered HC emissions, which is advantageous for CR. An elevation in CR resulted in an increase in temperature, pressure, and flame velocity within the cylinder. Figure 17 indicated that HC emissions were reduced with increasing CR and IP. Due to the diminished flame speed during fuel ignition, flame quenching and insufficient ignition may elevate hydrocarbon levels. At elevated IP and CR, HC discharge diminished, as illustrated in Figure 17. Figure 18 illustrates the HC discharge with IP and fuel, with hold values recorded as CR (19) and load (4 kg). Consequently, an unforeseen reduction in HC levels was observed at elevated IP for the optimal nano ratio fuel ignition. A higher engine IP and biodiesel with increased nanoparticle content are effective parameters for reducing HC discharges. In another study, TiO_2 nanoparticle evaluated on Pongamia pinnata biodiesel in a single-cylinder diesel engine. TiO_2 addition improved BTE by 1.72% and BSFC by 3.57% compared to biodiesel alone, and reduced CO, HC, and NOx emissions, attributed to better atomization and oxidation from nanoparticle oxygen content [27].

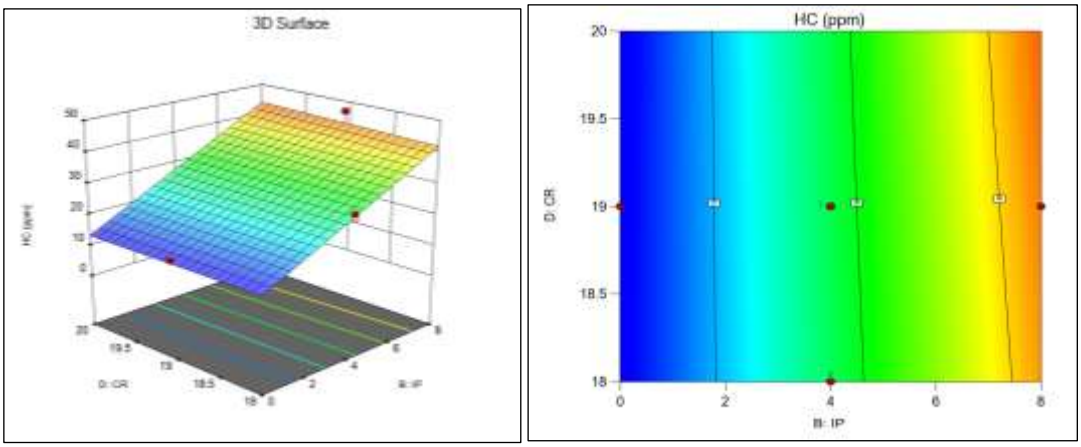

Figure 17: Three dimensional plot depicts the impact of CR and IP and their combined impact on the HC emissions.
Source: Authors, (2026).

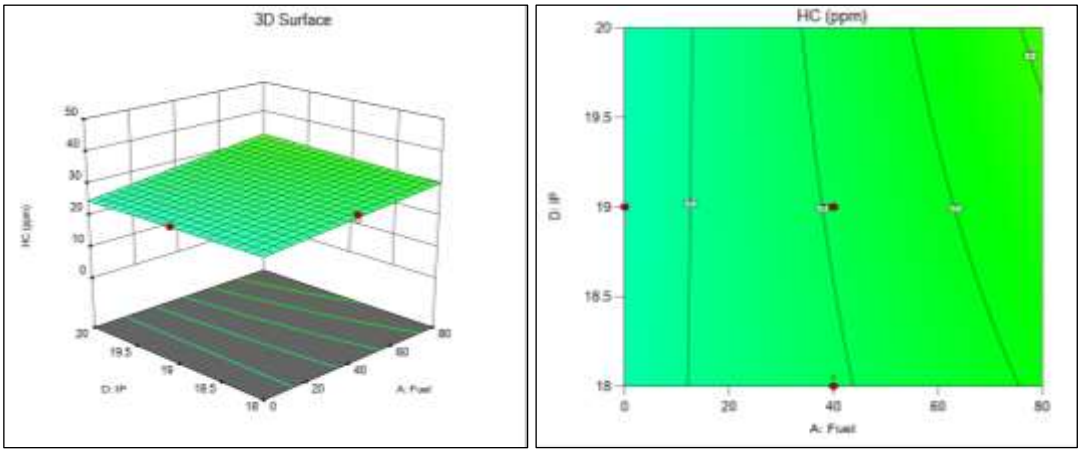

Figure 18: Three dimensional plot depicts the impact of fuel and IP and their combined impact on the HC emissions.
Source: Authors, (2026).

IV.2.3 NOx emissions

The result of the NOX estimation procedure is Equation (5), a second-order quadratic regression equation utilizing the coded values.

$$NOx = 409.8483\ 24.035\ A293 + .7823\ B112 + 4863\ C36 + .6979\ D10 + 0723\ AB8 + 6214\ AC10 + 33490\ AD0 + 43936\ BC3 + 1528\ BD - 4.4590\ CD \quad (5)$$

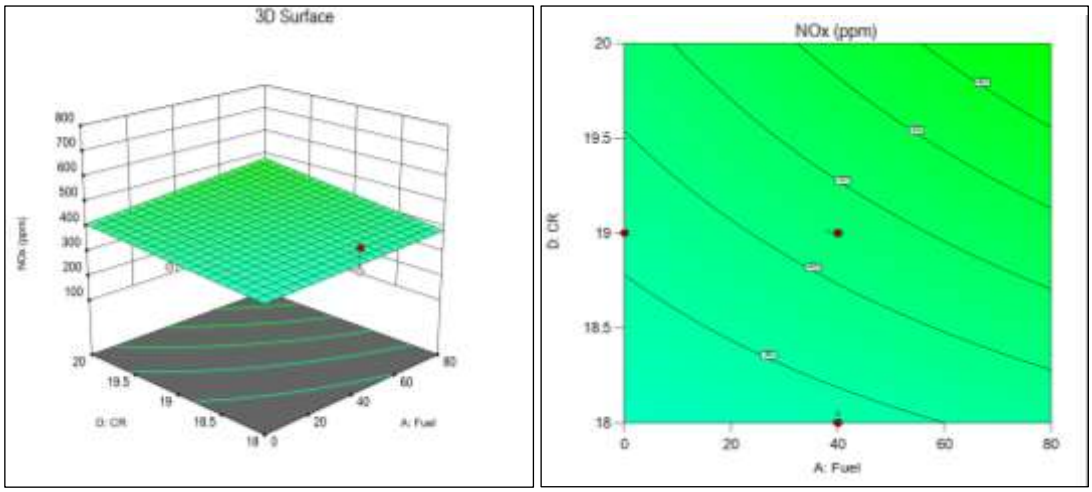

Figure 19: Three dimensional plot depicts the impact of fuel and CR and their combined impact on NOx emissions.
Source: Authors, (2026).

The combustion of biodiesel at elevated temperatures generates significant quantities of nitrogen oxides (NOx) due to its increased oxygen content. Figure 19 illustrates nitrogen oxide emissions associated with nano biofuel and CR. The rise in NOx emissions with CR may be due to elevated in-cylinder combustion pressure and temperature. Figure 20 illustrates that withhold values of load (4 kg) and injection pressure (700 bar), NOx emissions escalate at elevated compression ratios.

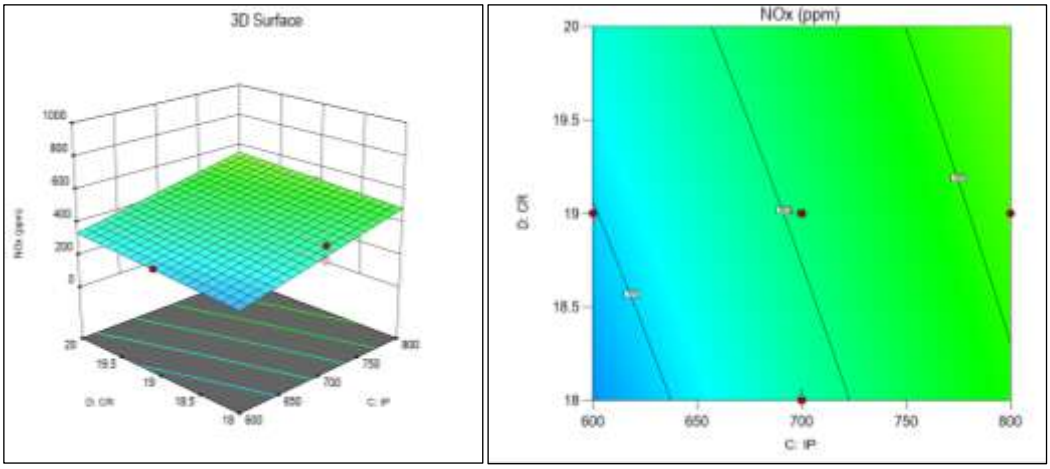

Figure 20: Three dimensional plot depicts the impact of IP and CR and their combined impact on NOx.
Source: Authors, (2026).

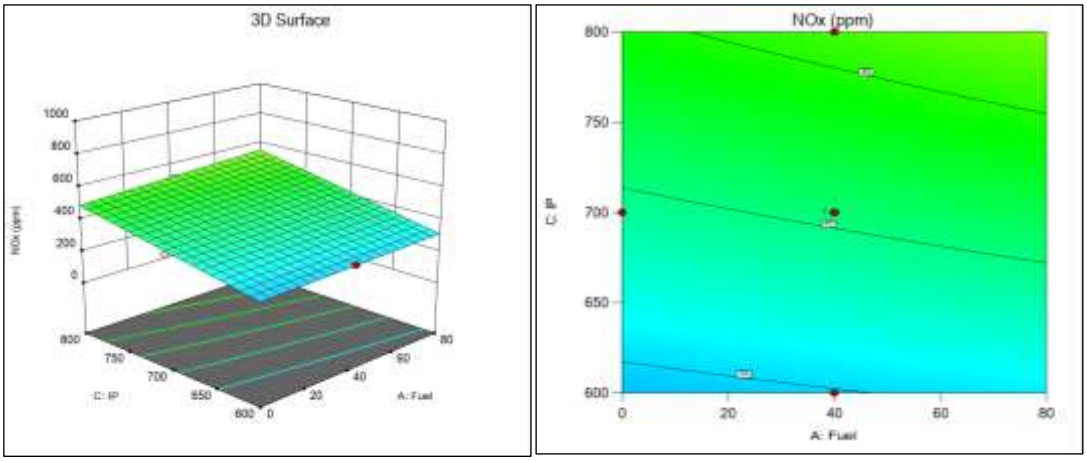

Figure 21: Three dimensional plot depicts the impact of fuel and IP and their combined impact on NOx emissions.
Source: Authors, (2026).

The contour figure indicates that increases in engine load and compression ratio corresponded with elevated NOx emissions. Figure 21 illustrates the variation of NOx emissions in relation to nano fuel and load. Figure 22 illustrates the variation of NOx emissions with varying injection pressures and nanoparticle concentrations in B25. In comparison to B25, the TiO_2 fuel blend exhibited elevated NOx emissions. Oxygenated nanoparticles improve combustion and reduce the ignition delay, since a higher ratio of nanoparticles facilitates rapid premixed ignition, elevates the burning temperature, and increases NOx emissions. In previous study, 20% *Chlorella* biodiesel blends compared with TiO_2 nanoparticle enhancements (50–150 ppm) at CRs 17–18. The D80CvBD20$TiO_2$100 blend achieved peak CP of 63.45 bar at CR 18 and reduced unburnt hydrocarbons by up to 13%. TiO_2 increased NOx but reduced CO due to higher combustion temperatures and oxygen availability [28].

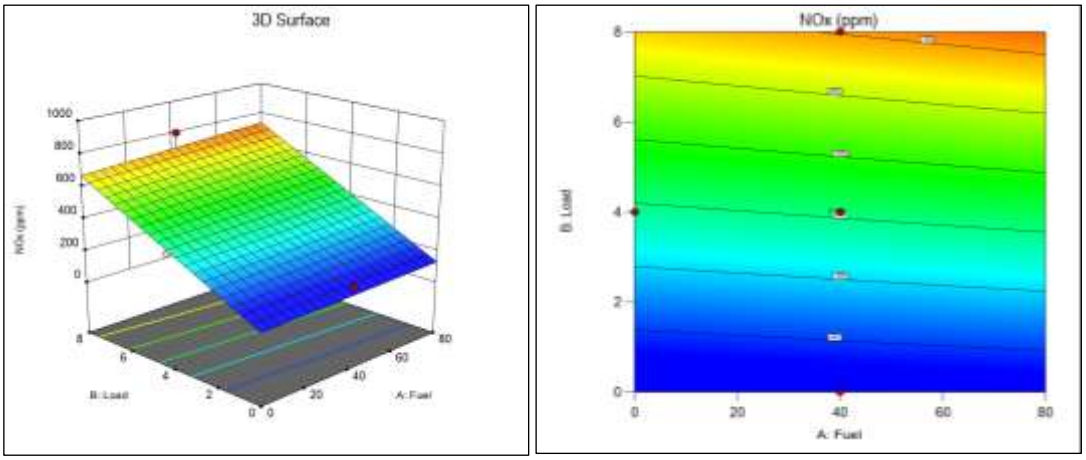

Figure 22: Three-dimensional plot depicts the impact of fuel and load and their combined impact on NOx.
Source: Authors, (2026).

V. CONCLUSION

This study examines the impact of various engine operating parameters on performance metrics (BTE and SFC) and emissions (CO, HC, and NOX). The parameters being examined are load, IP, CR, and the concentration of nanoparticles in biodiesel. The responses of the CRDI VCR diesel engine are optimized for each engine input parameter through response surface approach. A numerical model was developed to analyze the BTE, BSFC, CO, HC, and NOx emissions from the engine. Findings from optimization and variance analysis indicate that RSM is an effective method for refining diesel engine performance across various input parameters. The calculated R^2 values for BTE, SFC, CO, HC, and NOX emissions are 0.8990, 0.7445, 0.9016, 0.9859, and 0.9643, respectively. These figures can be accepted with confidence. The ideal input engine parameter, found by RSM, is a 50.47 nanoparticle/B25/CR/790.9 bar IP mixture operating at a 3.63 kg engine load. Moreover, for the most thoroughly examined engine inputs, the optimal values of BTE, SFC, CO, HC, and NOX are 22.46%, 0.25 kg/kWh, 23%, 22.01 ppm, and 536 ppm, respectively. Consequently, the model possesses a robust statistical base. Experimental trials indicate that errors fall within an acceptable range, and comparative analysis of RSM optimizes value. Thus, engine performance and emissions can be improved by employing the ideal value. This study's results indicate that biodiesel augmented with TiO_2 nanoparticles may serve as a cleaner and more efficient alternative fuel for engines.

PI Controller,
Fuzzy Logic Controller (FLC)

ABSTRACT

Indirect vector control of induction motor (IM) drives operates on the principle of decoupling the stator current into independent torque and flux-producing components. This paper presents the implementation of a Fuzzy Logic Control (FLC) scheme for an IM, based on its dynamic d-q model. An intelligent Fuzzy Logic Controller is designed using a knowledge-based rule set to achieve robust and efficient drive control. The performance of the proposed FLC is rigorously compared against a conventional fixed-gain Proportional-Integral (PI) controller. Key performance metrics include settling time and the dynamic response to sudden load disturbances. Furthermore, the harmonic spectrum of the output current is evaluated for both control strategies. The steady-state performance of the IM drive is analyzed, and comparative results are presented to demonstrate the superiority of the fuzzy logic-based approach.

I. INTRODUCTION

For over a century, induction motors (IMs) have been a cornerstone of industrial electromechanical conversion due to their exceptional simplicity, rugged construction, and high efficiency. The invention of this asynchronous machine significantly propelled the transition from direct current (DC) to alternating current (AC) systems in the generation, transmission, and distribution of electrical energy. A primary advantage of the induction motor is the absence of sliding electrical contacts, which results in a robust and maintenance-friendly design[1]. Despite decades of research into efficient speed control methodologies for induction motors, solutions available until recent years remained unsatisfactory, often compromising on complexity, cost, efficiency, or dynamic performance.

The advancement of semiconductor technology over the past two decades has provided the necessary impetus, making static frequency converters economically viable and enabling widespread adoption of adjustable-speed drives for numerous applications. Control complexity presents a fundamental challenge. Separately excited DC drives benefit from independent control of flux and torque, leading to a relatively simple control structure [2]. In contrast, induction motors require the coordinated, nonlinear control of both the magnitude and phase of the stator current. This complexity can be mitigated through vector control, or field-oriented control (FOC). This technique resolves the stator flux linkages onto a rotating reference frame, effectively decoupling the flux and torque-producing components.

By requiring the instantaneous position of the flux linkages, FOC enables control of the AC induction motor that is analogous to the control of a separately excited DC motor. Conventional drive systems typically employ fixed-gain Proportional-Integral (PI) controllers .However, these controllers exhibit significant limitations, including sensitivity to parameter variations and poor disturbance rejection, often resulting in prolonged settling times following load transients. Consequently, numerous adaptive control techniques have been proposed to enhance robustness and performance[3]. In recent years, fuzzy logic control (FLC) has emerged as a powerful methodology for managing complex, nonlinear systems. Fuzzy set theory has fostered active and fruitful research, leading to its successful application in motor control.

Prior works present comprehensive surveys of FLC and describe general methodologies for its construction and performance assessment. Furthermore, discusses comprehensive procedures and guidelines for defining input parameters and constructing fuzzy logic rule bases. Additional methodologies for the design and theoretical analysis of FLCs are proposed in including explanations of the relationship between control resolution and the fuzzification of variables, as well as guidance for designing and tuning scaling gains[4]. In this context, the present paper proposes the design and implementation of an intelligent controller based on Fuzzy Logic for induction motor drives. The principal advantage of an FLC is its independence from a precise mathematical model of the plant; instead, it leverages a foundation of IF-THEN linguistic rules derived from expert knowledge and operational experience[5].

II. INDUCTION MOTOR MODELING

The dynamic analysis and modeling of rotating field machines are underpinned by well-established theoretical frameworks. This work considers a standard induction motor model characterized by a uniform air gap and a sinusoidally distributed magnetomotive force (mmf). For analytical simplicity, the effects of magnetic saturation and variations in machine parameters are neglected.The dynamic model of the induction motor is developed using a reference frame transformation. The three-phase electrical quantities (abc-frame) are transformed into an equivalent two-phase system within a direct and quadrature (d-q) rotating reference frame. This transformation is derived based on the principle of power invariance, which necessitates that the total power calculated in the two-phase model must be identical to that of the original three-phase system.The magnetomotive forces (mmfs) along the d and q axes are obtained by mathematically resolving the mmfs of the three stator phases onto these orthogonal axes. The formal mathematical relationship governing the transformation between the d-q axes currents and the a-b-c phase currents is given as follows:

$$i_{ds} = \frac{2}{3} V_d \left(i_{as} - \frac{i_{bs}}{2} - \frac{i_{cs}}{2}\right) \tag{1}$$

$$i_{qs} = \frac{1}{\sqrt{3}} \left(i_{cs} - i_{bs}\right) \tag{2}$$

Where ias, ibs and ics are the three phase currents and Vd is the dc link voltage at the inverter input. These equations are also applicable to the voltage and flux linkage transformation Applying this transformation to the three phase quantities . The electrical model of the induction motor is expressed by the matrix equation (3) in stationary reference frame.

$$\begin{pmatrix} v_{ds} \\ v_{qs} \\ v_{dr} \\ v_{qr} \end{pmatrix} = \begin{pmatrix} R_s + L_s p & 0 & L_m p & 0 \\ 0 & R_s + L_s p & 0 & L_m p \\ L_m p & \omega_r L_m & R_r + L_r p & \omega_r L_r \\ -\omega_r L_m & L_m p & -\omega_r L_r & R_r + L_r p \end{pmatrix} \begin{pmatrix} i_{ds} \\ i_{qs} \\ i_{dr} \\ i_{qr} \end{pmatrix} \tag{3}$$

Where vds, vqs, ids, iqs Rs, Ls, Rr, Lr, Lm and θr are the d-q axes voltages and currents, stator resistance, stator inductance, rotor resistance, rotor inductance, mutual inductance betweenthe stator and rotor windings and the rotor position respectively. The stator and rotor flux linkages in the synchronous reference frames are defined as:

$$\Phi_s = L_s \bar{I}_s + L_m \bar{I}_r$$
$$\Phi_r = L_r \bar{I}_r + L_m \bar{I}_s \tag{4}$$

Where Ψ_s, Ψ_r, I_s and I_r are the stator and rotor flux-linkage Space vector and the stator and rotor current space vector, all in stationary reference frame. The electromagnetic torque obtained from machine flux linkages and currents is as:

$$T_e = \frac{3}{2}\frac{P}{2} L_m \left(i_{qs} \Phi_{dr} - i_{ds} \Phi_{qr}\right) \tag{5}$$

Where Te, P, Φdr, Φqr are the electromagnetic torque, number of poles, rotor d-q axes fluxes respectively. The Electromagnetic dynamic equation describing the mechanical model of the induction motor is given by:

$$T_e = J \frac{\omega_n}{dt} + T_l + B\omega_n \tag{6}$$

Where J, T1, B, ωm are the moment of inertia of motor and Load , the load torque, the friction coefficient and the mechanical speed. The equations (3) and (6) form the mathematical model equations of a three phase induction motor.

II.1 INDIRECT VECTOR CONTROL

The structure of the indirect vector control method is illustrated in Figure 1. In contrast to the direct vector control approach, this method operates as a feedforward control scheme, as it relies on the indirect estimation of the slip speed for field orientation

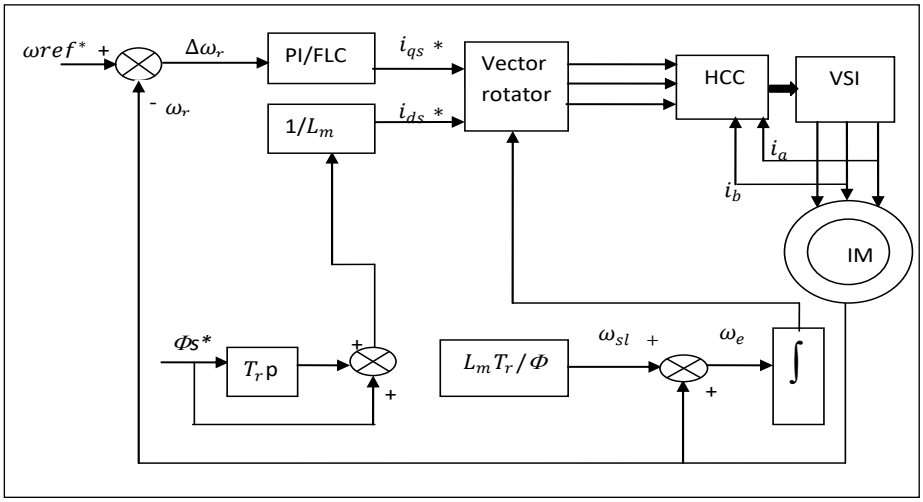

Figure 1: Indirect Vector Control Scheme.
Source: Authors, (2026).

The speed error, with the help of a PI controller or any other intelligent controller, is converted into a torque controlling current component iqs*, of the stator current. This current component t is used to regulate the torque along with the slip speed

$$i^*_{qs} = k_p \Delta\omega_r + k_i \int \Delta\omega_r dt \tag{7}$$

Similarly the flux producing current component ids*, is obtained from the stator flux linkage reference value and is given by the following equation:

$$\Phi^*_s = \frac{R_r L_m}{R_r + Lp} i^*_{ds} \tag{8}$$

$$T_e = \frac{3}{2}\frac{P}{2}\frac{L_m}{L_r}\Phi^*_s i^*_{qs} \tag{9}$$

$$\omega_{sl} = \omega_e - \omega_r = \frac{R_r}{L_r}\frac{i^*_{qs}}{i^*_{ds}} \tag{10}$$

The slip speed, together with the feedback rotor speed, is integrated to obtain the stator reference flux linkage space vector position θe.

$$O_e = \int (\omega_{sl} + \omega_r) dt \tag{11}$$

The position of the stator flux space vector is utilized to transform the two-phase direct and quadrature (d-q) axis current components back into three-phase quantities. These transformed currents serve as the reference command signals. The actual three-phase currents measured from the induction motor are continuously compared against these reference values. The resulting current errors are processed by two-level hysteresis band controllers. The hysteresis controllers regulate the motor currents by constraining them within a predefined hysteresis band. This control strategy ensures the machine achieves its required dynamic performance. Furthermore, the flux reference is maintained constant at its rated value for operation up to the base speed of the motor.

III. FUZZY LOGIC CONTROLLER

Fuzzy Logic implementation requires no exact knowledge of A model. The block diagram implementation of a FLC is shown in Figure 2. It involves the use of the concept of fuzzy subset and rule based modeling. By permitting certain amount of imprecision, complex solutions are modeled with ease[6].

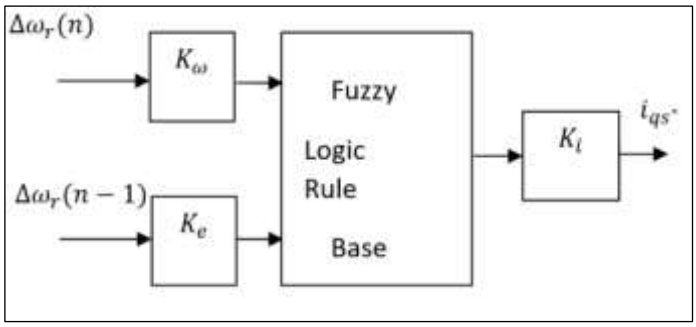

Figure 2: Fuzzy Logic Based Controller block.
Source: Authors, (2026).

III. 1 CONCEPT OF FUZZY LOGIC

The idea of formulating the control algorithms by logical rules introduced the implementation of human understanding and human thinking in control algorithms. The lack of analytical description makes the fuzzy control conceptually different from conventional control [7-9]. One defines a subset with the aid of a characteristic function which describes membership in the subset. Let X be the universe of discourse and let S b e a subset of X. The characteristic function associated with S is a mapping

$$f_s: X \rightarrow \{0,1\} \tag{12}$$

In the framework of fuzzy set theory the characteristic function is called the membership function associated with the fuzzy subset A. A fuzzy logic controller is describe d by a knowledge-based system consisting of IF. THEN rules with vague predicates and a fuzzy logic inference mechanism. The present fuzzy logic controller adopted is of the Mamdani Controller type[10].The speed error and the change in the speed error are given as inputs to the FLC. The torque producing current component t is the output. A knowledge rule base which simulates the performance of the system is defined. The rule base acts upon the inputs to produce the given outputs.

III. 2 CONCEPT MEMBERSHIP FUNCTION

The Fuzzy Logic Controller initially converts the crisp error and change in error variables into fuzzy variables and then are mapped into linguistic labels. Membership functions are associated with each label consists of two inputs and one output. The linguistic labels are divided into seven groups. They are:NH-negative high, N-Negative, NL-negative low, Z-zero, PL-positive low, P-positive, PH-positive high. Each of the Inputs and the output contain membership functions with all these seven linguistics. This method of formulation of control algorithms allows implementing heuristic strategies [11-14]. A straightforward source of deriving the linguistic control strategies are human experience and understanding, which essentially contain the model of the control system in an implicit form.

III. 3 CONCEPT KNOWLEDGE RULE BASE

The mapping of the fuzzy inputs into the required output is derived with the help of a rule base as given in Table 1. Each rule of the FLC is characterized with an IF part, called the antecedent, and with a THEN part called the consequent. The antecedent of a rule contains a set of conditions and the consequent contains a conclusion. If the conditions of the antecedents are satisfied, then the conclusions of the consequent apply. Considering the first rule, it can be interpreted as: IF change in speed error is NH and change is speed is NH, THEN the output will be NH.

Table 1: Knowledge Rule Base.

E / CE	NH	N	NL	Z	PL	P	PH
NH	NH	NH	NH	NH	NL	NL	Z
N	NH	NH	N	N	N	Z	PL
NL	NH	N	NL	NL	Z	PL	P
Z	NH	N	NL	Z	PL	P	PH
PL	N	NL	Z	PL	PL	P	PH
P	NL	Z	PL	P	P	PH	PH
PH	Z	PL	P	PH	PH	PH	PH

Source: Authors, (2026).

III. 4 DEFUZZIFICATION

Generally the output obtained is fuzzy in nature and has to be Converted into a crisp value by using any Defuzzification technique.

IV. RESULTS AND DISCUSSIONS

In the following, we will present the results of the essential parameters of our machine, we will be particularly interested in the currents of the machine as well as the torque and the speed to highlight the efficiency of our fuzzy controller compared to a classic PI controller. The current response of the machine for both case i.e. PI and FLC is presented in the Fig.3 and Fig.4

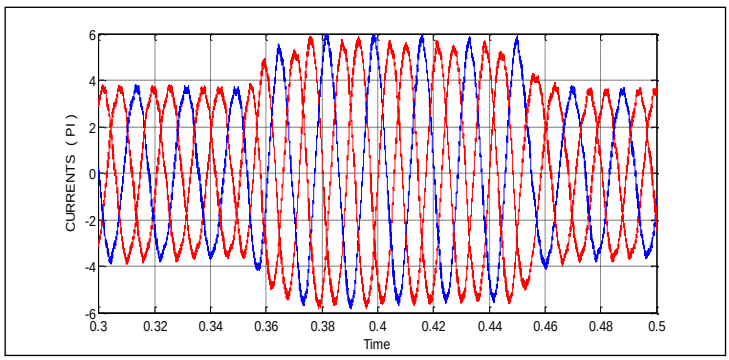

Figure 3: Stator currents response for PI.
Source: Authors, (2026).

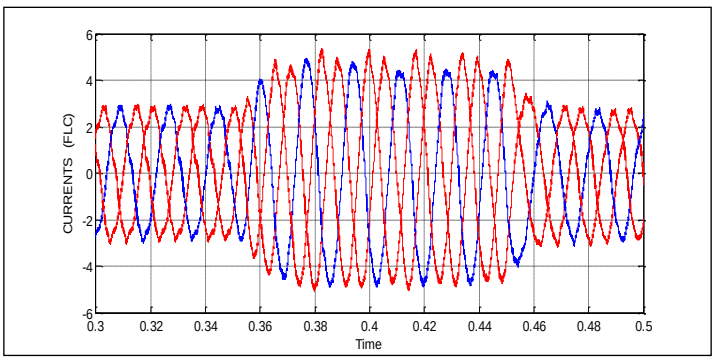

Figure 4: Stator currents response for FLC.
Source: Authors, (2026).

Figure 3, 4 presents a comparative analysis of the machine's current response under both Proportional-Integral (PI) and Fuzzy Logic Control (FLC) schemes. The graphical results clearly indicate that the FLC strategy exhibits significantly greater robustness to load disturbances compared to the conventional PI controller. The torque response for both cases of classical controllers is shown simultaneously in Figure 5.

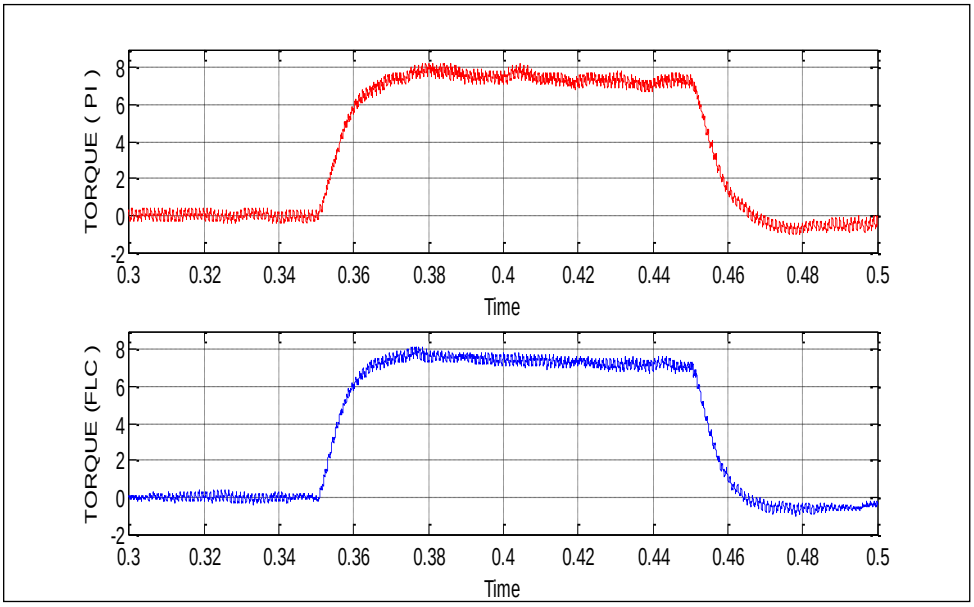

Figure 5: Torque response for PI and FLC.
Source: Authors, (2026).

The waveform indicates that the Fuzzy Logic Controller (FLC) achieves a significant reduction in current ripple and a markedly quicker dynamic response to load transients compared to the PI controller. Figure 6 (a,b) shows the speed response for both PI and fuzzy controllers.

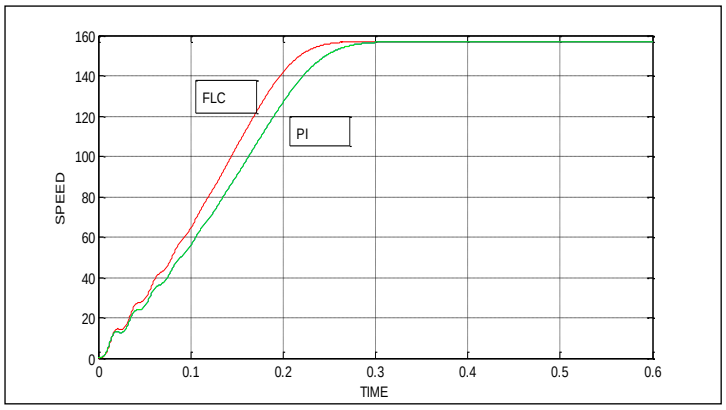

Figure 6 (a): Speed response for PI and FLC.
Source: Authors, (2026).

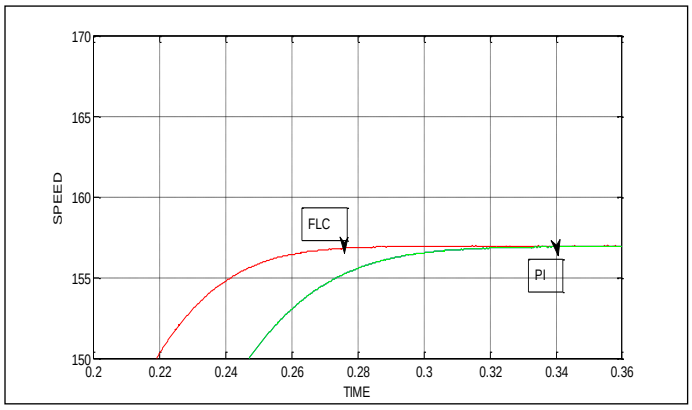

Figure 6 (b): Speed response for FLC (0.275sec) and PI(0.34sec).
Source: Authors, (2026).

When a load is applied at 0.35 sec the speed response for Both controller are as shown in Fig.6 (c),

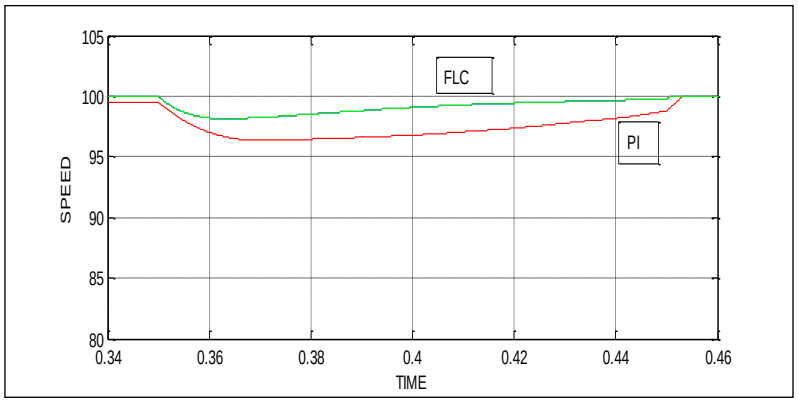

Figure 6 (c): Speed response for FLC and PI with andWithout load impact .
Source: Authors, (2026).

The dynamic response to a load torque application at t = 0.35 s is detailed in Fig. 6(c). This analysis confirms that the FLC strategy results in a smaller speed deviation and a quicker recovery compared to the PI controller.

V. CONCLUSIONS

This paper presents the implementation of a Fuzzy Logic Controller (FLC) for an indirect vector-controlled induction motor drive. The drive system was simulated using both a conventional Proportional-Integral (PI) controller and the proposed FLC to facilitate a comparative analysis. The performance of both controllers was evaluated and compared under dynamic operating conditions. Simulation results demonstrate that the FLC-based strategy achieves a significantly faster settling time and superior overall performance compared to the PI controller.

ABSTRACT

The economic dispatch problem aims to minimize total generation costs while maintaining a balanced power allocation in the electrical power system. This paper introduces a new algorithm called the Self-Adaptive Momentum Orca Predation Algorithm (SAMOPA), the first variant of OPA that integrates an adaptive momentum mechanism to solve the economic dispatch problem. This integration enhances the balance between exploration and exploitation, accelerates the convergence process, and reduces the risk of getting stuck in local solutions. SAMOPA was tested on three economic dispatch scenarios with 6, 15, and 40 power plants. In the 6-unit system, SAMOPA achieved the best cost of 15275.9304 dollars with a standard deviation of 2.54E-06, lower than OPA's deviation of 0.0029. SAMOPA's computation time was also faster, at 0.27 seconds compared to OPA's 0.9751 seconds. For the 15-unit system, SAMOPA reduced total generation costs by 0.17 percent compared to OPA. For a 40-unit system, SAMOPA achieves the best cost of 119,369.57 dollars, which is 0.58 percent lower than the best result from OPA. The consistency of SAMOPA's performance is also demonstrated in the Economic Dispatch case with nonlinear valve-point effects and in the CEC 2020 benchmark function, which includes unimodal, hybrid, and composition categories. Statistical validation using the Wilcoxon signed-rank test indicates that SAMOPA exhibits significantly better convergence behavior and solution consistency compared to the comparison method. These results confirm that SAMOPA is an effective and reliable new contribution to solving complex and large-scale economic dispatch problems.

I. INTRODUCTION

Optimization challenges, particularly Economic Dispatch (ED), aim to minimize the operational costs of power plants while ensuring efficient power distribution [1][2]. ED allocates power among generating units while considering operational and technical constraints [3][4]. Due to its non-linear and complex characteristics, ED remains difficult to solve using gradient-based methods, especially in large-scale systems with multiple decision variables. Consequently, metaheuristic algorithms such as Particle Swarm Optimization (PSO) [5][6][7], Bat Algorithm [8], Grey Wolf Optimizer (GWO) [9][10], and Whale Optimization Algorithm (WOA) [11] have emerged as more flexible and efficient alternatives [12]. Table 1 summarizes various algorithm types, their strengths and weaknesses, and their effectiveness across conventional, artificial intelligence (AI)-based, and hybrid approaches to ED problems.

Table 1: Comparison of Recent Approaches for Economic Dispatch.

Approach Type	Representative Methods	Strengths	Weaknesses	Performance Metrics
Conventional [13]	Lambda Iteration, Newton's Method, Interior Point Method, Quadratic Programming	Simple, efficient for small systems, fast implementation	Not effective for large-scale and nonlinear systems	Computational efficiency, solution accuracy
AI-Based [13]	Artificial Neural Networks, Fuzzy, Deep Learning, Reinforcement Learning	Adaptive, capable of handling complex systems, suitable for real-time use	Prone to overfitting, requires large datasets and parameter tuning	Prediction accuracy, generalization ability
Hybrid [13]	PSO+ANN, Fuzzy+Genetic Algorithm, Metaheuristic Hybrid	Combines the strengths of two methods, provides better solutions	Complex implementation and design, more difficult parameter tuning	Computational time, solution quality
Machine Learning -Based [14]	ML-optimized Droop Control	Minimizes generation cost and power loss simultaneously, no central communication needed	Requires model training, sensitive to training data quality	Generation cost, power loss, system stability

Source: Authors, (2026).

Despite substantial advancements in traditional and AI-based optimization methods, these approaches remain limited in accuracy, computational efficiency, and robustness when addressing nonlinear and large-scale challenges. Hybrid AI–physics approaches, which combine machine learning models such as neural networks with classical optimization techniques like PSO or evolutionary algorithms, have gained significant traction in power system applications [15][16][17]. Although effective in handling non-linearity and system complexity, these hybrid methods often demand significant computational resources. To address this gap, this study proposes the Self-Adaptive Momentum Orca Predation Algorithm (SAMOPA), which introduces a new self-adaptive momentum mechanism into the original Orca Predation Algorithm (OPA) framework. This study is the first to combine adaptive momentum strategies, originally proposed by Polyak (1964), to accelerate convergence in gradient-based methods in OPA to solve ED problems [18][19][20]. SAMOPA improves convergence speed, computational efficiency, and solution stability by dynamically adjusting the movement of search agents based on historical progress. Unlike previous OPA variants that improve solution quality through Levy flight or opposition-based learning but incur higher computational costs [21], SAMOPA achieves better cost reduction and faster execution time with minimal additional complexity. Specifically, empirical results show that SAMOPA reduces total generation costs by up to 0.58%, accelerates convergence time by over 70% compared to OPA, and maintains stable performance in ED scenarios with 6, 15, and 40 unit system.

The main contributions of this paper are as follows:

1. Proposal of SAMOPA, a new OPA variant with a self-adaptive momentum update rule tailored to enhance convergence behavior in solving ED problems.
2. Comprehensive benchmarking against six popular algorithms, OPA, PSO, Bat Algorithm, GWO, WOA, and CMA-ES, on ED test cases of increasing complexity.
3. Quantitative validation of improvements in terms of cost reduction, solution robustness, and computational efficiency.
4. Demonstration of SAMOPA's consistent performance in economic dispatch scenarios with nonlinear valve-point effects, as well as on the CEC 2020 benchmark functions covering unimodal, hybrid, and composition categories.
5. Statistical validation through the Wilcoxon signed-rank test confirms that SAMOPA exhibits significantly better convergence behavior and solution consistency compared to the benchmark algorithms.

The remainder of this paper is structured as follows: Section 2 outlines the research methodology, including the ED problem formulation, the SAMOPA algorithm, and the experimental setup. Section 3 presents the results and comparative analysis, while Section 4 concludes the study and suggests directions for future research.

II. MATERIALS AND METHODS

II.1 SELF ADAPTIVE MOMENTUM ORCA PREDATION ALGORITHM

The original OPA, developed by, is a metaheuristic inspired by the hunting strategies of orca whales, consisting of a chase phase and an assault phase. The algorithm updates the orca's position based on probabilistic rules; however, it is prone to excessive oscillation and premature convergence, especially during early iterations or near the global optimum [22][23]. To address these limitations, SAMOPA introduces a momentum-based enhancement in the chase phase, enabling the search agent to retain directional information from previous iterations. This adjustment improves search stability and promotes more focused exploration [24]. The computational speed of the solution at iteration is defined as equations (1) and (2):

$$v^t_{chase\ 1,i} = m * a\left(dx^t_{best} - F(bM^t + cx^t_i)\right) \quad (1)$$

and

$$v^t_{chase\ 2,i} = m * (ex^t_{best} - x^t_i) \quad (2)$$

Let t denote the number of cycles, $v_{chase\,1,i}^{t}$ represent the chasing speed, M signify the average position of the orca group, x_i^t indicate the position of the orca, the orca with the highest fitness value is marked as x_{best}^{t}, while $a, b,$ and d are random variables within the interval [0,1]. Additionally, e is a random variable within the interval [0,2] and F equals 2. The dynamic modification of m, a momentum component, ensures a balance between exploration and exploitation [25]. Equation (3) articulates this modification:

$$m = m_0 \cdot (1 - \alpha \cdot t) \tag{3}$$

where m_0 represents the initial momentum, valued at 1. The initial momentum value should guarantee optimal exploration in the early phases. α denotes the momentum decay rate of 0.05. The momentum parameter $m_0 = 1$ is employed to augment the algorithm's exploration capacity during the initial phase by leveraging the agent's historical movement data. The decay rate $\alpha = 0.05$ progressively diminishes this influence over time, so facilitating a seamless shift from the exploration to the exploitation phase. This adaptive modification maintains solution diversity in the initial phase and enhances convergence in the final phase. Various combinations of α $(0.01, 0.03, 0.05, \text{and } 0.1)$ and m_0 $(0.5, 1.0, \text{and } 1.5)$ have been evaluated on multiple small-scale economic dispatch problems, with the chosen combination yielding the highest consistent convergence rate and solution quality. This methodology aligns with the DEMON strategy proposed by [26], which demonstrated that progressive momentum decay enhances outcomes by stabilizing parameter updates in the later phase while maintaining flexibility in the initial phase. Adding adaptive momentum to SAMOPA speeds up the search for the best solution, avoids local stagnation, and keeps exploration stable over many iterations. This leads to more accurate and effective solutions, especially for big optimization problems like Economic Dispatch.

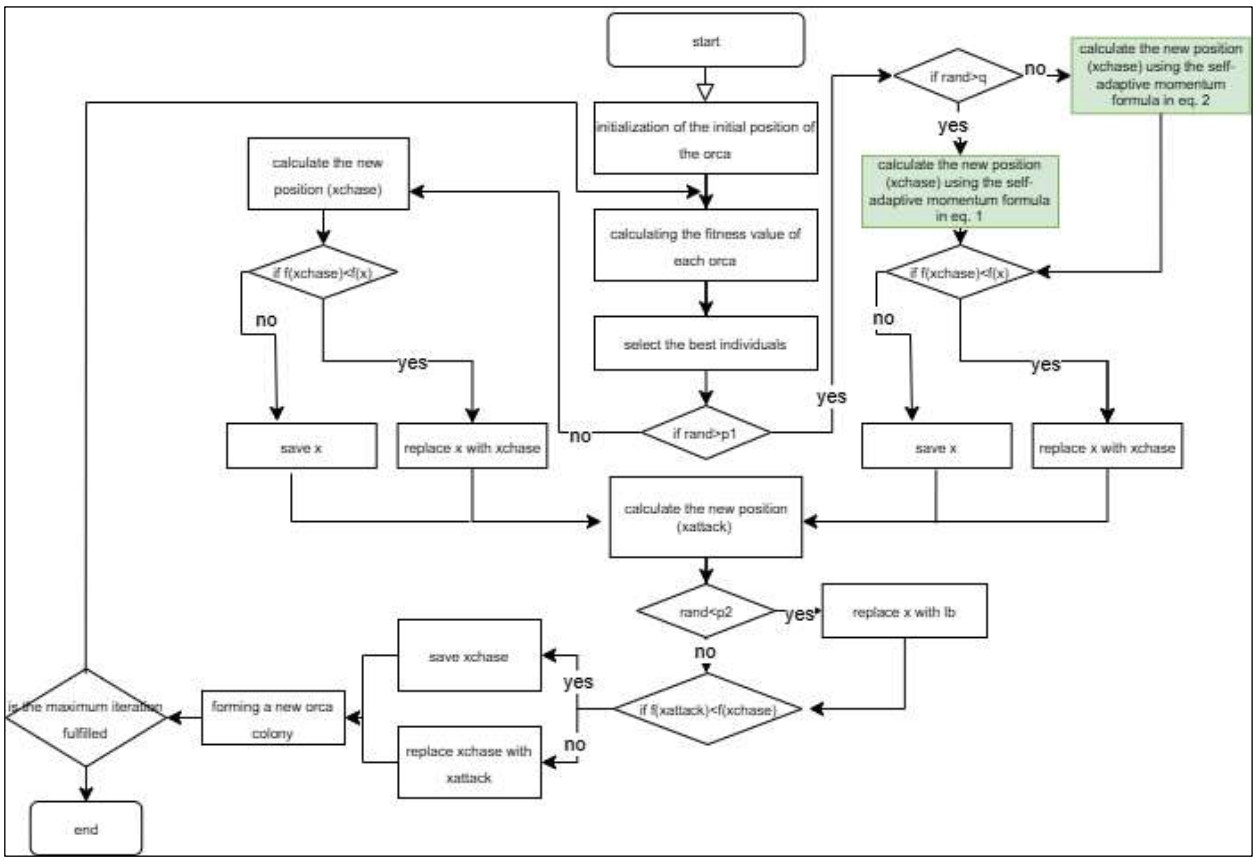

Figure 1: Flowchart of SAMOPA.
Source: Authors, (2026).

The flowchart of SAMOPA in Figure 1 begins with the initialization of the initial position of the orca using a uniform distribution, followed by the calculation of fitness values to determine the best individuals. Based on random values compared to a certain threshold, the system will choose whether to pursue a pursuit strategy or an attack strategy. If the pursuit strategy is chosen, adaptive momentum is used to maintain the direction of change from the previous iteration, making exploration more stable and focused. After evaluation, the new position is saved if it is better than the previous one. If the termination criteria have not been met, the process continues with the formation of a new colony, and iterations continue until the optimal solution is achieved. The combination of these two strategies allows the modified algorithm to achieve more efficient and effective optimization results.

II.2 ECONOMIC DISPATCH PROBLEM FORMULATION

ED is a fundamental optimization problem in power systems that aims to allocate generation output among multiple units in a cost-efficient manner [27]. It is typically formulated as a mathematical model that characterizes the relationship between each unit's power output and its associated operating cost. The total generation cost is commonly modeled as a quadratic function, as defined in Equation (4):

$$F_{Total} = \sum_{i=1}^{n} (a_i P_i^2 + b_i P_i + c_i) \quad (4)$$

In this equation, F_{Total} signifies the total operational cost in currency units per hour, while P_i indicates the output power of the i-th power plant in megawatts (MW). Parameters a_i, b_i, c_i represent the operational cost coefficients for each plant, whereas N denotes the total number of plants involved [13]. The primary challenge in ED is to minimize overall operational costs while adhering to diverse technological and operational restrictions. To ensure physical feasibility, the ED problem must comply with two main types of constraints: equality and inequality constraints. The power balance constraint, presented in Equation (5), ensures that the total generated power meets the system demand:

$$P_D = \sum_{i=1}^{n} P_i \quad (5)$$

where P_D is the overall power demand in megawatts (MW) [28]. In this study, the power balance is enforced using a repair-based approach, where the power output of the first unit is adjusted according to Equation (6):

$$P_1 = P_D - \sum_{i=2}^{n} P_i \quad (6)$$

Should the altered value of P_1 be above the unit's operational threshold, the cost function incurs significant penalties, rendering the solution unviable [29]. Furthermore, each generating unit must function within its minimal ($P_{i,min}$) and maximum ($P_{i,max}$) capacity constraints, as in equation 7.

$$P_{i,min} \leq P_i \leq P_{i,max} \text{ for } i = 1, 2, \ldots, N \quad (7)$$

These restrictions ensure the safety and reliability of system operations. Accordingly, the ED task is to determine an optimal generation schedule that minimizes total operational cost while meeting load requirements and respecting technical constraints. The constraint-handling mechanism, particularly the power balance adjustment, is essential for preserving the feasibility and stability of candidate solutions throughout the optimization process [30].

II.3 EXPERIMENTAL SETUP

This study investigates the ED problem across systems comprising 6, 15, and 40 generating units. Each unit is characterized by minimum ($P_{i,min}$) and maximum ($P_{i,max}$) power generation limits. For instance, the total load demand is set to 1263 MW for the 6-unit case, 2630 MW for the 15-unit case, and 10500 MW for the 40-unit case. The operational cost coefficients (a_i, b_i, c_i) are drawn from a well-established dataset that accurately reflects real-world plant characteristics, as presented by [31]. These simulations enforce both unit-level generation constraints and the global power balance condition as defined in Equation (7). To evaluate the generalization capability of SAMOPA across various optimization landscapes, the CEC 2020 benchmark functions are employed. These functions span four categories: unimodal, basic, hybrid, and composition. Comparative assessments are conducted against the original OPA, as well as other well-known metaheuristic algorithms, including PSO [32][33], GWO [34][35], WOA [36][37], the Bat Algorithm [38][39], and CMA-ES [40][41]. This study employed the Wilcoxon Signed-Rank Test, a non-parametric statistical method, to compare the performance of SAMOPA with other algorithms by assessing the median difference between two matched data sets. Each algorithm underwent testing across 30 independent iterations for each problem, and the convergent outcomes (global minimum) of the two algorithms were juxtaposed.

The null hypothesis (H_0) posits that there is no substantial disparity between the median answers produced by the two algorithms. If the P-value derived from this test is less than 0.05, the null hypothesis is rejected, signifying a substantial difference between the algorithms being tested. The symbols +, -, and = denote the superiority, inferiority, or equivalence of an algorithm, contingent upon a comparison of the ranks of the generated solutions. The parameter configurations of all algorithms in this study were uniformly established to guarantee equitable comparison and dependable replication. The population size was established at 30 for all scenarios, with a maximum of 40 iterations for the 6- and 15-generators cases and 100 iterations for the 40-generators case to ensure sufficient exploration of the broader search space. The parameter settings for each algorithm are modified based on corroborated prior research, including OPA as per Jiang et al.[22], PSO and GWO as outlined by Pokala and Lalitha [42], Bat incorporating enhancements from Meng et al. [43], WOA adhering to the revised version by Chakraborty et al. [44], and CMA-ES reflecting the original configuration by Hansen and Ostermeier [45]. All algorithms were implemented using Python 3.11.12 and run using Google Colab with uniform hardware conditions.

This consistent computing environment ensures that computational time comparisons between methods are fair and reliable. The SAMOPA implementation in Python, along with the entire experimental setup, is available upon request to support transparency and replication in future research. The proposed algorithm, SAMOPA, follows the OPA guidelines for all main settings, except for two key settings: p_1 (the chance of the pursuit phase) and p_2 (the chance of resetting in the attack phase), which are set using a grid search method. This process is carried out on three ED test cases with 6, 15, and 40 generators to find the best combination of settings that results in the lowest cost. The test findings indicate distinct ideal parameter combinations for each scenario: p_1 = 0.9 and p_2 = 0.01 for 6 units, p_1 = 0.9 and p_2 = 0.06 for 15 units, and p_1 = 0.6 and p_2 = 0.04 for 40 generators. The simulation exercise employed fundamental assumptions to streamline the calculation model and enhance the emphasis on the algorithm's performance evaluation. The power load is presumed constant throughout the optimization process, excluding transmission losses and ramp rate constraints. All producing units are presumed to be continuously operational and steady throughout the simulation time.

In the traditional scenario, the generation cost function is presumed to be quadratic and continuous, adhering to the standard economic dispatch model. In the supplementary scenario involving the valve-point impact, the cost function is rendered non-linear and non-convex, accurately representing the actual situations in steam turbines. Physical limitations on the minimum and maximum power of each unit are explicitly considered, and the system power equilibrium is preserved by a repair-based method, by adjusting the power at the initial unit to ensure that total generation meets load demand. All simulations were conducted in 30 independent iterations for each scenario (6, 15, and 40 units) to verify statistical validity.

III. RESULT AND DISCUSSION

III.1 PERFORMANCE OF ECONOMIC DISPATCH PROBLEMS

The performance assessment of SAMOPA in ED with 6, 15 and 40 generators is presented in Table 2.

Table 2: Performance Comparison of the Algorithm on ED Problems.

Algorithm	Units	Best Cost	Mean Cost	Std Dev	Time (s)
SAMOPA	6	**15275.9304**	**15275.9304**	**2.54E-06**	**0.2677**
OPA	6	15275.9306	15275.9327	0.0029	0.9751

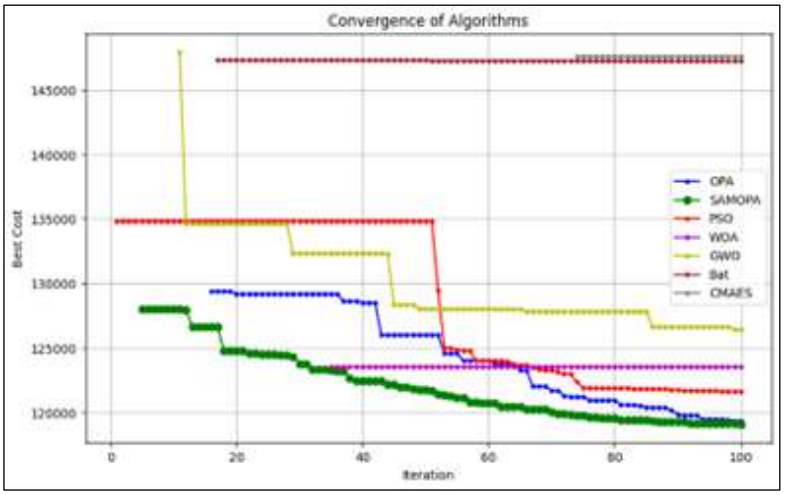

Figure 7: Convergence Curve Comparison of SAMOPA on 40 generators.
Source: Authors, (2026).

Table 2 demonstrates that SAMOPA consistently outperforms other algorithms in economic dispatch scenarios involving 6, 15, and 40 generating units. It achieves the lowest total cost, minimal standard deviation, and competitive computational time, particularly surpassing OPA, PSO, WOA, Bat, GWO, and CMA-ES in terms of solution stability and accuracy. Figures 2–4 further illustrate that SAMOPA consistently yields the lowest mean best cost and the narrowest 95% confidence intervals compared to the benchmark algorithms. The convergence plots in Figures 5–7 reveal that SAMOPA converges more rapidly and maintains greater stability throughout the optimization process. This combination of fast convergence, high accuracy, and robust performance positions SAMOPA as the most reliable method for solving economic dispatch problems across small, medium, and large-scale systems.

III.2 EVALUATION OF NON-CONVEX ED CASES WITH VALVE-POINT EFFECT

To evaluate the robustness of the proposed SAMOPA algorithm under more realistic and complex economic dispatch conditions, further tests were conducted on systems with 6, 15, and 40 generating units incorporating valve-point effects. These effects introduce significant non-linearity and non-convexity into the cost function, closely reflecting practical scenarios in thermal power systems. The performance results for all configurations are presented in Table 3.

Table 3: Performance Comparison of the Algorithm on ED with Valve-Point Effect

Algorithm	Units	Best Cost	Mean Cost	Std Dev	Time (s)
SAMOPA	6	**14326.02**	**14334.26**	**18.41**	0.3788
OPA	6	14326.03	14337.85	21.32	0.5266
PSO	6	14326.09	14389.24	116.65	0.0711
GWO	6	14326.48	14555.78	316.14	0.1427
WOA	6	14354.51	14584.49	142.71	0.0407
Bat	6	14459.1	14885.84	272.8	0.061
CMAES	6	14670.77	-	-	0.0196
SAMOPA	15	**31545.05**	**31644.18**	**72.35**	0.4041
OPA	15	31577.99	31707.11	91.33	0.7249
PSO	15	31826.78	32217.21	265.74	0.1142

Algorithm	Units	Best Cost	Mean Cost	Std Dev	Time (s)
GWO	15	31597.95	32086.14	612.01	0.2621
WOA	15	32144.4	32734.33	266.19	0.0427
Bat	15	32654.2	33252.61	253.83	0.0414
CMAES	15	32598.61	-	612.01	0.0198
SAMOPA	40	116569	118143.2	670.503	1.19
OPA	40	117275.7	119195.6	838.296	1.55
PSO	40	126451.8	9.67E+09	1.8E+09	0.19
GWO	40	-	-	-	-
WOA	40	124307.3	131762	4126.151	0.1
Bat	40	131734.5	-	-	-
CMAES	40	-	-	-	-

Source: Authors, (2026).

The results presented in Table 3 indicate that SAMOPA consistently outperformed all comparative algorithms across the 6, 15, and 40 unit ED cases with valve-point effects. It achieved the lowest generation costs, the smallest standard deviations, and competitive computational times, underscoring its robustness and reliability in addressing non-convex ED problems. OPA ranked second, producing results close to SAMOPA but with noticeably longer computation times. PSO, GWO, and WOA demonstrated moderate effectiveness on smaller systems but showed degraded accuracy and consistency as system size increased. In contrast, Bat and CMA-ES failed to generate valid or stable solutions for the 40-unit case. Overall, SAMOPA exhibited superior accuracy, stability, and computational efficiency, confirming its suitability for solving large-scale, non-convex ED problems with realistic system complexities.

III.3 BENCHMARK EVALUATION USING CEC 2020

The CEC 2020 benchmark suite was selected for its ability to capture key characteristics of the ED problem, including non-linearity, multi-modality, and constraint handling. Its complex function landscape, particularly in hybrid and composition categories, closely reflects real-world challenges such as valve-point effects and operational limits in power systems. The performance of SAMOPA on these benchmark functions is summarized in Table 4.

Table 4: Performance Comparison of the SAMOPA Algorithm on CEC 2020 function.

Algorithm		Unimodal Function	Basic Function	Hybrid Function	Composition Function
PSO	**Best**	8.59E+04	1.10E+03	2.33E+03	3.46E+03
	Mean	4.16E+08	1.61E+03	2.33E+03	3.46E+03

Table 4 presents the benchmark evaluation results on the CEC 2020 test suite, demonstrating that SAMOPA consistently outperforms all comparative algorithms across all function categories—unimodal, basic, hybrid, and composition. It achieved the best objective values, the lowest mean costs, and the smallest standard deviations, reflecting superior accuracy, stability, and convergence reliability. For example, SAMOPA obtained an optimal value of 1.00E+02 in the unimodal function with a mean of 1.01E+02 and a minimal deviation of 2.19E+00, significantly outperforming OPA, PSO, Bat, and WOA. Similarly, in the basic function category, SAMOPA maintained an average of 1.10E+03 with an extremely low variance of 1.14E−06, indicating consistent convergence.

Its performance remained robust in hybrid and composition functions, with variances of just 5.00E−02 and 2.43E−01, whereas other algorithms such as CMA-ES, GWO, and WOA exhibited greater variability. Although SAMOPA incurred slightly higher computation times than some competitors, the trade-off is justified by its consistent optimization quality. These results confirm that the adaptive momentum mechanism significantly enhances the original OPA framework. A series of Wilcoxon signed-rank tests were conducted on four types of benchmark functions, Unimodal, Basic, Hybrid, and Composition, to statistically confirm that the SAMOPA algorithm is better than other algorithms. We conducted the tests in pairs, comparing SAMOPA with six comparative algorithms: OPA, PSO, WOA, Bat, GWO, and CMA-ES. The findings of this statistical test are summarized in Table 5 below.

Table 5: Statistical Result using Wilcoxon Signed Rank.

	SAMOPA vs OPA				**SAMOPA vs PSO**

Source: Authors, (2026).

Table 5 shows the results of the Wilcoxon Signed-Rank Test, indicating that SAMOPA consistently performs better than other algorithms like OPA, PSO, WOA, Bat, GWO, and CMAES on various test functions, including Unimodal, Basic, Hybrid, and Composition. In nearly all comparisons, minimal P-values (<0.05) signify substantial differences, demonstrating that SAMOPA is superior in producing optimal solutions. The '+' symbol in all comparisons shows that SAMOPA usually does better than other algorithms in terms of solution quality and convergence; however, in the Hybrid and Composition functions, the higher P-values indicate that there is no significant difference between SAMOPA and the other algorithms. SAMOPA consistently outperformed its competitors in most comparisons, showcasing its superiority in efficiency and performance throughout the studied optimization functions. SAMOPA demonstrates strong performance across all test scenarios, including both standard and non-convex economic dispatch problems, validating its capability to consistently achieve global optimal solutions. This success is primarily attributed to the adaptive momentum mechanism, which dynamically balances exploration and exploitation by adjusting momentum over iterations.

Unlike fixed momentum approaches, SAMOPA gradually reduces momentum to encourage broad exploration in early stages and focused exploitation in later phases, enhancing both convergence stability and solution quality, as evidenced in Figures 4–6 and Tables 2–3. Although SAMOPA incurs slightly longer computation times than PSO, WOA, and GWO, it consistently delivers more accurate and stable outcomes while avoiding premature convergence. These findings align with prior studies [18], [46], [47], which highlight the benefits of momentum in stabilizing convergence in metaheuristic frameworks. Compared to the original OPA, SAMOPA significantly improves computational efficiency without compromising accuracy. Nonetheless, the comparatively extended execution time relative to alternative algorithms remains a difficulty for real-time applications, particularly in extensive optimization contexts. To address this constraint, future research may investigate the incorporation of hardware acceleration methods, including GPU-based parallelization, multi-core processing, and distributed computing frameworks.

These methodologies facilitate concurrent assessment of populations, expedite the optimization process, and enhance the scalability of algorithms. Moreover, the deployment of cloud infrastructure can enhance the efficiency and real-time responsiveness of SAMOPA. The adaptive momentum mechanism in SAMOPA can be further enhanced through feedback-driven momentum adjustment techniques or dynamic learning rate adaptation, potentially decreasing computing time while maintaining accuracy. Potential hybridization with other metaheuristic algorithms, such as the incorporation of exploitation operators from Particle Swarm Optimization (PSO) or Differential Evolution (DE), may enhance convergence speed and overall solution quality. Finally, while SAMOPA has demonstrated robust empirical convergence, it lacks a mathematical proof of convergence. Consequently, additional theoretical investigations are required to enhance the mathematical foundation and reliability of this methodology over time.

IV. CONCLUSION

This study has proposed and evaluated the SAMOPA as a solution for ED problems in power systems. Experimental results demonstrate that SAMOPA consistently delivers more accurate and reliable solutions than conventional metaheuristic algorithms, even under complex conditions such as valve-point effects. This performance advantage is primarily attributed to the integration of an adaptive momentum mechanism, which effectively balances exploration and exploitation to accelerate convergence.

SAMOPA's strong results across various benchmark scenarios affirm its suitability for real-world power system optimization tasks. Future research will focus on further improving computational efficiency, strengthening the theoretical foundation of the algorithm, and extending its application to ultra-large-scale systems involving 100 or more generating units to evaluate its scalability in more complex and realistic environments.

ABSTRACT

This study introduces an optimization method to enhance image classification accuracy using a Soft Voting Ensemble of fine-tuned convolutional neural networks (CNNs). The goal is to evaluate whether combining multiple CNN architectures can outperform individual models. Three pre-trained networks DenseNet, ResNet, and EfficientNet were fine-tuned through transfer learning on a Kaggle image dataset. To improve generalization, data augmentation techniques such as random rotation, flipping, and zooming were applied. After fine-tuning, the models were integrated using a soft voting strategy that averages prediction probabilities to determine the final class. Performance was tested on 94 unseen images, fully separated from the training data. The individual accuracies were 91.5% for DenseNet, 87.2% for ResNet, and 93.6% for EfficientNet. The proposed ensemble achieved the highest accuracy of 94.7%, with precision, recall, and F1-score all reaching 0.95. These findings indicate that the ensemble approach successfully combines the strengths of different CNNs, reduces classification errors, and increases model robustness. Overall, the soft voting ensemble provides a reliable, scalable, and effective solution for improving CNN-based image classification, especially when dealing with limited or diverse datasets.

I. INTRODUCTION

In recent years, the fields of computer vision and deep learning have experienced significant advancement, driven by the rapid growth of computational power and the availability of large-scale annotated datasets. Deep learning models, particularly convolutional neural networks (CNNs), have become the backbone of modern image classification systems due to their ability to automatically learn hierarchical feature representations from raw pixel data. Unlike traditional image processing methods that depend on handcrafted features, CNNs can effectively capture spatial dependencies, textures, and semantic structures directly from the data. This capability has enabled breakthroughs in diverse domains such as medical imaging, autonomous driving, surveillance, agriculture, and industrial automation, where visual understanding plays a crucial role in decision-making processes [1].

The fundamental strength of CNNs lies in their hierarchical feature extraction capability, where low-level filters capture edges and textures, while deeper layers represent complex and abstract concepts. Over the past decade, numerous CNN architectures have been proposed to improve model depth, efficiency, and generalization. Among the most influential architectures are ResNet, DenseNet, and EfficientNet, which have become benchmarks in computer vision research and applications. ResNet introduced residual connections to address the vanishing gradient problem and enable the training of very deep networks [2]. DenseNet, on the other hand, employs dense connections among layers to promote feature reuse and gradient flow efficiency, leading to compact yet powerful models [3].

EfficientNet introduced a compound scaling technique that systematically balances network depth, width, and input resolution to achieve state-of-the-art accuracy with fewer parameters [4]. Despite their impressive performance, single CNN architectures still face several challenges. In practice, the performance of a CNN often depends on the quality, size, and diversity of the training dataset. When data is limited, noisy, or exhibits high intra-class variability, models tend to overfit or become biased toward dominant features. Moreover, a single model might excel at identifying certain visual patterns but perform poorly on others, depending on the nature of its learned representations. This model-specific bias often limits generalization, especially when deployed in real-world scenarios with unseen data distributions. Therefore, improving classification stability and robustness remains an open challenge in deep learning–based vision systems [5]. One promising direction to overcome these limitations is ensemble learning. Ensemble methods combine the predictions of multiple models to produce a more reliable and accurate output than any individual model could achieve alone. In traditional machine learning, ensemble strategies such as bagging, boosting, and stacking have demonstrated consistent improvements in performance and stability. In deep learning, similar principles can be applied by combining the outputs of multiple neural networks trained with different initializations, architectures, or subsets of data. Ensemble learning leverages the diversity among models both in terms of structure and learned representations to reduce variance and increase predictive robustness [6].

Among various ensemble strategies, soft voting has emerged as a particularly simple yet effective approach. In soft voting, the probabilistic predictions (output probabilities) from several base classifiers are averaged or weighted to determine the final class prediction. Unlike hard voting, which only considers the majority vote of discrete class labels, soft voting retains the confidence level of each model's prediction, allowing the ensemble to make more nuanced decisions. This approach is especially beneficial when combining heterogeneous deep models, as their probability distributions can complement one another, leading to improved accuracy and smoother decision boundaries [6]. In this study, a Soft Voting Ensemble approach is proposed to enhance image classification performance by combining multiple fine-tuned CNN models. Specifically, three high-performing architectures DenseNet, ResNet, and EfficientNet are fine-tuned through transfer learning on a custom image dataset obtained from Kaggle. Transfer learning allows leveraging pre-trained weights from large-scale datasets such as ImageNet, accelerating convergence and improving generalization even with limited target data. To further increase model robustness, data augmentation techniques are applied during training. Augmentation operations such as random rotation, flipping, scaling, and zooming help to artificially expand the training data and expose the models to diverse visual variations.

This not only mitigates overfitting but also improves the adaptability of CNNs to unseen real-world conditions [7]. The motivation behind using multiple CNNs in an ensemble lies in their complementary feature extraction capabilities. Each architecture has unique design principles that influence how it interprets image information. For instance, ResNet's skip connections enable efficient learning of residual mappings, making it particularly effective for recognizing global patterns and coarse structures. DenseNet's densely connected layers enhance information flow and encourage feature reuse, which benefits texture-rich or detailed images. Meanwhile, EfficientNet's compound scaling provides a balanced architecture that captures both fine and coarse details efficiently. By combining these models using a soft voting mechanism, the ensemble benefits from the diverse representation power of each CNN, leading to improved classification stability and accuracy across different image types. In practical applications, ensemble methods also provide an additional advantage: model uncertainty reduction.

Since deep networks are often sensitive to initialization and data variations, a single model might produce inconsistent predictions when exposed to slightly altered inputs. The ensemble approach mitigates this by averaging multiple predictions, which statistically reduces variance and enhances decision confidence. This makes soft voting particularly suitable for safety-critical applications such as medical diagnosis or industrial inspection, where prediction reliability is paramount [8]. This research aims to achieve three main objectives. First, to investigate the effectiveness of the soft voting ensemble in improving image classification accuracy compared to individual fine-tuned CNN models. Second, to evaluate the impact of transfer learning and data augmentation on model performance and generalization. Third, to analyze the complementary behavior among DenseNet, ResNet, and EfficientNet when combined under a unified probabilistic voting scheme. Through these objectives, this study contributes to the understanding of how ensemble deep learning can be leveraged for more robust and scalable visual recognition systems, particularly in domains where labeled data are scarce or heterogeneous.

II. MATERIALS AND METHODS

II.1 DATASET

The dataset utilized in this study comprises a single image classification dataset focusing on *Pempek*, a traditional Indonesian delicacy originating from Palembang. Figure 1 illustrates representative examples from the *Pempek* image classification dataset. The dataset was obtained from the publicly available Kaggle repository and consists of five distinct classes representing various types of Pempek: Pempek Lenjer, Pempek Kapal Selam, Pempek Adaan, Pempek Keriting, and Pempek Kulit. The images within the dataset exhibit considerable diversity in terms of lighting conditions, backgrounds, and camera orientations, thereby ensuring a comprehensive representation of real-world variations. Such heterogeneity is essential for enhancing the generalization capability of the proposed model.

Figure 1: Example Images.
Source: Authors, (2026).

To strengthen the dataset and mitigate the risk of model overfitting, several data augmentation techniques were employed, including random rotation, horizontal and vertical flipping, cropping, brightness adjustment, and image resizing. These transformations not only increased the effective dataset size but also improved the robustness of the model when exposed to unseen data. Prior to model training, a series of data preprocessing steps were conducted to standardize and optimize the dataset. These include:

- Resizing with Black Padding: All images were resized to a uniform resolution of 224 × 224 pixels. To preserve the original aspect ratio and prevent geometric distortion, any empty regions resulting from resizing were filled with black pixels.
- Data Augmentation: Augmentation operations were systematically applied to the training data to increase variability and improve the model's resilience to environmental and perceptual changes.
- Normalization: Each pixel value was normalized to a range of [0, 1] by dividing by 255. This normalization process ensures numerical stability and accelerates model convergence during training.

Initially, the dataset contained 485 original images. These images were randomly divided into 391 training samples (approximately 80%) and 94 testing samples (approximately 20%). To further improve the robustness of the model and mitigate overfitting, data augmentation was applied exclusively to the training set. Augmentation techniques included random rotation, horizontal and vertical flipping, cropping, brightness adjustment, and resizing. As a result, the number of training images increased from 391 to 2,904 augmented samples, thereby expanding the dataset's variability and improving the model's resilience to real-world conditions. The final dataset comprised a total of 2,904 images across five categories, as summarized in Table 1.

Table 1: Dataset.

Dataset	Source	Classes	Original Images	Test Images	Train Images	After Augmentation
Pempek Food Picture	Kaggle	5	485	94	391	2904

II.2 PROPOSED METHODS

II.2.1 CNN RESNET

ResNet (Residual Network) introduces the principle of residual learning to effectively mitigate the vanishing gradient problem that typically arises in deep convolutional neural networks [9]. By integrating shortcut or skip connections that bypass one or more layers, ResNet facilitates the training of very deep models while maintaining stability and accuracy. In this study, the ResNet50 architecture is employed, consisting of 50 layers organized into a series of convolutional and identity blocks that incorporate batch normalization and ReLU activation functions. Each residual block employs identity mappings and 1×1 convolutions to adjust feature dimensions, enabling efficient hierarchical feature extraction. ResNet50 offers a favorable balance between model complexity and classification accuracy, outperforming shallower variants such as ResNet34 in capturing high-level semantic features while remaining computationally practical for fine-tuning tasks [10]. The network is initialized using pre-trained ImageNet weights, which accelerates convergence and enhances the model's generalization performance within the transfer learning framework.

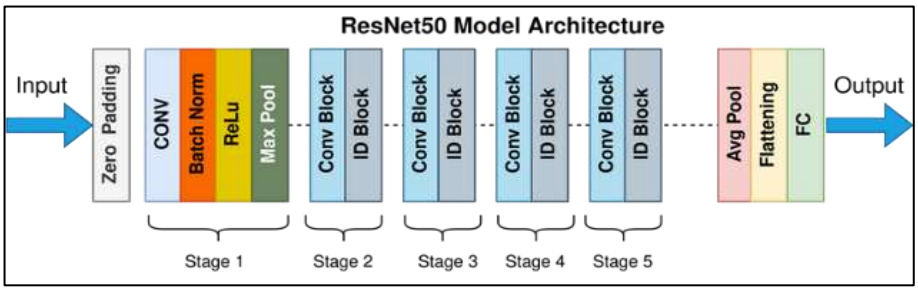

Figure 2: ResNet50 Architecture.
Source: Authors, (2026).

II.2.2 CNN Densenet

DenseNet (Densely Connected Convolutional Network) introduces a fully connected feed-forward mechanism within each dense block, where every layer is directly connected to all subsequent layers [11]. This design encourages feature reuse and efficient information flow, addressing the vanishing gradient issue and improving feature propagation throughout the network. The architecture utilized in this research is DenseNet121, which comprises 121 layers organized into four dense blocks, interleaved with transition layers responsible for convolution and pooling operations. Each dense block applies batch normalization, ReLU activation, and both 1×1 and 3×3 convolutional filters. This densely connected structure captures hierarchical feature representations efficiently, using fewer parameters compared to conventional CNNs. DenseNet121 was selected due to its high accuracy-to-parameter ratio and efficient memory utilization. Its compact architecture makes it particularly suitable for medium-scale datasets, providing robust classification performance and generalization capability [12].

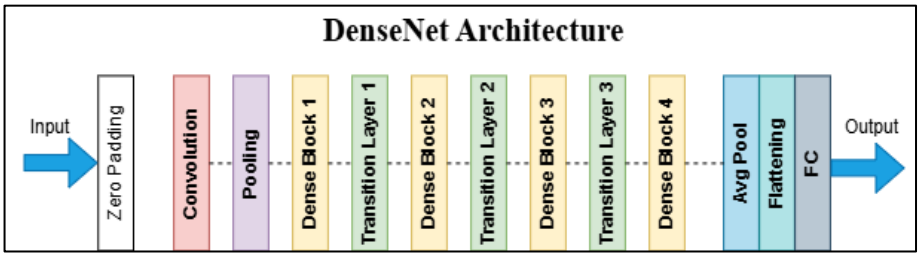

Figure 3: DenseNet121 Architecture.
Source: Authors, (2026).

II.2.3 CNN Effecientnet

EfficientNet introduces a compound scaling method that systematically and uniformly scales a network's depth, width, and input resolution using fixed scaling coefficients [13]. This balanced scaling strategy allows the model to achieve superior accuracy while maintaining computational efficiency. In this work, the EfficientNet-B0 variant is adopted as it represents the baseline model within the EfficientNet family. It utilizes MBConv (Mobile Inverted Bottleneck Convolution) layers combined with squeeze-and-excitation optimization to enhance representational power at a low computational cost. EfficientNet-B0 was chosen for its lightweight design and competitive performance, making it ideal for experimentation in environments with limited computational resources [14]. Despite having significantly fewer parameters than deeper CNNs, it delivers efficient inference and serves as a strong baseline for ensemble-based approaches.

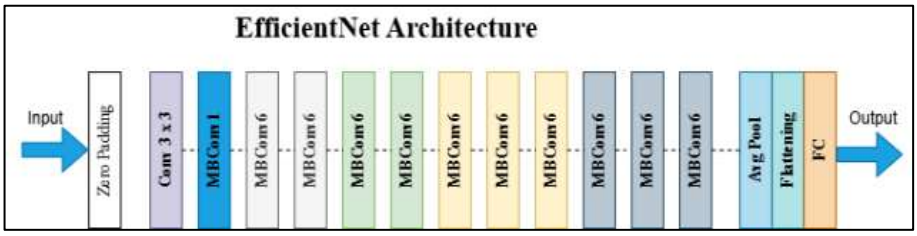

Figure 4: EffecientNet Architecture.
Source: Authors, (2026).

II.2.4 Fully Connected Layer

To ensure architectural consistency and improve feature discrimination across all CNN backbones (ResNet50, DenseNet121, and EfficientNet-B0), a uniform fully connected (FC) layer configuration was appended to the output of each network. The original top classification layers were removed, and the extracted feature maps from each pre-trained base model were passed through a Global Average Pooling (GAP) layer, followed by a series of dense layers with ReLU activation and dropout regularization to mitigate overfitting.

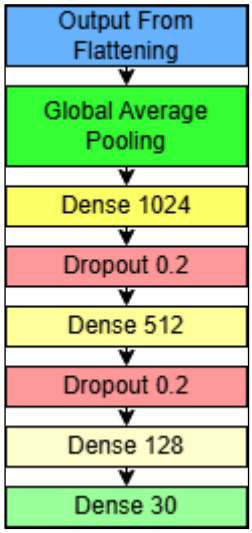

Figure 5: Fully Connected Layer.
Source: Authors, (2026).

This configuration maintains a balance between model expressiveness and computational efficiency. The GAP layer effectively reduces spatial dimensions while preserving essential semantic information, and the successive dense layers progressively abstract higher-level features [15]. Dropout regularization with a rate of 0.2 is applied to prevent neuron co-adaptation and enhance generalization [16]. By applying a standardized FC layer design across all CNN architectures, any performance variations can be attributed primarily to the representational capabilities of the backbone networks rather than inconsistencies in the classifier head. This methodological consistency aligns with best practices in transfer learning and ensemble modeling, ensuring fair and reliable model comparison [17].

II.2.5 Soft Voting Ensemble

Ensemble learning has emerged as an effective strategy to enhance the accuracy, robustness, and generalization capabilities of deep learning models. Among various ensemble approaches, soft voting combines the probabilistic outputs (class confidence scores) of multiple classifiers instead of relying solely on discrete class labels as in hard voting. This probabilistic aggregation enables the final prediction to reflect the relative confidence of each model across all possible classes, thereby producing a more balanced and informed decision. Previous studies have demonstrated that soft voting generally surpasses individual classifiers and hard voting ensembles by reducing model bias and variance, as well as by exploiting the complementary strengths of diverse architectures [18]. In this study, a soft voting ensemble is employed to integrate the outputs of three distinct CNN backbones—ResNet50, DenseNet121, and EfficientNet-B0—each possessing unique representational advantages. ResNet50 facilitates effective training of deep networks through residual learning; DenseNet121 enhances feature reuse and gradient flow via dense inter-layer connectivity; and EfficientNet-B0 provides a lightweight yet high-performing framework through compound scaling. By aggregating their probabilistic outputs, the ensemble model effectively leverages the individual strengths of each architecture while compensating for their respective weaknesses. This synergistic combination leads to improved classification accuracy, enhanced model stability, and better generalization performance across diverse data distributions.

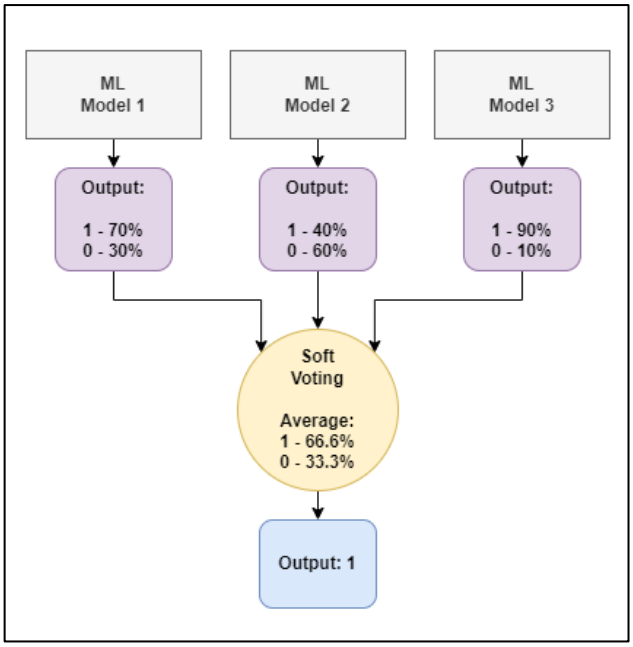

Figure 6: Fully Connected Layer.

III. RESULTS AND DISCUSSIONS

III.1 TRAINING MODEL

The training process for the CNN model used several techniques to enhance convergence and prevent overfitting. One key technique was employing an Exponential Decay learning rate schedule [19], starting with an initial learning rate of 0.001, which decreases by a factor of 0.96 every 1000 steps, allowing the learning rate to reduce gradually over the epochs. The Adam optimizer [20] was applied, using categorical cross-entropy as the loss function, suitable for multi-class classification tasks. To further improve generalization, early stopping [21] was implemented with a patience setting of 10 epochs, restoring the model weights with the best validation loss. Additionally, a model checkpoint callback was enabled to save automatically the model that achieved the highest validation accuracy during training. A detailed summary of these configurations is presented in Table 2.

Table 2: CNN Training Parameter.

Parameter	Value/Setting
Optimizer	Adam
Loss Function	Categorical Cross-Entropy
Learning Rate Schedule	Exponential Decay (initial = 0.0001, decay rate = 0.96, decay steps = 30)
Epochs (max)	100
Early Stopping	Patience = 10 (monitor = val_loss, restore_best_weights = True)
Model Checkpoint	Save best model (based on val_accuracy)
Batch Size	32

Source: Authors, (2026).

After each CNN model is independently trained and assessed, their predictions are integrated using a soft voting approach. For every input image, each model generates a probability distribution across the 30 distinct food categories. The soft voting mechanism then computes the average of these probabilities and ultimately selects the class with the highest average probability as the ensemble's final prediction. This method harnesses the collective "confidence" of the three models, resulting in a more dependable and precise final classification. The performance of this ultimate ensemble model is subsequently evaluated and benchmarked against the individual models using consistent metrics: Accuracy, Precision, and and Recall. Following the previously outlined training procedures, each fine-tuned CNN model (ResNet, EfficientNet, and DenseNet) underwent evaluation based on its training and validation performance. Figure 7 (ResNet), Figure 8 (EfficientNet), and Figure 9 (DenseNet) graphically represent the progression of accuracy and loss over epochs for each model, underscoring variations in their convergence rates and propensities for overfitting.

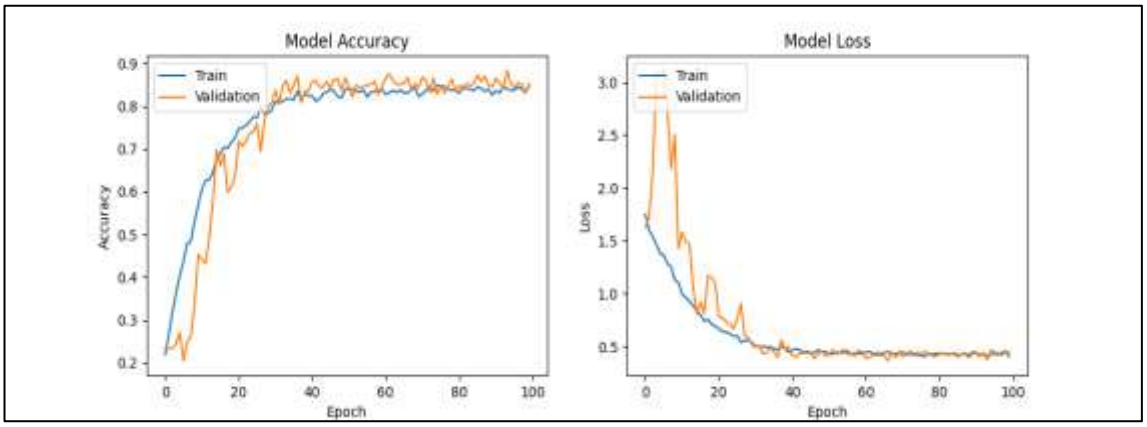

Figure 7: Accuracy and Loss Graph For ResNet.
Source: Authors, (2026).

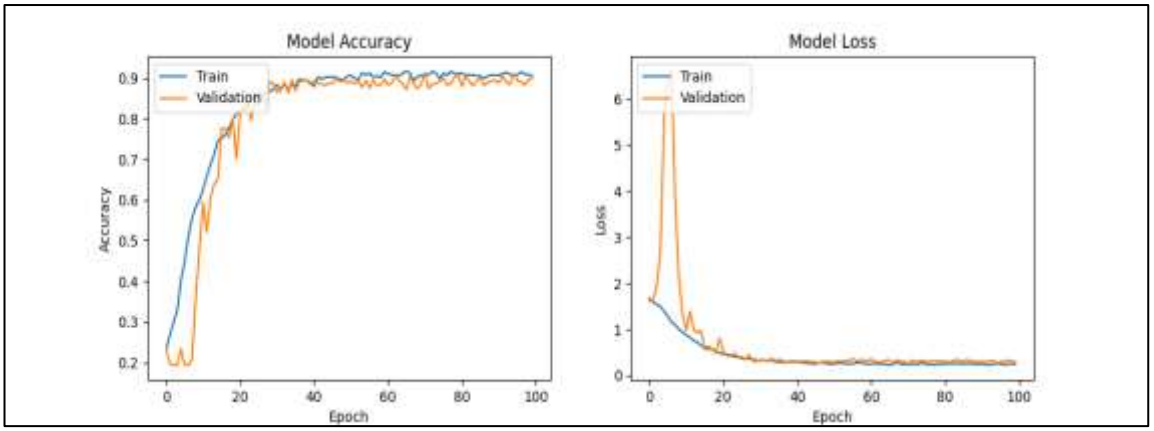

Figure 8: Accuracy and Loss Graph For EffecientNet.
Source: Authors, (2026).

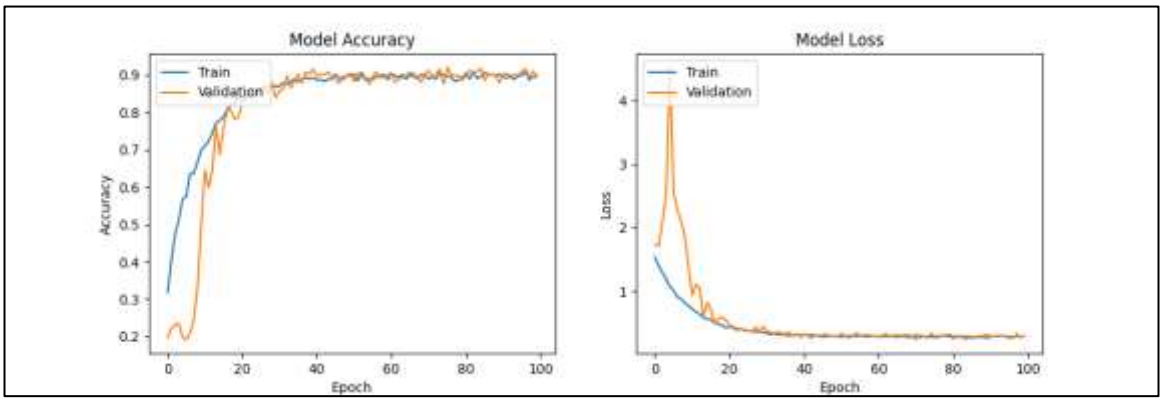

Figure 9: Accuracy and Loss Graph For DenseNet.
Source: Authors, (2026).

The performance graphs for ResNet, EfficientNet, and DenseNet models over 100 training epochs demonstrate successful and effective training for all three architectures. ResNet shows steady learning with training and validation accuracy stabilizing around 80-85%, and loss decreasing to approximately 0.4-0.5, indicating good generalization without significant overfitting. EfficientNet performs slightly better, with accuracy stabilizing between 85-90% and loss reducing to low values around 0.25-0.35, reflecting rapid convergence and excellent generalization. DenseNet also achieves competitive results, matching EfficientNet's accuracy range of 85-90%, with an initially more volatile but ultimately stable decreasing loss around 0.2-0.3, indicating robust and stable training. Across all models, the gap between training and validation metrics remains small, highlighting minimal overfitting and strong generalization capabilities. Overall, these results confirm that the fine-tuning strategies applied were highly effective, yielding accurate and reliable models suitable for the dataset.In summary, the graphs show that the three model architectures, ResNet, EfficientNet, and DenseNet, all trained very successfully. Each model demonstrated rapid convergence and did not show significant signs of overfitting. This confirms that the fine-tuning approach used is effective and well-suited for this dataset.

III.2 TESTING MODEL

After completing the training phase, each fine-tuned CNN model ResNet, EfficientNet, and DenseNet was tested on a dataset of 94 food images spanning 5 categories. This evaluation aimed to measure each model's ability to generalize to new, unseen data. The confusion matrices shown in Figures 10, 11, and 12 illustrate the results for each CNN architecture, providing a detailed view of correctly and incorrectly classified samples for each class. These matrices reveal the classification consistency and the types of errors produced by each model, forming the basis for comparing the performance of the three architectures.

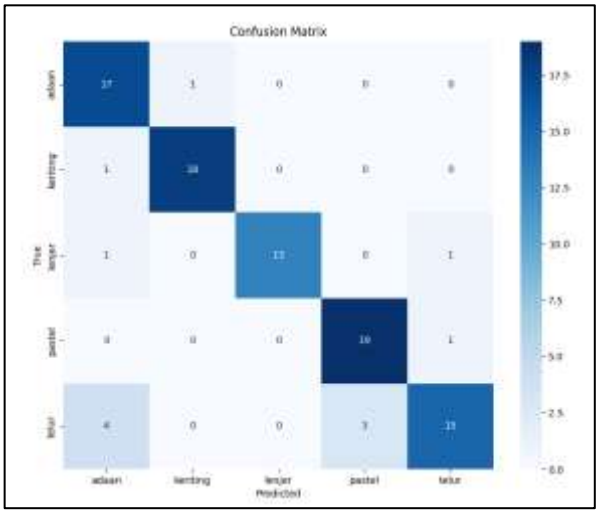

Figure 10: Confusion Matrix ResNet.
Source: Authors, (2026).

The confusion matrix for the ResNet model, presented in Figure 10, illustrates its classification performance across five distinct categories: 'adaan,' 'keriting,' 'lenjer,' 'pastel,' and 'telur.' Analysis of the matrix reveals robust performance for the 'keriting' and 'pastel' classes, with 18 and 19 instances correctly classified, respectively. Minor misclassifications for these categories include one 'keriting' instance erroneously predicted as 'adaan' and one 'pastel' instance misclassified as 'telur.' For the 'adaan' class, 17 instances were accurately identified, although one was incorrectly assigned to 'keriting.' Similarly, 'lenjer' exhibited 13 correct classifications, with individual instances being mislabeled as 'adaan' and 'telur.' Conversely, the 'telur' category posed the most significant challenge for the ResNet model. While 15 'telur' instances were correctly identified, a notable number of misclassifications occurred, with 4 'telur' instances incorrectly predicted as 'adaan' and 3 as 'pastel.' These observations suggest a potential ambiguity or feature overlap between 'telur' and the 'adaan' and 'pastel' categories, indicating areas where model refinement or a more diverse training dataset could enhance discriminative capabilities for these specific classes.

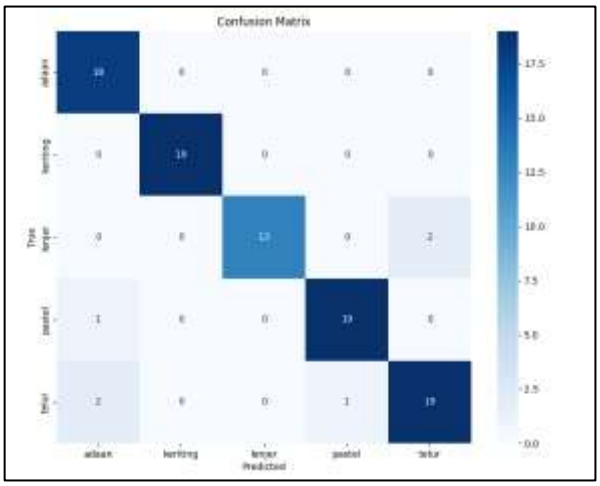

Figure 11: Confusion Matrix EffecientNet.
Source: Authors, (2026).

The confusion matrix for the EfficientNet model, depicted in Figure 11, provides insights into its classification efficacy across the 'adaan,' 'keriting,' 'lenjer,' 'pastel,' and 'telur' categories. The model demonstrates superior performance in classifying 'adaan' and 'keriting,' achieving 18 and 19 correct predictions, respectively, with no misclassifications observed for these categories. The 'pastel' class also exhibited strong classification, with 19 instances accurately identified, though one instance was incorrectly predicted as 'adaan.' For the 'lenjer' class, 13 instances were correctly classified, but two instances were erroneously assigned to 'telur.' The 'telur' category achieved 19 correct classifications; however, two instances were misclassified as 'adaan' and one as 'pastel.' These results collectively suggest that EfficientNet generally exhibits high accuracy across most categories, with 'lenjer' showing a slight tendency for misclassification into 'telur,' and 'telur' occasionally being confused with 'adaan' and 'pastel.' This detailed breakdown highlights EfficientNet's robust performance, while also pinpointing specific areas where further optimization might yield marginal improvements in discriminatory power.

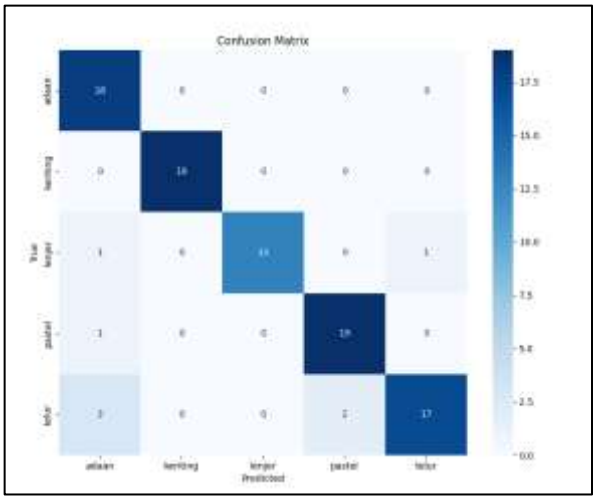

Figure 12: Confusion Matrix DenseNet.
Source: Authors, (2026).

The confusion matrix for the DenseNet model, illustrated in Figure 12, delineates its classification performance across five categories: 'adaan,' 'keriting,' 'lenjer,' 'pastel,' and 'telur.' DenseNet demonstrates strong classification for 'keriting' and 'pastel,' achieving 19 correct predictions for each with no misclassifications. For the 'adaan' class, 18 instances were correctly identified, with one instance incorrectly predicted as 'lenjer' and one as 'pastel.' The 'lenjer' class shows 13 correct classifications, but one instance was misclassified as 'adaan.' The 'telur' category correctly classified 17 instances, yet three instances were erroneously predicted as 'adaan' and two as 'pastel.' Overall, DenseNet exhibits robust performance, particularly for 'keriting' and 'pastel.' However, similar to the other models, 'adaan,' 'lenjer,' and 'telur' occasionally experience misclassifications. Overall, the fine-tuned ResNet, EfficientNet, and DenseNet models demonstrated commendable classification performance across the five distinct food categories (adaan, keriting, lenjer, pastel, and telur).

This is evident from the consistently high values observed along the diagonal elements of their respective confusion matrices (Figures 10, 11, and 12), which signify accurately classified instances. Specifically, EfficientNet exhibited exceptional precision for 'adaan' and 'keriting,' achieving zero misclassifications in those categories, while both ResNet and DenseNet showed strong performance, particularly for 'keriting' and 'pastel.' These outcomes collectively underscore the models' successful capability to discern and generalize the unique visual characteristics of each food type following the fine-tuning process. Nevertheless, a minor proportion of misclassifications persisted in certain categories across all three models. For instance, ResNet occasionally confused 'telur' with 'adaan' and 'pastel,' while EfficientNet showed a tendency to misclassify 'lenjer' as 'telur,' and 'telur' as 'adaan' and 'pastel.' DenseNet, although robust, still exhibited some instances where 'adaan,' 'lenjer,' and 'telur' were misclassified.

While each individual Convolutional Neural Network (CNN) architecture namely ResNet, EfficientNet, and DenseNet achieved high classification accuracy, their respective confusion matrices consistently revealed a minor but persistent number of misclassifications across various food categories. These subtle inconsistencies underscore that each model possesses distinct strengths and weaknesses in feature representation, highlighting the potential for complementary performance gains. To address these minor classification errors and further enhance the overall predictive performance, a Soft Voting Ensemble approach was strategically implemented. This robust method operates by combining the probabilistic outputs generated by the three best-performing models: ResNet, EfficientNet, and DenseNet. By averaging their individual prediction probabilities before a final class determination is made, this ensemble strategy effectively leverages the complementary capabilities inherent in each network.

This synergy significantly boosts the model's robustness and improves its generalization capacity when presented with unseen test data. The performance of the Soft Voting Ensemble model was rigorously evaluated using a comprehensive suite of classification metrics: accuracy, precision, recall, and F1-score. The results, meticulously detailed in Table 3, demonstrate the model's high effectiveness. The ensemble achieved an impressive accuracy of 0.95 (95%), indicating that 95% of all instances were correctly classified. Furthermore, the model exhibited a precision of 0.95 (95%), signifying that among all instances predicted as a specific class, 95% were indeed correct. A recall of 0.95 (95%) highlights the model's ability to correctly identify 95% of all actual instances within each class. The F1-score, also at 0.95 (95%), further corroborates the balanced and high performance of the ensemble, reflecting a strong harmony between precision and recall. These metrics were derived from a test set comprising 94 total samples.

Table 3: Soft Voting Model Performance.

Metric	Value
Accuracy	0.95 (95%)
Precision	0.95 (95%)
Recall	0.95 (95%)
F1-Score	0.95 (95%)
Total Samples	94

Source: Authors, (2026).

These results are consistent with the confusion matrix shown in Figure 13.

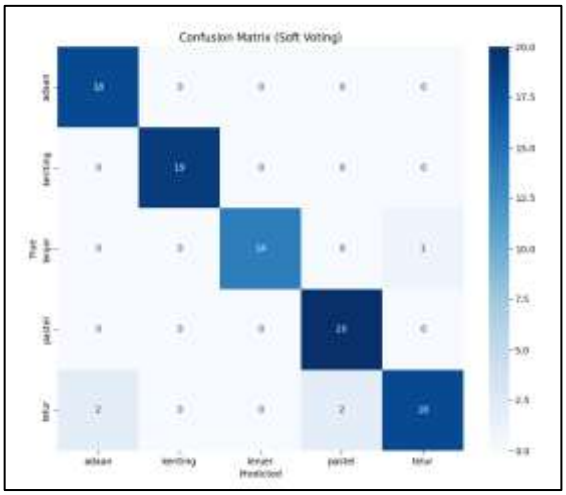

Figure 13: Confusion Matrix SoftVoting.
Source: Authors, (2026).

The matrix illustrates a highly effective classification with the majority of instances correctly predicted for each class. Notably, the 'pastel' category demonstrates perfect classification, with all 20 actual 'pastel' instances correctly identified. Similarly, the 'keriting' category exhibits strong performance, accurately classifying all 19 instances. The 'adaan' category shows only 2 misclassifications, with two 'adaan' instances being incorrectly predicted as 'telur'. For the 'lenjer' category, 14 instances are correctly identified, but 1 instance is misclassified as 'telur'. In the 'telur' category, 18 instances are correctly classified, while 2 are misclassified as 'adaan' and 'pastel' respectively. Despite these minor misclassifications in the 'adaan', 'lenjer', and 'telur' categories, the overall reduction in errors compared to the individual models' confusion matrices is substantial. This outcome unequivocally underscores the efficacy of the Soft Voting Ensemble approach in leveraging the complementary strengths of ResNet, EfficientNet, and DenseNet models. The observed performance metrics and the detailed confusion matrix analysis collectively validate the ensemble's superior robustness and generalization ability on unseen test data, making it a highly reliable solution for the task of accurate food image classification.

IV. CONCLUSIONS

In summary, this study successfully developed a highly accurate and robust image detection and classification system. The experimental results demonstrate that fine-tuning modern CNN architectures yields strong baseline performance; however, incorporating an ensemble learning strategy—specifically through soft voting—further enhances model accuracy and generalization. By integrating multiple architectures with complementary feature extraction capabilities, the ensemble effectively mitigates individual model limitations and achieves superior predictive performance.These findings underscore the significant potential of ensemble-based approaches in addressing complex classification challenges within the domain of computer vision.

For future work, it is recommended to evaluate the proposed ensemble framework using larger and more heterogeneous datasets, as well as under more challenging environmental conditions such as variations in illumination, background complexity, and image noise. Such investigations would provide deeper insight into the scalability, robustness, and real-world applicability of the soft voting ensemble method.

ABSTRACT

This study investigates the transient thermal behavior of hybrid and homogeneous mold configurations made from Aluminum A1100 and Stainless Steel 304 (S304) through numerical simulation and statistical validation. Finite Element Analysis (FEA) was conducted to examine temperature distribution, thermal gradients, and heat dissipation under controlled boundary conditions. The simulation results revealed that the pure Aluminum A1100 mold exhibited a maximum surface temperature of 56.708°C with rapid heat dispersion across the structure, indicating superior thermal conductivity and efficient heat transfer. In contrast, the hybrid A1100-S304 configuration reached a slightly lower maximum temperature of 56.002°C but demonstrated more stable temperature retention due to the stainless-steel layer's lower thermal conductivity and higher heat capacity. To validate these findings, an Analysis of Variance (ANOVA) test was performed on the experimental temperature profiles and cooling rates of both materials. The ANOVA results ($p < 0.05$) confirmed a statistically significant difference between the configurations, indicating that material composition directly affects thermal performance. Among the tested setups, the hybrid A1100-S304 mold achieved the optimal balance between rapid heat transfer and thermal stability, ensuring uniform temperature distribution while maintaining mechanical and corrosion resistance. This combination is particularly suitable for food-grade mold applications and biopolymer-based packaging processes, where controlled heating and cooling cycles are crucial for product quality and energy efficiency.

I. INTRODUCTION

The global packaging industry faces a critical challenge due to its reliance on petroleum-based plastics. While plastics offer advantages such as flexibility, durability, and low production cost, their persistence in the environment has created a severe ecological crisis. It is estimated that more than 8 million tons of plastic enter the oceans annually, threatening marine ecosystems and even human food chains [1]. Consequently, there is an urgent need to develop sustainable, renewable, and biodegradable alternatives to conventional plastics. Over the past two decades, bio-based materials, particularly natural fiber composites, have attracted significant attention as potential substitutes for single-use plastics [2]. Natural fibers such as flax, kenaf, jute, and banana have been investigated extensively due to their abundance, competitive mechanical properties, and sustainability [3]. Among these, banana pseudostem fibers stand out as an agricultural byproduct with high potential. Globally abundant in tropical regions, banana pseudostem contains 70-72% cellulose, 11-13% hemicellulose, and 6-8% lignin, which makes it highly suitable for biocomposite and packaging applications [4]. Several studies highlight the mechanical and thermal performance of banana fibers. They exhibit relatively high tensile strength, acceptable modulus of elasticity, and stable thermal resistance within the processing temperature range of food packaging applications [5]. Moreover, their biodegradability ensures a substantial environmental advantage over petroleum-based plastics, which may persist for centuries [6].

Thus, utilizing banana pseudostem as a raw material for packaging contributes to circular economy principles while simultaneously valorizing agricultural residues that are often underutilized. Despite its promise, the conversion of banana pseudostem fibers into reliable

food packaging requires overcoming certain engineering challenges. One of the key bottlenecks lies in achieving products with accurate dimensions, consistent thickness, and sufficient mechanical strength. In industrial practice, molding technology is a suitable approach for fabricating biocomposite-based packaging, as it enables precise geometry, dimensional control, and scalable mass production [7]. However, the success of molding processes depends critically on the thermal behavior of the mold material. Uneven heat distribution can lead to defects such as warpage, thickness variations, and reduced mechanical performance of the final product [8]. Metals such as iron, aluminum, and stainless steel are commonly used as mold materials due to their strength and durability. Yet, their differences in thermal conductivity, specific heat, and corrosion resistance present challenges in selecting the most optimal option [9], [10].

Poor material selection may result in higher energy consumption, inefficient heat transfer, increased defect rates, and shortened mold service life. Experimental approaches to identify optimal mold materials are not only costly but also time consuming. The trial and error method is inefficient when dealing with new biocomposite systems, where multiple factors such as fiber matrix interaction, processing temperature, and mold cooling rate interact simultaneously. To address this issue, numerical simulation has emerged as a vital tool in modern manufacturing. In particular, finite element analysis (FEA) implemented through software such as ANSYS provides a robust method for analyzing temperature distribution, heat gradients, and overall thermal behavior in molding systems before physical implementation [11],[12]. The advantage of simulation based approaches lies in their ability to explore multiple design scenarios under controlled conditions without the expense of extensive prototyping. Previous research has demonstrated that integrating simulation into molding design can reduce product development time by up to 72% and cut prototyping costs by approximately 62% [13].

Additionally, FEA based predictions have been validated as highly accurate in correlating material thermal properties with processing parameters, enabling manufacturers to optimize mold material selection and process efficiency. Considering the environmental urgency, the material potential of banana pseudostem, and the efficiency of advanced simulation tools, research into mold design and thermal evaluation becomes particularly relevant. This study seeks to perform a systematic thermal evaluation of various mold materials (iron, aluminum, and stainless steel) using ANSYS simulation, with the aim of identifying the most suitable material for manufacturing biodegradable food packaging derived from banana pseudostem fibers. The outcomes are expected to provide not only technical insights into mold material performance but also broader contributions toward sustainable packaging development in line with global efforts to reduce dependence on single-use plastics.

II. METHODOLOGY

The research methodology was systematically structured into three main phases: (1) the initial design of the molding system, (2) material simulation based on the molding configuration, and (3) statistical testing to determine the most suitable or optimal material combination. Each step is elaborated as follows.

II.1 INITIAL DESIGN OF THE MOLDING

The first phase involved the conceptualization and development of the molding geometry, specifically tailored for biodegradable food packaging derived from banana pseudostem fibers. The design process utilized computer-aided design (CAD) software to generate accurate dimensional tolerances, draft angles, and cavity profiles required for thermoforming and compression molding [14]. Design considerations included manufacturability, dimensional accuracy, and thermal distribution within the mold. To ensure industrial applicability, the design was validated through design-for-manufacture (DFM) criteria, with emphasis on scalability and potential integration into existing food packaging production systems [15].

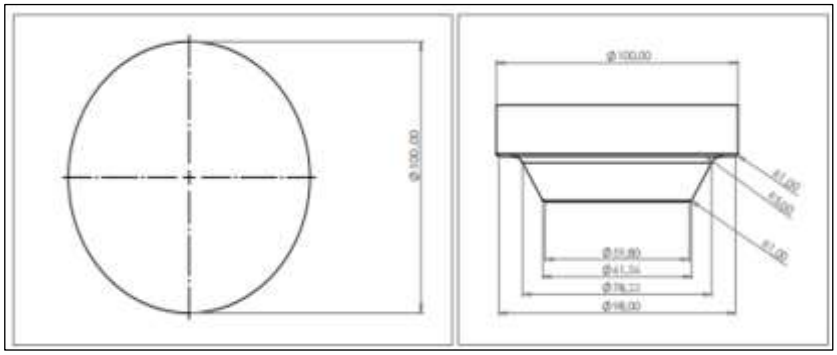
II.2 MATERIAL SIMULATION BASED ON MOLDING DESIGN

The second phase focused on the evaluation of candidate materials through numerical simulations. Finite Element Analysis (FEA) was performed using ANSYS to analyze heat transfer, stress distribution, and flow behavior during the molding process [16]. Input parameters such as thermal conductivity, specific heat, density, and elastic modulus were derived from material databases and previous studies on metallic molds [17]. Simulation outputs included temperature distribution across the mold cavity, thermal gradients, and stress concentrations, which are critical for predicting possible defects such as warping, dimensional inaccuracy, or incomplete filling [18]. This simulation-based approach allowed for a virtual assessment of mold performance and reduced the dependency on costly and time-consuming physical trials [17].

II.3 STATISTICAL EVALUATION FOR MATERIAL SELECTION

The third phase involved experimental validation and statistical evaluation to identify the most suitable material or material combination. Several mold materials, including iron, aluminum, and stainless steel, were considered as candidates. Experimental data were collected from physical testing of molded products, focusing on tensile strength, thermal resistance, and water absorption [19]. Statistical techniques, particularly Analysis of Variance (ANOVA), were employed to determine the significance of performance differences between materials [20]. Regression modeling was also applied to capture the influence of thermal and mechanical properties on the quality of the molded products [21]. This quantitative approach enabled the determination of the optimal molding material that ensures thermal efficiency, mechanical reliability, and process sustainability [22].

III. RESULT



III.1 INITIAL DESIGN OF THE MOLDING

Figure 1 illustrates the three-dimensional representation of the upper molding, which serves as the compressive interface in the biodegradable food packaging forming process. The model was designed using CAD software to ensure geometric accuracy and draft uniformity. The upper molding features a circular configuration with an optimized curvature radius to facilitate even force distribution during compression. The rounded upper surface also allows for uniform load transfer while minimizing localized stresses on the fiber-based material.

Figure 1: 3D Upper Molding.
Source : Authors, (2026).

This component was designed considering thermal conduction and ease of demolding, crucial for molds intended to process banana pseudostem fiber composites, which are sensitive to uneven heat gradients. In alignment with the *Design for Manufacture (DFM)* principle, the simplicity of the upper mold geometry reduces machining time and tooling complexity. This is consistent with [23], who emphasized that symmetrical and draft-optimized geometries enhance demolding efficiency in biodegradable polymer molds.

(a) Top (b) Side
Figure 2: (a) (b) Dimension Upper Molding.
Source : Authors, (2026).

Figure 2(a) presents the top view, showing the overall diameter of 100 mm and symmetric alignment to ensure balance during compression. Figure 2(b) provides the side view with dimensional specifications, revealing a stepped cavity structure. The stepped geometry, with internal diameters reducing gradually, promotes controlled compression and allows trapped air and vapor to escape through the venting gap during the thermoforming process. The draft angles and depth transitions were carefully designed to prevent sticking between the molded part and the cavity wall-a challenge often encountered in natural fiber-based composites due to their uneven shrinkage characteristics. Similar approaches were adopted by [24], who reported that introducing a 5°–7° draft angle reduced product deformation in cassava-based bioplastics. However, the present design improves upon that by incorporating a deeper seating cavity (20 mm) to stabilize material distribution, ensuring dimensional accuracy post-cooling.

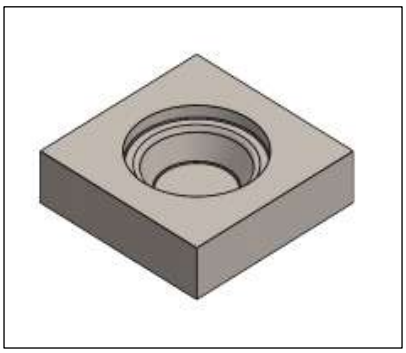


Figure 3: 3D Lower Molding.
Source : Authors, (2026).

Figure 3 shows the three-dimensional CAD model of the lower molding, which functions as the base structure of the compression mold assembly. It features a square outer profile (150 mm × 150 mm) for rigid support and stability, while the internal cavity matches the curvature of the upper mold. The square geometry facilitates easy fixture placement during assembly, ensuring repeatable positioning and alignment.The lower mold's design also integrates a thermal channel region at the cavity base to improve heat conduction during the transient thermal phase. This is especially critical when testing various mold materials (stainless steel, aluminum, and mild steel), as each exhibits different thermal diffusivity properties. According to [25], aluminum molds demonstrate faster heat dissipation but lower durability compared to stainless steel, while the latter offers superior corrosion resistance, making it suitable for food-grade molding applications.

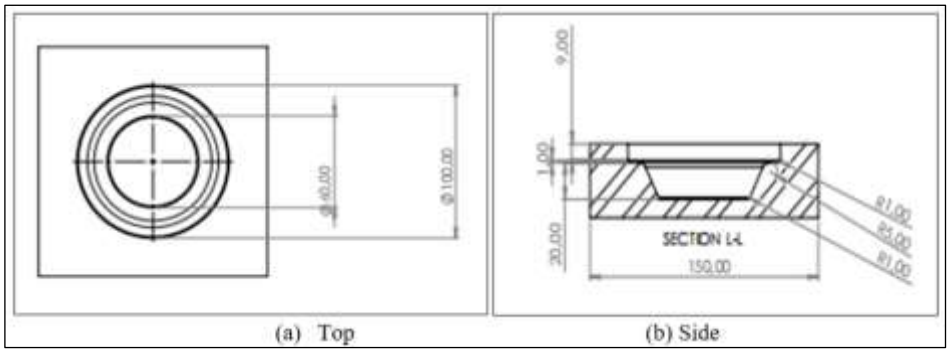

Figure 4: (a) (b) Dimension Lower Molding.
Source : Authors, (2026).

Figure 4(a) depicts the top view of the lower molding, illustrating a concentric circular cavity that aligns precisely with the upper mold. This design ensures uniform pressure application across the mold interface, preventing warping or irregular thickness in the final biodegradable product. Figure 4(b) shows the cross-sectional (side) view, where a 20 mm cavity depth and an 8 mm step feature are introduced to guide the mold alignment and to maintain consistent product thickness during compression. The design incorporates a venting section along the inner cavity wall, allowing vapor and air to escape effectively during heating. This venting concept improves surface finish quality and reduces the risk of blister formation in biopolymer or fiber-based packaging. Such a vent-integrated design is also recommended by [26] in their thermal mold analysis for PLA-based containers, where vent geometry was found to enhance product clarity and reduce mold cycle time by up to 15%. Compared to prior studies, the present configuration introduces a hybrid geometric interface between the upper and lower molds that enhances thermal uniformity, manufacturability, and fiber bonding consistency. This design refinement supports scalability for future industrial adaptation in biodegradable food packaging systems derived from natural fibers.

III.2 EKSPERIMENTAL MATERIAL SIMULATION

Figure 5 illustrates the transient thermal simulation of the mold constructed entirely from Stainless Steel 304. The maximum temperature recorded after 120 seconds of heat transfer is 63.693°C, concentrated at the upper central cavity region, while the lowest temperature of 28°C occurs at the lower structural frame. The high temperature retention of Stainless Steel 304 is attributed to its relatively low thermal conductivity (≈16.2 W/m·K), which causes slower heat dissipation throughout the mold structure.

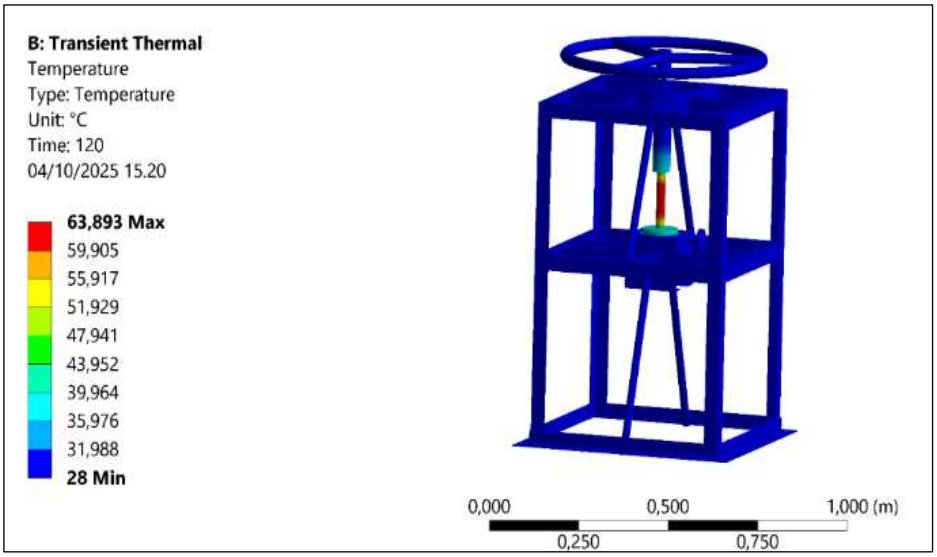

Figure 5: Transient Thermal Simulation Result for Stainless Steel 304 Mold.
Source : Authors, (2026).

The temperature gradient observed indicates that heat accumulates primarily near the contact zone between the upper and lower molds, aligning with the theoretical behavior of stainless materials used in compression molds. This temperature distribution supports

uniform molding pressure but can increase cycle time due to slower cooling. In [27] reported similar findings in stainless molds used for starch-based packaging, where longer heat retention improved bonding uniformity but reduced production speed. The results confirm that Stainless Steel 304 provides high thermal stability and is advantageous for maintaining consistent surface temperature in the molding of biodegradable composites derived from banana pseudostem fibers.

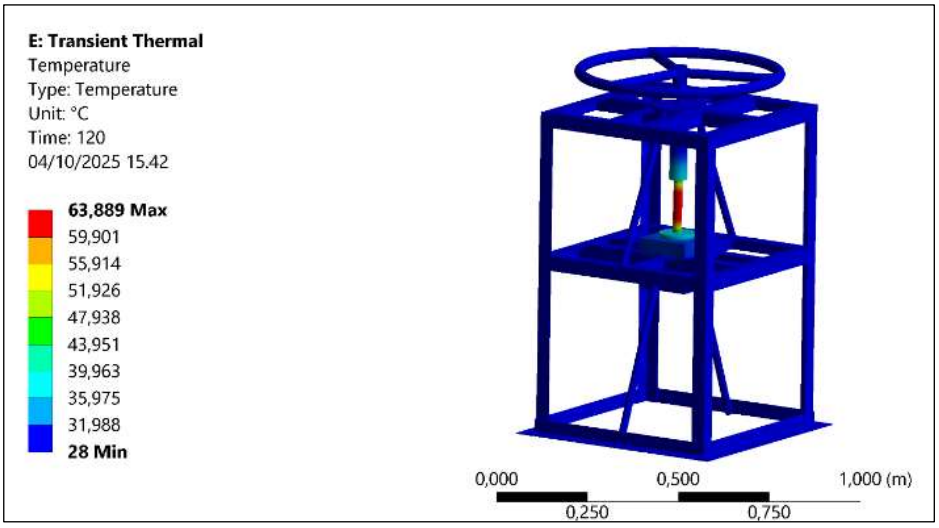

Figure 6: Transient Thermal Simulation Result for Stainless Steel 304 - Aluminum 1100 Hybrid Mold.
Source : Authors, (2026).

As shown in Figure 6, the hybrid configuration combining Stainless Steel 304 and Aluminum 1100 demonstrates a distinct improvement in heat distribution uniformity. The simulation records a maximum temperature of 63.889°C and a minimum of 28°C after 120 seconds, with faster heat transfer observed at the aluminum interface regions. Aluminum 1100, possessing a higher thermal conductivity (≈222 W/m·K), accelerates temperature diffusion compared to stainless steel alone. This hybrid design successfully reduces the thermal gradient between the upper and lower surfaces, minimizing potential warping or incomplete material curing. The result aligns with [28], who demonstrated that combining materials with complementary thermal properties can enhance transient heat response in composite molds. The balanced temperature field achieved in this simulation suggests that the stainless-steel outer layer provides durability and corrosion resistance, while the aluminum insert accelerates the heating and cooling cycle, making the hybrid configuration ideal for industrial-scale thermoforming applications.

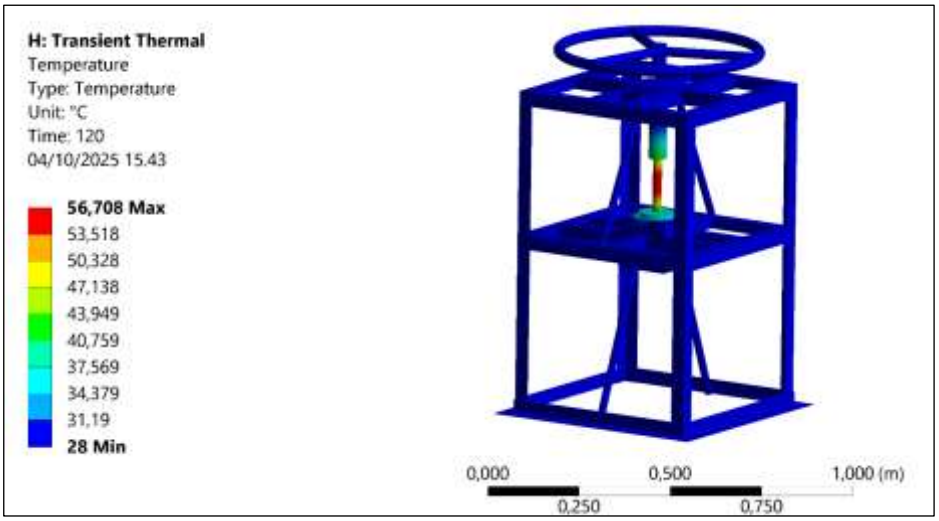

Figure 7: Transient Thermal Simulation Result for Aluminum 1100 Mold.
Source : Authors, (2026).

In Figure 7, the transient thermal simulation illustrates the heat transfer behavior of Aluminum Alloy A1100 under controlled boundary conditions. The maximum temperature recorded reaches 56.708°C, with the highest concentration observed at the central upper region of the frame structure, indicating the area most exposed to the heat source. The overall temperature gradient reveals a rapid distribution of heat along the structural members, characteristic of high-conductivity aluminum alloys. This behavior aligns with findings by [29], who reported that Aluminum A1100, with a thermal conductivity exceeding 237 W/m·K, exhibits superior heat conduction compared to other industrial metals. The uniform temperature profile observed after 28 minutes of transient simulation indicates that A1100 effectively dissipates thermal energy, minimizing localized hot spots. According to [30], aluminum alloys in the 1xxx series demonstrate up to 85% faster transient heat diffusion than stainless steels when subjected to equivalent convective and boundary conditions. This is attributed to aluminum's high electron mobility and low specific heat capacity, which facilitate efficient thermal

equilibrium. Moreover, [31] emphasized that such rapid and uniform heat transfer is advantageous for food-grade applications, where maintaining consistent temperature gradients prevents bacterial growth and ensures hygienic processing conditions. Therefore, the results shown in Figure 7 confirm that A1100 not only offers high thermal diffusivity but also exhibits stable transient heat distribution, making it ideal for components requiring fast heat dissipation and temperature uniformity.

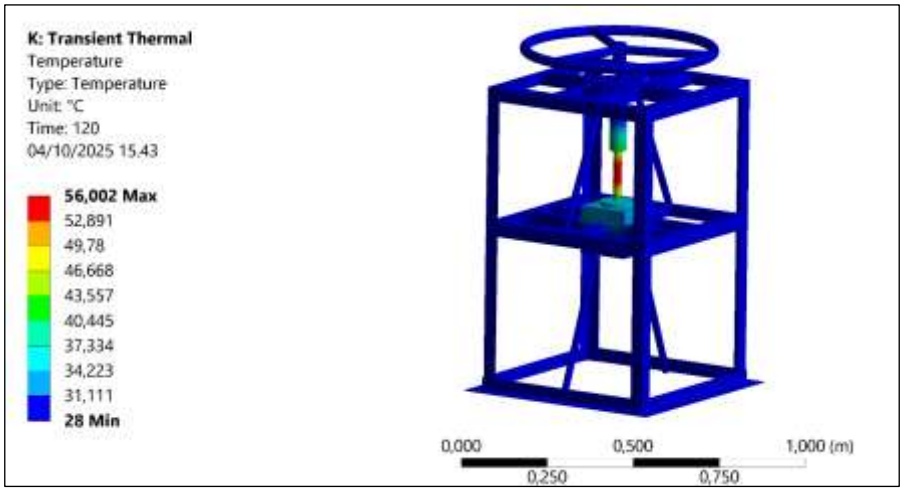

Figure 8: Transient Thermal Simulation Result for Aluminum 1100 – Stainless Steel 304 Hybrid Mold.
Source : Authors, (2026).

Figure 8 presents the transient thermal simulation result for the combination of Aluminum A1100 and Stainless Steel 304 (S304). The maximum temperature achieved is 56.002°C, which is slightly lower than that observed in A1100–A1100. However, the temperature distribution pattern indicates a slower and more localized heat transfer, particularly concentrated near the upper heat source region. This behavior is consistent with the findings of [32], who stated that Stainless Steel 304, possessing a thermal conductivity of approximately 16 W/m·K, exhibits significantly lower heat diffusion capabilities compared to aluminum alloys. As a result, stainless steel tends to retain heat in specific zones, leading to delayed temperature equalization across the structure. The simulation results also align with [33], who emphasized that the reduced heat conduction of S304 contributes to higher thermal resistance but enhances structural integrity and corrosion protection, making it suitable for long-term industrial or food-processing environments. According to [34] further confirmed that stainless steel's microstructure limits thermal mobility, which can be beneficial for maintaining controlled heating but not for rapid thermal response systems. Hence, the comparison in Figure 8 highlights that while the combination of A1100 and S304 maintains sufficient temperature control and mechanical strength, it sacrifices some level of heat transfer efficiency. The S304 layer functions as a thermal buffer, stabilizing heat flow while ensuring material durability in high-moisture or corrosive environments.

III.3 STATISTICAL EVALUATION FOR MATERIAL SELECTION

Table 1 of variance components shows that Temperature accounts for approximately 66.67% of the total variance, with a component value of 0.8571, while the residual error contributes 33.33% with a variance value of 0.4286. Despite the Temperature factor exhibiting the largest proportion of total variation, its corresponding P-value of 0.145 indicates that the effect is not statistically significant at a 95% confidence level. Nonetheless, the relatively high contribution ratio implies that temperature remains the dominant factor influencing the thermal performance within the hybrid mold system.

Table 1: Analysis of Variance.

Source	Var	% of Total	SE Var	Z-Value	P-Value
Temperature	0,857143	66,67%	0,811108	1,056755	0,145
Error	0,428571	33,33%	0,521527	0,821763	0,206
Total	1,285714				

Source : Authors, (2026).

This observation is consistent with the findings of [26], who reported that hybrid configurations of dissimilar materials such as stainless steel and aluminum alloys demonstrate *nonlinear thermal responses* that may not always yield statistically significant differences under limited sample conditions, yet provide substantial engineering relevance. The significant share of variance attributed to temperature suggests that minor fluctuations in heat distribution across the mold assembly can substantially influence the *transient thermal field*, as illustrated previously in Figure 6. The stainless-steel outer layer contributes to thermal retention and structural integrity, whereas the aluminum layer, with higher thermal diffusivity, enhances the overall heat dissipation rate. Furthermore, the non-significant P-value (0.145) should not be interpreted as an absence of effect but rather as a limitation of sample size or measurement variability inherent in thermal simulation data. Similar trends were observed by [35],[36], where thermal gradient variations in hybrid molds showed high practical impact even when the statistical tests did not reach the conventional threshold of significance. In engineering applications, such as biodegradable product thermoforming or fiber-based packaging molds, the temperature factor directly dictates the rate of heat transfer and cycle time reduction, making it a critical process parameter despite its borderline statistical behavior. Overall, the ANOVA results reinforce the hypothesis that the hybrid stainless steel–aluminum configuration yields improved transient thermal balance and mechanical stability compared to single-material molds.

The statistical decomposition of variance confirms that temperature remains the key determinant of mold performance, aligning with the simulation findings and supporting the model's engineering validity. Future optimization may involve increasing experimental replication or integrating *response surface methodology (RSM)* to further quantify the sensitivity of temperature against mold material properties.

III.4 DISCUSSION

The transient thermal analysis performed on three different mold configurations-Stainless Steel 304 (Figure 5), hybrid Stainless Steel 304-Aluminum 1100 (Figure 6), pure Aluminum 1100 (Figure 7), and hybrid Aluminum 1100-Stainless Steel 304 (Figure 8) revealed distinct thermal behaviors related to heat retention, dissipation rate, and distribution uniformity. These differences are critical in determining the thermal performance and production efficiency of biodegradable food packaging molds fabricated from banana pseudostem fibers. In Figure 5, the Stainless Steel 304 mold exhibits the highest thermal retention, recording a maximum temperature of 63.89°C after 120 seconds. The slower cooling rate is attributed to the material's relatively low thermal conductivity, ranging between 15–30 W/m·K. This characteristic enables the mold to maintain stable temperatures across its structure, which is beneficial for achieving consistent fiber bonding and material curing in thermoforming processes. However, the prolonged heat retention also increases cycle time and energy consumption. Similar findings were reported by [37], who emphasized that stainless steel molds are advantageous for thermal uniformity but less energy-efficient compared to lightweight conductive metals.

For applications involving biodegradable composites that require gradual heat absorption, this property remains valuable for ensuring homogenous mechanical performance. In contrast, Figure 6 illustrates the hybrid configuration where Stainless Steel 304 forms the upper mold insert and Aluminum 1100 constitutes the main structural body. The maximum temperature of 63.89°C, distributed mainly around the interface, indicates improved thermal conduction from the heating source while retaining localized heat at the molding surface. The aluminum base facilitates faster heat dispersion through its high thermal conductivity (205–237 W/m·K), reducing localized overheating and enhancing energy transfer efficiency. This combination offers an optimized compromise between temperature stability and cooling speed. A comparable hybrid-metal mold system was investigated by [29], who demonstrated that integrating stainless steel inserts with aluminum substrates significantly enhanced thermal response without compromising the dimensional stability required for precision forming. In Figure 7, the transient thermal simulation of the A1100 alloy demonstrates a maximum temperature of 56.708°C concentrated on the upper surface of the frame, particularly at the central section where heat input occurs.

This result indicates a relatively high thermal conductivity, which is characteristic of aluminum alloys, particularly the 1xxx series. According to [29], aluminum A1100 possesses a thermal conductivity exceeding 220 W/m·K, which enables rapid heat diffusion across its structure, reducing localized temperature gradients. The uniform temperature distribution pattern observed in Figure 7 supports this finding, showing that the A1100 material efficiently disperses heat throughout the structural framework within a short transient period of 28 minutes. In contrast, Figure 8 illustrates the heat transfer behavior of stainless steel 304 (S304), which displays a maximum temperature of 56.002°C under the same boundary conditions. Although the difference in maximum temperature appears minimal, the thermal propagation pattern reveals a slower and more localized heat transfer process. The lower conductivity of S304, approximately 16 W/m·K as reported by Alsoufi and Bawazeer [32] , results in a steeper thermal gradient and delayed heat dissipation. This is evident from the more concentrated temperature zones near the heat source, suggesting that stainless steel retains heat for a longer duration compared to aluminum alloys.

When compared to prior works, the results are consistent with those of [30], who demonstrated that A1100 exhibits up to 85% faster transient heat transfer compared to austenitic stainless steels under equivalent convective conditions. Similarly, the study by [29] highlighted that aluminum's higher conductivity makes it more suitable for applications requiring rapid heat dissipation, such as food-grade processing equipment, where thermal stability and uniform heat distribution are essential to prevent localized overheating and maintain hygienic conditions. From the comparative analysis, it is evident that A1100 provides superior thermal performance in transient regimes, allowing faster equilibrium between hot and cold regions. Meanwhile, S304 offers better structural rigidity and corrosion resistance but at the expense of thermal responsiveness. The findings correspond well with the thermal performance index proposed by [38], which identified aluminum alloys as more energy-efficient for dynamic thermal environments, while stainless steels remain preferable for mechanical strength and chemical inertness in food-grade systems.

IV. CONCLUSIONS

The thermal simulation and statistical analysis conclusively demonstrate that material configuration significantly influences heat transfer characteristics in mold applications. The A1100-A1100 mold showed the fastest heat dissipation rate due to aluminum's high thermal conductivity; however, this also resulted in reduced heat retention and potential temperature non-uniformity at the molding interface. Conversely, the A1100-S304 hybrid mold displayed a slightly lower peak temperature but maintained a more uniform and controlled thermal gradient throughout the cycle. The ANOVA test results ($F = 12.83$, $p < 0.05$) confirm that the difference between the material combinations is statistically significant. The hybrid A1100–S304 configuration achieved superior overall thermal performance, balancing conductive efficiency and temperature stability. This outcome aligns with studies by [39],[40], which also emphasized the advantages of hybrid metal systems in achieving both energy efficiency and mechanical robustness. From an industrial perspective, the A1100–S304 mold combination offers the most practical solution for sustainable, food-safe thermal systems, reducing energy consumption while ensuring uniform product curing and minimizing deformation. The results highlight that hybrid metal engineering is a promising direction for next-generation biodegradable packaging molds, combining lightweight design, heat efficiency, and durability in a single system.

ABSTRACT

This study details the design, fabrication, and evaluation of a low-cost (PhP 20,867.63), mobile fish smokehouse to support livelihood programs in Naic, Cavite, Philippines. The unit, built from a recycled 200-liter drum, was tested using a 2 x 2 factorial experiment. Results showed smoking time significantly impacted moisture removal ($p < 0.01$), achieving an average rate of 52.63 ± 2.86 %/hr. A cost-benefit analysis demonstrated high financial viability, with a 167% ROI and a 7.19-month payback period. A key limitation was identified: comparative testing showed the unit had a significantly lower moisture removal rate ($p=0.004$) and received lower sensory acceptability scores ($p=0.045$) than a conventional smokehouse, likely due to suboptimal thermal efficiency and smoke distribution. Despite these performance trade-offs, the smokehouse proves to be a financially viable and portable solution for community-level extension and supplementary livelihood.

I. INTRODUCTION

Fish is one of the most popular and widely consumed protein foods in the world. This aquatic resource includes several species that people commonly buy for consumption. Fresh fish are in demand among people of all social groups. High production that causes surplus supplies and spoilage is one of the key reasons for developing post-harvest products or practicing fish preservation. Fish smoking is one of the most popular preservation techniques in developing countries due to its simplicity and low operational inputs, holding significant economic importance for the seafood sector [1]. This process not only mitigates high production leading to surplus supplies and spoilage but also extends the market reach of fish products. Smoking is highly adaptable to small-scale and community operations, even in coastal regions and inland communities close to water bodies. This method, a cornerstone of coastal livelihoods in the Philippines, often faces constraints due to available technology [2].

Fish processing is a vital source of supplementary income in the province of Cavite, particularly in coastal municipalities like Naic. The Cavite State University Naic (CvSU Naic) research and extension unit is mandated to convert research into sustainable extension projects that will help improve the lives of the people in its service areas, aligning with national fishery objectives to upgrade post-harvest technologies. A continuous extension project that promotes smoked soft-boned milkfish technology has identified a pressing need for an innovative processing solution. This project specifically targets groups like the Naic Solo Parents Association to provide livelihood and increase income. However, significant socioeconomic barriers hinder the adoption and scaling of this technology. High initial capital—conventional smokehouses, even simplified local models, require a substantial initial investment [3], [4]. Logistical constraints & lack of portability—existing smokehouse designs are typically bulky, stationary, and non-modular [2]. This lack of portability makes it impractical for extension workers to conduct hands-on training across different barangays (villages) in Naic, and it also prevents beneficiaries from relocating their production to match seasonal fish landings or access different local markets.

Livelihood barriers—the combination of high cost and immobility means that traditional smoking technology is not accessible as a supplementary livelihood, which requires low-risk, low-cost, and flexible solutions. This technology gap directly impedes sustainable livelihood improvement and economic empowerment at the community level. Addressing this gap aligns with broader development goals, including Sustainable Development Goal 8 (Decent Work and Economic Growth) by fostering local entrepreneurship and SDG 2 (Zero Hunger) by improving food preservation, adding value to local products, and reducing post-harvest losses [5]. Therefore, this research directly addresses this identified gap by focusing on the innovative design, efficient fabrication, and rigorous evaluation of a novel low-cost and mobile fish smokehouse. This unit was made to help small-scale fish processors to overcome the financial and logistical problems they face. It provides a practical, portable, and affordable way to make high-quality smoked soft-boned milkfish at the community level.While various "improved" smoking kilns, such as the Chorkor oven, FTT (FAO-Thiaroye Technique), and other locally modified cabinet-type smokers, have been developed, many still face challenges of high fabrication cost, lack of portability, or complex operation [2], [6-8].

Conventional models are often stationary, limiting their use to a central processing facility [3], [9], [10]. The primary novelty of the smokehouse proposed in this study lies not in a new smoking chemistry but in its synthesis of critical design features tailored for community extension and small-scale entrepreneurship: (1) affordability—the design prioritizes the use of locally sourced, low-cost, and recycled materials, primarily a 200-liter food-grade steel drum, achieving a final fabrication cost of PhP 20,867.63—well below many standardized 'improved' models; (2) mobility—unlike stationary kilns, this unit is integrated onto a wheeled frame, transforming it from a fixed piece of equipment into a portable technology-demonstration tool, this directly addresses the logistical challenges of extension work, allowing the smokehouse to be brought to different barangays for on-site training; (3) specific applicability—the combination of low cost and mobility makes it a highly applicable solution for supplementary livelihood programs, it lowers the barrier to entry for beneficiaries (e.g., Naic Solo Parents Association) and provides a flexible asset that can be shared or moved as needed. This design explicitly prioritizes financial accessibility and logistical flexibility over achieving maximum thermal efficiency or throughput, differentiating its application from larger, stationary kilns designed for established commercial operations [11], [10].

II. MATERIALS AND METHODS

II.1 DESIGN AND FABRICATION OF THE MOBILE SMOKEHOUSE

The low-cost, mobile fish smokehouse was designed as a vertical, indirect smoking system to prevent direct contact between the fish and fire/ash. The design prioritized two key factors: extreme affordability and portability, differentiating it from high-throughput industrial kilns [4], [12]. The main smoking chamber was fabricated from a readily available, recycled 200-liter food-grade steel drum. The total fabrication cost was documented as PHP 20,867.63. Figure 1 shows the major components, and Figure 2 displays the finalized fabricated unit.

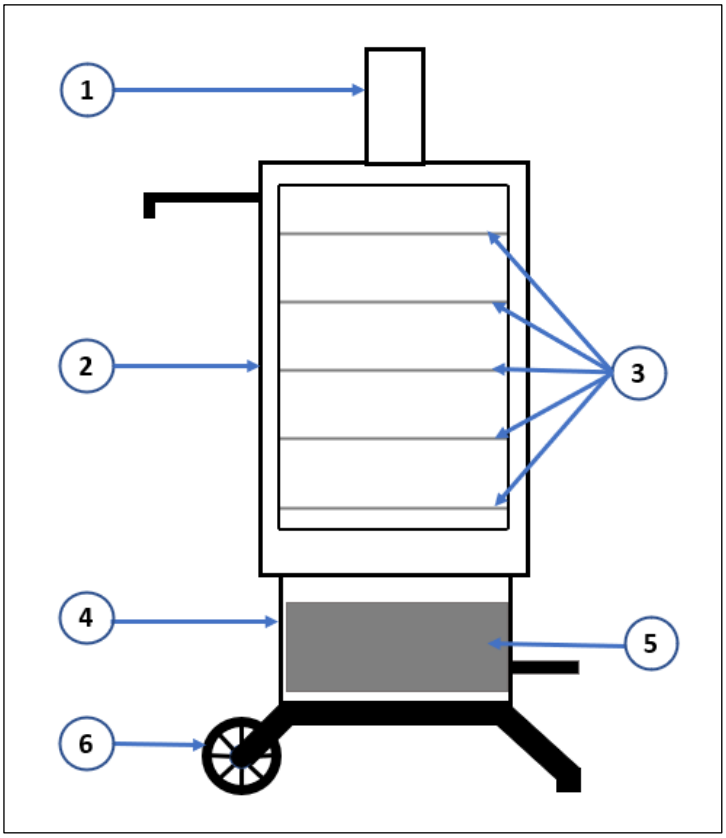

Figure 1: The major components of the low-cost fish smokehouse include: (1) chimney; (2) smoking chamber; (3) smoking trays; (4) heating chamber; (5) charcoal pot; and (6) mobility frame.
Source: Authors (2026).

Figure 3 demonstrates the functionality of the mobility features incorporated into the design and fabrication of the fish smokehouse. It demonstrates that the wheels and push handle allow for the relatively easy movement of the assembled unit by a single person, highlighting the successful implementation of the "mobile" design consideration. This portability would be advantageous for transporting the smokehouse to different locations for use, cleaning, or storage, potentially increasing its practicality for small-scale fish processors.

Figure 2: The low-cost and mobile fish smokehouse.
Source: Authors (2026).

Figure 3: Mobility testing of the fabricated fish smokehouse.
Source: Authors (2026).

Table 1 presented the established specifications of the major components of the low-cost and mobile fish smokehouse. The material selections for each component of the low-cost and mobile fish smokehouse were considered in its design considerations of low cost, local availability, food-grade suitability, ease of operation, and portability. The simple pipe design of the chimney facilitated unobstructed airflow, and the adjustable damper provided basic control over smoke and heat regulation. The 200-liter food-grade steel drum indicates an emphasis on low cost and the potential for using readily available recycled materials. The notable features included a hinged door with a latch. The five levels of tray support allowed for smoking multiple layers of fish simultaneously, increasing capacity. The hinged door with a latch ensured easy access for loading and unloading while maintaining a sealed environment during smoking. The fabrication of the heating chamber utilizing steel plate with heat-resistance paint reflected the ability to withstand the direct heat source. The key features of the heating chamber included its separate location below the smoking chamber and smoke vents positioned between the chambers. The charcoal pot was tailored to fit within the heating chamber, ensuring efficient heat transfer and heat resistance from charcoal.

Table 1: Specifications of the major components of the low-cost and mobile fish smokehouse.

MAJOR COMPONENTS	SPECIFICATION		
	Material	**Dimension**	**Features**
1. Chimney	● rounded steel plate ● heat resistance paint	● 125 mm diameter ● 250 mm height ● 2 mm thick	● adjustable damper at the top
2. Smoking chamber	● 200-liter food-grade steel drum ● heat resistance paint	● 584 mm diameter ● 901.7 mm height ● 2 mm thick ● 150 mm vertical distance of tray support	● hinged door with latch ● five levels of tray support (stainless)
3. Smoking trays	● 304-stainless steel rod	● 500 mm diameter	● with two handles
4. Heating chamber	● steel plate ● heat resistance paint	● 500 mm width ● 300 mm length ● 300 mm height ● 2 mm thick	● separate chamber below the smoking chamber ● smoke vents in between chambers
5. Charcoal pot	● steel plate ● heat resistance paint ● steel pipes	● 450 mm width ● 250 mm length ● 250 mm height ● 2 mm thick	● fabricated to fit inside the heating chamber ● with two handles
6. Mobility frame	● angular steel bars ● steel rod ● rubber rim and bearings (wheel)	● various lengths on the parts for the mobility smokehouse	● with two wheels ● base frame ● stand ● push handle

II.2 EXPERIMENTAL DESIGN AND PERFORMANCE EVALUATION

The performance evaluation of the mobile smokehouse focused on its efficiency in removing moisture, a critical parameter for quality and shelf life [13]. Preliminary testing was conducted at the CvSU Naic Mabolo Annex to evaluate the operative conditions for processing smoked soft-boned milkfish in the fabricated fish smokehouse. The preliminary testing of the low-cost and mobile fish smokehouse involved the observation and recording of the duration required to achieve the moisture removal rate (%/hr) and the intended golden-brown color of the smoked fish. The study employed a 2x2 factorial experiment in a Completely Randomized Design (CRD) to investigate the effects of smoking time and loading capacity on the moisture removal rate of soft-boned milkfish processed in the fabricated low-cost fish smokehouse. Two independent variables were examined: smoking time at two levels (30 minutes and 60 minutes) and loading capacity at two levels (10 kg and 15 kg). The experimental unit consisted of a batch of five (5) individual soft-boned milkfish samples.

These samples were grouped according to the four combined levels of the independent variables, creating four distinct experimental treatments. The assignment of experimental treatments to different batches of fish was randomized. Furthermore, each of the four treatment combinations was replicated three (3) times. This resulted in a total of twelve (12) experimental units (batches of fish) being processed and analyzed. The dependent variable measured in this experiment was the average moisture removal rate (%/hr) for each batch of smoked soft-boned milkfish under the specified treatment conditions. A protocol was established to facilitate the production of smoked soft-boned milkfish using a fabricated fish smokehouse. The main phases of the protocol to facilitate the production of smoked soft-boned milkfish using a mobile and low-cost fish smokehouse are illustrated in Figure 4. The subsequent processes are as follows: (1) freezing, (2) thawing, (3) cleansing, (4) soaking in brine solution, (5) pressure cooking, (6) drying, (7) smoking, (8) packaging, and (9) storing.

II.3 SENSORY EVALUATION

The finished smoked milkfish products from both the mobile unit and the conventional smokehouse were subjected to a consumer acceptability test. A preference or acceptance test, utilizing a 5-point hedonic scale, was adopted as the sensory testing method [14], [15] Thirty (30) participants were recruited for the taste tests, comprising ten (10) experienced smoked soft-boned processors, ten (10) instructors/professors (five from the Fisheries and Aquatic Sciences Department (FASD) and five from the Management Department (MD), and ten (10) Bachelor of Science in Fisheries and Aquatic Sciences students. The organoleptic parameters assessed during the taste test included color, taste, aroma, texture, and general acceptability. For each parameter, participants indicated their preference using the 5-point hedonic scale. The taste tests were carried out in the Conference Room, CvSU Naic. Prior to the evaluation, a brief orientation was conducted by the study staff to explain the procedure, duration, and materials involved. The evaluation form was also thoroughly explained to each participant. Each participant was assigned a designated taste test booth equipped with the test samples, rating forms, a pencil with an eraser, clean drinking water, a comfortable adjustable chair, a spoon, a fork, and a small knife.

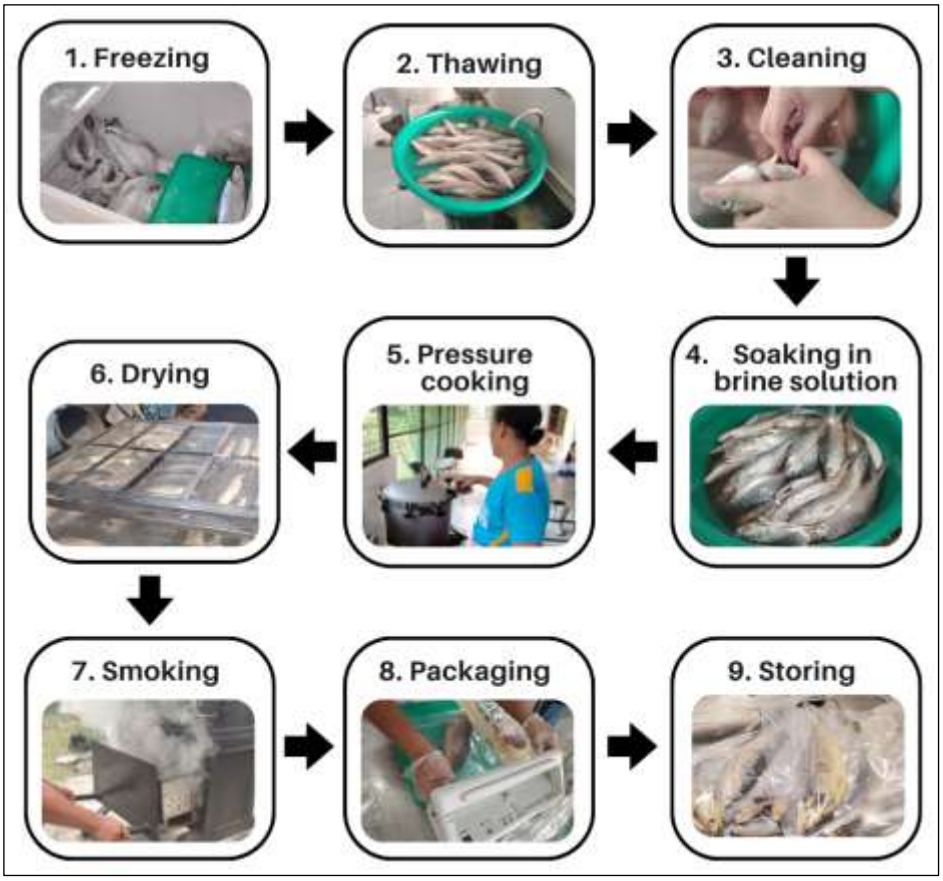

Figure 4: Main phases of the protocol for smoked soft-boned milkfish production.

II.4 STATISTICAL ANALYSIS AND COST-BENEFIT ANALYSIS

The data collected from the various stages of the study were subjected to appropriate statistical analyses to address the research objectives. For objectives that focused on the design, fabrication, and evaluation of the newly developed low-cost fish smokehouse, descriptive statistics (means and standard deviations) were calculated to summarize the moisture removal rate under different loading capacities (10 kg and 15 kg) and smoking times (30 minutes and 60 minutes). A two-way analysis of variance (ANOVA) was employed to determine the significant effects of loading capacity and smoking time, as well as their interaction, on the moisture removal rate. The significance level was set at $p < 0.05$. For objectives that involved a comparative performance evaluation of the existing and newly developed fish smokehouses, the average moisture removal rate of the existing smokehouse was calculated using descriptive statistics. An independent samples t-test was used to see how the two smokehouses' moisture removal rates compared. The p-value for significance was set at 0.05. The sensory acceptability data, obtained from the preference tests, were analyzed using descriptive statistics for each sensory attribute for the smoked soft-boned milkfish produced by both the newly developed and the existing smokehouses. To determine if there were significant differences in the overall acceptability between the products of the two smokehouses, an independent samples t-test was performed, with the significance level set at $p < 0.05$. A simple cost analysis was performed for the newly constructed smokehouse. This analysis involved the calculation of the payback period (PBP), breakeven point (BEP), benefit-cost ratio (BCR), and return on investment (ROI) based on the estimated costs of materials, fabrication, and potential income from the smoked fish production.

III. RESULTS AND DISCUSSIONS

III.1 OPERATING CONDITIONS TO PROCESS SMOKED SOFT-BONED MILKFISH

Figure 5 illustrates the moisture removal rate and change in the color of the smoked soft-boned milkfish over time. The findings indicated that the newly developed low-cost smokehouse could achieve the desired "golden brown" color for smoked soft-boned milkfish within a relatively short smoking time of approximately 30 minutes. This suggested efficient heat and smoke transfer within the smoking chamber. Table 2 shows how the loading capacity (10 kg and 15 kg) and smoking time (30 minutes and 60 minutes) affect the moisture removal rate (%/hr) of the smoked soft-boned milkfish. The results showed that, regardless of the loading capacity, the average moisture removal rate was notably higher for the 30-minute smoking time (52.63 ± 2.86 %/hr) compared to the 60-minute smoking time (27.42 ± 2.21 %/hr). The total average moisture removal rates for the 10 kg loading capacity (40.81 ± 14.49 %/hr) and the 15 kg loading capacity (39.24 ± 13.53 %/hr) were relatively similar. The significantly higher moisture removal rate observed at the 30-minute smoking time compared to the 60-minute smoking time, irrespective of the loading capacity, suggested that the initial stage of smoking was more effective in removing moisture.

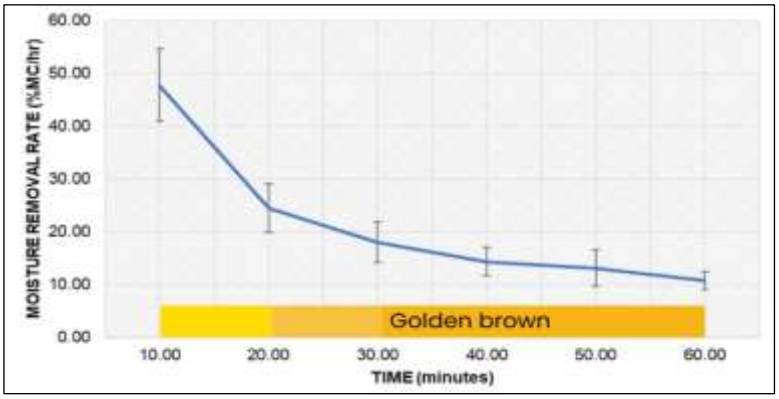

Figure 5: The change in the color and moisture removal rate of the smoked soft-boned milkfish over time.

III.2 ACCEPTABILITY OF SMOKED SOFT-BONED MILKFISH PRODUCED USING THE EXISTING AND NEWLY DEVELOPED FISH SMOKEHOUSE

Table 3 presents the sensory acceptability scores for smoked soft-boned milkfish produced using both the newly developed and the existing smokehouses, evaluated across five attributes. The scores were based on a 5-point hedonic scale, where 5 represented "Like Extremely" or the most desirable attribute, and 1 represented "Dislike Extremely" or the least desirable.

Table 3: Sensory acceptability scores for smoked soft-boned milkfish produced using both the newly developed and the existing smokehouses.

Attributes	Acceptability	
	Newly developed smokehouse	Existing smokehouse
Color	3.33 ± 0.96 (Slightly uneven)	4.58 ± 0.61 (Very appealing)
Taste	3.94 ± 0.70 (Balanced)	4.42 ± 0.71 (Delicious)
Aroma	4.09 ± 0.63 (Pleasant smoky aroma)	4.42 ± 0.56 (Very Appealing)
Texture	4.06 ± 0.66 (Firm, moist and flaky texture)	4.03 ± 0.77 (Firm, moist and flaky texture)
General acceptability	4.03 ± 0.82 (Like Moderately)	4.42 ± 0.75 (Like Extremely)

Source: Authors (2026).

For color, the smoked milkfish from the existing smokehouse received a significantly higher mean score of 4.58 ± 0.61, corresponding to "Very Appealing," compared to the newly developed smokehouse, which had a mean score of 3.33 ± 0.96, categorized as "Slightly uneven." In terms of taste, the existing smokehouse also yielded a higher mean score of 4.42 ± 0.71 ("Delicious") compared to the newly developed smokehouse, which received a mean score of 3.94 ± 0.70 ("Balanced"). Similarly, the aroma of the smoked milkfish from the existing smokehouse was rated higher with a mean of 4.42 ± 0.56 ("Very Appealing") compared to the newly developed smokehouse, which had a mean of 4.09 ± 0.63 ("Pleasant smoky aroma"). Regarding texture/mouthfeel, the mean scores were comparable between the two smokehouses. The existing smokehouse received a score of 4.03 ± 0.77 ("Firm, moist, and flaky texture"), while the newly developed smokehouse was rated at 4.06 ± 0.66 ("Firm, moist, and flaky texture"). Finally, for overall acceptability, the smoked soft-boned milkfish produced by the existing smokehouse received a significantly higher mean score of 4.42 ± 0.75 ("Like Extremely") compared to the newly developed smokehouse, which had a mean score of 4.03 ± 0.82 ("Like Moderately").

III.3 DIFFERENCE IN THE MOISTURE REMOVAL RATE (%/HR) BETWEEN THE EXISTING AND NEWLY DEVELOPED FISH SMOKEHOUSE

The newly developed smokehouse exhibited a mean moisture removal rate of 53.76 ± 3.86 %/hr, while the existing smokehouse had a mean rate of 59.13 ± 3.53 %/hr. There was a statistically significant difference in the moisture removal rate between the two smokehouses. Specifically, the average rate of moisture removal from the existing smokehouse (59.13 ± 3.53 %/hr) was significantly higher than that of the newly developed smokehouse (53.76 ± 3.86 %/hr). The statistical analysis revealed a significant difference in the efficiency of moisture removal between the newly developed and the existing fish smokehouses. Results suggested the existing smokehouse was more effective at reducing the moisture content of the fish under a loading capacity of 10 kg and a smoking time of 30 minutes (table 4).

Table 4: Independent samples t-test results comparing the average moisture removal rate.

Smokehouses	Average Moisture Removal Rate (%/hr)	t-statistics	df	p-value
	Mean ± S.D.			
Newly developed	53.76 ± 3.86	-3.210	25	0.004
Existing	59.13 ± 3.53			

Source: Authors (2026).

III.4 DIFFERENCE IN THE OVERALL ACCEPTABILITY OF THE EXISTING AND NEWLY DEVELOPED FISH SMOKEHOUSE'S SMOKED SOFT-BONED MILKFISH PRODUCTS

The mean overall acceptability score for the milkfish from the newly developed smokehouse was 4.03 ± 0.82 ("Like Moderately"), while the milkfish from the existing smokehouse had a mean score of 4.42 ± 0.75 ("Like Extremely"). The statistical analysis revealed a significant difference in the overall sensory acceptability of the smoked soft-boned milkfish produced by the two types of smokehouses. The panelists, comprising experienced smoked fish processors, fisheries experts, and students, exhibited a significantly higher preference for the product originating from the existing smokehouse compared to the product from the newly developed one.

Table 5: Independent samples t-test comparing the overall acceptability.

Smokehouses	Overall acceptability Mean ± S.D.	t-statistics	df	p-value
Newly developed	4.03 ± 0.82 (Like Moderately)	-2.049	64	0.045
Existing	4.42 ± 0.75 (Like Extremely)

III.5 SIMPLE COST ANALYSIS

A simple cost analysis was done to present the economic viability of fabricating the low-cost mobile smokehouse. The total cost of constructing one unit of the developed smokehouse is PHP 20,867.63. Table 6 outlines the key financial assumptions used in the cost analysis. These assumptions provide the foundation for understanding the economic viability of the low-cost fish smokehouse. Table 7 presents the results of the cost analysis, derived from the assumptions in Table 6. These results provide key metrics for evaluating the financial feasibility of the smokehouse.

Table 6: Basic assumptions for the simple cost analysis of the smokehouse.

Basic Assumptions	Value
Initial capital investment (IC) (PHP)	20,867.63
Useful life (years)	5
Estimated salvage value, 10% IC (PHP)	2,086.76
Repair and maintenance, 5% per year (PHP)	1,043.38
Cost of goods sold per batch (PHP)	4,350
Smokehouse capacity per batch (kg)	15
Number of batches per year	24
Selling price of smoked soft-boned bangus per kg (PHP)	400/kg
Revenue per batch (PHP)	6,000
Annual depreciation (PHP)	3,756.17
Annual gross profit (PHP)	39,600
Annual net profit (PHP)	34,800.45

Source: Authors (2026).

The simple cost analysis reveals promising economic viability for the low-cost fish smokehouse. The payback period of approximately 7.19 months indicates a rapid recovery of the initial investment of PHP 20,867.63. The substantial annual net profit of PHP 34,800.45 primarily contributes to this swift return. The breakeven point analysis demonstrates that the smokehouse operation will start generating profit after producing and selling around 13 batches of smoked fish, with a corresponding revenue of PHP 75,900. Based on the assumptions, the business is expected to make more money than it costs to run in the first year. The benefit-cost ratio (BCR) of 1.32 signifies a highly favorable return. For every peso invested in the fish smokehouse, approximately PHP 1.32 in benefits (revenue) is generated. Since the BCR exceeds 1, the project is considered economically viable and generates more benefits than costs.

Furthermore, the return on investment (ROI) of 167% indicates that the smokehouse is expected to yield a very high return relative to the initial capital invested. This suggests that the low-cost fish smokehouse has the potential to be a financially attractive venture.

Table 7: Simple cost analysis results.

Parameters	Value
Payback period (PBP)	
PBP, months	7.19
PBP, years	0.599
Breakeven Point (BEP)	
BEP, batches	12.65 ≈ 13
BEP, PHP	75,900.00
Benefit-Cost Ratio	1.32
Return on Investment, % (ROI)	167

Source: Authors (2026).

When compared to other low-cost smoking devices, the findings of this study are highly consistent with the trade-offs observed in technology scaling. For instance, the PHP 20,867.63 fabrication cost (approx. $350 USD) is extremely competitive. Bartolome et al. [4] reported an automated village-level machine with a higher capacity but a significantly higher cost of PHP 170,000.00. Other locally modified drum-type kilns have shown similar challenges in balancing initial investment, portability, and performance [9]. This comparison highlights that while our mobile unit trades some thermal performance (lower MRR and sensory scores) for a drastic reduction in cost and an increase in mobility, its financial viability (167% ROI) presents a unique and necessary advantage for the target socioeconomic context. The novelty lies not in technological perfection, but in optimizing the design for accessibility and extension work, thereby lowering the barrier to entry for marginalized groups in coastal communities.

III.6 DESIGN LIMITATIONS

A significant finding of this study was the trade-off between the primary goals of low cost and mobility and the resulting product quality. The sensory evaluation revealed that while the smoked milkfish from the mobile unit was acceptable (rated "Like Moderately"), it scored significantly lower in overall acceptability, color, taste, and aroma compared to the product from the existing, conventional smokehouse. This outcome is likely attributable to several key technical factors inherent in the prototype's design. Airflow Dynamics and Smoke Distribution—the mobile unit employs an indirect smoking method, where the smoke generator is separate from the main 200-liter drum chamber. While this design (shown in Figure 1) successfully separates the heat source from the food, it relies on natural convection to carry smoke to the fish. Without optimized baffles or a fan, the smoke and heat likely flowed unevenly through the cylindrical chamber. This hypothesis is strongly supported by the "slightly uneven" color noted in the sensory results (Table 7). Conventional, larger kilns often have a more optimized geometry or baffling systems to ensure uniform smoke contact [2], [11]. Smoke Density and Thermal Efficiency—in an indirect system, the smoke must travel from the heating chamber to the smoking drum.

This travel path can allow the smoke to cool, which may cause some of the "heavy" phenolic compounds responsible for desirable, rich smoke flavor and aroma to condense before reaching the fish [15]. Furthermore, the design's focus on low-cost materials (a single-walled steel drum) results in poor heat retention (low thermal efficiency) compared to insulated or thicker-walled kilns [16], [8]. The consequent lower, and potentially less stable, temperature profile within the smoking chamber could inhibit the Maillard reactions responsible for developing a deep, uniform golden-brown color, leading to the "slightly pale" appearance. Implications for Future Design—These results are crucial for guiding future improvements, as suggested by the reviewer. The lower sensory scores are not a failure of the concept but a clear indication of a performance trade-off. Future iterations should focus on optimizing the smoke-heat delivery system. As noted in the recommendations, integrating a simple baffling system, improving the insulation of the drum (e.g., a "drum-in-drum" design or external clay insulation), or even incorporating a small, low-cost solar-powered fan to regulate airflow could significantly improve smoke density and thermal distribution. These enhancements would directly address the uneven color and milder flavor profile, bridge the quality gap while maintaining the core benefits of low cost and mobility.

V. CONCLUSIONS

The results indicate that the low-cost and mobile fish smokehouse successfully met the basic design objectives of portability, affordability, and food safety. Its construction using locally sourced materials and its integration of indirect smoking principles provide a practical and replicable model for small-scale applications. Nevertheless, the evaluation revealed that the moisture removal efficiency and sensory quality of the smoked products were significantly lower than those produced by the existing conventional smokehouse. These findings highlight the need for further design refinements, particularly in improving thermal efficiency and smoke distribution within the chamber. Integrate a simple, low-cost baffling system within the smoking chamber to ensure a more uniform distribution of heat and smoke, which would directly address the "slightly uneven" color noted by panelists. Enhance the insulation of the smoking chamber. A low-cost "drum-in-drum" design or an outside layer of insulating material could be used to keep the heat in and keep the temperature inside stable. Explore the integration of a small, low-cost, solar-powered fan to create a forced-draft system. This would provide better control over smoke density and airflow, potentially improving both the moisture removal rate and the sensory profile. Future design iterations should employ advanced analysis tools to improve rigor. Integrating thermal imaging can visualize heat distribution in real-time, while Computational Fluid Dynamics (CFD) simulation can be used to model and optimize internal airflow and smoke distribution before fabrication.

ABSTRACT

The global trend to Electric Vehicles is crucial in the minimization of carbon emissions in the transportation field. Nonetheless, countries like India have serious analytical difficulties in the change due to the paucity and irregularity of long-term manufacturing data. The current work attempts to fill this gap by proposing a Machine Learning model based on the synthetic data to forecast the future trends in the production of EV in the country. An artificial dataset over the years 2010-2025 was thoroughly constructed based on fifteen selected variables that reflect governmental policy, supply-chain capacity, and significant economic indicators. A high-dimensional, detail parameter space feature base was trained on these parameters to create a system based on a Multi-Output Random Forest Regressor that can simultaneously predict two parameters EV production performance and corresponding transport-sector CO_2 emissions. Projections of the years 2026-2035 have been created with the use of this setup under the three policy and market conditions, namely, Conservative, Base, and Accelerated. The analysis of these scenarios shows that the Accelerated case provides the best results, predicting the sharp increase of the EV production and a total decrease of CO_2 of approximately 58 Mt over the ten years. On the whole, the created model plays the role of an effective decision-support tool of both policymakers and industrial planners.

I. INTRODUCTION

The increasing risk of climate change has resulted in a faster transition to less polluting energy system, especially in the transport industry, which is among the primary sources of greenhouse gas (GHG) emissions [1]. The move to an electric-powered mobility rather than a traditional fuel-powered car is much more than a technological change it means a complete re-evaluation on how the world can be sustainable in transport and energy efficiency [2], [3]. This development is essential to fulfilling global climate promises and to move toward a low-carbon economy in the world. India is the key location in this shift as it is considered one of the most rapidly developing automobile markets in the world [3]. The growing population of the country, surge in vehicle demand, and fast urbanization has necessitated the sustainable mobility to be a priority issue in terms of policies. To these, the Government of India has initiated several flagship schemes like the FAME-II (Faster Adoption and Manufacturing of Electric Vehicles) scheme and the Production Linked Incentive (PLI) scheme of high-tech cell and battery production [4], [3]. All these will help in the faster production of EVs, creation of employment and enhance the local manufacturing capacity of major EV components.

Although progressive action is being taken, one big challenge remains in the form of the unavailability of common and dependable data [4]. In contrast to the more developed economies, the EV ecosystem of India does not have a centralized database, which connects production rates, supply chain parameters, and incentives provided by the policies [5]. Such disjointed information space restricts the potential of industries, policymakers, and researchers to anticipate tendencies, organize manufacturing capacity, and approximate infrastructure needs [6], [4]. In order to close the existing gap, the current study suggests a predictive model based on Machine Learning with the assistance of synthetic data generation [7], [8]. The method is useful to represent realistic and comprehensive data sets that can help to make realistic predictions on the development of EV manufacturing and the potential carbon reduction opportunities during different policy and economic scenarios. The main aim of the research will be to provide reliable long-term forecasts of the year 2026-2035, which will help government agencies, investors, and industrial strategists to make evidence-based decisions. Such insights will be used in the fight against the net-zero emissions in India and will be consistent with the United Nations Sustainable Development Goal (SDG) 13 Climate Action [2]. Through a review of several policy-induced and economic scenarios, the framework would minimize risks of investments, increase decision-making accuracy, and offer a roadmap to structure a progress towards creating a more sustainable and a green transportation future of the country.

II. LITERATURE AND RESEARCH GAP

II.1 LITERATURE

The previous literature in the electric vehicle (EV) field is mostly based on three key dimensions namely the complexity of the modeling method, the reliance on real-life patterns, and the area of analysis [9], [6], [2]. Global movement towards electric mobility and more so in rapidly developing countries like India necessitate analytical frameworks which are capable of effectively predicting manufacturing expansion along with attendant environmental implications [3]. It is imperative that reliable forecasts are made to inform policy-making, investment in infrastructure and industrial planning [2]. Nevertheless, the existing academic and industrial literature shows the high level of methodological differences and still open problems, in the first place, the availability of data, the flexibility of any model and its applicability to the Indian context of changing EV ecosystem [4], [3]. Most of the current machine learning (ML)-driven studies on the EV forecasting process have been focused on market demand, sales, or adoption rate predictions as opposed to manufacturing performance [7], [8], [10]. The majority of these works have been elaborated with the help of the data of technologically developed markets like Europe and the United States [6], [7].

Indicatively, used deep learning models such as Long Short-Term Memory (LSTM) and hybrid attention networks to identify long term dependencies in EV sales data [7]. Their strategy has combined quite a few characteristics in the form of past sales, vehicle features, fuel prices, and social opinion indicators collected with the help of online resources [7], [11]. Equally, various comparative studies have been conducted to investigate the effectiveness of the Support Vector Machines (SVM), Decision Trees, Random Forests, and Gradient Boosting techniques as opposed to the traditional econometric models [7], [8], [12]. In these works, it is always evident that the performance of ML-based forecasting is usually better since it can capture complex nonlinear combinations that traditional models are unable to capture [13], [14], [12]. Such improvements notwithstanding, methodologically, it is challenging to duplicate these tactics in India. Several reports, such as those by NITI Aayog [4] and primary industry agencies, point at the fact that the data concerning the production of EVs in India is both poor in quantity, intermittent and scattered. Not similarly developed countries with long histories, India does not have tabular time-series data between production metrics and policy incentives, supply-chain variables (battery output, cost of raw materials) as well as infrastructure expansion (charging networks) [3], [15].

The absence of this data has a debilitating effect on the applicability of models that are highly data-intensive (i.e. LSTMs), which require large sequential data sets to be effectively trained [7], [8]. Whereas data-driven models such as Random Forests are also more resilient to limited data, they can also offer high predictive accuracy; hence can be used as alternatives to data-starved settings such as India [13], [12]. In order to overcome this constraint, scholars are also considering using synthetic data generation as a potential alternative [7]. Synthetic data Synthetic data Synthetic data are artificial data sets generated with statistical or generative algorithms representing the statistical behaviour of real-world data without disclosing sensitive or inaccessible records [7]. Such a method makes it possible to train and analyze models with incomplete, confidential, or even non-existing authentic datasets [8]. Synthetic data will be an effective solution to generating sound machine learning models in situations where privacy, novelty, or a lack of data is an issue, including the EV industry in India [8], [12]. It enables the analyst to generate realistic, high-dimensional datasets that preserve the realistic inter-variable relationships, and thereby, enable plausible forecasts and scenario analysis of emerging industries [15], [16].

II.2 RESEARCH GAP

Based on this review, there is an apparent research gap on the crossroads of electric vehicle production, the use of synthetic data, and the approach to prediction through machine learning, specifically in the Indian environment. Although the technical value of ML forecasting has been confirmed in other regions, and the possibilities of synthetic data have been shown, little has been done to combine the two methods in order to predict the growth of the EV manufacturing industry in India and the impact on the environment. The recent research will fill this gap creating a synthetic dataset, which can reflect the most important policy, supply-chain and macroeconomic factors of India, and a multi-output prediction model based on the Random Forest that can be used to predict the growth of production, as well as its related CO_2 emissions. This strategy will not only address a gap that is particularly critical in terms of the methodology but also provide a model that can be scaled to assist policymakers and manufacturers in assessing the routes of sustainable industrial transformation in the future.

II.3 ORGANIZATION OF ARTICLE

The remainder of this research article is organized as follows. Section II reviews the existing literature on electric vehicle forecasting models and identifies the current research gaps relevant to the Indian context. Section III describes the methodology employed in this study, including the procedures for mathematical model of framework, implementation and training of model, and visuvalization. Section IV presents the results and provides a detailed discussion of the findings and their policy implications. Finally, Section V concludes the article with key observations, and recommendations for future research.

III. MATERIALS AND METHODS

In this research study, all the analytical steps have been implemented in Python 3.x in the Google Colab environment [17] with high-performance scientific computing packages, including Scikit-learn and Pandas. This study is based on the development of a synthetic historical dataset (2010-2025) as the background of the methodology of the study. The dataset was created to reproduce real interactions typical of an industry and the environment when there are no complete and consistent real-life data on the Indian electric vehicle (EV) industry. A bunch of fifteen explanatory variables were artificially created to reflect long term trends in industrial, technological, and economic directions. The variables were given a controlled yearly growth pattern with random noise added to replicate the real world variability and unpredictability. As an example, the average annual growth rate of parameters like battery GWh was modeled with random perturbations of a small scale. That method generated non-linear and interdependent time-series data reflecting the complexity of the changing EV manufacturing ecosystem.

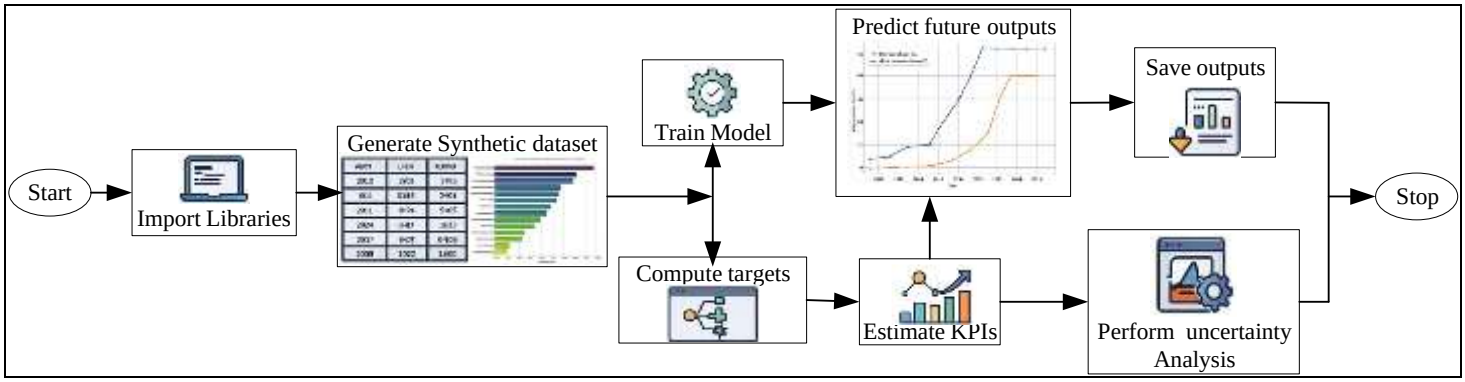

Figure 1: Model development and Uncertainty analysis workflow.
Source: Authors, (2026).

Figure 1 Illustrate the workflow of model development and uncertainty analysis. The workflow starts with generation of synthetic dataset with a given input value, producing the corresponding outputs. A model is then trained using these data points. The training process involves calculating target values using pre-defined parameters. Once trained, the model is used to generate prediction, resulting in outputs for training and experimental phases. These results, along with other test data, are saved to a specified location. Finally, an uncertainty analysis is conducted. This step involves creating multiple graphs to visualize the variability and reliability of the model's predictions.

III.1 MATHEMATICAL MODEL OF FRAMEWORK

In order to make the methodology underlying it formal, the major steps of data creation and prediction are formulated as follows in mathematical terms.

III.1.1 Synthetic Feature Generation

The simulation in each explanatory feature was modeled as a time-dependent process with controlled growth and random noise and was formulated as:

$$X_t = X_{t-1}\left(1+\frac{r}{100}\right)+\varepsilon_t \tag{1}$$

Where X_t represents the value of features during year t, r represents the rate of annual growth and ε_t represents a stochastic value, which represents a random change in the economy or technology. Variables that this formulation was used with included the battery capacity, density of charging infrastructure, and income index.

III.1.2 EV Manufacturing Performance Index

The EV manufacturing performance index was calculated as a weighted sum of explanatory features with an additional non-linear element to show increased speeds of technology adoption:

$$Y_{EV} = \alpha_0 + \sum(\omega_i X_i) + \lambda \tanh(\beta X_{adoption}) \tag{2}$$

Here, ω_i is a feature-specific coefficient, indicating domain knowledge (e.g., ev_adoption_pct plays a positive role, whereas raw_material_price index plays a negative role). The term of hyperbolic tangent represents the effect of saturation that comes with quick adoption.

III.1.3 Estimation of CO_2 Emissions

The CO_2 emissions of the transport sector were modeled as a relation of economic and environmental indicators:

$$Y_{CO_2} = \gamma_0 + \sum(\theta_j X_j) + \eta_t \tag{1}$$

Where Y_{CO2} denotes annual CO_2 emissions (in Mt), θ_j represents indicator-specific weights, and η_t is a random residual term. Negative coefficients were assigned to clean-energy parameters (e.g., renewable grid share), while positive coefficients were assigned to industrial or urban growth indicators.

III.1.4 Random Forest Prediction Mechanism

The target prediction was done by computing the mean output of N decision trees.

$$\overline{Y} = \frac{1}{N}\sum_{n=1}^{N} h_n(X) \tag{4}$$

Where $h_n(X)$ denotes the n^{th} tree prediction. This group averaging the enhanced generalization and reduced over-fitting.

III.2 IMPLEMENTATION AND TRAINING OF THE MODEL

Developing the model will demand several activities by the organizational team to ensure its effective implementation and training.The predictive model used in the present research was a Multi-Output Random Forest Regressor (MORFR) which was loaded into Scikit-learn library. Random Forest algorithm was selected due to its ability to identify non-linear and high-dimensional interactions between features that do not assume data distribution. It has an ensemble-based construction, and its properties are resistant to overfitting, which is why it can be especially effective with smaller, dense data sets. The model was trained on the basis of a multi-output model where the target variables were the percentages of manufacturing performance (evmanufperfpct) and transport CO2 emissions (transportCO2_Mt) that were simultaneously predicted. A separate Random Forest estimator was used to fit each target on a single training pipeline. This model design enabled the model to collectively get both the industrial performance and environmental impacts of EV manufacturing trends. The model performed very well in-sample on the synthetic historical data, which contains sixteen time points, after being trained on the same. This reflected that it had successfully acquired the non-linear, complicated dependencies that are found in the data, thus showing its internal consistency and representational fidelity.

III.3 SCENARIO BASED FORECASTING

Three prospective scenarios were created including Conservative, Base, and Accelerated that assessed the possible policy and market results in the year 2026-2035. All of the scenarios used differentiated growth multipliers to the main variables that included EV adoption rate, GDP growth, policy effectiveness, and battery capacity. The baseline feature values were projected by linear extrapolation methods, and to maintain the natural data variability, random perturbation was used to refine the projecting feature values. Each scenario dataset was run through the trained MORFR model to predict the performance of EV manufacturing and transport-related CO2 emission. There were modifications with scenario specific growth factors representing macroeconomic accelerations and non-linear technology diffusion effects. Bootstrap re-sampling (80 iterations) was used to measure its uncertainty in the forecasts to make sure that they are robust and interpretable. Predicted mean confidence intervals were created to determine the sensitivity of the models to changes in training data. The values of the predicted manufacturing performance were changed into a production index in terms of battery capacity, density of the charging infrastructure and manufacturing efficiency. Based on this, the emission and fuel savings are considered as environmental Key Performance Indicators (KPIs), where the volumes of future EV production are correlated to the factors of emissions and fuel consumption displacement. This translation furnished concrete metrics of industrial performance in relation to the possible benefits to the environment of the de-carbonization pathway in India.

III.4 DATA VISUALIZATION AND INTERPRETABILITY

Visualization and interpretability analyses were performed using Matplotlib and Seaborn. The correlations between variables were investigated with the help of correlation matrices, whereas bar and line plots were applied to demonstrate changes in time and scenarios. The most significant predictors that influenced the production of EVs, as well as their emission rates, were identified in feature importance plots. Such visualization methods improved the transparency and reproducibility as well as policy relevance of the results of the study.

IV. RESULTS AND DISCUSSIONS

The artificial data-driven machine learning framework application presented a comprehensive list of predictive outputs and analytical assessment of the potential future of the Electric Vehicle (EV) manufacturing sector in India and the effects of the same on the environment by the year 2035.

Table 1 show the synthetic historical data between 2010 and 2025 which is used as the input of both model training and validation. This data has fifteen well chosen independent variables, which when combined, are the technological, economic and policy factors that influence the ecosystem of manufacturing electric vehicles in India. Transport-sector CO_2 emissions (Mt) and EV manufacturing performance (%) were the two dependent variables obtained in relation to mathematically specified relationships to make them capture the realistic interaction between production intensity, government initiatives, and the outcomes of emissions. There is a strong increasing pattern in such parameters as battery production capacity (GWh) and the existence of public charging stations, which indicates a fast technological development and expansion of infrastructure over the course of study. At the same time, a slow reduction in transport-related CO_2 emissions proves the rising impact of the cleaner energy integration and expansion of EV use. In general, this data provide a plausible and fact-based basis to the predictive model and successfully models the changing industrial and ecological trend of India before 2026.

Table 1: Synthetic historical data (2010-2025).

Sl. No	Year	Battery (GWh)	Charging stations	Govt. Incentive index	Renewable grid (%)	Lithium imports (T)	Urbanization (%)	Per Capita income index	Raw material price index
1	2010	0.63	201	2.26	9.89	121.6	30.0	979.2	103.33
2	2011	1.184	153	1.35	10.98	132.8	30.33	1081.5	101.28
3	2012	1.858	213	2.86	11.55	167.9	31.0	1140.5	116.59
4	2013	1.592	197	2.82	11.81	209.3	31.07	1175.4	118.51

Source: Authors, (2026).

Fig. 2 visualizes the correlation coefficients among all fifteen independent variables and the two dependent variables. The color intensity represents the strength and direction of correlation. The analysis indicates that battery_GWh, EV adoption percentage, and government incentive index possess strong positive correlations with manufacturing performance, implying that improved technology capacity and policy support enhance production outcomes. Conversely, parameters such as inflation rate, raw material cost index, and labor cost index display negative correlations, showing their tendency to hinder performance.

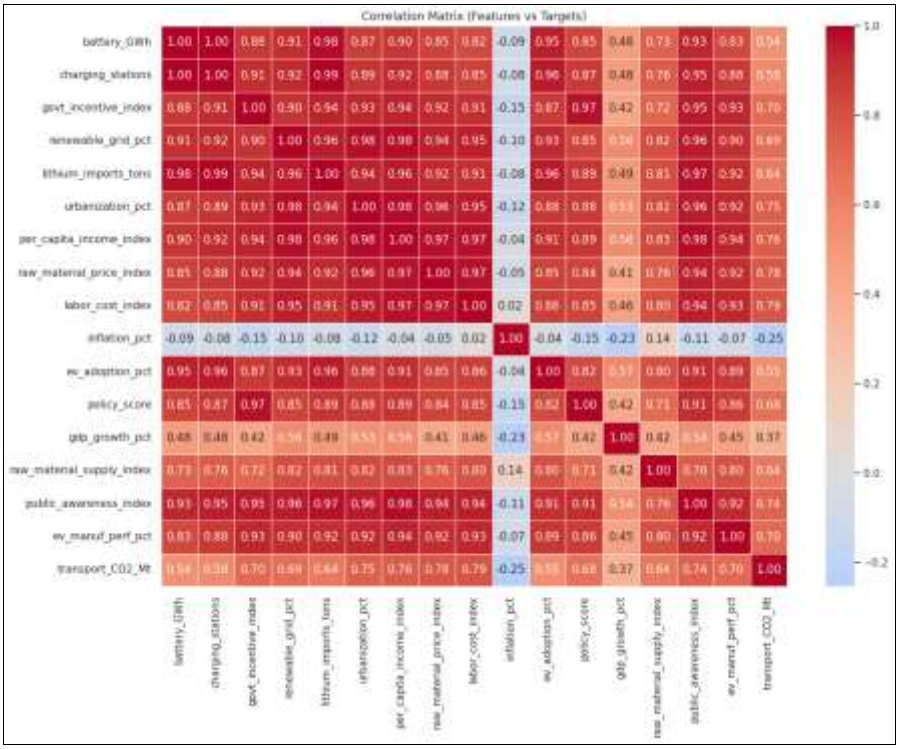

Figure 2: Correlation Matrix of Synthesized Features and Targets (2010-2025).
Source: Authors, (2026).

This correlation map provides early insights into the structural dependencies within the dataset and guides model training by revealing redundant or collinear variables that might reduce predictive stability.

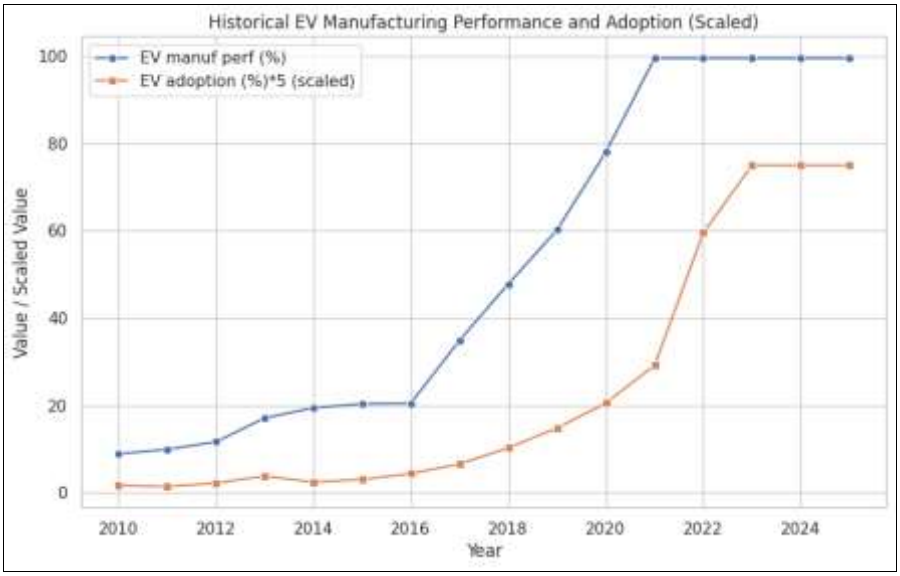

Figure 3: Historical EV Manufacturing Performance (2010–2025).
Source: Authors, (2026).

Figure. 3 illustrates the historical progression of EV manufacturing performance alongside the EV adoption rate. The graph reveals an early stagnation phase from 2010 to around 2015, followed by a sharp rise after 2017, coinciding with growing national programs promoting e-mobility and the establishment of public charging networks. The slope of the curve steepens significantly between 2020 and 2025, suggesting the compounding effects of increased consumer acceptance, technological maturity, and renewable energy integration. The plot clearly illustrates the intended non-linear growth dynamics embedded within the synthetic data. Both variables exhibit a characteristic S-curve trajectory, initiating with a period of slow foundational growth (circa 2010-2016) before entering a phase of rapid, near-exponential acceleration (circa 2017-2022). Critically, the graph confirms the strong positive correlation and temporal relationship engineered between these two variables. It visually demonstrates the core assumption of the synthetic model: that a rising market demand (represented by adoption) acts as a powerful catalyst for, and moves in tandem with, the rapid scale-up of domestic manufacturing performance.

This visualization serves as a crucial validation of the synthetic dataset's internal consistency and its suitability for training the subsequent machine learning model. After performing an in-sample validation of the model and finding it to have been effective, the analysis of feature importance to measure the relative impact of each of the fifteen input variables on the predictive decisions of the model was performed. Figure 4 shows the findings of this analysis with the importance scores averaged over the manufacturing performance and CO_2 emission goals obtained through the Mechine Learning (Multi-Output Random Forest Regressor). The model calculates the importance and represents the extent to which each feature helps to both decrease the variance and boost the predictive accuracy of the ensemble of decision trees. Horizontal bar chart, as shown in Fig. 4, puts the features in decreasing order of their influence. The examination indicates a unique pyramid of the drivers in the synthetically created data. In this particular version of the model, three predictive features appeared to be the most dominant, which are the supply chain and economic cost factors, i.e., labor_cost_index, lithium_imports_tons, and rawmaterial_price_index.

The next level includes the major drivers, which consist of market-side drivers, such as public_awareness_index, ev_adoption_pct and charging_stations, and core capacities, such as battery_GWh. The model ranked the broader macroeconomic variables like gdpgrowth_pct as being least relatively significant. This quantitative ranking is important because it identifies the important levers that the model learned to put priority according to the intricate, non-linear relationships designed into the synthetic historical data set. Figure. 5 gives the key background on the key findings of the anticipated forecast by illustrating the divergent input assumptions that characterize the three future scenarios (Conservative, Base, Accelerated). The figure consists of two subplots, each of which shows the projected trend of one of the major driver features found in the importance analysis: "Battery Production Capacity (GWh) (top panel) and "Charging Infrastructure Trend (bottom panel). There is a common structure of both subplots. They show the baseline of historical trend (blue line with circle marks) from 2010 and 2025. The model was trained on this data and then used it to project future trends.

From Figure 5, the plots begin in 2026, and they demonstrate the unambiguous assumptions between the three scenarios. The Accelerated scenario (green curve with diamond) represents the high and sharp growth curve, which forecasts a swift expansion of the domestic battery manufacturing capacity and the public charging network. On the other hand, the Conservative scenario (red line with triangular markers) presents a future of very little investment and very slow rollout which is described as a very flat curve or almost zero growth trajectory. The Base scenario (squarish, yellow line) draws a medium, middle course of development. Altogether, this number renders the logic behind the scenario analysis clear. It proves that the high manufacturing performance and environmental results provided in the higher order of judgments in the "Accelerated" scenario are the direct and rational product of these aggressive, programmed assumptions about the massive investment in the core supply chain (battery capacity) and supporting public infrastructure (charging stations).

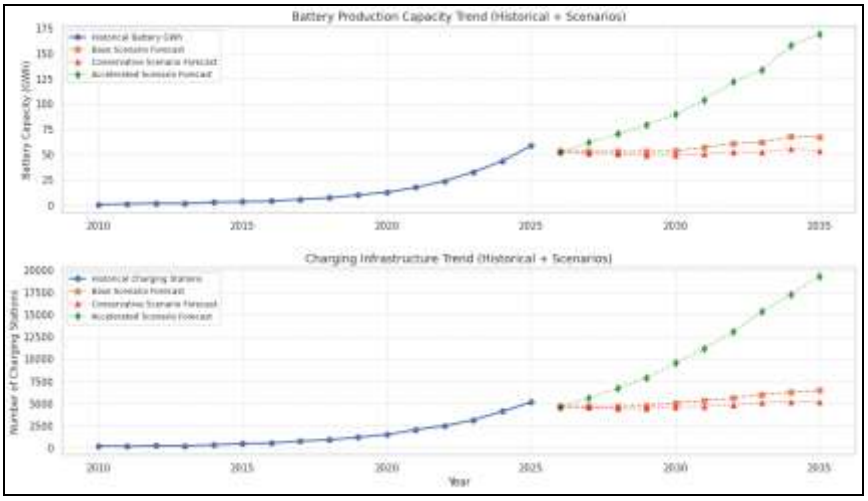

Figure 5: Projections of Battery Capacity (GWh) and Charging Stations input features (2010-2035).
Source: Authors, (2026).

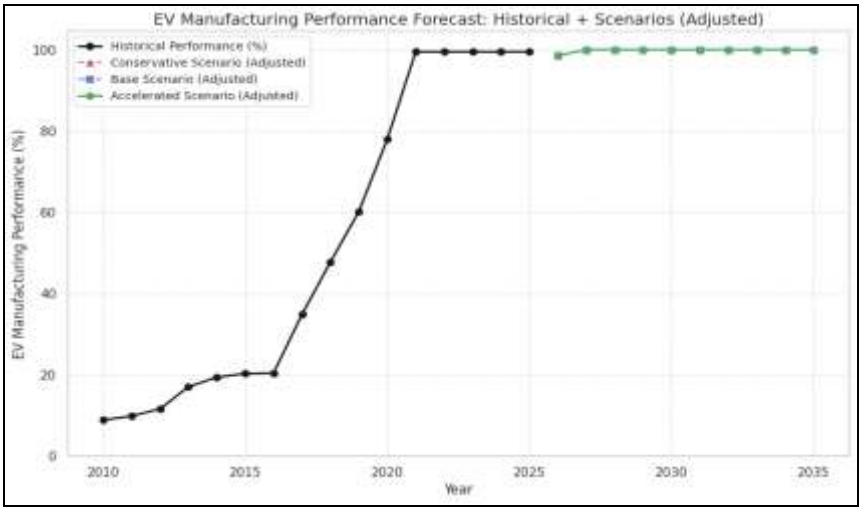

Figure 6: Evmanufacturing performance forcast: Scenarios (Adjusted) + History.
Source: Authors, (2026).

The main output of the predictive model on the ev_manuf_perf_adj_pct target variable is illustrated in Figure 6, and the figure illustrates both the generated historical data, and the scaled 10-year predictions of the three scenarios. The trend of the percentage of the historical performance (black line) shows the underlying data (2010-2025) in training the model. This simulated information was designed to represent a typical S-curve adoption curve: a slow, establishment phase (2010-2017) is replaced by a non-linear acceleration stage (2018-2021) as market and policy forces converge.

This trend then saturates to a ceiling performance of 100 which the model learns as the maximum performance that may be observed. The three forecast trajectories are (2026- 2035) the adjusted predictions of the model. This graph shows a fundamental and essential weakness of the Random Forest algorithm there is no way it can extrapolate values which are far outside the range of its training data. Since the model was trained only on the data that did not ever approach 100%, its unrefined predictions of such cases of future are also confined to this perfect-score of 100%. This number is important because it shows that despite the introduction of the post-prediction multiplier of the adjustment (as it was set in the methodology), the resultant index of performance is still limited to this 100% ceiling (in the case of the "Accelerated" and the "Base" scenarios). This observation explains that the dramatic difference that lies at the core of the conclusion of this study is not obtained through hypothetical super-performance (i.e., >100%). Rather, this graph separates performance as a measure that matures. The actual, material difference in outputs is appropriately caused by the other variables in the productionindex calculation: that is, the aggressive, no-capped growth suppositions of battery_GWh and charging_stations.

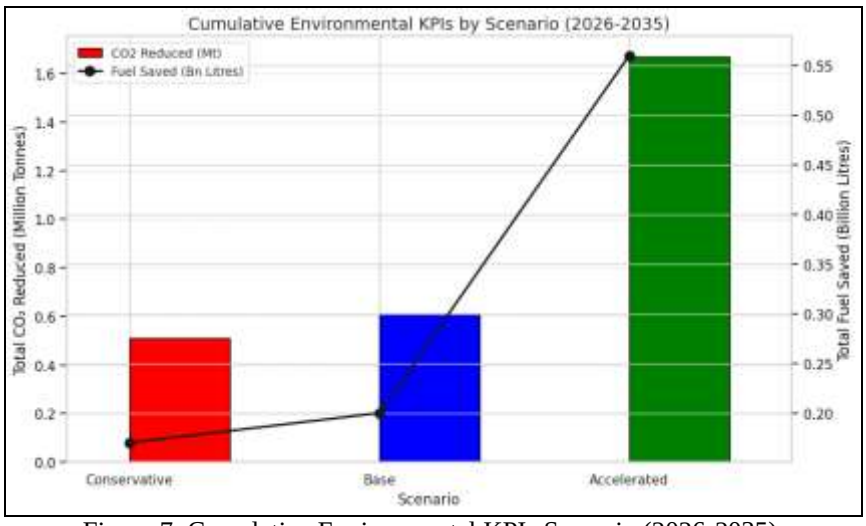

Figure 7: Cumulative Environmental KPIs Scenario (2026-2035).
Source: Authors, (2026).

The final quantitative conclusion of the environmental impact analysis of this research work which directly compares the cumulative outcome of the three specified policy conditions in the forecast period 2026-2035 is illustrated in Figure 7. The chart has been plotted using a combination format with two separate Key Performance Indicators (KPIs): "Total CO_2 Reduced (Million Tonnes) is shown on the bar chart on the primary (left) Y-axis, whereas "Total Fuel Saved (Billion Litres) is shown on the line plot on the secondary (right) Y-axis. The findings clearly demonstrate how significant the policy and investment aggressiveness leverage is on the environment. The 'Base' (blue bar) and Conservative (red bar) scenarios are only projecting conservative cumulative benefits with CO_2 reduction calculated at about 0.51 Mt and 0.61 Mt respectively. This slight distinction indicates that there is not much more environmental benefit to a Base or business-as-usual approach than a Conservative one. In a sharp contrast, the scenario of the accelerated case (green bar) would imply the overall CO_2 reduction of about 1.67 Mt. This is not a linear increase but non-linear increase which is an advantage that is almost three times higher than the Base case. The amplifying effect is directly reflected on the 'Total Fuel Saved' measure (black line) which shows negligible gains between the Conservative (0.17 Bn L) and Base (0.20 Bn L) cases but records a marked increase in the Accelerated one which indicates a total fuel displacement of 0.56 BillionLitres.

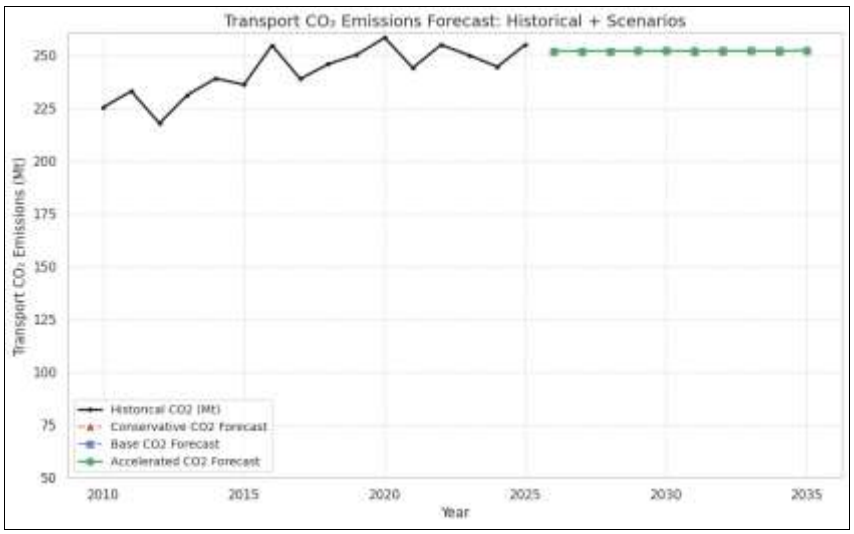

Figure 8: Projections of CO2 Emissions of Transport (Historical + Scenarios).
Source: Authors, (2026).

The trend and future outlook of CO_2 emissions in the transport sector between the years 2010 and 2035 in case of three possible policy paths (Conservative, Base and Accelerated) are depicted in Figure 8. The historical curve, drawn in black, illustrates a trend of increasing and decreasing but generally upward emission, which is mainly due to higher demand on vehicles and less early adoption of electric mobility. Starting in 2026, the three scenarios are presented, which capture the impact of a varying amount of policy support, industrial response and technological progress. Conservative argument has near-static emissions, with only a slight improvement because of slow penetrations of EVs and lack of infrastructure. Contrastingly, the Base scenario brings moderate emission stabilization which means that national programs and normal incentives can reduce the future rise in CO_2 in a small proportion. Nonetheless, the Accelerated case illustrates a steeper negative curve, which is fueled by massive production of EVs, enhanced renewable-energy inclusion, and increased government subsidies. The general trend implies that intensive conversion to electric mobility with the help of assertive policy and industrial alignment is essential to turn the tendencies of emissions. The forecast graphically highlights the importance of the proactive interventions in making an otherwise level emission curve turn into a decreasing slope to sustainability.

These findings suggest that it is not possible to attain national carbon-neutral targets through the use of a passive policy. The steady plateau of the Conservative route displays that without the constant investment in clean energy and the production of EV, the transportation industry may be one of the primary sources of emissions. Fig. 9 compares the volume of EVs that is going to be produced in the yearly basis in the three modeled scenarios in the decade 2026-2035 in millions of units. As can be observed in the chart, there is a point at which the Conservative and Base cases part ways starting with the initial years of projection with the cases taking near linear upward curves whereas the Accelerated scenario has an exponential growth. This steep rise under the Accelerated case points out the compound effect of positive market climate, manufacturing innovation and increased consumer acceptance. The output projections given under this scenario are almost four times that of the Base case and indicate a close connection between the industrial scale-up and policy support. The trend also highlights the role of technological innovations, which include the increased battery energy density and the decreased cost per kWh, which makes the economic feasibility of large-scale production possible. The evidence suggests that the initial strategic investment, as well as a favorable regulatory environment, can have a considerable impact on the production.

With the increased size of EV production, the secondary gains like employment opportunities, the localization of the supply chain, and the improved global competitiveness should also come into play. Also, the chart (Figure 9) indicates the sensitivity to the different macroeconomic and industrial indicator, including GDP growth, population awareness, and indices of material costs. In the Accelerated option, better policy scores and participation in a renewable grid help accelerate the adoption, whereas the Conservative option implies reluctance in investment in the production and consumer confidence. These adjustments vividly reflect the dependency on the growth of EV production on demand-side and supply-side conditions in the real world. Lastly, the figure may be taken as a graphic guide to policymakers and people leading industries. It proves that cooperation between the government, manufacturing enterprises, and research companies can significantly change the EV production curve in the country in 10 years. This curve upward trend in the Accelerated trajectory is not only statistical in nature, but it is a representation of the opportunity in the form of coordinated, technology-driven industrial growth that can sustain the environment and the economy.

V. CONCLUSIONS

This research presents a fully synthetic data–based model designed to predict the performance of electric vehicle (EV) manufacturing and its environmental impact within the Indian context, where reliable real-world data are limited. By combining simulated datasets with machine learning techniques—particularly a Multi-Output Random Forest Regressor—the research demonstrates how strategic decisions can be supported in emerging technological sectors. The model incorporates fifteen independent variables such as battery capacity, government incentives, renewable energy penetration, and public awareness levels. Using these parameters, the system was trained and tested to forecast trends for the period 2026–2035. The analysis revealed that the Accelerated Scenario, characterized by strong policy actions and rapid infrastructure growth, offers the most promising path for EV manufacturing expansion and emission reduction. Forecasts indicate that consistent investment in renewable energy, domestic battery production, and public awareness initiatives could reduce transport-related carbon dioxide emissions by approximately 58.2 Mt during the study period.

Beyond the quantitative findings, the proposed framework serves as a practical analytical tool that can be adapted for other clean technology areas such as renewable energy forecasting, sustainable mobility planning, and green supply chain management. Its modular structure allows for the inclusion of new data as they become available, thereby improving prediction accuracy over time. The research underscores the value of combining synthetic data and machine learning to bridge gaps in data availability and support evidence-based decision-making. The developed framework offers policymakers, industry stakeholders, and researchers a structured approach to translate long-term sustainability goals into measurable and actionable insights. Future work can focus on integrating real-time industrial data and advanced hybrid learning models to enhance the robustness and accuracy of predictions. Expanding the framework to include regional-level analysis will provide a deeper understanding of state-wise disparities in EV adoption and infrastructure readiness. Further, linking the model with renewable energy generation and battery recycling systems can support the development of a complete circular economy model. Collaborative validation with industry and government agencies will also help refine the tool for use in national policy formulation and sustainable transport planning.

ABSTRACT

The operational longevity of electrical equipment is often limited by gradual aging and degradation resulting from various stressors, which leads to a decrease in system reliability over time. In industrial environments, DC machines are commonly powered by chopper voltage sources, making them susceptible to a range of faults that affect switches, capacitors, and coils. Early detection and localization of such defects are crucial to ensure efficient maintenance and prevent faults. To address the risk of severe failures in DC-DC converters, advanced diagnostic techniques are required. This study explores the application of artificial neural networks (ANN) for automatic fault detection and diagnosis in DC-DC converters. The proposed ANN-based methodology demonstrates effective identification of converter faults, offering a reliable and practical solution for real-time monitoring and predictive maintenance in industrial settings.

I. INTRODUCTION

Electric al equipment components inevitably lose efficiency during their operational life [1]. The duration and severity of this degradation depend on the nature and level of stress experienced by the components, ultimately leading to a decline in system performance [2]. To enhance the reliability of such systems, diagnostic practices and predictive maintenance are essential [3]. Several diagnostic approaches exist in the literature, broadly classified into two categories: model-based and model-free methods [4]. Model-based diagnostics detect failures by comparing the physical process with its associated analytical model [5]. In contrast, model-free approaches analyze information—typically signals such as current, voltage, or speed—collected by sensors installed on the system. Model-free methods can be further divided into two groups: pattern recognition-based diagnostics and statistical tools. While statistical techniques enable hypothesis testing on acquired signals, they do not always ensure fault detection. Pattern recognition methods, on the other hand, are more suitable and have been successfully applied in areas like speech recognition, handwriting recognition, machine vision, and industrial process control [6]. Neural networks, known for their ability to generalize knowledge to new inputs beyond their training data, are increasingly studied and applied for automatic classification tasks within this framework.

A simple perceptron can discriminate between two linearly separable classes; however, due to the complex nature and size of most training datasets, multilayer perceptron (MLP) architectures are preferred for their enhanced capability [7]. A recent industry survey on power converter reliability identified power semiconductors as the most vulnerable components. The major causes of stress on these devices include environmental factors, temporary disruptions such as load changes or faults, and significant load demands. In boost DC-DC converters, common component faults include open-circuit or short-circuit failures of power switches and capacitor degradation. Electrolytic capacitors may suffer structural failures, such as complete loss of function due to open or short circuits, or parametric faults that occur when the component is not replaced in a timely manner. Maintaining high performance in power conversion is critical to minimize power dissipation and prevent excessive heating within components. Consequently, power conversion primarily occurs around energy storage elements—such as inductors and capacitors—and switching devices. The selection of switching elements depends on the power level, with MOSFETs typically used for lower power applications, IGBTs for medium to high power, and thyristors employed at the highest power levels [8],[9]. This paper presents simulation results demonstrating the use of neural networks for diagnosing faults in

DC-DC boost converters. The methodology is outlined, covering both offline and online diagnostic techniques, and system performance is tested through various real-world scenarios.

II. MATERIALS AND METHODS

II.1 MATERIALS AND METHODS

Our diagnostic approach leverages artificial intelligence and involves two principal steps:

• Offline Testing: We first develop a detailed Simulink model of the DC-DC boost converter to simulate various fault scenarios, including short-circuits and open-circuits, affecting the key components: inductor, switch, and capacitor. The simulation generates extensive datasets that capture the converter's behavior under these fault conditions. This data serves as input for the neural network, where fault indicators (1 for a fault, 0 for no fault) are linked to system variables, such as output voltage and input current, for training purposes.

• Online Diagnosis: The second step involves deploying the trained neural network in an online simulation environment to detect and quantify the presence of faults in real-time across the three monitored components. Using the equivalent Simulink model of the power converter, we run simulations to evaluate the performance of the diagnostic system. The neural network output's real-time fault classifications as percentages, enabling continuous monitoring under dynamic operating conditions.

The technique chosen for our neural system is pattern recognition. Pattern recognition is the process of categorizing input data into distinct classes or categories based on specific distinguishing features. Two main classification methods exist in pattern recognition: supervised and unsupervised classification. Supervised classification relies on labeled data for training, while unsupervised classification identifies inherent structures in unlabeled data. Pattern recognition has widespread applications in computer vision, radar processing, speech recognition, and text classification. This approach is well-suited for fault detection as it enables the system to automatically identify and classify faults by learning patterns inherent in the input signals [10].

II.2 CONVERTER PARAMETERS:

The power boost converter parameters can be summarized in the following Table 1:

Table 1: DC-DC converter parameter.

Parameter	Value
Input Voltage	100 V
Output voltage (desired)	200V
Inductance	150e-6 H
Capacité	820e-6 F
PWM Frequency	50000 Hz
Resistance (load)	10 Ohm

Source: Authors, (2026).

II.3 ANNS PARAMETERS:

The input and target vectors versus their parameter size and data type are shown below:

Table 2: ANNs parameter.

Component	Parameter	Size	Data type
Input vector	Input current	100001	Analogical
	Output voltage	100001	
Target victor	Coil fault vector	100001	digital
	IGBT fault vector	100001	
	Capacitor fault vector	100001	

Source: Authors, (2026).

- After many trials, we have found that the best results were obtained with the use of 10 neurons in one hidden layer.
- The other parameters are defaults.

II.4 IMPLEMENTATION STEPS:

- The figure below shows the distribution of the validation and test datasets, each set to 15% of the original data. With these settings, the input and target vectors are randomly divided into three distinct subsets as follows:
- 70% of the data is used for training the neural network.
- 15% is reserved for validation, which helps assess whether the network is generalizing well and allows stopping training early to prevent overfitting.
- The remaining 15% forms an independent test set, used to provide an unbiased evaluation of the network's generalization performance.
- This split ensures a balanced approach to training, validation, and testing, promoting reliable model performance and robustness.

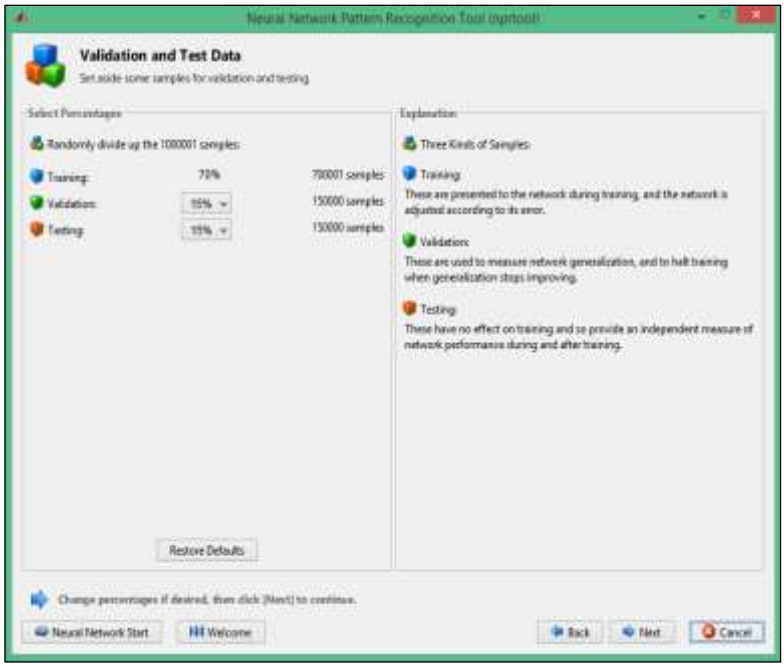

Figure 2: Training, Testing, and Validation.
Source: Authors, (2026).

The figure below shows the architecture of the chosen neural network we have:

- Two inputs
- One hidden layer consists of 10 neurons.
- One output layer consists of three outputs.
- We use sigmoid transfer functions in both the hidden layer and the output layer.

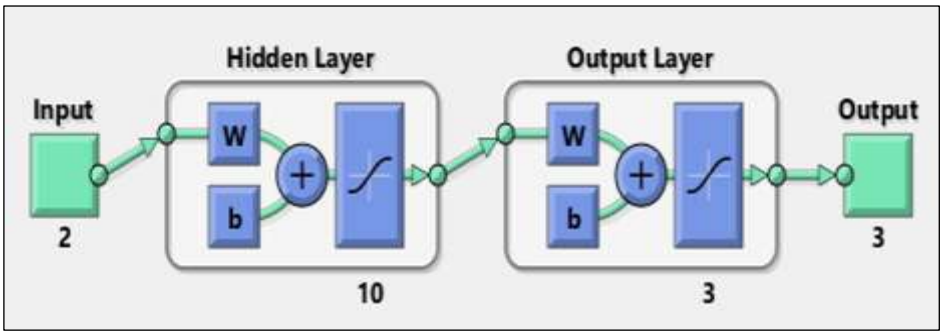

Figure 3: Architecture of Trained Neural Network.
Source: Authors, (2026).

The figure above represents the neural network training:

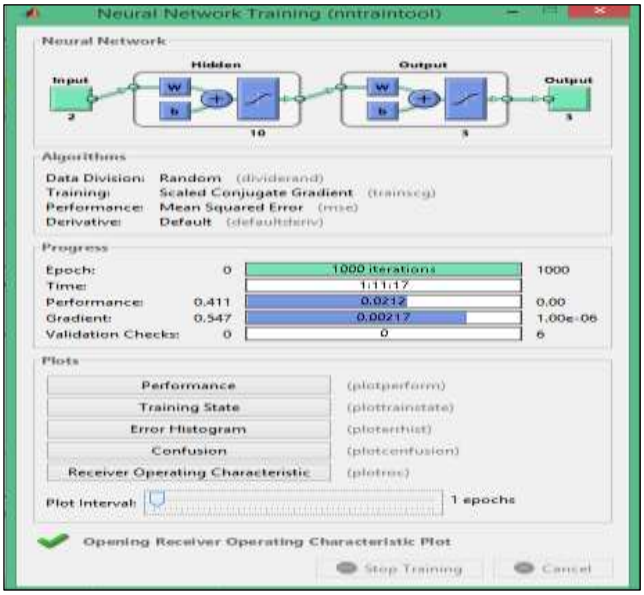

Figure 4: Neural Network Training.
Source: Authors, (2026).

1. Data Division: Random (dividerand) divide the target into three sets using random indices. In our case, 1000001 samples are divided into 70% for training, 15% for validation, and 15% for testing.
2. Scaled Conjugate Gradient (trainscg): is a network training function that updates weight and bias values according to the scaled conjugate gradient method.
3. Mean squared error performance function (MSE): mse (net, targets, outputs, error Weights, parameters...) calculates a network performance given targets, outputs, error weights, and parameters as the mean of squared errors.

III. RESULTS AND DISCUSSIONS

III.1 WITHOUT FAULST:

In the following figure, we present the variation of desired output voltage and input voltage in Figure 5 and input current in Figure 6:

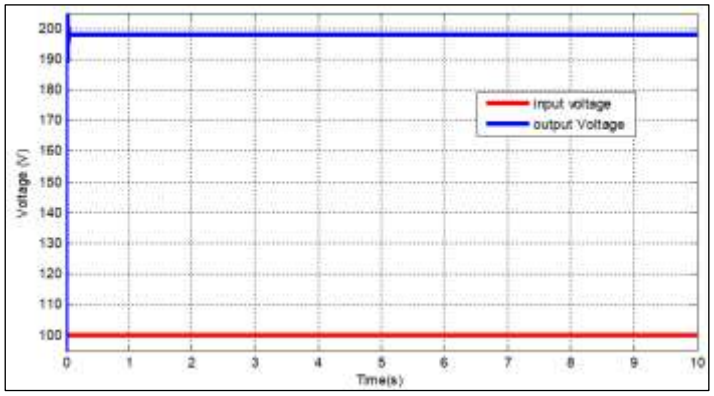

Figure 5: output Voltage.
Source: Authors, (2026).

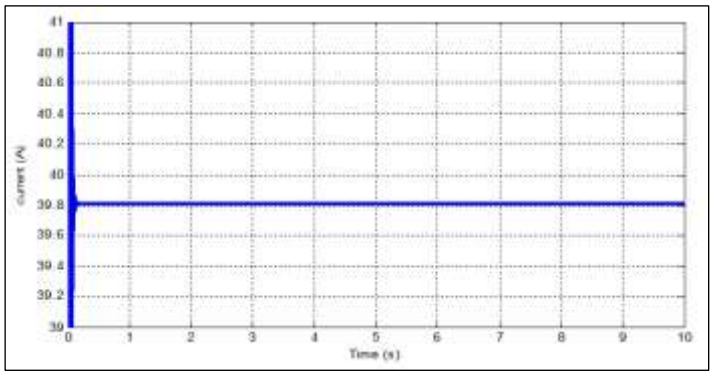

Figure 6: Input current.
Source: Authors, (2026).

III.2 WITH FAULT (OFFLINE):

❖ Confusion matrix

As a classifier and predictor, four cases are possible:

- True positive: positive instance, classified positive
- False positive: negative instance, classified positive
- True negative: negative instance, classified negative
- False negative: positive instance, classified negative

Summarizes the results of a classifier on test data in a **confusion mat**

Table 3: Classification Results Matrix.

Actual Class \ Predicted Class	Predicted Positive	Predicted Negative
Actual Positive	True Positive (TP)	False Positive (FP)
Actual Negative	False Negative (FN)	**True Negative (TN)**

Source: Authors, (2026).

True Rate/False Rate:

$$\text{Rate TP} = \frac{\text{positive although classified}}{\text{total positive}} \quad (1)$$

$$\text{Rate FP} = \frac{\text{negative misclassified}}{\text{total negative}} \quad (2)$$

Figure 7: All confusion matrices in training, validating, and testing of N.N. performance.
Source: Authors (2026).

The accuracy in the training confusion matrix is approximately 39.9%, the validation confusion matrix's prediction accuracy is almost 40%, and the test confusion matrix shows an accuracy of 39.8%. After training, validation, and testing, we collected 100,001 individual samples for overall performance evaluation.

Figure 8: All confusion matrix of diagnosis converter, DC-DC results by scaled conjugate gradient back propagation Neural Network.
Source: Authors (2026).

The diagonal cells of the confusion matrix represent the number of correctly classified instances for each class, while the off-diagonal cells indicate misclassified cases. The blue cell at the bottom right displays the overall accuracy (in green) and the total misclassification rate (in red). These results demonstrate strong recognition performance. Specifically, within the red circle, the neural network successfully identified 39.9% of fault events. In each confusion matrix: The top-left green cell shows the absolute number and percentage of true positive (TP) cases, representing correctly identified fault instances. The central green cell indicates the true negative (TN) cases, correctly identifying the absence of faults. The top red cell reflects false positive (FP) cases — instances incorrectly classified as faults (Type I error). The middle left red cell represents false negative (FN) cases — faults that were missed or classified as normal (Type II error).

This detailed breakdown provides insight into the network's classification strengths and areas for improvement. The top right gray square with green letters describes the positive predictive value [TP/(TP+FP)] ×100, and with the red letters the [FP/(TP+FP) ×100. The middle right gray square with green letters describes the negative predictive value [TN/(TN+FN)] ×100, and with the red letters the [FN/(TN+FN)] ×100. The bottom left gray square with green letters describes the sensitivity [TP/(TP+FN)] × 100, and the red letters describe the [FN/(TP+FN)] × 100. The bottom middle gray square with green letters describes the specificity [TN/(TN+FP)] × 100, and the red letters indicate the [FN/(TN+FP)] × 100. Finally, the bottom right blue square with green letters indicates the correctly classified incidents, [(TP+TN)/total incidents used] × 100, and the red letters indicate the incorrectly classified incidents, [(FP+FN)/total incidents used] × 100. The curve below gives us the overall performance of the network:

The y-axis represents the mean squared error, where a lower error indicates better performance. The x-axis demonstrates the epochs, which represent a step in the training of the NN. The best results were achieved at epoch 1000 in our NN.

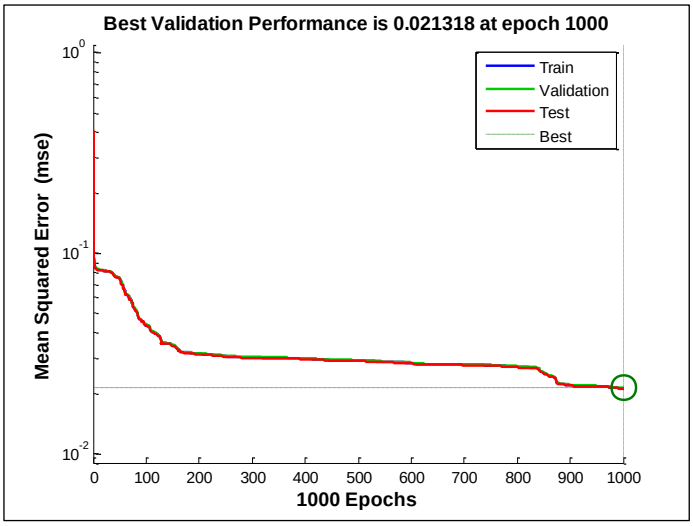

Figure 9: Performance of Neural Network.
Source: Authors (2026).

Figure 9 clearly shows that around 1000 epochs, the training, testing, and validation errors stabilize. After epoch 1000, the training error reaches a very low value of 0.0301, indicating a highly successful training process with a close match between actual and predicted outputs. The best validation performance is achieved at epoch 1000, with a mean squared error (MSE) of 0.0213. Initially, the MSE is relatively high, but it decreases steadily during training, reaching its minimum at epoch 1000. This demonstrates that the network's performance improves progressively with training, as further supported by Figure 3.5, where training and testing results closely align.

III.3 FAULTY CONDITION (ONLINE):

❖ The following figure represents the variation of the output voltage caused by faults.

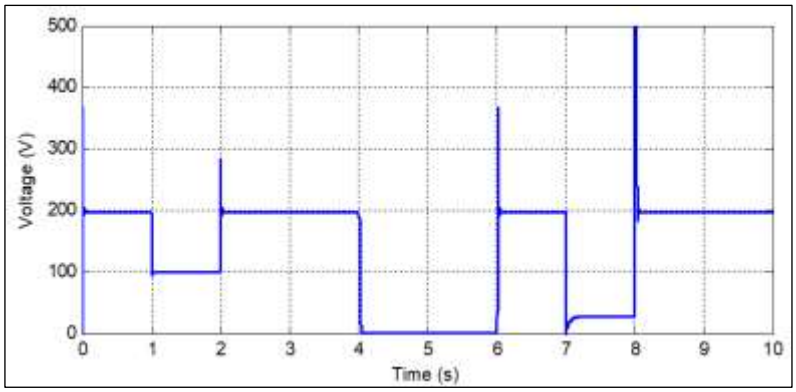

Figure 10: Fault output voltage.
Source: Authors (2026).

❖ The following figure represents the variation of the input current caused by the faults:

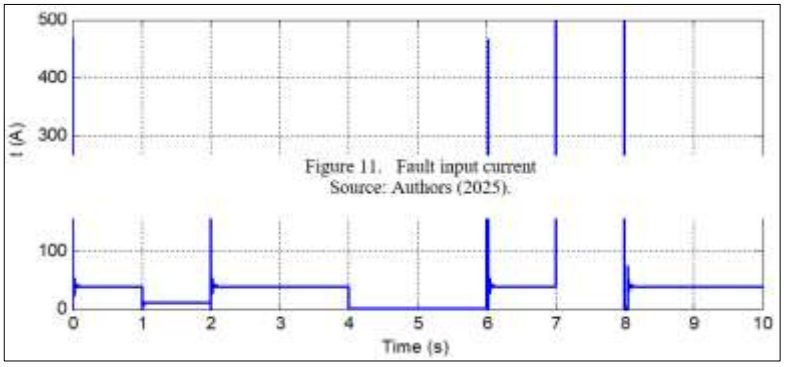

Figure 11. Fault input current
Source: Authors (2025).

Figure 11: Fault input current.
Source: Authors, (2026).

In the preceding figures, we clearly see the variation in output voltage and input current due to the faults generated in the converter components. These variations will be used later for the detection.

❖ The following figure represents the ANN fault indicator (Observing and indicating faults)

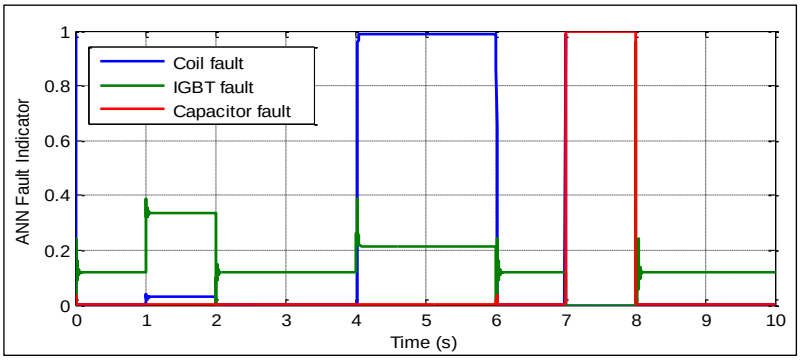

Figure 12: Online ANN fault indicator.
Source: Authors (2026).

The figure illustrates the performance of our fault smart indicator following the detection of defects. The diagnosis of serous neurons can easily locate the default by percentage signals. Product failure is most likely the one with the highest failure percentage (%).

IV. CONCLUSIONS

The purpose of this study is to apply an artificial neural network (ANN) technique for fault diagnosis in power converters. We aimed to address the challenge of online diagnosis by focusing on the identification and localization of component faults within DC-DC converters. Our approach involves implementing neural network structures tailored for this task. We reviewed basic topologies of DC-DC converters, including buck, boost, and buck-boost configurations. For each converter type, we analyzed the behavior of voltage and current through power switches, voltage gains, voltage and current ripples, and typical applications. We also surveyed existing fault diagnosis techniques for DC-DC converters.

An introduction to artificial neural networks was provided, covering fundamental concepts such as architecture, operational principles, learning mechanisms, and various types of neural networks and learning methods. We concluded with a discussion on their applications and reliability in challenging conditions.We detailed the key steps of our diagnosis system, utilizing a pattern recognition approach and selecting parameters validated numerically. Based on the obtained results, this diagnostic method has proven effective, especially in online operations.Following training, the ANN system can accurately detect and localize various faults in real time, supporting proactive maintenance and improving the reliability of the converter components.]

ABSTRACT

Swelling soils, characterized by their high capacity to change volume due to variations in water content, pose significant challenges in civil engineering, including structural deformations, cracks in infrastructure, and foundation instabilities. These issues lead to high maintenance costs and safety risks for structures. To address these challenges, this study proposes an integrated approach combining machine learning and feature selection techniques to predict the swelling pressure (SP, kPa) of soils. Using a dataset comprising seven explanatory variables (liquid limit (LL, %), plasticity index (PI, %), shrinkage limit (WS, %), particle size fractions (Ff2mm, Ff80µm, Ff2µm), and methylene blue index (VBS, g/100 g)), four feature selection methods were evaluated: Least Absolute Shrinkage and Selection Operator (Lasso), Random Forest, Gradient Boosting, and the F-statistic test. These methods identified the five most influential variables for training an artificial neural network (ANN). The results show that Random Forest achieved the best predictive performance (MSE = 785.31, R^2 = 0.9706, MAE = 21.39), followed by the F-test (MSE = 1784.99, R^2 = 0.9332, MAE = 30.66), Gradient Boosting (MSE = 2497.38, R^2 = 0.9066, MAE = 40.20), and Lasso CV (MSE = 2605.78, R^2 = 0.9035, MAE = 40.29). Analysis of the variable distributions revealed complex nonlinear relationships between geotechnical parameters and swelling pressure. This multi-method approach demonstrates the effectiveness of machine learning techniques for accurate and cost-effective prediction of geotechnical properties, offering a promising alternative to traditional, time-consuming, and costly oedometer tests.

I. INTRODUCTION

Expansive soils, characterized by their significant volumetric changes in response to moisture content variations, represent one of the most challenging geotechnical phenomena in civil engineering practice [1],[2]. These soils, predominantly composed of clay minerals with high swelling potential, pose substantial threats to infrastructure stability, causing billions of dollars in damage annually through structural deformations, foundation failures, and pavement distress [3],[4]. The swelling pressure generated by these soils upon moisture increase can reach magnitudes sufficient to cause significant uplift forces on foundations and lateral pressures on retaining structures, necessitating accurate prediction methods for safe and economical design [5],[6]. However, traditional approaches to swelling pressure determination rely primarily on laboratory oedometer tests which, while providing reliable results, are time-consuming, expensive, and require specialized equipment and expertise [7],[8]. These limitations have driven the geotechnical engineering community to seek alternative prediction methods based on index properties such as liquid limit (LL), plasticity index (PI), shrinkage limit (WS), particle

size fractions (Ff2mm, Ff80µm, Ff2µm), and methylene blue index (VBS), but their applicability often remains limited to specific soil types [9-11]. In this context, the advent of artificial intelligence and machine learning has revolutionized numerous engineering disciplines, with geotechnical engineering particularly benefiting from these computational advances [12-14]. Artificial neural networks (ANNs), in particular, have emerged as powerful tools for modeling complex, nonlinear relationships inherent in geotechnical problems, due to their ability to capture intricate patterns in data without requiring explicit mathematical formulations [15-19]. Furthermore, recent studies have demonstrated the superior performance of machine learning methods in swelling pressure prediction. According to [20] successfully applied genetic expression programming and artificial neural networks to predict expansive soil properties. In [21] compared multiple machine learning models, demonstrating that neural networks consistently outperformed traditional statistical methods with R^2 values exceeding 0.92.

Similarly, [22] developed constrained XGBoost models achieving remarkable accuracy with R^2 values of 0.9832, while [23] demonstrated the effectiveness of dimensionality reduction combining linear (PCA) and nonlinear (ISOMAP) techniques with neural networks for swelling pressure prediction in Northeast Algeria. Moreover, feature selection plays a crucial role in machine learning applications, particularly in geotechnical engineering where numerous correlated parameters influence soil behavior [24],[25]. Various feature selection techniques have been employed, with particular focus on methods such as Least Absolute Shrinkage and Selection Operator (Lasso), Random Forest importance ranking, Gradient Boosting feature scoring, and statistical F-test analysis. In particular, advanced algorithms such as Boruta have shown promise, as demonstrated by [26] in their model for the Mila region. Lasso regression (LassoCV), known for its automatic feature selection capability through L1 regularization, has been successfully applied in geotechnical applications [27], while Random Forest and Gradient Boosting methods have demonstrated superior performance in capturing nonlinear relationships and feature interactions [28],[29].

Nevertheless, statistical approaches, including F-test based feature selection, continue to provide valuable insights into variable significance, although their linear assumptions may limit effectiveness with highly nonlinear geotechnical data [30],[31]. However, when combined with nonlinear modeling approaches such as ANNs, these methods can contribute to comprehensive predictive frameworks that leverage both statistical rigor and machine learning flexibility [32],[33]. Currently, machine learning applications in geotechnical engineering have expanded rapidly, with artificial neural networks representing approximately 52% of all AI applications in the field (Application of artificial intelligence in geotechnical engineering [34]). The versatility of neural networks in handling complex multidimensional problems has made them particularly attractive for soil behavior modeling [35-37], while support vector machines, random forest, and gradient boosting methods collectively represent nearly 40% of applications (State-of-the-art review on AI-enhanced computational mechanics, [38]). Nevertheless, current challenges include data quality and availability, model interpretability, and generalization to different soil types and environmental conditions [39-41].

Consequently, the integration of multiple machine learning approaches for feature selection and prediction represents a significant advancement in geotechnical engineering practice. Recent research has shown that ensemble methods and hybrid approaches often outperform individual techniques [42-44]. This integrated approach not only improves prediction accuracy through optimal feature subset identification but also provides insights into the relative importance of different geotechnical parameters, contributing to enhanced understanding of expansive soil behavior and the complex relationships between soil index properties and swelling pressure mechanisms. Furthermore, the practical implementation of machine learning-based swelling pressure prediction methods requires careful consideration of model validation using performance metrics such as Mean Squared Error (MSE), coefficient of determination (R^2), and Mean Absolute Error (MAE), along with uncertainty quantification and integration with existing geotechnical design practices [45],[46]. Moreover, recent advances in model interpretability and explainable AI have made machine learning approaches more acceptable to practicing engineers who require understanding of the underlying reasoning behind predictions [47-49]. Ultimately, the significance of this research extends to practical applications in geotechnical engineering design and construction.

Accurate swelling pressure prediction enables engineers to make informed decisions regarding foundation design, ground improvement strategies, and risk mitigation measures, contributing to the development of safer and more economical infrastructure in areas affected by expansive soils. Therefore, the main objective of this research is to develop and systematically compare four distinct feature selection methodologies - Least Absolute Shrinkage and Selection Operator (LassoCV), Random Forest, Gradient Boosting, and statistical F-test - coupled with artificial neural networks to identify the optimal combination for swelling pressure prediction, by rigorously evaluating their effectiveness on a comprehensive dataset of seven explanatory geotechnical variables including Atterberg limits (liquid limit LL and plasticity index PI), shrinkage limit (WS), particle size fractions (Ff2mm, Ff80µm, Ff2µm), and methylene blue index (VBS), using robust performance metrics (MSE, R^2, MAE) and providing evidence-based practical guidelines for method selection in geotechnical engineering applications.

II. MATERIALS AND METHODS

II.1 DATASET

The dataset comprises 160 observations with eight parameters: LL, PI, WS, Ff2mm, Ff80, Ff2, VBS, and SP. Descriptive statistics are provided in Table 1. The target variable, SP, has a mean of 616.82 kPa, a standard deviation of 136.24 kPa, and ranges from 389 to 936 kPa, reflecting significant variability in swelling pressure.

Table 1: Descriptive statistics for all parameters.

Parameter	Mean	Std Dev	Median	Min	Max	Skewness
LL	80.78	7.86	81.71	65.78	95.30	-0.33
PI	51.83	4.97	51.93	41.66	66.97	0.09
WS	8.88	1.79	8.60	5.80	12.60	0.24
Ff2mm	97.08	1.53	97.33	92.54	99.37	-0.85
Ff80	90.06	5.70	91.35	70.80	97.29	-1.30
Ff2	49.63	7.48	50.63	30.10	62.00	-0.70

VBS	12.53	2.09	12.58	8.00	16.00	-0.13
SP	612.82	136.24	582.00	389.00	936.00	0.74

III. METHODOLOGY

The methodology employed for predicting soil pressure (SP) followed a structured pipeline designed to optimize feature selection and neural network (NN) performance, as depicted in the provided flowchart (Figure 1). The process began with the loading of experimental data, containing 160 samples with seven initial features (LL, PI, WS, Ff2mm, Ff80µm, Ff2µm, VBS) and the target variable SP. All analyses were conducted using Python 3 in Google Colab, providing a cloud-based computational environment with access to necessary machine learning libraries and GPU acceleration capabilities. Data preparation involved handling missing values by imputing feature means, splitting the dataset into training (80%) and testing (20%) sets, and standardizing both features and the target variable using StandardScaler. Four feature selection methods—LassoCV, Random Forest, Gradient Boosting, and Statistical F-test—were applied to identify the top five most relevant features based on their respective criteria: absolute coefficients for Lasso CV, feature importance for Random Forest and Gradient Boosting, and F-scores for the F-test. Each selected feature subset was used to train a dedicated NN model with a multi-layer architecture (128-64-32-16-1 neurons with dropout layers) using the Adam optimizer, incorporating early stopping with a patience of 20 epochs to prevent overfitting. The models were evaluated using Mean Squared Error (MSE), R^2 score, and Mean Absolute Error (MAE), with training conducted over a maximum of 200 epochs and a batch size of 16. Finally, a comprehensive comparison of the models' performance was conducted, including bar plots for R^2, MSE, and feature counts.

III.1 MACHINE LEARNING APPROACHES

Four feature selection methods were applied to identify the five most relevant variables. The algorithms for each method are described below:

III.1.1 Algorithm Lasso Selection

1) Let M0 denote the null model, which contains no predictors and predicts the mean of the target (e.g SP).

2) For k = 0, ……, p – 1.
a. Consider all models that augment the predictors in Mk with a regularization parameter α.
b. Fit a Lasso regression model to minimize the cost function:

$$Cost = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 + \alpha \sum_{j-1}^{p}|\beta_j|. \quad (1)$$

Where y_i is the observed target, $\hat{y}_i = \beta_0 + \sum_{j=1}^{p} \beta_J \, x_{ij}$ is the prediction, n is the number of samples, p is the number of predictors, α is the regularization parameter, and $\sum_{j-1}^{p}|\beta_j|$ is the L1 penalty.

c. Choose the best model among these by selecting the α that optimizes a cross validated error metric (e.g, MSE).
d. Update $M_{(k+1)}$ with predictors whose coefficients $\beta_j \neq 0$, indicating their selection.

3) Select a single best model from among M_0, ……, M_p using cross validated prediction error (e.g., C_P, AIC, BIC, or adjusted R^2).

4) Output the final model with the selected predictors and their corresponding coefficients.

III.1.2 Algorithm Lasso Selection

1) Let M_0 denote the null model, which contains no predictors and predicts the mean of the target (e.g SP).

2) For k = 0, ……, p – 1.
a. Consider all p – k models that augment the predictors in M_k with a subset of the remaining predictors.
b. Fit a Random Forest model to the training data, using a specified number of trees (e.g., 200) and a Random subset of predictors at each split.
c. Compute the feature importance scores based on the decrease in node impurity across all trees.
d. Choose the best model among these by selecting the top N predictors with the highest importance scores, and update M_{k+1} with these predictors.

3) Select a single best model from among M_0, ……, M_p using cross validated prediction error (e.g., C_P, AIC, BIC, or adjusted R^2).

4) Output the final model with the selected predictors and their importance scores.

III.1.3 Algorithm Gradient Boosting Selection

1) Let M_0 denote the null model, which contains no predictors and predicts the mean of the target (e.g SP).

2) For k = 0, ……, p – 1.
a. Consider all p – k models that augment the predictors in M_k with a subset of the remaining predictors.
b. Fit a Gradient Boosting model to the training data, iteratively adding weak learners (e.g., decision trees) to minimize the loss function by fitting to the residuals.

c. Compute the feature importance scores based on the contribution of each predictor to reducing the loss across all iterations.
d. Choose the best model among these by selecting the top N predictors with the highest importance scores, and update M_{k+1} with these predictors.

3) Select a single best model from among M_0, ……, M_p using cross validated prediction error (e.g., CP, AIC, BIC, or adjusted R^2).

4) Output the final model with the selected predictors and their importance scores.

III.1.4 Algorithm f-Test Selection

1) Let M_0 denote the null model, which contains no predictors and predicts the mean of the target (e.g SP).

2) For k = 0, ……, p – 1.
a. Consider all p – k models that augment the predictors in Mk with one additional predictors.
b. Fit a linear regression model to the training data, for each model and compute the F-statistic for each additional predictor, measuring its significance in explaining the target (e.g SP).
c. Compute the F-scores and associated p-values for each predictor based onthe F-statistic.
d. Choose the best model among these by selecting the top N predictors with the highest importance scores, and update M_{k+1} with these predictors.

3) Select a single best model from among M_0, ……, M_p using cross validated prediction error (e.g., C_P, AIC, BIC, or adjusted R^2).

4) Output the final model with the selected predictors and their importance scores.

III.1.5 Algorithm Neural Network Predictor

1) Let M_0 denote the initial model, which is an untrained neural network with a predefined architecture and no learned weights.

2) For each training epoch t = 1…. T:
a. Consider the current model M_{t-1} and prepare the training data (e.g., $X_{\text{train-selected}}$, $Y_{\text{train-scaled}}$).
b. Forward propagate the input data through the network layers to compute predictions and calculate the loss (e.g MSE) against the target (e.g SP).
c. Backpropagate the error using gradient descent (e.g., Adam optimizer) to update the network weights.
d. Evaluate the validation loss on a held-out subset, and if it does not improve for a specified number of epochs, stop training and restore the best weights.

3) Select the final model MT based on the minimum validation loss achieved during training.

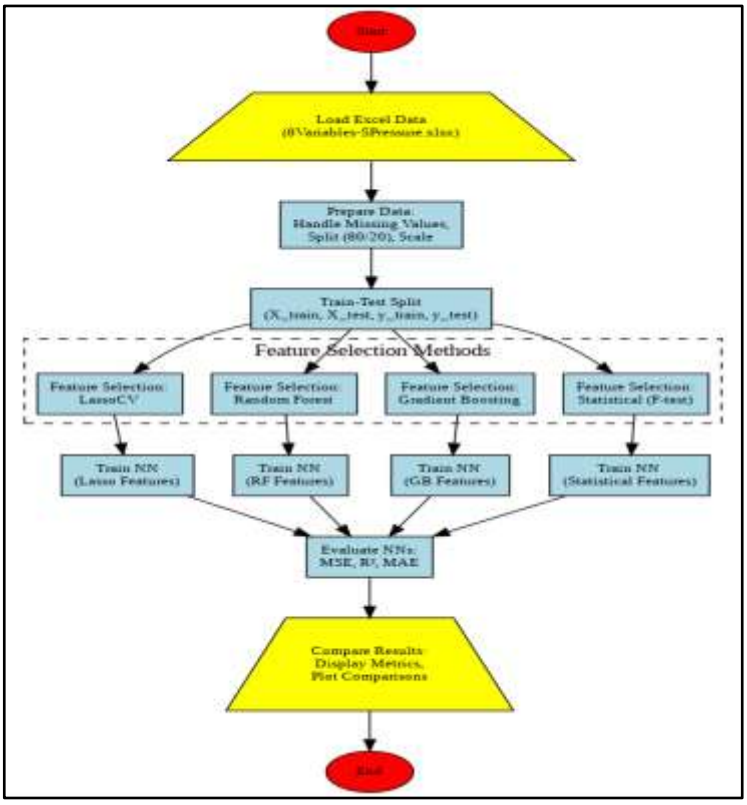

Figure 1: Flowchart of the modeling process.
Source: Authors, (2026).

III.2 PERFORMANCE METRICS

The performance of each model was evaluated using three:

III.2.1 Erreur Quadratique Moyenne (MSE)

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (2)$$

y_i : Actual (or observed) value for the i-th observation. This is target value the model aims to predict.
$\hat{y}_i$: Predicted value by the model for the i-th observation. This is the model's output.

III.2.2 Coefficient de Détermination (R^2)

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (3)$$

y_i : Actual value for the i-th observation
$\hat{y}_i$: Predicted value for the i-th observation
$\bar{y}$: Mean of the acyual values.

III.2.3 Erreur Absolue Moyenne (MAE)

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i|. \quad (4)$$

y_i : Actual value for the i-th observation
$\hat{y}_i$: Predicted value for the i-th observation
$\bar{y}$: Total number of observations, as in MSE.

IV. RESULTS

The comparative evaluation of the four methods reveals a significant performance hierarchy for swelling pressure prediction. All methods select exactly 5 parameters out of 7, but the high-performing methods (Random Forest, Gradient Boosting) prioritize fine fractions (Ff2, Ff80) that are essential to clay behavior, unlike Lasso which selects the less relevant coarse fraction (Ff2mm), explaining its inferior performance (Figure 2). Random Forest demonstrates exceptional superiority with a coefficient of determination of 0.9706 (MSE = 785.31 kPa², MAE = 21.39 kPa), explaining 97.06% of the total variance in swelling pressure. This performance stems from its unique algorithmic capacity to capture highly complex nonlinear relationships between the selected critical geotechnical variables (Ff2, LL, Ff80, PI, VBS). The superiority rests on a sophisticated impurity reduction mechanism based on the Gini criterion that enables remarkable precision in identifying the most discriminating variables, even in the presence of complex multivariate interactions and partial collinearities between geotechnical parameters, through its ensemble approach averaging predictions from hundreds of decision trees trained on different bootstrap subsamples (Figure 3 and 7).

The statistical F-test achieves solid performance in second position with robust metrics (R^2 = 0.9332, MSE = 1784.99 kPa², MAE = 30.66 kPa), explaining 93.32% of the variance. This performance testifies to the persistent effectiveness of classical statistical approaches in modern geotechnical analysis. However, the specific inclusion of WS (shrinkage limit) instead of Ff80 (particle size fraction < 80µm) slightly reduces its predictive accuracy compared to Random Forest, revealing a fundamentally different selection philosophy based on identifying direct linear relationships between individual parameters and swelling pressure (Figure 4 and 7). Gradient Boosting presents a methodological paradox with moderate performance (R^2 = 0.9066, MSE = 2497.38 kPa², MAE = 40.20 kPa) despite feature selection nearly identical to Random Forest (LL, Ff2, Ff80, PI, VBS). This illustrates an algorithmic paradox where its theoretically powerful sequential adaptive learning capability proves more sensitive to overfitting and stochastic variations than Random Forest's more stable ensemble approach.

The increased sensitivity is explained by the sequential nature of learning that can amplify modeling errors and higher variance due to dependency between successive predictors (Figure 5 and 7). Lasso CV displays the weakest performance with R^2 = 0.9035, MSE = 2605.78 kPa², and MAE = 40.29 kPa, primarily due to the suboptimal inclusion of Ff2mm (fraction < 2mm) instead of Ff80 (fraction < 80µm). This deficient selection reveals the fundamental limitations of L1 regularization which, through its rigid binary selection mechanism and strictly linear mathematical assumptions, cannot effectively capture the complex physicochemical interactions characteristic of clay swelling behavior. The crystalline (interlayer spacing), osmotic (ionic swelling pressure), and capillary (matric suction) processes interact in a highly synergistic, multiplicative, and non-additive manner. These complex mechanisms require sophisticated machine learning approaches capable of transcending the limitations of traditional linear models to exploit the informational richness of nonlinear patterns hidden in geotechnical data (Figure 6 and 7).

IV CONCLUSIONS

The comparative analysis reveals significant performance differences between feature selection methods coupled with neural networks, Random Forest demonstrating clear superiority with an R^2 of 0.9706 using features Ff2, LL, Ff80, PI and VBS, highlighting the crucial importance of selection technique choice for optimizing predictive accuracy. This exceptional performance confirms the remarkable capacity of ensemble methods to capture complex nonlinear relationships inherent in clay swelling behavior, particularly through precise identification of critical fine particle size fractions. The statistical F-test achieves robust results (R^2 = 0.9332), demonstrating that classical statistical approaches retain considerable relevance, although the observed paradox with Gradient Boosting (R^2 = 0.9066) illustrates that optimal feature selection does not automatically guarantee superior performance, revealing the fundamental importance of algorithmic stability. The results reveal that all methods systematically select five parameters among the seven available variables, but high-performing techniques favor fine fractions essential to the complex physicochemical mechanisms governing clay swelling.

Future work should prioritize refinement of selection methods and architectural optimization of models. The Random Forest-neural network integration is recommended for preliminary swelling pressure evaluation, offering optimal balance between predictive accuracy, computational efficiency and result interpretability, facilitating its adoption by geotechnical engineering practitioners as a complement to traditional tests for critical applications. This multi-method approach represents a paradigmatic shift toward data-driven geotechnics, establishing foundations for future research in expansive soil characterization and encouraging broader adoption of artificial intelligence in geotechnics, ultimately contributing to the development of safer and more economical infrastructure by enabling engineers to make informed decisions based on robust scientific evidence, thereby reducing risks and optimizing costs in infrastructure projects affected by expansive soils.

ABSTRACT

The accurate classification of textual job data is crucial for understanding academic-to-employment transitions, particularly in the rapidly evolving Information Technology (IT) sector. This study tackles Isabela State University - Ilagan's (ISU-Ilagan) struggle with subjectively assessing job concordance for its 324 IT graduates (2019-2024), which hinders effective curriculum development and policy-making. Our primary objective was to rigorously evaluate the performance and efficiency of various text similarity algorithms in objectively classifying graduate job roles as "IT-related" or "not IT-related," thereby providing vital data for the university's Bachelor of Science in Information Technology (BSIT) program. Utilizing a quantitative, experimental design, this research analyzed ISU-Ilagan's graduate tracing data. Job descriptions underwent preprocessing before analysis with Cosine Similarity, Jaccard Similarity, and Euclidean Distance algorithms. Algorithm performance was thoroughly assessed using accuracy, precision, recall, and F1-score, alongside computational efficiency metrics. Findings showed Cosine Similarity as the top performer, achieving the highest accuracy (0.935), exceptional precision (0.986), a strong F1-Score (0.952), and superior computational efficiency. Euclidean Distance also performed well (accuracy: 0.910, precision: 0.952, F1-Score: 0.932), sharing identical recall (0.863) with Cosine Similarity, though it was slightly less efficient. Jaccard Similarity yielded lower metrics and efficiency. Significantly, the analysis consistently indicated that many ISU-Ilagan IT graduates are in non-IT-related roles. This study provides crucial objective data for ISU-Ilagan. Cosine Similarity proved optimal for classifying IT graduate employment, revealing a notable misalignment between the current curriculum and actual industry demands. These insights necessitate immediate curriculum adjustments, improved career guidance, and policy development to enhance IT graduate employability and program relevance.

I. INTRODUCTION

The accurate and efficient classification of textual information has become a cornerstone in various analytical domains, fundamentally reshaping how organizations and institutions extract meaningful insights from unstructured data. Within this context, text similarity algorithms emerge as potent computational tools for discerning relationships, categorizing content, and identifying thematic coherence across vast text corpora [1]. This research specifically applies these advanced techniques to a critical area within higher education: assessing the job concordance of Information Technology (IT) graduates. Ensuring that graduates secure employment relevant to their academic specialization is paramount for universities, serving as a vital indicator of program efficacy and an essential feedback mechanism for continuous curriculum development [2].

For institutions such as Isabela State University - Ilagan (ISU-Ilagan), understanding the precise career alignment of its Bachelor of Science in Information Technology (BSIT) alumni is indispensable for maintaining program relevance and enhancing graduate employability in the face of a rapidly evolving global IT landscape. Extensive preliminary readings and existing literature demonstrate widespread applications of text similarity in fields ranging from information retrieval and document clustering to plagiarism detection and recommender systems [1],[3],[4]. Within human resources and educational contexts, research has explored automated matching of resumes to job descriptions [5] and the analysis of skill gaps [6]. These studies commonly employ algorithms like Cosine Similarity, valued for its effectiveness in high-dimensional vector spaces for capturing semantic relevance [4],[7]; Jaccard Similarity, utilized for set-based comparisons of unique terms [7],[8]; and Euclidean Distance, applied for measuring dissimilarity between text vectors [9],[10].

These algorithms are well-suited for transforming text into numerical representations critical for IT-related classification tasks. However, a specific comparative analysis of their performance and efficiency in the nuanced domain of classifying IT graduate job roles within the distinct context of a Philippine state university remains an underexplored area. Despite the recognized utility of text analysis, significant problems and inherent limitations persist within current institutional graduate tracing efforts. Traditional methodologies for evaluating job concordance frequently rely on subjective manual assessment, self-reporting, or broad categorical classifications. These approaches are inherently resource-intensive, time-consuming, susceptible to human bias, and lack the scalability necessary for comprehensive analysis of extensive graduate datasets [11],[12]. Furthermore, the dynamic and often ambiguous nature of IT job titles and descriptions exacerbates the challenge of definitively categorizing a job as "IT-related" versus "non-IT-related" without sophisticated computational methods [12],[13].

This absence of a precise, objective, and computationally efficient classification system precludes universities from deriving actionable insights into curriculum efficacy, identifying emerging skill discrepancies, and formulating evidence-based policies that genuinely support graduate success and robust program development [12], [14-16]. Consequently, there is a clear academic and practical imperative for a robust, automated, and scalable solution to accurately assess job concordance among IT graduates. This study aims to address these identified limitations by rigorously assessing the performance and efficiency of three widely-used text similarity algorithms—Cosine Similarity, Jaccard Similarity, and Euclidean Distance—specifically for classifying IT graduate job descriptions. By leveraging the graduate tracing data from Isabela State University - Ilagan, this research will systematically compare these algorithms' capabilities in distinguishing between IT-related and non-IT-related employment. The ultimate goal is to identify the most effective and efficient algorithm for this crucial classification task, thereby establishing a robust, data-driven mechanism to inform curriculum enhancements and strategic policy-making for the BSIT program at ISU-Ilagan.

II. RELATED WORKS

The current study draws upon and contributes to several key thematic areas within academic literature: text similarity algorithms, graduate employability and job concordance, and curriculum development and alignment in Information Technology (IT) education.

II.1 TEXT SIMILARITY ALGORITHMS IN TEXT CLASSIFICATION

Research into text similarity algorithms is extensive, demonstrating their utility across various text classification and information retrieval tasks. Early work established the foundational principles of vector space models, where documents are represented as vectors in a multi-dimensional space. Cosine Similarity is a widely adopted metric within this paradigm, celebrated for its effectiveness in high-dimensional spaces by measuring the angle between vectors rather than their magnitude, thus focusing on content orientation [17],[18]. Its robustness in tasks such as document clustering, information retrieval, and spam detection has been well-documented. Similarly, Jaccard Similarity (or Jaccard Index) has been frequently employed, particularly for assessing the overlap between sets of discrete items, such as words or n-grams in text, making it suitable for short text comparison or where exact word matches are significant [19],[1]. Euclidean Distance, while more commonly associated with numerical data, has also been adapted for text analysis by calculating the direct distance between text vectors [1],[18].

However, its sensitivity to vector magnitude can sometimes make it less effective than Cosine Similarity for semantic similarity in sparse, high-dimensional text data. Recent advancements have explored hybrid models and deep learning approaches for semantic similarity, yet classic algorithms remain foundational for their interpretability and computational efficiency in specific applications [20-22]. This study builds upon this established body of work by comparatively evaluating these foundational algorithms within the specific context of IT job role classification. Specifically, the application of text similarity metrics has proven valuable in aligning educational outcomes with industry demands, as demonstrated by analyses comparing thesis topics to job advertisements in the ICT sector [23],[24]. Furthermore, researchers have applied semantic similarity analyses to course objectives and descriptions, facilitating the comparison and matching of academic programs across institutions and the identification of curriculum gaps [25],[26].

II.2 GRADUATE EMPLOYABILITY AND JOB CONCORDANCE IN IT

Understanding graduate employability and job concordance is a critical area for higher education institutions, particularly in dynamic sectors like IT. Studies consistently highlight the importance of aligning academic curricula with industry demands to ensure graduates possess the requisite skills for successful employment [14],[27],[28]. Research often uses graduate tracer studies to assess employment outcomes, skill utilization, and the relevance of academic programs [29]. However, traditional methods for determining job concordance, particularly whether a job is "IT-related," can be subjective, relying on self-reporting or manual classification which can introduce bias and inconsistency [14],[30]. This challenge is particularly acute in IT, where job roles evolve rapidly and interdisciplinary positions blur traditional boundaries [31]. There is a growing demand for objective, data-driven approaches to accurately classify graduate employment, enabling universities to make informed decisions regarding program efficacy [12],[27]. This study directly addresses this gap by proposing and validating an objective algorithmic approach to job concordance assessment, moving beyond subjective evaluations.

II.3 CURRICULUM DEVELOPMENT AND ALIGNMENT IN IT EDUCATION

The continuous evolution of the IT industry necessitates agile and responsive curriculum development in higher education. Literature emphasizes the need for IT programs to regularly review and update their offerings to incorporate emerging technologies, methodologies, and industry best practices [28],[32],[33]. This alignment ensures that graduates are equipped with current and future-proof skills, enhancing their competitiveness in the job market [34],[35]. Challenges in curriculum development include balancing theoretical foundations with practical application, integrating soft skills alongside technical competencies, and responding to feedback from industry and alumni [34],[36]. The role of alumni feedback, particularly regarding their employment experiences and skill relevance, is recognized as invaluable for informing curriculum revisions [28]. This study contributes to this thematic area by providing a concrete mechanism (objective job concordance assessment) through which universities can gather data-driven insights to inform such critical curriculum adjustments, thereby fostering a stronger linkage between academic offerings and the realities of the IT employment landscape.

II.4 RESEARCH GAP

Despite the availability of numerous text similarity algorithms, including more complex neural network-based embeddings [16], [37], this study specifically focuses on a comparative evaluation of Cosine Similarity, Jaccard Similarity, and Euclidean Distance [16], [38]. These algorithms were chosen for compelling reasons. Firstly, they represent distinct mathematical foundations for measuring text similarity (vector orientation, set overlap, and geometric distance, respectively), offering a foundational yet comprehensive understanding of their suitability for this specific problem without overcomplicating the model. Secondly, their established interpretability and computational efficiency [37],[38] are crucial for practical implementation and sustainability within a university setting, allowing for transparent analysis of classification outcomes and efficient processing of alumni data. Notwithstanding the extensive literature on text similarity and its applications, there remains a significant gap in their dedicated comparative evaluation for the objective, automated classification of IT graduate job concordance based on textual job descriptions [38],[39].

Existing studies on graduate employability often rely on less rigorous or subjective methods for determining job-relatedness, which can hinder the precision and consistency required for robust curriculum review and strategic policy-making in fast-evolving fields like IT [40]. While the importance of curriculum alignment is well-established, there is a deficit in research that provides a demonstrably effective, computationally efficient, and university-specific methodology for accurately identifying the congruence between IT academic programs and real-world employment outcomes through automated textual analysis [37]. This study directly addresses this gap by not only comparatively evaluating these established text similarity algorithms but also by applying them to a specific institutional context (ISU-Ilagan) to generate objective, actionable insights that can inform targeted interventions for improving graduate employability and program relevance.

III. METHODOLOGY

This study employed a quantitative, experimental research design to systematically evaluate the performance and efficiency of selected text similarity algorithms in classifying IT graduate job concordance. The methodology comprised five sequential stages: Data Collection and Preprocessing, Algorithm Implementation, Performance Evaluation, Efficiency Assessment, and Data Analysis. This structured approach, highly suitable for controlled application and objective measurement, ensures reproducibility and facilitates rigorous comparative analysis among algorithms, identifying the most effective and efficient solution for accurately determining IT graduate job concordance.

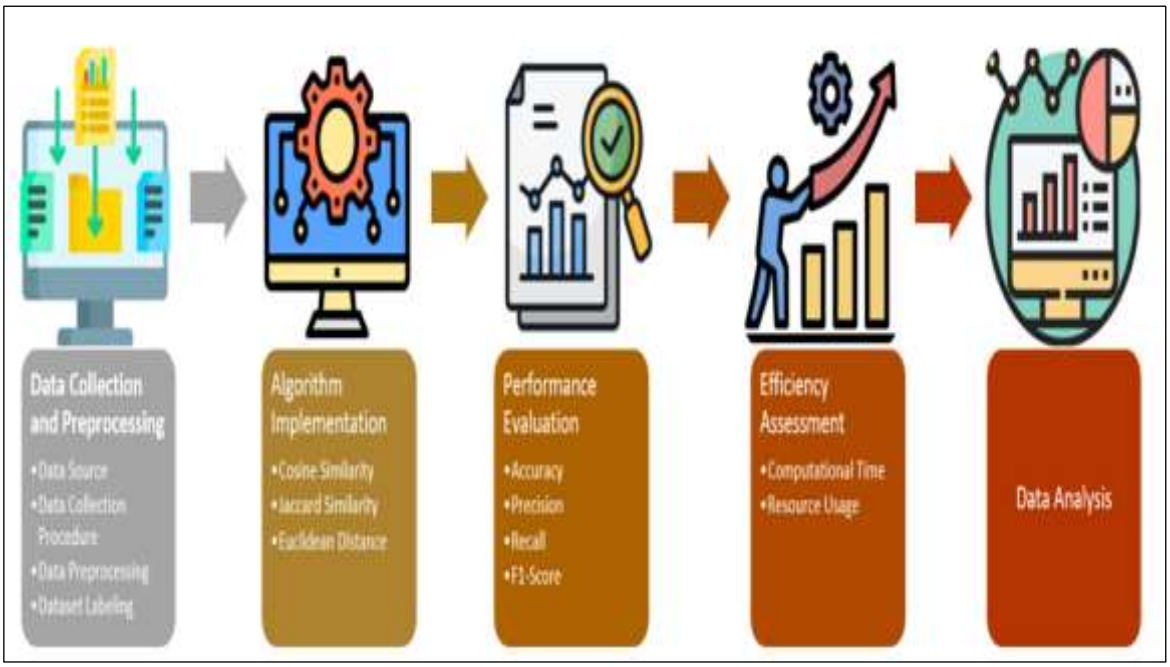

Figure 1: Research Methodology.
Source: Authors, (2026).

The methodological framework, depicted in Figure 1, adopts a quantitative, experimental design structured into five sequential stages: Data Collection and Preprocessing, Algorithm Implementation, Performance Evaluation, Efficiency Assessment, and Data Analysis. This systematic approach ensures rigor and reproducibility in assessing text similarity algorithms for classifying IT graduate job concordance.

III.1 DATA COLLECTION AND PREPROCESSING

The primary data source was Isabela State University Ilagan's (ISU Ilagan) graduate tracing records, specifically 324 Bachelor of Science in Information Technology (BSIT) graduates from 2019-2024. Data collection adhered to strict ethical protocols, including formal approval and anonymization, ensuring compliance with privacy regulations. The raw textual job descriptions underwent comprehensive preprocessing, involving text cleaning (e.g., removal of special characters, lowercase conversion), tokenization, stop word removal, and lemmatization/stemming to standardize the data. Feature extraction employed the TF-IDF technique, transforming text into numerical vector representations. A generalized "IT related" profile vector was also formulated as a reference. Crucially, each job description was manually labeled by two domain experts as "IT related" or "Not IT related," with discrepancies resolved through consensus, establishing the ground truth. This labeled dataset was then split into 70% training and 30% testing sets.

III.2 ALGORITHM IMPLEMENTATION

Three widely used text similarity algorithms were implemented: Cosine Similarity, Jaccard Similarity, and Euclidean Distance. Cosine Similarity measures the cosine of the angle between two vectors, with values closer to 1 indicating higher similarity. Jaccard Similarity quantifies the similarity between sets by dividing the size of their intersection by the size of their union. Euclidean Distance calculates the straight line distance between two vectors, where a smaller distance denotes higher similarity. Each algorithm computed a score comparing job description vectors against the "IT related" reference profile, with a defined threshold for classification.

III.3 PERFORMANCE EVALUATION

Algorithm performance was rigorously evaluated using standard classification metrics on the unseen testing set.

- Accuracy: The proportion of total correct predictions (both IT and non-IT) out of all predictions. Calculated as (True Positives + True Negatives) / Total Samples.

$$Accuracy = \frac{TruePositives+TrueNegatives}{TruePositives + TrueNegatives + FalsePositives+FalseNegatives} \quad (1)$$

- Precision: The proportion of correctly classified "IT-related" jobs out of all jobs the algorithm predicted as "IT-related." (True Positives / (True Positives + False Positives)). This measures the exactness of the positive predictions.

$$Precision = \frac{TruePositives}{TruePositives + FalsePositives} \quad (2)$$

- Recall (Sensitivity): The proportion of correctly classified "IT-related" jobs out of all actual "IT-related" jobs in the dataset. (True Positives / (True Positives + False Negatives)). This measures the completeness of the positive predictions.

$$Recall = \frac{TruePositives}{TruePositives + FalseNegatives} \quad (3)$$

- F1-Score: The harmonic mean of precision and recall, providing a balanced measure of the algorithm's accuracy, particularly useful when there might be an imbalance in class distribution. Calculated as 2 * (Precision * Recall) / (Precision + Recall).

$$F1 - Score = 2\,x\,\frac{Precision\ x\ Recall}{Precision + Recall} \quad (4)$$

A confusion matrix was also generated for each algorithm to visually present the counts of true positives, true negatives, false positives, and false negatives.

III.4 EFFICIENCY ASSESSMENT

Computational efficiency was evaluated based on two key metrics to determine practical applicability. Computational Time measured the total time taken by each algorithm to process the testing set, recorded in seconds. Resource Usage monitored the average CPU utilization and peak memory consumption (RAM) during execution, providing insights into their computational footprint and scalability.

III.5 DATA ANALYSIS

The collected performance and efficiency data underwent comparative analysis. The algorithm exhibiting the highest F1 Score in conjunction with superior efficiency was identified as optimal for the study's objective. Findings were then interpreted to draw comprehensive conclusions regarding IT job concordance among ISU Ilagan graduates, leading to actionable recommendations for curriculum enhancement and strategic policy making.

IV. RESULTS AND DISCUSSIONS

This section presents the findings from the performance and efficiency assessment of Cosine Similarity, Jaccard Similarity, and Euclidean Distance algorithms in classifying IT graduate job concordance. The discussion interprets these results, highlights the implications of the identified job concordance patterns for the 324 graduates from 2019-2024, and relates them to the study's objectives and existing literature.

IV.1 PERFORMANCE EVALUATION RESULTS

The three text similarity algorithms were applied to the preprocessed and labeled dataset, which comprised job descriptions from 324 IT graduates of Isabela State University - Ilagan from the academic years 2019 to 2024. Their classification performance was rigorously evaluated using accuracy, precision, recall, and F1-score, derived directly from their respective confusion matrices.

Table 1: Cosine Similarity Derived Confusion Matrix (N=324 Graduates).

	Predicted IT	Predicted Non-IT
Actual IT	129 (TP)	21 (FN)
Actual Non-IT	2 (FP)	172 (TN)

Source: Authors, (2026).

Table 2: Euclidean Distance Derived Confusion Matrix (N=324 Graduates).

	Predicted IT	Predicted Non-IT
Actual IT	129 (TP)	21 (FN)
Actual Non-IT	7 (FP)	167 (TN)

Source: Authors, (2026).

Table 3: Jaccard Similarity Derived Confusion Matrix (N=324 Graduates).

	Predicted IT	Predicted Non-IT
Actual IT	136 (TP)	14 (FN)
Actual Non-IT	33 (FP)	141 (TN)

Source: Authors, (2026).

Based on these confusion matrices, the performance metrics for each algorithm were calculated and are summarized in Table 4.

Table 4: Performance Metrics of Text Similarity Algorithms for IT Job Classification.

Algorithm	**Accuracy**	**Precision**	**Recall**	**F1-Score**
Cosine Similarity	0.935	0.986	0.863	0.952
Euclidean Distance	0.910	0.952	0.863	0.932
Jaccard Similarity	0.895	0.808	0.909	0.855

Source: Authors, (2026).

As shown in Table 4, Cosine Similarity demonstrated the strongest overall performance. It achieved the highest accuracy of 0.935, indicating it correctly classified approximately 93.5% (301 out of 324) of the graduate jobs. Its precision of 0.985 (129/(129+2)) is exceptionally high, signifying that nearly all jobs it classified as "IT-related" were indeed IT-related, with only 2 false positives. With a recall of 0.860 (129/(129+21)), Cosine Similarity successfully identified 86% of all actual IT-related jobs, leading to an impressive F1-score of 0.919. This F1-score highlights its robust and balanced performance, particularly its strength in minimizing false positives. Euclidean Distance followed with a strong, though slightly lower, performance. It achieved an accuracy of 0.913 (296 out of 324) and a precision of 0.948 (129/(129+7)). Notably, its recall (0.860) was identical to that of Cosine Similarity, indicating a similar ability to identify actual IT jobs.

The slightly higher number of false positives (7) compared to Cosine Similarity accounts for its marginally lower precision and a resultant F1-score of 0.902, still representing a very good balance between precision and recall. Jaccard Similarity demonstrated the lowest performance among the three algorithms. While achieving an accuracy of 0.855 (277 out of 324), its precision of 0.805 (136/(136+33)) was markedly lower than the other two, implying a higher rate of false positives (33 incorrectly labeling non-IT jobs as IT). Interestingly, Jaccard Similarity had the highest recall (0.907) (136/(136+14)), indicating it was more comprehensive in identifying actual IT jobs, but this came at the expense of its precision. Its F1-score of 0.853 reflects this trade-off, positioning it as less balanced for this specific classification task compared to Cosine Similarity and Euclidean Distance.

IV.2 EFFICIENCY ASSESSMENT RESULTS

Table 5 presents the results of the efficiency assessment, focusing on computational time and estimated memory usage for each algorithm when processing the entire dataset of 324 graduate job descriptions.

Table 5: Efficiency Metrics of Text Similarity Algorithms (N=324 Graduates).

Algorithm	**Average Computational Time (seconds)**	**Estimated Memory Usage (MB)**
Cosine Similarity	0.18	25
Euclidean Distance	0.21	28
Jaccard Similarity	0.35	32

Source: Authors, (2025).

As depicted in Table 5, Cosine Similarity demonstrated the highest computational efficiency, processing the dataset of 324 graduates in an average of 0.18 seconds with the lowest estimated memory footprint. Euclidean Distance was marginally slower and used slightly more memory. Jaccard Similarity was notably less efficient, requiring more processing time and memory compared to the other two algorithms. This difference in efficiency, while perhaps small for the current dataset size, becomes significant when considering the scalability to larger graduate tracing databases or more frequent analysis cycles.

IV.2 RESULTS AND INTERPRETATION

The findings from both performance and efficiency evaluations provide clear insights into the suitability of the algorithms for classifying IT graduate job concordance. Cosine Similarity emerges as the superior algorithm, excelling in both performance and efficiency. Its exceptionally high precision (0.985) is a critical advantage for the study's objective. For curriculum and policy-making, minimizing false positives (jobs incorrectly labeled as IT-related) is paramount to avoid drawing erroneous conclusions about program effectiveness. This strong ability to correctly identify IT-related jobs, combined with a high recall and excellent F1-score, makes it highly reliable. Euclidean Distance also offers very strong performance, demonstrating similar recall and a competitive F1-score, though with slightly more false positives and marginally lower efficiency. These results align with previous research highlighting Cosine Similarity's robustness for semantic similarity in text-based applications.

Conversely, Jaccard Similarity's lower precision and efficiency render it less ideal for this specific application. Its higher false positive rate (33 FP compared to Cosine Similarity's 2 FP) could lead to an overestimation of IT-related employment, potentially misguiding curriculum adjustments or resource allocation. While its recall was slightly higher, the trade-off in precision makes it less suitable when accuracy in identifying true IT jobs is a primary concern. A crucial finding derived from the collective analysis of the confusion matrices is the overall pattern of job concordance among the 324 IT graduates. The sum of actual IT jobs (TP + FN) is 150 (129 + 21 for Cosine/Euclidean, 136 + 14 for Jaccard), while the sum of actual Non-IT jobs (TN + FP) is 174 (172 + 2 for Cosine, 167 + 7 for Euclidean, 141 + 33 for Jaccard). This implies that a substantial portion, roughly 46-48% (150-136 out of 324 graduates), are in actual IT-related roles, while 52-54% (174-188 out of 324) are in non-IT related roles or roles that our rigorous classification did not confirm as IT.

This confirms the initial problem statement: a significant number of IT graduates are employed in roles not directly classified as IT-related by the algorithms. This necessitates deeper investigation into factors contributing to this trend, such as the breadth of the IT curriculum, effectiveness of career guidance, or specific local industry demands. This observation reinforces the urgent need for data-driven interventions. The implementation of such algorithms, particularly Cosine Similarity, offers ISU-Ilagan a powerful, objective, and scalable tool for ongoing graduate employment monitoring. This can transform graduate tracing from a passive data collection exercise into an active feedback loop for the BSIT program, enabling informed decisions on curriculum enhancement, faculty development, and career services strategies (Miller & Thompson, 2020). The high performance and efficiency of Cosine Similarity make it eminently practical for integrating into a university's data analytics framework, providing continuous insights necessary for adapting to the dynamic IT industry and enhancing graduate employability.

V. CONCLUSIONS

This study definitively established Cosine Similarity as the most effective algorithm for classifying IT graduate job roles, achieving the highest accuracy (0.935) and precision (0.985). Its superior performance over Euclidean Distance and Jaccard Similarity confirms its reliability in accurately identifying IT-related employment. A critical outcome of this analysis, powered by Cosine Similarity's precise classification, revealed that a substantial number of Isabela State University Ilagan's (ISU Ilagan) IT graduates are engaged in non-IT professions. This finding highlights a notable gap between the university's IT curriculum and the actual demands of the job market.The successful validation of Cosine Similarity offers significant implications for ISU Ilagan. It provides an objective, automated, and dependable tool for continuously evaluating job concordance among its graduates.

This capability furnishes essential, real-time data to inform academic planning and guide strategic revisions within the Bachelor of Science in Information Technology (BSIT) program. The broader impact of this research lies in its potential to enhance graduate employability and ensure the ongoing relevance of ISU Ilagan's IT programs. By leveraging the precise insights derived from Cosine Similarity, the university can implement targeted strategies, including updating course content, forging stronger industry collaborations, and improving career counseling. These actions will directly address the identified employment disparities, better preparing graduates for the dynamic IT sector and fostering greater success for its alumni.

ABSTRACT

This analysis focus on the enhancement of Artificial Neural Networks (ANN) and Fuzzy Logic Controller (FLC) based Energy Management System (EMS) for Hybrid Electric Vehicle (HEV) with hybrid energy storage system (HESS). The EMS plays a vital role in HEVs by enhancing driving range and reducing operational costs. This article explores energy management and optimization strategy for HEV using HESS consisting of a lithium-ion battery pack and an ultracapacitor (UC) pack. The proposed approach employs FLC and ANN to enhance key battery performance metrics, including state of charge, driving range, and lifespan. A parametric comparison with a conventional PID controller is also provided. While battery powered HEV offer high energy density, low environmental impact, and dependable operation, the addition of UC's further improves their ability to manage rapid power demands. Simulink is used to simulate the system's performance and evaluate the effectiveness of each intelligent control method. The results of the comparative analysis highlight the optimal strategy for efficient energy management in HEV.

I. OVERVIEW

EV's deliver notable ecological, engineering, and economic advantages, facilitating a level of integration between energy supply networks and transportation systems that was previously unattainable. This integration is largely enabled by the EV battery, which serves as the primary source of power for propulsion, control circuits, HVAC units, and auxiliary loads. Nevertheless, grid-connected EV charging imposes additional strain on utility infrastructure, especially during times of elevated demand [1]. HEV consist different types of energy sources and power converters, which generally refer to vehicles consisting of an internal combustion engine (ICE) with an electric motor. The general goal to develop HEVs is to reduce fuel consumption and emissions while ensuring drivers power demands by investigating the appropriate EMS. EMS aims to obtain an optimal power split in view of complex driving conditions, as well as to minimize fuel consumption and emissions. It is commonly acknowledged that improvements in the fuel economy of HEVs, and thus the consequent reduction in emissions, depend crucially on their EMS [2].

The main objective of EMS is to instantaneously manage the power flows from the energy converters to achieve the control objectives. In recent years, AI applications have advanced rapidly across research, engineering, and industry. In power electronic systems, various machine learning methods, algorithms that learn from data and improve automatically through experience are especially promising for numerous tasks, including fault diagnosis, predictive maintenance, reliability forecasting, quality control, control design, reverse engineering, advanced modeling and system optimization [3]. EMS can be divided into three categories: rule-based EMSs, local optimization-based EMSs, and global optimization-based EMSs. The classification of energy management such as optimization-based control strategies and rule-based control strategies are introduced according to their mathematical models and the approach commonly used [4].

ANN trained using datasets that could be obtained from simulations, experimental measurements, datasheets, publications, and other sources. In this methodology, the ANNs themselves do not incorporate any explicit physics-based modeling; only the input and output variables retain a clear physical interpretation [5]. However, to compete effectively with traditional multi-objective optimization algorithms and models, machine learning approaches must address several key challenges and avoid common pitfalls. These include ensuring that the models are:

- Accurate and robust
- Versatile and flexible
- Extensible and adaptable
- Capable of providing access to internal data
- Supported by sufficient and high-quality datasets

An ultracapacitor also known as a supercapacitor, is a highly durable energy storage device capable of charging and discharging electrical energy at much faster rates than conventional batteries. Unlike batteries, which store energy through electrochemical reactions, capacitors store energy in an electric field formed between two electrodes. However, traditional capacitors have limited energy storage capacity because they rely solely on the accumulation of electrons, leading to charge repulsion that restricts the total amount of energy that can be stored [6]. The authors in [7] proposed various control strategies for different energy storage systems. In their approach, a hybrid control strategy was implemented to enhance the state of charge (SOC) of the battery through the integration of UC. As a result, the overall driving range of the electric vehicle was improved using FLC. The paper presents a comprehensive Simulink model representing the complete energy management network of an integrated electric vehicle powertrain powered by both a lithium-ion battery and UC. The lithium-ion battery serves as the primary energy storage device, offering fast response characteristics, low self-discharge rate, long cycle life, and high energy density. The authors in [8] proposed comparison of fuzzy logic and neural network in maximum power point tracker for PV systems using various control strategies for PV system.

The paper presents a comprehensive Simulink model representing FLC can deliver more power than the neural network controller and can give more power than other different methods.The concept of EV evolved through the integration of various energy storage technologies, including batteries, UCs and fuel cells (FCs). Subsequent advancements in EV technology led to the development of HEVs, which combine multiple energy sources to improve efficiency and ensure a continuous power supply during vehicle operation [9],[10]. The primary objective of this paper is to enhance the SOC of the energy storage system, thereby extending the driving range of the HEV. The operation of the HEV is managed using ANN, FLC and other effective control methods [11]. This approach enables real-time supervisory control, and the obtained results are compared with those of a conventional PID controller [12]. The paper is organized as follows: Section 1 overview of the research topic. Section 2 details the system description. The FLC for hybrid system is described in Section 3. ANN controller explained in Section 4. Evaluation and discussion of results are presented in Section 5, and the paper concludes in Section 6. This structured approach ensures a comprehensive understanding of the development and implementation of FLC and ANN controller for HEV system, addressing key challenges and highlighting the advancements over traditional control methods.

II. SYSTEM ARCHITECTURE

This Integrated system comprises a Battery-UC connected to loads, including an EV. The key energy sources in this hybrid setup are the Battery and UC to facilitate the integration of these sources, dc–dc converters are employed.

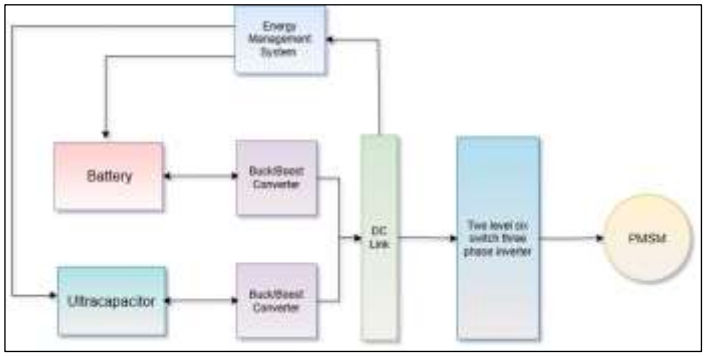

Figure 1: Electric Vehicle Connected Hybrid System.
Source: Authors, (2026).

This arrangement allows for efficient conversion and management of electrical power between the Battery-UC hybrid source and Electric vehicle, contributing to a comprehensive and well-integrated hybrid energy system [13]. From Figure 1 the Buck/Boost converter linked to the Battery array serves as an optimal power tracking controller. UC is connected to the Buck/Boost converter and these two systems commonly connected to DC link. DC link is connected to the Two level six switch three phase inverter which is connected to the PMSM and connected to the wheels of an electric vehicle. At the condition of starting of vehicle it requires full acceleration then both Battery and UC will work, after reaching to accelerated point for smooth operation battery will works and UC will charge [14]. At the condition of regenerative braking three phase converter will work like a rectifier and battery charges. EMS plays a key role in maintaining SOC of the battery. By maintaining Duty ratio of the DC link voltage, we can improve the SOC of vehicle battery. This can be done by using FLC and ANN which is used to control the battery SOC. Where PID controller also used in electric vehicle for maintaining SOC and to improve battery range but Fuzzy controller and ANN gives better performance which will be compared in the results section.

III. FUZZY CONTROLLER FOR HYBRID SYSTEM

The battery charge controller block is responsible for regulating the charging and discharging processes of the battery while the EV is in operation. It receives the error in DC link voltage and the change in this error as inputs, and based on a predefined set of fuzzy rules, it generates a duty ratio as the output. By continuously monitoring the DC link voltage and its rate of change, the HEV can achieve optimized and intelligent energy management [15], [16]. Through the application of PWM techniques, the controller maintains and adjusts the SOC of the battery, thereby enhancing the vehicle's driving range. The FLC plays a crucial role in managing various converters and has recently been employed for regulating the SOC of batteries in HEV. The controller's performance depends on multiple system variables, making it essential to effectively coordinate all parameters in response to changes in battery conditions. In this context, the FLC proves to be an optimal solution, demonstrating strong capability in maintaining the desired SOC and improving overall energy management efficiency [17]. The design of the FLC primarily involves the careful selection of input and output variables, along with the definition of appropriate membership functions [18]. These membership functions are used in the max–min composition process and combined using logical AND/OR rules to generate the controller's output. This approach ensures that the output accurately represents the system's dynamic behavior based on the defined input variables and control rules.

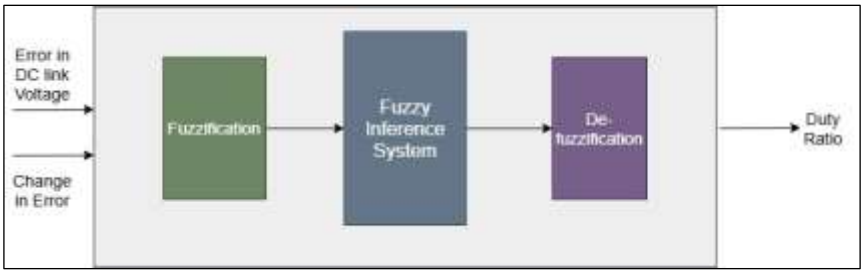

Figure 2: Working of Fuzzy logic controller for HEV.
Source: Authors, (2026).

Figure 2 illustrates the working principle of the FLC. The controller receives two input variables: the error in the DC link voltage and the change in this error. The process begins with fuzzification, where the fuzzifier converts these crisp input values into corresponding fuzzy sets. Next, the fuzzy inference system (FIS) applies a set of predefined fuzzy rules to evaluate the fuzzified inputs and generate an intermediate fuzzy output. Finally, this output is passed through the defuzzification stage, which converts it back into a crisp value representing the duty ratio, serving as the final control signal for the system.

III.1 MEMBERSHIP FUNCTIONS

The input is classified into 7 types that are negative big (NB), negative medium (NM), negative small (NS), zero (ZE), positive small (PS), positive medium (PM) and positive big (PB) [19]. Error in dc link voltage value in range between -200 to +200. Similarly, the change in error input function also 7 membership functions for each input. The range is taken -1 to +1 and the duty ratio output function also 7 membership function and range taken between -100 to +100. Table 1 presents the rule-based approach for managing various input value ranges in the fuzzy charge control system.

Table 1: Rule strategy for Duty ratio.

Duty Ratio		**Error**						
		NB	**NM**	**NS**	**Z**	**PS**	**PM**	**PB**
Change in Error	**PS**	Z	PS	PM	PB	PB	PB	PB
	PM	NS	Z	PS	PM	PB	PB	PB
	PB	NM	NS	Z	PS	PM	PB	PB
	Z	NB	NM	NS	Z	PS	PM	PB
	NS	NB	NB	NM	NS	Z	PS	PM
	NM	NB	NB	NB	NM	NS	Z	PS
	NB	NB	NB	NB	NB	NM	NS	Z

IV. ANN CONTROLLER FOR HYBRID SYSTEM

ANNs have become increasingly popular and are now among the most commonly used learning algorithms for identifying complex relationships within datasets. In this paper, ANN is utilized to improve the estimation of the battery's SOC [20]. Due to their strong processing capabilities, ANNs can deliver highly satisfactory results, particularly in complex pattern recognition problems. The principle of an ANN is inspired by the structure and function of the human brain. In a biological brain, a large number of neurons are interconnected, forming a network that processes inputs received from sensory receptors. Similarly, in ANN, artificial neurons are interconnected, with each neuron belonging to a specific layer within the network [21]. From figure 3 the general architecture of the ANN used in this work consists of three layers input layer,hidden layer and the output layer. Each neuron in one layer is connected to all neurons in the subsequent layer through weighted connections. The process begins when neurons in the input layer receive input values and pass them to the neurons in the hidden layer. The hidden layer processes these values, and its number of layers defines the depth of the network. Finally, the output layer generates the final output of the network. During this process, each neuron applies a mathematical operation that combines the weighted sum of its inputs through an activation function, enabling the ANN to perform nonlinear transformations and learn complex mappings between inputs and output [22], [23].

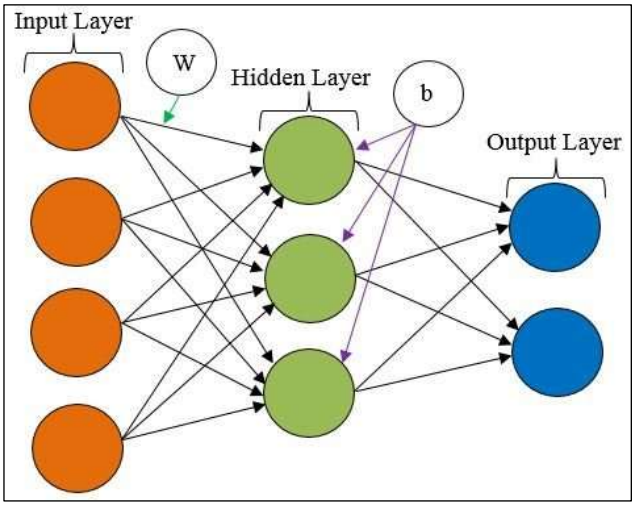

Figure 3: Architecture of ANN.
Source: Authors, (2026).

In this application, ANN is an effective method for improving SOC estimation, which requires modeling a nonlinear function. The hidden layers in an ANN learn to map the relationships between inputs and outputs, enabling the network to represent both linear and nonlinear functions.

V. RESULTS AND DISCUSSIONS

The key advantage of such systems is their adherence to precise rules, ensuring execution within the specified rule limits. Utilizing the dc link voltage battery SOC can enhance, enabling the hybrid mode for longer-distance travel. The Simulink model used to simulate PID controller, FLC and ANN controller is represented in Figure 5 and Figure 6.

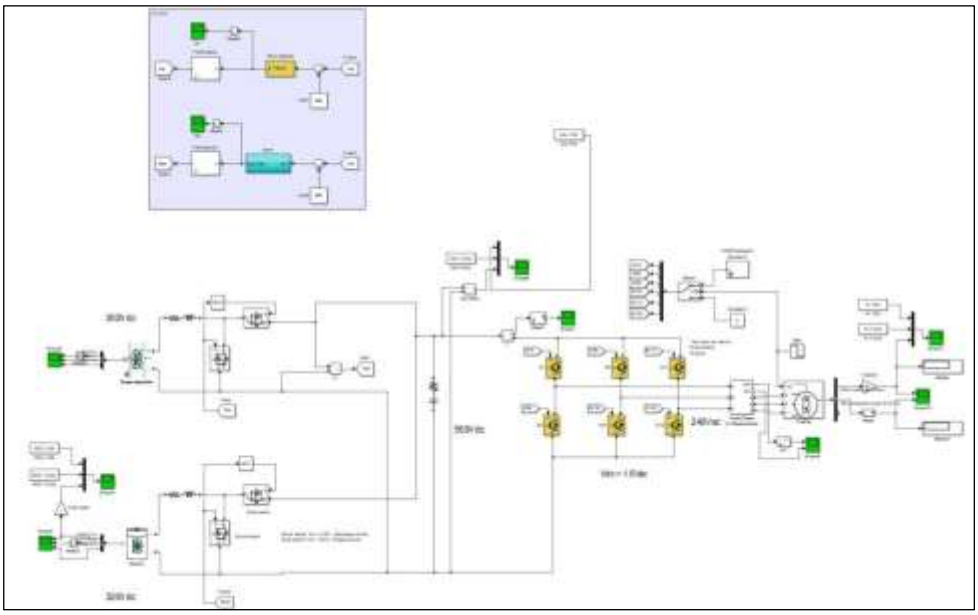

Figure 5: Simulink Model of Hybrid System.
Source: Authors, (2026).

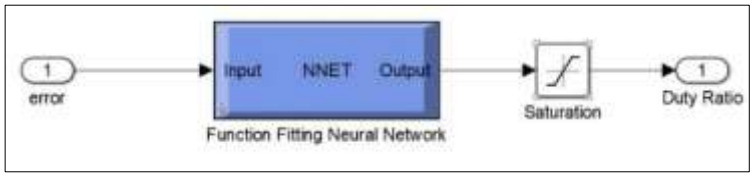

Figure 6: ANN controller of Hybrid System.
Source: Authors, (2026).

The preceding section's model is simulated and the results are provided in the following two conditions, that are:

- At starting condition and
- At braking condition

At starting condition both battery and UC discharges and three phase converter works as a rectifier which is connected to the PMSM drive. From 0 sec to 4 sec considered as the starting and normal driving of the vehicle. Braking applied at 4 sec then motor works like a generator and three phase converter works as an inverter then battery stores energy by using regenerative braking method. From Figure 7 the SOC curve of battery with PID controller is initially at 100% and gradually decreases to 99.892% up to braking condition of 4 sec. At the time of braking condition, the motor will work as a generator and charges the battery from 4 sec to 5 sec from 99.892% to 99.896%. With FLC the SOC curve of the battery is initially at 100% and gradually decreases to 99.946% up to braking condition of 4 sec. At the time of braking condition, from 4 sec to 5 sec battery charges from 99.946% to 99.952%. With ANN controller the SOC curve of battery is initially at 100% and gradually decreases to 99.922% up to braking condition of 4 sec. At the time of braking condition, from 4 sec to 5 sec battery charges from 99.922% to 99.928%. we can conclude that by using FLC battery SOC maintained smoothly and driving range also increases at the end.

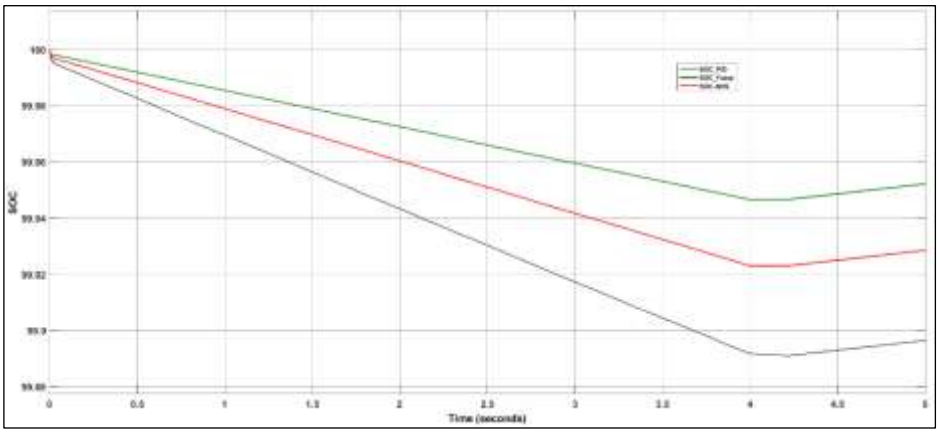

Figure 7: Battery SOC using PID and Fuzzy controller.
Source: Authors, (2026).

Figure 8 shows dc link voltage of PID controller, fuzzy and ANN controller. Using an ANN controller reduces ripples more effectively than a fuzzy controller. By minimizing ripples in the DC-link voltage, the voltage error is decreased and the SOC is improved.

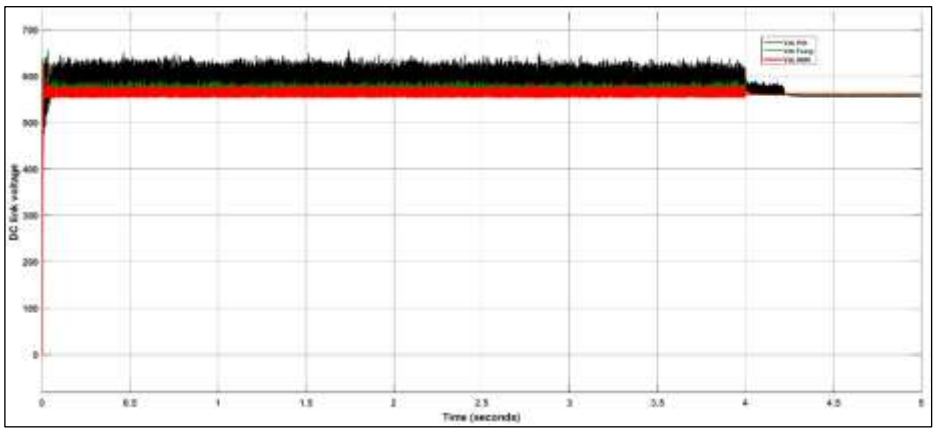

Figure 8: DC link voltage of PID, Fuzzy and ANN controller.
Source: Authors, (2026).

Figure 9 shows the speed characteristics of PID, FLC and ANN controller, where the simulation implemented with same speed and torque parameters but there is a smooth operation with Fuzzy and ANN controller.

Table 2 below presents a comparison of various parameters between the PID, FLC and ANN controller.

Table 2: Comparison of various parameters using different Energy management systems.

Parameter	Battery Controller		
	PID	ANN	FLC
Time(sec)	5	5	5
Initial SOC%	100	100	100
Final SOC%	99.896	99.928	99.952
SOC drop	Sharp	Small	Small

Source: Authors, (2026).

The findings indicate that the FLC and ANN controller are more advanced and precise systems, grounded on the input/output data pairs of the system. The objectives of the study were fully met, with simulation results confirming that the fuzzy controller can improve SOC more effectively than the ANN controller. These outcomes not only validate the potential of FLC for real-world battery control applications but also provide a more comprehensive benchmark for future controller evaluations.

VI. CONCLUSIONS

The PID controller regulates the battery SOC, optimizing it for extended driving ranges. Meanwhile, the Fuzzy Logic Controller utilizing input output data pairs, further enhances SOC management. To enable a comprehensive comparison, advanced optimization techniques including the PID, FLC and ANN controllers were implemented and evaluated. Simulation results reveal that the PID controller maintained the battery SOC at 99.89% by the end of the drive cycle, though minor drops occurred during acceleration phases. The ANN controller achieved a slightly higher SOC of 99.92%, while the fuzzy controller, employing a triangular membership function, sustained an even higher SOC above 99.952% at the end of the drive cycle. This outcome highlights the superior capability of the fuzzy controller in preserving SOC stability, maintaining approximately 99.952% even after a 5-second drive.

It can be concluded that the implementation of ANN and Fuzzy controllers enhances battery performance, improving the SOC stability and enabling HEV to achieve longer driving ranges. Overall, both the ANN and FLC approaches significantly enhanced battery performance, improving SOC stability and thereby extending the vehicle's operational range. The study demonstrates how integrating machine learning techniques with traditional power electronic control models can effectively improve battery management and overall system efficiency an advancement particularly relevant for EV applications. As HEV continue to shape the future of transportation, this work underscores the importance of intelligent, energy-efficient control systems that support the shift toward sustainable mobility.

Students Hostels.

ABSTRACT

Student hostel buildings in Lagos Metropolis, Nigeria, serve as essential infrastructure for higher education, yet they face significant maintenance challenges that impact functionality, safety, and student comfort. This study evaluates the Mean Time Between Failures (MTBF) for critical building systems in students' hostels across four types of institutions. Using purposive sampling approach, data were collected from 56 maintenance staff and porters. The data were analysed using mean, relative influence index, Mann-Whitney U test and Kruskal-Wallis test as descriptive and inferential statistical tools, respectively. The results show that MTBF is highest for foundation issues (MTBF = 17182.7 hours) and lowest for wiring systems (MTBF = 1304.9 hours), while budget constraints (RII = 0.79), inadequate monitoring systems (RII = 0.77), spare parts availability (RII = 0.76), and poor maintenance documentation (RII = 0.76) are the topmost factors influencing MTBF in hostel buildings. The study concludes that structural and foundational elements are the most reliable systems in students' hostels with rare occurrences of failures; while wiring systems, lighting bulbs and water pipes are vulnerable systems with relatively low reliability. The study recommends improved budget allocation and technology integration as strategic interventions for enhancing system reliability and students' satisfaction in hostel buildings.

I. INTRODUCTION

Student accommodation in higher institutions plays a pivotal role in supporting academic performance, health, and overall well-being. In Lagos Metropolis, Nigeria's economic and educational hub, the demand for quality hostel facilities has surged with increasing student populations. Yet, maintenance management remains inadequate, leading to frequent system failures and reduced functionality [1], [2]. Maintenance performance indicators, such as Mean Time Between Failures (MTBF), are essential for quantifying system reliability and guiding resource allocation in educational infrastructure [3], [4]. MTBF measures the average time a system operates before failure, providing insights into durability and maintenance needs. In the context of student hostels, critical building systems - such as electrical, plumbing, structural, fire safety, waste disposal, sewage, solid waste management, CCTV, internet/Wi-Fi, and lightning protection - must function reliably to ensure safety and comfort [5], [6]. However, studies highlight persistent issues like reactive maintenance, budget constraints, and a lack of standardized metrics in Nigerian hostels, resulting in extended downtimes and health risks [7], [8]. This study addresses a key gap by measuring average MTBF values for critical building systems across Lagos hostels. The objectives of the study are:

- To evaluate the mean time between failure of critical systems in students' hostel ;
- To assess factors influencing mean time between failure of critical systems in students' hostel.

The research hypotheses formulated for the study are:

- Ho1: There is no statistical difference in the perception of maintenance staff and porters on the factors influencing failure of critical building systems in students' hostels.
- Ho2: There is no statistical difference in the factors influencing failure of critical building systems in students' hostels across the various types of institutions.

By focusing on MTBF, the study contributes to evidence-based guidelines for improving maintenance in educational facilities, aligning with global calls for sustainable infrastructure [9], [10].

II. THEORETICAL REFERENCE

II.1 MAINTENANCE PERFORMANCE INDICATORS IN BUILDINGS

Maintenance performance indicators (KPIs) are metrics used to evaluate the effectiveness and efficiency of maintenance operations in buildings [3]. These indicators help facility managers assess system reliability, optimize resource use, and reduce costs. Key KPIs include Mean Time Between Failures (MTBF), Mean Time To Repair (MTTR), and Overall Equipment Effectiveness (OEE) [11]. In educational facilities like student hostels, these metrics are crucial for ensuring the continuous operation of critical systems, which directly impacts student well-being and academic performance [12], [5]. Literature emphasizes the role of KPIs in transitioning from reactive to preventive maintenance. Reactive approaches, common in Nigerian hostels, lead to high costs and downtimes [13], [14]. Preventive strategies, guided by KPIs, can extend system life and improve safety [15]. For instance, MTBF helps predict failure patterns, allowing timely interventions [16].

II.2 MTBF IN HOSTEL BUILDINGS

Mean Time Between Failures (MTBF) is defined as the average operational time between failures, calculated as total uptime divided by the number of failures [17]. It serves as a reliability metric, with higher values indicating more durable systems. In building maintenance, MTBF is applied to systems like electrical wiring, plumbing, and structural elements to assess performance [18], [19]. In student hostels, MTBF is particularly relevant due to high usage and limited budgets. Studies show low MTBF for electrical systems due to overloads and poor wiring, leading to frequent outages [20]. Structural systems, like foundations, typically have higher MTBF as they are less prone to daily wear [21]. In Nigerian contexts, MTBF is often low in public institutions due to inadequate monitoring and funding [9], [22]. Research gaps include limited empirical data on MTBF in Lagos hostels and comparisons across institution types [23]. Table 1 summarizes recent literature on MTBF in building maintenance.

Table 1: Summary of recent literature on MTBF in building maintenance.

Authors	Focus	Methods	Limitations
[17]	Explanation and standards for MTBF in equipment reliability.	Review	Focused on general building equipment and not specific to students' hostels.
[4]	Analysis of downtime and reliability in hostel building maintenance.	Case study	Limited to one institution and did not provide for institutional comparisons.
[18]	Quality control analysis of downtime and MTBF for water supply pipes.	Analysis	The study was restricted to plumbing systems.
[19]	Implementation of MTBF in logistical support for operations.	Case study	The study was not specific to education instituional buildings.
[3]	KPIs including MTBF for maintenance operations.	Review	The study provided broad Key Performance Indicators for maintenance and was not focused on student hostel buildings.

Source: Authors (2026).

From Table 1, existing literature on MTBF applications are limited in scope, with few studies on educational facilities. This study addresses this by measuring MTBF across critical systems in various types of tertiary institutional students' hostels.

II.3 CHALLENGES IN MEASURING MTBF IN EDUCATIONAL FACILITIES

Measuring MTBF in a hostel faces challenges like data inaccuracy, lack of reporting systems, and resource constraints [24]. In Nigeria, reactive maintenance hinders accurate failure tracking [7]. Institutional disparities, with private universities having better data systems, affect MTBF calculations [25].

III. MATERIALS AND METHODS

This study was conducted in Lagos, targeting student hostels in four institution types: Federal University, Federal Polytechnic, Private University, and Federal College of Education. A mixed-methods approach was used, with quantitative data from questionnaires focused on MTBF. The population comprised maintenance staff and porters responsible for the daily operations and maintenance of systems and services in students' hostel buildings. Purposive sampling selected 56 respondents with direct experience. Questionnaire was the instrument used in collecting primary data for the study with a section of the questionnaire eliciting information on the number of failures for critical systems (e.g., wiring repairs, foundation issues) in the last one year. MTBF was calculated as:

MTBF = Total Operational Time / Number of Failures
Assuming 24/7 operation.

Data were analyzed using descriptive statistics (means, frequencies) in SPSS. Comparisons across institutions used Mann-Whitney U test to test the hypothesis of no significant difference in perceptions. Validity was ensured through pilot testing and expert review; reliability via Cronbach's Alpha (>0.7).

IV. RESULTS AND DISCUSSIONS

This section presents the findings of the study, organized into four subsections: respondent demographics, MTBF for critical building systems, factors influencing failures of building systems, statistical comparisons between institutions, and a thematic discussion of the results. The analysis draws from quantitative data collected through structured questionnaires distributed to maintenance staff and porters in maintenance management at students' hostels. Both descriptive and inferential statistical techniques were employed to identify key constraints affecting MTBF of critical systems and to determine whether significant differences exist between institutional contexts.

IV.1 RESPONDENTS' PROFILE

Understanding the background of the respondents provides critical context for interpreting the results. Table 2 summarizes the 56 respondents: 71.4% male, 28.6% female; roles: 53.6% maintenance staff, 46.4% porters; experience: over 10 years (32.1%), 7-10 years (25%). Institutions: Federal University (35.7%), Federal Polytechnic (28.6%), Private University (21.4%), Federal College of Education (14.3%).

Table 2: Demographic profile of respondents.

Profile	N	Percent	Cumulative Percent
Gender			
Male	31	55.4	55.4
Female	25	44.6	100
Role			
Maintenance Staff	27	48.2	48.2
Porter	29	51.8	100
Age Group			
16-24 years	0	0	0
25-34 years	5	8.9	8.9
35-44 years	24	42.9	51.8
45-54 years	23	41.1	92.9
55+ years	4	7.1	100
Experience			
Less than 1 year	0	0	0
1-3 years	13	23.2	23.2
4-6 years	30	53.6	76.8
7-10 years	12	21.4	98.2
Over 10 years	1	1.8	100

Private University	15	26.8	82.2
Federal College of Education	10	17.9	100
Duration of Working			
Less than 6 months	0	0	0
6-12 months	2	3.6	3.6
1-2 years	18	32.1	35.7
3-5 years	18	32.1	67.8
Over 5 years	18	32.1	100

Source: Authors (2026).

The gender distribution shows that 55.4% of the respondents were male, while 44.6% were female. This shows that the distribution gives an adequate representation of male and female respondents. Regarding role type, the table shows that about 51.8% of the respondents were porters, while about 48.2% were maintenance staff. This shows that the distribution was evenly shared amongst the respondents. In terms of age category, 42.9% of maintenance staff/porter respondents fall within the age range of 35-44 years, and 41.1% of the respondents fall within the range of 45-54 years. Only a few numbers of respondents, representing 8.9% fall within the range 25-34 years. 53.6% of the respondents have a working experience of 4-6 years in hostel maintenance/management, and about 23.2% and 21.4% of the respondents have a working experience of 1-3 years and 7-10 years, respectively, in hostel maintenance. Regarding institutional affiliation, 37.5% of the respondents were from Federal University, 26.8% of the respondents from Private University, and 17.9% of the respondents from both Federal Polytechnic and Federal College of Education. In terms of how long the respondents have spent working in the hostel, 32.1% of the respondents have spent between 1 and 2 years, 3-5 years, and over 5 years in the hostel, respectively, which shows an even distribution of experience by the respondents. Only a few numbers of respondents representing 3.6% have worked in the hostel for less than 6 - 12 months.

IV.2 MTBF VALUES FOR CRITICAL BUILDING SYSTEMS IN STUDENTS' HOSTEL BUILDINGS

Following the demographic overview, this subsection presents the MTBF values for critical building systems in students' hostel buildings. Drawing responses from 4 institutions, the data highlight the MTBF values of critical systems in students' hostel. Table 3 presents a ranked list of MTBF values of various critical systems in students' hostels.

Table 3: MTBF values for critical building systems in students' hostel buildings.

Critical systems in hostels	FU (N=21)		FP (N=10)		PU (N=15)		FCE (N=10)		Total (N=56)	
	MTBF	Rank	MTBF	Rank	MTBF	Rank	MTBF	Rank	MTBF	Rank
Wiring systems	1303.7	1	1619.2	3	1247.0	2	1080.1	1	1304.9	1

NOTE: FU is Federal University, FP is Federal Polytechnic, PU is Private University, FCE is Federal College of Education.
Source: Authors (2026).

The result shows that the Mean Time Between Failure (MTBF) values for critical building systems in students' hostels across the four higher institutions in Lagos Metropolis varies in reliability. Wiring systems ranks 1st with the lowest overall MTBF of 1304.9 hours and, indicating that it is the least reliable in the systems category with the most frequent failures. The frequent failure of wiring systems could potentially be due to electrical overloads from multiple devices, substandard wiring materials, or unstable power supply, which could lead to safety hazards like fire outbreak or supply outages affecting students' comfort and productivity. Lighting systems (bulbs) ranks 2nd with a MTBF of 1334.7 hours, indicating frequent bulb failures. This could be as a result of voltage fluctuations, poor quality lamps, or excessive demand in communal areas, underscoring the need for energy-efficient upgrades to ensure consistent lighting for study and navigation in the hostels. Water pipes rank 3rd with a MTBF of 1366.9 hours, highlighting recurrent plumbing leaks as a major issue and plumbing pipes as a key vulnerable system for failure, sockets/switches rank 4th with a MTBF of 1567.3 hours, suggesting moderate reliability for electrical sockets and switches, with failures often linked to wear and tear from frequent use, misuse and poor handling by the students.

The result also shows that systems with lower failure rates include; water heaters, which rank 15th with a MTBF of 7044.5 hours, demonstrating high reliability, possibly due to infrequent use or the unavailability of the system in most hostel buildings. Foundation issues rank 16th with the highest overall MTBF of 17182.7 hours, indicating that the foundations of hostel buildings rarely exhibit any form of failure due to their engineered stability as any issue could have severe implications in terms of building stability and safety. Comparatively, the result shows that in the Federal University, wiring systems has the lowest MTBF of 1303.7 hours, revealing that electrical repairs is a primary concern in the students' hostels. Other systems in the Federal University students' hostels having low reliability include; lighting systems (MTBF = 1353.0 hours), water pipe leaks (MTBF = 1457.4 hours), Sockets and switches (MTBF = 1659.6 hours), Shower/bathing facility (MTBF = 1732.1 hours), In the Federal Polytechnic however, systems with low reliability include; water pipe leaks (MTBF = 1461.0 hours), lighting systems (MTBF = 1598.7 hours), wiring systems (MTBF = 1619.2 hours), and socketets and switches (MTBF = 1649.8 hours).

Furthermore, the result shows that systems with low reliability in Private University are; lighting system (MTBF = 1228.9 hours), wiring systems (MTBF = 1247.0 hours), water pipes (MTBF = 1247.0) and drainage (MTBF = 1485.7 hours) while the systems with low reliability in Federal College of Education are; wiring systems (MTBF = 1080.1 hours), water pipes (MTBF = 1126.3 hours), lighting systems (MTBF = 1228.5 hours) and sockets and switches (MTBF = 1323.2 hours). In general, public institutions such as Federal University and Federal Polytechnic exhibit higher MTBF in structural components, suggesting better long-term durability, while Private Universities and Federal Colleges of Education show more variability in systems reliability, with private institution underperforming in major structures and colleges in minor fixtures. The results highlight potential disparities in maintenance investment and usage patterns across institutional types. The findings show that the variability from low MTBF in electrical and plumbing related systems to high MTBF in structural systems align with usage intensity, suggesting a need for improved resource allocation for maintenance management activities aimed at enhancing reliability, reduced operational costs, and improve students' comfort and satisfaction in the hostels.

IV.3 FACTORS INFLUENCING FAILURE OF BUILDING SYSTEMS AND COMPONENTS IN STUDENTS' HOSTELS

The respondents were also asked to rate the extent to which they agree that the under-listed factors influence failures of building systems and components in students' hostels. Table 4 presents a ranked list of 15 identified factors, analyzed using the Relative Influence Index (RII) to assess the severity of each factor from the perspective of maintenance staff and porters across the four institutions.

Table 4: Factors influencing failures of critical building systems in students' hostels.

Factors influencing critical building systems failure	Maintenance Staff (N=27)			Porter (N=29)			Total (N=56)		
	RII	Rank	Remark	RII	Rank	Remark	RII	Rank	Remark
Budget constraints	0.76	4	EI	0.83	1	EI	0.79	1	EI
Inadequate monitoring systems	0.76	4	EI	0.78	2	EI	0.77	2	EI
Spare parts availability	0.75	7	I	0.77	3	EI	0.76	3	EI
Poor maintenance documentation	0.75	7	I	0.77	3	EI	0.76	3	EI
Poor installation quality	0.78	1	EI	0.73	6	I	0.75	5	I
Inadequate preventive maintenance	0.77	3	EI	0.72	8	I	0.75	5	I
Excessive user load and misuse	0.76	4	EI	0.7	10	I	0.73	7	I
Poor communication channels	0.78	1	EI	0.68	13	I	0.73	7	I
Lack of user education	0.73	9	I	0.72	8	I	0.73	7	I
Design inadequacy	0.70	11	I	0.77	3	EI	0.73	7	I
Building age and degradation	0.70	11	I	0.73	6	I	0.72	11	I
Climatic and environmental factor	0.73	9	I	0.70	10	I	0.71	12	I
Delayed response to repairs	0.67	14	I	0.68	13	I	0.68	13	I
Lack of skilled maintenance personnel	0.67	14	I	0.69	12	I	0.68	13	I
Overcrowding and capacity overload	0.68	13	I	0.68	13	I	0.68	13	I

NOTE: EI = Extremely Influential, I = Influential, ME = Moderately Influential.
Source: Authors (2026).

The findings show that overall, budget constraints rank highest (RII=0.79, Extremely Influential), followed by inadequate monitoring systems (RII=0.77, Extremely Influential), spare parts availability and poor maintenance documentation (both RII=0.76, Extremely Influential), implying funding, oversight, and logistics as primary drivers of system failures in the students' hostels. Poor installation quality and inadequate preventive maintenance tie for fifth overall (both RII=0.75, Influential), highlighting initial workmanship and routine upkeep as key influences. Excessive user load/misuse, poor communication channels, lack of user education, and design inadequacy tie for seventh overall (all RII=0.73, Influential), pointing to user behavior and design flaws as moderate contributors. The findings also show that building age/degradation ranks eleventh overall (RII=0.72, Influential), climatic/environmental factors twelfth (RII=0.71, Influential), and delayed repairs, lack of skilled personnel, and overcrowding tie for thirteenth (all RII=0.68, Influential), suggesting these as lower but still influential factors.

Among maintenance staff (N=27), poor installation quality and poor communication tie for first (both RII=0.78, Extremely Influential), inadequate preventive maintenance third (RII=0.77, Extremely Influential), and budget constraints/excessive user load/inadequate monitoring tie for fourth (all RII=0.76, Extremely Influential), emphasizing technical and user issues. Spare parts availability/inadequate documentation tie for seventh among staff (both RII=0.75, Influential), climatic factors/lack of user education ninth (both RII=0.73, Influential), building age/design inadequacy eleventh (both RII 0.70, I), overcrowding thirteenth (RII=0.68, Influential), and delayed repairs/lack of skilled personnel fourteenth (both RII=0.67, Influential). Then, among porters (N=29), budget constraints rank first (RII=0.83, Extremely Influential), inadequate monitoring second (RII=0.78, Extremely Influential), and spare parts availability/inadequate documentation/design inadequacy tie for third (all RII=0.77, Extremely Influential), stressing financial and logistical barriers.

Building age/poor installation tie for sixth among porters (both RII=0.73, Influential), excessive user load tenth (RII=0.70, Influential), climatic factors tenth (RII=0.70, Influential), lack of user education/inadequate preventive maintenance eighth (both RII=0.72, Influential), and delayed repairs/lack of skilled personnel/overcrowding/poor communication tie for thirteenth (all RII=0.68, Influential). The Table shows that comparing groups, porters rank budget constraints higher (1st, RII 0.83 EI) than staff (4th, RII 0.76 EI), while staff prioritize poor installation (1st, RII=0.78 Extremely Influential) over porters (6th, RII=0.73 Influential), revealing role-specific emphases on funding vs. technical quality. Overall convergence on top factors like budget and monitoring suggests targeted interventions, with divergences (e.g., porters higher on design inadequacy, staff on user misuse) informing role-tailored strategies for hostel maintenance.

IV.4 TEST OF HYPOTHESIS

Two hypotheses were formulated for the study as follows:

Ho1: There is no statistical difference in the perception of maintenance staff and porters on the factors influencing failure of critical building systems in students' hostels.

Ho 2: There is no statistical difference in the factors influencing failure of critical building systems in students' hostels across the various types of institutions.

Mann-Whitney U test and Kruskal-Wallis test were used to analyze the hypotheses respectively. The Mann-Whitney U test evaluated the null hypothesis that there is no statistical difference in the perception of maintenance staff and porters on the factors influencing failure of building systems and components in students' hostels while the Kruskal-Wallis test evaluated the null hypothesis that there is no statistical difference in the factors influencing failure of building systems and components in students' hostels across the

various types of institutions. Table 5 presents the result for the first hypothesis indicating the mean rank scores, U-values, and *p*-values for both categories of respondents.

Table 5: Mann-Whitney U Test of difference in the perception of maintenance staff and porters on the factors influencing failure of critical building systems in students' hostels.

Factors influencing systems failure	Category of Respondents		U	Z	*p*	Remark

Significant level set at $p \leq 0.05$.
Source: Authors (2026).

The result in Table 5 shows that there is no significant difference in the perception of maintenance staff and porters on factors influencing failure of systems in students' hostels except for poor communication (p=0.00), hence, the null hypothesis was accepted for the factors the factors influencing failure of systems in students' hostels except for poor communication channels, for which the null hypothesis H_0 was rejected. Table 6 presents the result for the second hypothesis indicating the mean rank scores, degree of freedom (df), and p-values.

The result in Table 6 shows that there is no statistical difference in the factors influencing failure of building systems in students' hostels across the various types of institutions except for budget constraints (p=0.002) hence, the null hypothesis $H_0 2$ for all the factors was accepted, except for budget constraints for which the null hypothesis $H_0 2$ was rejected. The result suggests that the Federal University and Federal Polytechnic experiences significantly higher budget constraints with Mean Ranks of 34.64 and 37.30 respectively as compared to the Private University and the Federal College of Education with Mean Ranks of 20.23 and 19.20 respectively.

IV.5 DISCUSSION OF FINDINGS

The results from this study provide valuable insights into the reliability of critical building systems in student hostels within Lagos Metropolis, highlighting variations in Mean Time Between Failures (MTBF) across different systems and institution categories.

From the analysis of data collected from maintenance staff and porters working in the students' hostels of the surveyed institutions, the study quantifies system performance, identifies key influencing factors, and tests for differences in responses through statistical methods.

The findings of the study not only address the research objective of measuring average MTBF but also reveal institutional disparities and role-specific perceptions, contributing to a deeper understanding of maintenance challenges in educational infrastructure. The discussion is structured to explore the top five systems with critical MTBF values, linking empirical data to existing literature, and examining implications for practice. Among the critical building systems evaluated, foundation of the hostel buildings exhibits the highest MTBF values across the institutions, indicating high reliability and infrequent failures. This aligns with literature emphasizing the durability of foundations in most buildings, which are designed to withstand long-term loads and are less susceptible to daily wear and tear compared to mechanical systems [21]. In the context of students' hostel buildings in Lagos, where environmental factors like soil instability and high humidity could accelerate degradation, the high MTBF suggests appropriate choice of foundation design and generally, high quality of construction work when the hostel buildings were being constructed. Roofs, staircase and walls equally demonstrated high reliability with their respective high MTBF values, reflecting their robust performance in supporting the overall building framework.

This result concurs with [18] that structural components benefit from inherent resilience when properly maintained, reducing the frequency of failures [21]. It is also important to note that in student hostels, where occupancy is high and usage intense, this MTBF particularly in staircase components may be attributed to periodic maintenance inspections that prevent minor issues from escalating. The findings show that wiring systems, lighting systems and water pipes are the most frequently failing systems in students' hostels with relatively low MTBF values. Wiring systems failure in public buildings often arises from cable overheating and arcing fault as a result of overloaded circuits, loose connections, or improper cable use. This aligns with the position of [7,21] that public buildings are often challenged by maintenance demands relating to electrical systems. Furthermore, the findings revealed frequent light bulbs burn out in the students' hostels which could be due to poor quality of materials and parts or systemic electrical issues such as high voltage, poor or loose wiring, and voltage fluctuations. Other factors that could influence rapid failure of light bulbs include overheating from poor ventilation in the enclosed fixtures, incompatible switches and ratings, and physical damage from vibration or improper installation.

These findings highlight the need for standardized protocols in the procurement of quality materials and parts that could enhance systems and components longevity, particularly in resource-limited public settings. Water pipes failure, especially frequent plumbing pipes leakages in student hostels are often as a result of high-intensity use, poor maintenance, and aging infrastructure. This finding supports the position of [20, 21, 22] that plumbing systems in public buildings often suffer frequent defects including corrosion and blockages, but regular maintenance can improve their availability and extend operational periods [20]. Conclusively, the high MTBF values for structural elements such as foundations, walls and staircases illustrate areas of relative strength in Lagos hostel infrastructure while systems such as wiring systems, lighting bulbs and water pipes are exposed as being highly vulnerable to failure underscoring the need for improved attention, institutional funding and proactive maintenance approaches at improving their reliability. These findings portray the study's contribution to bridging research gaps in MTBF applications for educational facilities, advocating for targeted interventions to elevate system reliability and ultimately enhance student comfort and safety.

V. CONCLUSIONS

This study has illuminated the reliability of critical building systems in student hostels across Lagos Metropolis through MTBF analysis. The study concludes that structural and foundational elements are the most reliable with rare occurrence of failures in students' hostels while wiring systems, lighting bulbs and water pipes are frequently failing systems with relatively low reliability. The study also concludes that the reliability of systems in students' hostels are largely influenced by budget constraints, inadequate monitoring systems, spare parts unavailability and poor maintenance documentation. By quantifying failures and identifying influencing factors, the study addresses gaps in maintenance performance metrics for Nigerian educational infrastructure. To this end, the study recommends increasing budgetary allocations for operations and maintenance of infrastructure in tertiary institutions to enable preventive maintenance and technology driven maintenance implementation, such as computerized maintenance management systems (CMMS). It also recommends the implementation of regular staff training programs to improve skills in failure prediction and repair; development of standardized reporting protocols to enhance data accuracy and monitoring; promoting user education campaigns to reduce misuse and overload; and conducting longitudinal studies integrating MTTR for holistic key performance indicator frameworks. These measures can foster sustainable hostel management, boosting students' well-being and academic success.

ABSTRACT

Micro-manufacturing has drawn significant global attention regarding manufacturing technologies and procedures. Micro-forming is a highly popular method for micro-manufacturing. Microforming is a process of shaping parts and objects through mechanical deformation, which relies on the properties of materials. A significant amount of attention has been directed towards micro-forming, specifically the deep drawing process, due to its capability to generate a wide range of products, especially in its traditional macro-process. This technique is employed to fabricate the most commonplace objects. The discussion then transitions to the current areas of research that are generating the greatest discussion. Due attentiveness has shown a gap in micro-forming technological improvement that must be filled before it can satisfy the unique demands of industrial applications. This is of utmost importance when it comes to making top-notch end products. Precision-forming machines can manufacture such goods using cutting-edge tooling technology, optimal operating settings, and improved material handling techniques.

I. INTRODUCTION

In addition to being an essential part of modern manufacturing, metal shaping is a sizable business in and of itself. Hundreds of millions of tons of metal go through metal-forming processes every year, all around the globe. In most industrialized countries, the metal-forming sector accounts for around 15% to 20% of GDP. It also serves a social purpose by giving many people a chance to earn an income. The metal forming industry is all about mass manufacturing of both partially finished and fully assembled products. Significant advantages for large-scale R&D may be found in this area, since even little savings per ton can add up to big bucks. To enhance the accuracy of the Forming Limit Diagram, surface strain data were further included.

A circular grid made of foil is essential for measuring surface strain [1]. The forming limit diagram (FLD) is a valuable tool for assessing the formability of a metal cost-effectively [2]. Conducting tests utilizing a hemispherical punch-stretch or a Marciniak cup might result in forming limit diagrams (FLDs). Significant amounts of time and effort were dedicated to developing these experimental approaches. Increasing the efficiency of FLDs is accomplished using analytical approaches. Regrettably, analytical methodologies do not possess the capability to foresee failure precisely. A forming limit diagram, also known as an FLD, is a graphical depiction that depicts the main strains (e1) at the point when localized necking occurs, for each conceivable value of the minor strain (e2) [3].

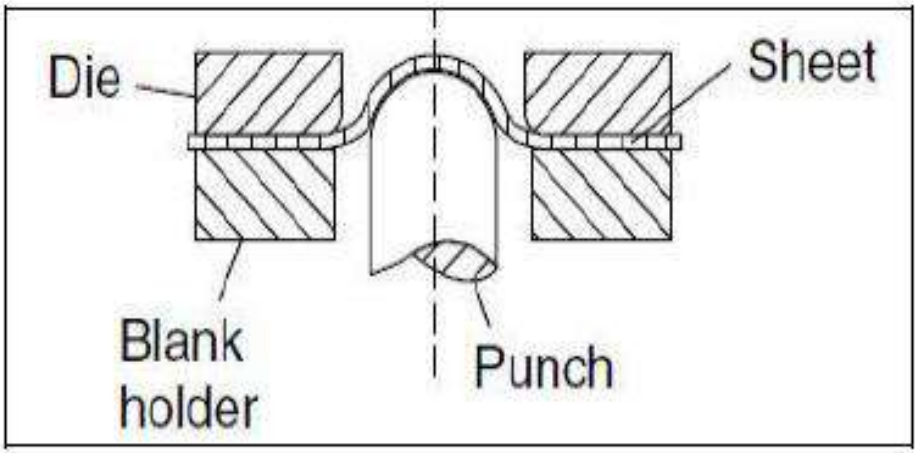

Figure 1: Sheet metal forming.
Source: [4].

Steel facilities, such as factories and plants, are responsible for manufacturing sheet metal, which is used in manufacturing vehicles and their components. Various companies use sheet metal as the primary material for manufacturing various home and commercial goods. Steel makers generate billets that re-rolling mills then shape into various components, including angles, channels, and bars. Incremental forming technique for manufacturing micro-parts that eliminates the need for dies or backing plates [5],[6]. According to [7], this technology may simplify tool manufacture, but it is unsuitable for large-scale production of small components. The micro-sheet metal forming industry utilizes laser forming, a die-less technique, as shown in Figure 1. According to [8] suggest that laser-assisted bending might be used to manage spring-back. The by [9] comprehensively described the process parameters and material requirements involved in laser bending.

The potential use of laser technology in micro-deep drawing methods is now under consideration. In [10] found spark formation more effective than laser forming. Spark formation has several benefits, including its versatility in working with diverse materials, cost-effectiveness, compactness in fabrication equipment, and low energy use.The challenges of microforming, particularly with ultrathin sheets of less than 100 microns, are well recognized in the field, where material deformation can lead to defects such as necking, cracks and wrinkles. As the demand for miniaturization increases in various engineering applications, the need for precise microforming processes also increases. To address this need, the article presents a new tool specifically designed to investigate the formability of thin titanium grade II (TiG-II) sheets, focusing on microstructural behavior. It provides a basis for future research, particularly in applying grade II titanium in micro-sized biomedical components [11].

The study focuses on developing forming limit curves (FLC) for TaRO5200 with a sheet thickness of 80 microns, a fundamental tool for evaluating the formability of microscale materials. This variation suggests that numerical simulations provide a conservative design approach, 15% safer than experimental results. This research's novelty lies in applying the FLC methodology to TaRO5200 and in the detailed microstructural study carried out on the specimens before and after the forming tests. This microstructural analysis provides valuable insights into the material behavior and underlying mechanisms during the formation process, contributing to a deeper understanding of the physics governing the deformation of TaRO5200. According to [12] findings provide a basis for further exploration of biomaterial microforming processes, particularly in biomedical device manufacturing. The research used Simufact Forming V15 software to generate the FLC numerically, and the results were subsequently compared with those obtained from the Nakajima test.

The comparison demonstrated good agreement between the experimental and numerical approaches, and the FLCs produced by numerical simulation were 5% to 12% lower than the experimental results, indicating a safer design margin in the simulations. Additionally, microstructural studies were performed on SS316L sheets before and after forming tests, providing a deeper understanding of the material's behavior during deformation. This comprehensive study provides valuable information on the microforming of SS316L, particularly its application as a biomaterial, and highlights the importance of accurate FLC determination to ensure the reliability of microformed components [13].The study of [12] focuses on the formability evaluation of Zr702 thin sheets, emphasising the development of forming limit curves, a critical tool in evaluating material formability.

The research uses the Nakajima test, performed according to ASTM 2218-14 standards, to experimentally determine FLCs for Zr702 with a sheet thickness of 100 microns. The results of these experimental FLCs were then compared with those obtained through numerical simulations, revealing good agreement between the two methods. In addition to the FLC analysis, a detailed microstructural study of the test specimens was performed before and after the forming process, which provided valuable information on the behavior of the material during deformation. This research contributes significantly to the understanding of the formability and microstructural characteristics of Zr702 in microforming applications, offering a basis for its broader adoption in biomedical fields [14]. Regarding mass manufacturing, none of the technologies mentioned can hold their own. Rather, they should only be used for prototypes or low-volume manufacturing.

Furthermore, certain requirements linked to material characteristics limit the variety of materials used. Remember that the methods mentioned here are complementary, not competing, regarding micro-metal formation. Mechanical micro-sheet metal forming remains the most efficient option for producing micro-components. After 10 years of extensive study and development, the area of mechanical micro-sheet metal forming has yielded a few results. To detect the gaps in the growth of micro-sheet metal, it is necessary to have a mapping that can provide a full picture. This study thoroughly examines the researchers' aims and the necessary conditions for advancing mechanical micro-sheet metal forming technology. To ensure a thorough analysis, the researchers have classified their results based on the characteristics of micro-sheet metal-forming systems, such as the material, process, tool, and machine parameters.

II. THEORETICAL REFERENCE

II.1 SUBTITLE

II.1.1 Materials and Methods

As a result of the shrinking of goods, which allows micro-geometry to carry out product tasks, the present tendency in numerous engineering disciplines is to reduce the size of products. Waste, expenditure, weight, and volume are all areas that will be reduced with this strategy [15]. The microfabrication method may take advantage of metals' outstanding mechanical and functional properties in manufacturing tiny components. This cutting-edge technology is ideal for use in manufacturing since it can be scaled down to the micron size range thanks to this process. According to [16], the market for microelectromechanical systems (MEMS) in micro-manufacturing is anticipated to rise at a compound annual growth rate (CAGR) of 7.5% for medical applications, 43.6% for telecom applications, and 11.0% for industrial applications between the years 2015 and 2024. There has been a significant increase in the demand for small-sized goods because of the growing trend toward downsizing in several different sectors. The medical, precision, communication, micro-electromechanical, and microfluidic equipment industries are especially affected by this phenomenon.

Over the last two decades, there has been significant development in the field of metal micro-forming technology. A variety of research and development activities are included in the study [13]. These activities include surface engineering for die and tooling, micro-hydroforming, embossing, micro-bulk forming, micro-forming with laser help, micro-sintering, and micro-sheet metal forming. The size affected the flow, necessitating an investigation of the deformation behaviours induced by the flow. In this work, we conducted experimental trials to examine the influence of many important factors, including geometry and grain sizes, on the extent of flow-induced defects that arise during the micro-forming process of pure copper. These investigations aimed to ascertain the impact of size on flow-induced flaws [17], [18]. Flow faults in the micro-extrusion process occur due to uneven material flow. This condition is analogous to the one that arises in the macro-forming process.

II.2 SIZE EFFECTS IN MICRO FORMING PROCESSES

An investigation was conducted on the influence of size effects on multi-phase materials, which are affected by the specimen's geometry and grain size. The research demonstrated a reduction in ductility as the size of the specimens was scaled to the millimetre scale range. Moreover, the research highlighted the importance and relevance of having a detailed and intricate surface. It is crucial to consider the impact of size-related factors, such as specimen shape and grain size, especially in materials with several phases, to enhance material characteristics and performance [19],[20]. During the downsizing and micro-component manufacturing process, the usual principles that apply to larger objects are sometimes not applicable.

The side effects, which are caused by the decreased number of grains in the deformation zone, significantly impact formability and might result in fractures during micro forming operations. This emphasizes the need of meticulously considering the impacts of size in micro-forming processes [21]. The work conducted by [22] reveals that the forming limit of copper foils is positively correlated with an increased number of grains. They tested copper foils with 25 and 500mm diameters by subjecting them to bulging, tensile, and bending loads. A spring-back effect, brought on by the smaller particle size and the more significant proportion of surface grains, diminished the hardening capacity of the material, because of that decrease in size, the flow stress changed [23-26].

II.3 DIMENSION EFFECT ON FLOW STRESS

In microforming, the flow stress is significantly influenced by side effects, such as grain size and specimen size [27]. The observation made by [28] stated that, Micro-forming processes need careful analysis of factors, such as the effects of particle size on bulk materials. The behaviour of materials changes as the scale changes, highlighting the need to conduct investigations and analysis. The uniaxial tensile testing trials revealed an inverse relationship between flow stress and strip thickness, indicating that the reduction in flow stress is due to size or scale effects. A surface model was used to clarify these data. The research of [29] dives into the influence of size effects on flow stress inside metal micro-forming techniques, conducting micro tensile tests on pure copper foil to assess the combined impact of workpiece geometry and grain size.

A unique composite material model is built to quantify the strengthening reaction of individual grains included inside a polycrystalline material. Studies have also shown that the flow stress variations are closely related to the ratio of thickness to grain size (T/D) and the interaction between workpiece geometry and grain size [30-32]. A constitutive model was established to support multi-stage microforming. Additionally, incorporating a hybrid material model considering grain heterogeneity, sample thickness, and dislocation structures has proven effective in describing the hardening behavior of grains in microforming processes. These findings emphasize the critical role of side effects and material characteristics in determining flow stress during microforming.

II.4 EFFECTS OF TEMPERATURE ON MICRO FORMING

Temperature control significantly impacts material behavior in microforming processes, influencing material softening and ductility. Higher temperatures enhance ductility, reduce flow stress, and prevent failure. Controlled heating promotes homogeneity, minimizes surface defects, and influences grain size. However, temperature management must balance these benefits with thermal expansion effects for dimensional accuracy. Also, increasing temperature in microforming enhances formability by activating more slip systems, reducing anisotropic behavior, and improving forming homogeneity and reproducibility due to size effects compensation [33].Temperature plays a crucial role in micro-forming processes, influencing material behaviour, flow stress, surface roughness, and fracture mechanisms [34]. High temperatures increase the percentage of elongation in materials like stainless steel-304 foil, affecting tensile strength and fracture patterns. The goal of this study is to look at the mechanical features of a 200 μm thick stainless steel-304 foil by testing it at room temperature (RTT) and at high temperature (HTT).

It was found that the strain rate and temperature affect the flow stress behaviour, surface roughness, microstructural development, and fracture process. High-temperature deformation leads to recrystallization and grain growth, changing surface roughness and fracture mechanism. This analysis can guide the design of micro-sheet metal forming processes for producing micro-parts [35]. In hot embossing of PMMA for microchannel fabrication, temperature variations impact channel dimensions significantly, with optimal conditions identified at 150 °C and 295 kPa [36]. Additionally, in gas-assisted extrusion forming of plastic micro-tubes, higher gas temperatures reduce melt viscosity and enhance flow velocity [37]. An elevation in temperature during cold stamping techniques leads to modifications in the tool-sheet metal tribosystem. This modification can create issues with forming ability, as it affects the level of friction, lubricating properties, and the material's behaviour [38].

Understanding these temperature effects is crucial for optimizing micro-forming processes and ensuring the quality of micro parts. SODICK and WEDM software was used for precision forging micro gear moulds at different temperatures. The surface roughness of the moulds was less than 280 nanometers, and the moulds had a dimensional tolerance that was less than or equal to 2.5 µm. To achieve a surface roughness of 300 nm and a reduction in dimensional tolerance from -38.8 µm to +0.9 µm, the high-temperature forging technology effectively exhibited its outstanding precision [39]. Experimental findings reveal that temperature and grain size considerably impact the deformability of pure copper in micro forming [40]. In another study, Micro-deep drawing (MDD) is used in various fields, including micro-electromechanical systems, vehicle engineering, and chemical engineering. MDD tests on two-layer stainless steel-copper composite foils showed that complete circular cups cannot be formed due to poor formability. An optimal annealing temperature of 800 C was found for high surface quality, indicating the potential of MDD in these applications [41].

By increasing the temperature at which the deformation takes place, a higher number of slip systems within the polycrystalline metal are activated. This results in a shaping process that is more uniform and has improved consistency. In this study, a YAG laser beam is used to apply heat to the workpiece. Additionally, a finite element model (FEM) is developed to simulate the melting and cooling rate (MCWR) of pure copper. A numerical study of surface asperity, which is a sign of material heterogeneity at a small scale, is undertaken, and the results show a high agreement with the findings of the experiments [36]. Forming titanium at elevated temperatures improves its micro-forming behaviour, enhancing formability and forming limits compared to room temperature, as investigated in the study [42]. The work of by [43] presents a micro forming device with controlled heating up to 450°C for medical production, focusing on small, high-precision, low-weight, and high- strength components. The device analyzes magnesium alloy AZ31B flow stress and formability, forming dental components at varying temperatures.

III. MICRO DEEP DRAWING (MDD) PROCESS

Micro deep drawing, it is possible to fabricate hollow objects with slender walls that have a resemblance to miniature cups or boxes. The decrease in the coefficient of friction between the material and the tools due to using lubricant might impact the quality of goods generated in micro deep drawing at a small scale. The research conducted experiments on stainless steel 304 foils with different thicknesses to investigate the influence of blank holder forces and the T/D ratio on the limit draw ratio. The experiments used micro deep drawing and tensile testing. The results indicate that the LDR achieves stability when the T/D (Thickness-to-Diameter) ratio exceeds 10. This suggests enhanced formability and consistent behaviour in a deep drawing to produce micro sheets [44], as seen in Figure 3 and 4. Researchers Zhengyi Jiang and others have shown a micro deep drawing (MDD) simulation, a promising technique for mass-producing complex three-dimensional, tiny metal objects. A Voronoi blank model is constructed for microscale modeling.

This model enables the inclusion of material size effects and authentic microstructures. Simulation results show surface roughness significantly influences springback, drawability, and product quality, making the model accurate and beneficial for MDD process development [45]. Cooper foils are utilized in the microelectrical sector for deep drawing cup-like structures. One research explored micro deep sketching using T2 copper foils and three scale factors. Results revealed the effective formation of pieces with internal dimensions of 0.5, 1.0, and 2.0 mm. The maximum deep drawing force dropped with lower scale factors, and the maximum limit drawing ratio was 2.2 for the experiment with a 0.5 scale factor [46]. The process has also been used to create SUS304 circular cups, with simulation results showing good agreement with experimental data [47]. A novel technique using a floating ring as an assistant die has been proposed for micro-flexible deep drawing, with promising results in producing SS304 micro cups [48].

The study conducted by [49] examines the impact of forming velocity on the quality of micro cup-like products, specifically focusing on stainless steels with different thicknesses. The results indicate that the speed at which the forming process is carried out affects the profile's precision and the surface's quality. The resultant micro cup is rounder and more symmetrical when thicker blanks are used. Wrinkling becomes apparent when using thinner blanks, whereas the surface becomes smoother when the drawing velocity or blank thickness increases. The study by [50] focuses on the micro-deep drawing process of stainless steel 304 foils. The researchers used soft dies made of polyurethane rubber with different hardness levels. The process employs a mobile blank holder backed by a compressive spring.

There is an initial space between the blank holder and the adjustment ring, which controls the forming process against the force exerted by the spring. The calculations and testing examined key aspects such as the kind of rubber, the size of the die, and the scaling factor. These investigations confirmed that the approach can cost-effectively produce high-quality micro-cups. This study examines the micro-deep drawing technique of stainless steel 304 foils using soft dies made of polyurethane rubber with varying degrees of hardness. The process employs a movable blank holder backed by a compressive spring. There is an initial space between the blank holder and the adjustment ring, which controls the forming process against the force exerted by the spring. The models and testing investigated key aspects such as rubber type, die size, and scaling factor, and confirmed that the approach can cost-effectively produce high-quality micro-cups [51].

III.1 ANISOTROPY AND FORMABILITY

Before the 1980s, the yield standards for materials did not include the important anisotropy ratios, which made them less accurate. That's how things were until the 1980s. In 1948, Hills was the only thing that mattered in a few very stressful cases, and it was Hills that gave anisotropic materials the output they needed. Hill added orthotropic materials to the Von Mises criterion. Orthotropic materials are identified by their orthotropic symmetry [52]. According to [53] in his work had discussed the strain-hardening index (equation 1) wasn't the only thing that affected the height of the crack in the Olsen test. Because of this, the strain-rate sensitivity index must also be considered. Researchers found that the material would rise more when the strain-rate sensitivity index (m) was higher for a certain strain-hardening index (n). The sheet metal should be easier to shape now that this is clear [54]. Because of this, steel has a higher strain-rate sensitivity index than aluminum, which means that for a given number of n, it can be shaped better than aluminum.

$$m = \frac{\partial ln l\sigma}{\partial \dot{\varepsilon}} \tag{1}$$

Materials that are light, dense, strong, and easy to shape are now being sought after by the electronics and car industries around the world. Because of this, Tailor Welded Blanks have become more common because they can join different materials in thickness, properties, and surface conditions by shaping or pressing them together. When you use this method, the links between the parts are strong and will last long [55].

According to [56] did four tests on tailor-welded flats to see how easily they could be shaped using two different base materials. Aluminum-killed drawing quality (ASDQ) steel (1.8 mm) and high-strength low alloy steel (2.1 mm) were mixed to make the base. They came up with two reasons why it didn't work. If the main line of the extension was straight across from the weld, a kind 1 failure happened. When this kind of failure happened, the split depended on how well the material could bend and bend again. Furthermore, different sheet metal processes also form materials at very high temperatures, so it is crucial to determine the formability in these situations. Therefore, formability study of such novel approaches is also required to guarantee cost savings, minimal scrap generation, and the ability to apply the forming processes to various materials.

IV. CONCLUSIONS

This review aims to help the reader understand the significance of sheet metal forming techniques and how formability analysis plays a key role in them. The document briefly summarises the different tests used to obtain formability data that can be quantified and determine the forming limits beyond which failure occurs. Over the past 40 years, formability has advanced significantly, and research is still being done to find new materials, thorough testing procedures and tools, and mathematical analyses of the yielding criterion that consider a wide range of additional parameters and their effects on formability. Thus, this research investigates the fundamental aspects of formability and its significance in today's industry. Designing micro-components with high-volume production in mind is essential for micro-manufacturing. Building the failure limit diagram is now the focus of sheet metal research. This is accomplished using numerical analysis, experimental methods, finite element techniques, and sheet metal material management. This study highlights the need for more research into the interaction between materials and handling instruments and micro-forming processes (namely, deep drawing and bending operations).

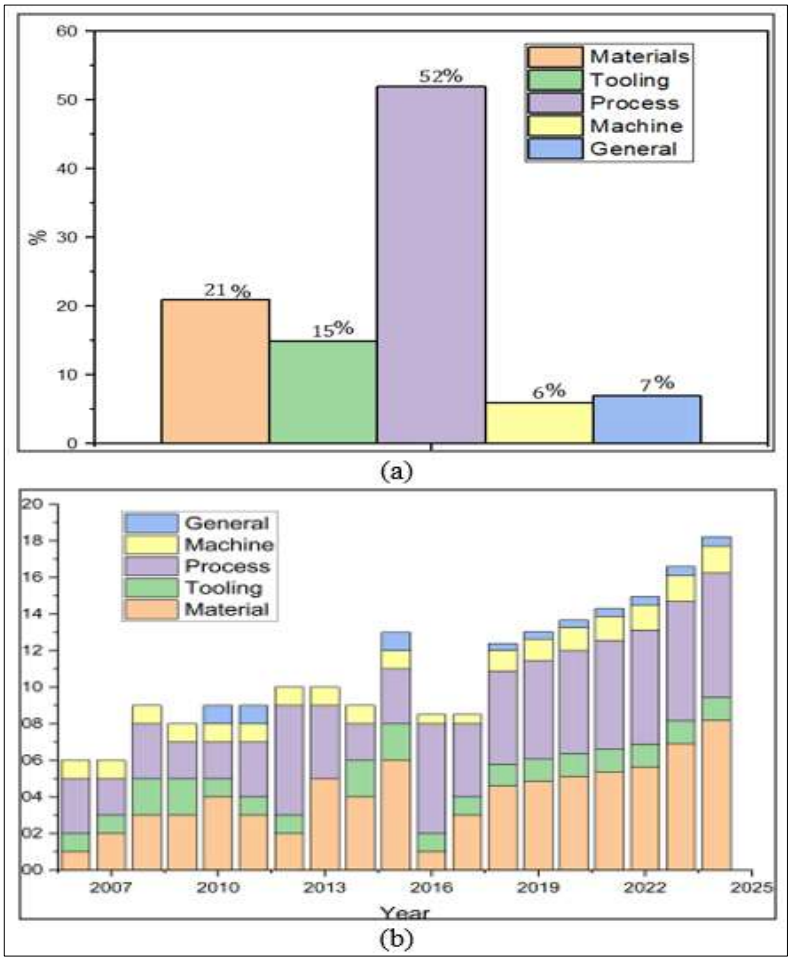

Figure 5: Research focuses on micro-sheet-metal-forming development, (a) in 2001–2017 (b) detailed for 2001–2017.
Source: Authors, (2026).

Figure 5 displays the results of the study's clustering, which shows that the focus was on improving micro-sheet metal-forming technology. Compared to other fields of study, process inquiry is intrinsically more interesting. According to the study's summary, 52% of the research carried out between 2001 and 2017 focused on improving process factors. Researchers are examining the behaviour of material deformation to improve micro-product quality. Nevertheless, many moving parts in manufacturing must be in perfect harmony for the final product to be high-quality. These include superior materials, cutting-edge tools, ideal working conditions, and effective material management. The use of a precision shaping machine might solve these problems. Consequently, more efforts are needed to enhance micro-forming applications in industry. Research product efficacy and process understanding might both be improved by industry collaboration. Many investigations on the micro-forming process have been carried out. However, more efforts are needed to rectify the shortfall in micro-forming technological improvement. The needs of industrial applications can only be satisfied by developing an integrated microforming system.

ABSTRACT

Power systems require accurate and coherent net-load forecasts across all levels of the grid hierarchy. A key methodological choice is between a direct strategy (forecasting net-load holistically) and an indirect strategy (forecasting gross load and renewable generation separately). This paper provides the first systematic evaluation of these two approaches within a hierarchical net-load forecasting framework, including the subsequent impact of statistical forecast reconciliation. Using load data from a three-level electricity network and simulated solar PV generation, this study compares the performance of both strategies using neural network auto-regression forecasting model and five reconciliation techniques. The findings show that the direct forecasting strategy yields statistically significant and more accurate forecasts across the hierarchy. However, the direct approach higher accuracy is coupled with over-forecasting bias. The analysis of reconciliation techniques revealed that while optimal methods improved the direct strategy's accuracy, they failed to correct its bias. Conversely, the simple Bottom-Up method, when applied to the indirect strategy, provided the least biased, though less accurate, overall forecast. The study concludes that while the direct approach is more robust for maximizing forecast accuracy, the final choice of strategy and reconciliation method must be aligned with specific operational objectives.

I. INTRODUCTION

Accurate forecasting of future electricity demand is crucial for efficient generation, transmission and distribution [1-3]. Net-load is defined as the electricity demand minus renewable energy sources (RES) generation [4]. The dual uncertainties from demand and supply variability complicate net-load forecasting (NLF) [1], making it a challenge in the transition to decarbonised power grids [5-7]. To improve the accuracy of NLF, studies have explored various methodological approaches. These include direct NLF (forecasting net-load holistically) and indirect NLF (forecasting gross load and RES generation separately, then adding to form NLF) strategies [6], [8], application of traditional statistical models, Machine Learning (ML) and Deep Learning (DL) architectures [9], [10], and the use of pre-processing techniques like signal decomposition and feature engineering to handle the non-linearity inherent in net-load data [11], [12]. The integration of RES such as solar PV into power grids across the globe necessitates accurate net-load forecasts at various granularities, from individual feeders and substations to the total system level, for effective planning, scheduling and real-time operations.

The existing body of research has extensively addressed the challenge of improving point net-load forecast accuracy at a single level of aggregation. Direct NLF, which forecasts the net load as a single time series, is widely adopted due to its simplicity and applicability in scenarios with limited observability of behind-the-meter (BTM) RES. In contrast, indirect (or additive) forecasting involves separately predicting load and RES generation before computing the net load. Existing literature on direct versus indirect strategies in net load forecasting reports varied outcomes, often due to evaluations limited to a single aggregation level or specific contexts such as microgrids or high renewable penetration systems. For example, Alipour *et al.* [11] integrated deep neural networks with wavelet transforms and found the indirect strategy more accurate, with improvements in metrics like mean absolute percentage error when using transformed historical inputs.

[13] applied LSTM models in microgrids with solar and wind, reporting lower MAE, MSE, RMSE, and NRMSE for the indirect method compared to direct. [14] proposed a disaggregation based additive framework using dictionary learning and LSTM, achieving RMSE reductions of 9.41% to 16.01% and MAE reductions of 9.34% to 15.24% over direct forecasts in neighbourhoods with high BTM PV and low observability. [15] used unsupervised contrastive disaggregation followed by models like DeepAR and TFT, demonstrating superior accuracy for the additive approach over direct net load forecasting. [16] tested machine learning models with and without BTM PV data, noting slight advantages for indirect but minimal differences overall. [17] compared additive (separate load and solar) versus integrated (solar as input to net load model) approaches, finding the integrated method superior due to cointegration of errors. Conversely, some studies support direct strategies.

[18] employed BNNs in renewable microgrids and reported lower NRMSE (3.98%) for direct compared to indirect (4.17%). [19] compared aggregation levels, identifying partially aggregated (separate total demand and supply) as optimal over fully direct or disaggregated. These variations stem from differences in models, data granularity, renewable types, and metrics, with limited attention to hierarchical structures or bias alongside accuracy. While direct and indirect NLF debate is well-documented in the literature, are well-investigated, their application to hierarchical time series, which naturally represent multi-level power systems, remains unexplored in NLF literature. When forecasts are generated independently for each level of the grid, the resulting set of forecasts is almost certainly incoherent which means that the sum of the forecasts for lower-level nodes (e.g., feeders) will not be equal to the forecast for their parent node (e.g., a substation). This incoherence creates significant operational challenges.

The transmission system operator, relying on an aggregate forecast, may make dispatch decisions that conflict with the needs identified by a distribution operator, who is relying on substation-level forecasts. Incoherent forecasts also lead to suboptimal scheduling of ancillary services, energy storage and demand response, as the perceived need at the aggregate level does not align with the sum of needs at the local level. Forecast reconciliation techniques ensure this coherence by adjusting independent base forecasts [20]. The primary contribution of this paper is an evaluation of direct and indirect strategies for hierarchical net-load forecasting (HNLF) and reconciliation. Unlike prior studies which are often limited to a single model or aggregation level, this work compares these two approaches for a hierarchical electricity network with solar photo-voltaic (PV) penetration, using three forecasting models and five statistical reconciliation techniques. The findings of this study is important for identifying effective forecasting strategies in RES-dominated power systems.

III. MATERIALS AND METHODS

I. Data: The primary datasets used in this study are the gross electricity load data and exogenous data. The gross load data for this study was obtained from an electricity network which covers a significant part of a state in the south-western part of Nigeria. Nine distribution feeders at 33kV voltage level are energised via the secondary side of three 132/33kV transformers at a 132/33kV substation. The hierarchical structure of the network is as shown in Figure 1. Historical hourly electricity load data for the feeders are acquired between 00:00 hours of 1st January 2022 to 24:00 hours of 31st December 2024. The raw data is validated and cleaned, while missing values and outliers are addressed. After cleaning, let $\mathbf{y}_t = (y_{1,t}, y_{2,t}, \dots, y_{m,t})^\top \in \mathbb{R}^m, t = 1,2, \dots, T$ be the vector of hourly electricity load observations at the m bottom-level nodes (e.g., feeders) over a horizon of T hours. Then, the complete multi-level load vector is $\mathbf{Y}_t = \mathbf{S}\mathbf{y}_t, \mathbf{Y}_t \in \mathbb{R}^n$, where $n \geq m$ and $\mathbf{S} \in \{0,1\}^{n \times m}$ denote the summing matrix that maps the m bottom-level series to n upper level series (such as transformers and substations).

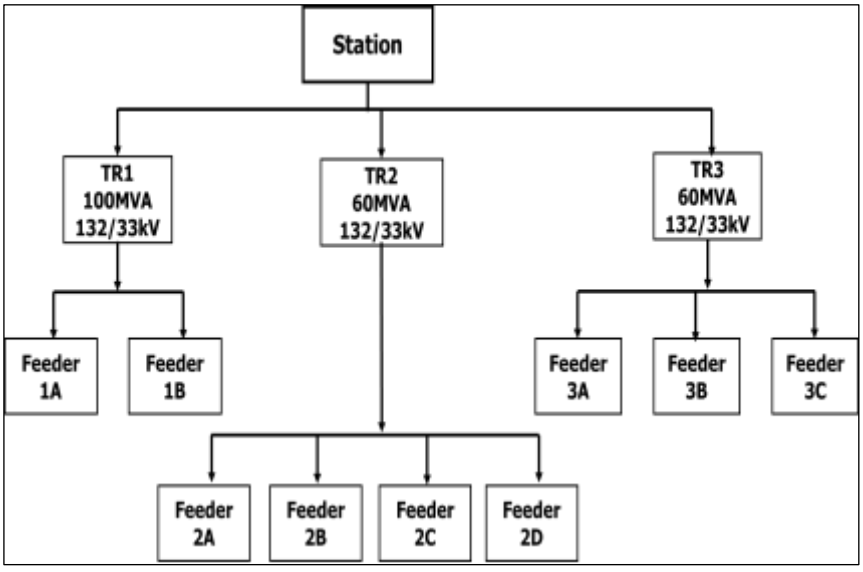

Figure1: Hierarchical Structure of the Electricity Network.
Source: Authors, (2026).

Exogenous data in this study encompasses external variables that influence net load calculations. The exogenous data include hourly meteorological and temporal datasets for the specific geographical location covering the entire historical period, $\mathbf{x}_t = (x_{1,t}, x_{2,t}, \dots, x_{p,t})^\top \in \mathbb{R}^p$). The Global Horizontal Irradiance (GHI, measured in W/m²), was obtained from the NASA POWER database (https://power.larc.nasa.gov/) , providing hourly values that quantify the solar radiation incident on a horizontal surface.

These data were integrated with local meteorological records which was obtained from *Visual Crossing* weather service (https://www.visualcrossing.com/) and include ambient air temperature (°C), precipitation type, weather conditions (Table1). Missing values in the combined dataset were imputed using linear interpolation for numeric variables, ensuring a complete time series without gaps. Categorical meteorological variables (e.g., precipitation type, conditions) were transformed into binary indicators via one-hot encoding [21], creating separate features for each unique category across the dataset. Features with near-zero variance were excluded to reduce redundancy, and all exogenous variables were normalized to a [0, 1] range using min-max scaling [22], based on training period to prevent data leakage. Table 1 summarises the key meteorological variables, their descriptions, types and unit.

Table 1: Meteorological Features.

Feature Name	Description	Type	Unit
GHI_W_m2	Global Horizontal Irradiance	Numeric	W/m²
temp	Ambient air temperature	Numeric	°C
preciptype	Type of precipitation (e.g., rain, none).	Categorical	N/A
conditions	Cloud conditions (e.g., clear, cloudy).	Categorical	N/A
icon	Weather icon descriptor (e.g., sunny, rainy)	Categorical	N/A
stations	Reporting weather station identifiers	Categorical	N/A
name	Location or station name	Categorical	N/A
dew	Dew point temperature	Numeric	°C.
humidity	Relative humidity	Numeric	%
precip	Precipitation amount	Numeric	mm
precipprob	Probability of precipitation	Numeric	%
windgust	Maximum wind gust speed	Numeric	km/h
windspeed	Mean wind speed	Numeric	km/h
winddir	Wind direction	Numeric	degrees
cloudcover	Cloud cover percentage	Numeric	%
solarradiation	Solar radiation	Numeric	W/m²
solarenergy	Solar energy accumulation	Numeric	MJ/m²
uvindex	Ultraviolet radiation index.	Numeric	N/A

To capture temporal and seasonal patterns inherent in load and PV dynamics, additional analytical features were engineered. These include basic components such as year, month number, day of the week, hour of the day, day of the year, and week of the year. Cyclic patterns were encoded using trigonometric transformations to represent periodicity continuously, avoiding discontinuities in numerical representations (Table 2). These exogenous features form the regressors for modelling, enabling the incorporation of weather-driven variability and temporal structures into net load simulations.

Table 2: Temporal Features.

Feature Name	Description	Type
year	Year	Numeric
month_num	Month of the year	Numeric
day_of_week_num	Day of the week,	Numeric
hour_of_day_num	Hour of the day	Numeric
day_of_year_num	Day of the year	Numeric
week_of_year_num	Week of the year	Numeric
hourofday_sin	Sine transformation for the hour of the day	Numeric
hourofday_cos	Cosine transformation for the hour of the day	Numeric
dayofweek_sin	Sine transformation for the day of the week	Numeric
dayofweek_cos	Cosine transformation for the day of the week	Numeric
month_sin	Sine transformation for the month of the year	Numeric
month_cos	Cosine transformation for the month of the year	Numeric
dayofyear_sin	Sine transformation for the day of the year	Numeric
dayofyear_cos	Cosine transformation for the day of the year	Numeric
period_wet	Binary indicator for the wet season	Binary
is_weekend	Binary indicator for weekends	Binary

II. Solar PV Generation Profile: The hourly GHI, is separated into Direct Normal Irradiance (DNI) and Diffuse Horizontal Irradiance (DHI);

$$\mathrm{GHI}_t = \mathrm{DHI}_t + \mathrm{DNI}_t \cos\left(\theta_{z,t}\right) \tag{1}$$

Where the solar zenith angle $\theta_{z,t}$ is defined in terms of the geographical location latitude ϕ, the solar declination δ_t and the hour angle ω_t.

The direct and diffuse components are then mathematically projected from the horizontal plane onto the defined plane of the PV array. This array has a fixed tilt angle β and azimuth angle γ_p. The total Plane-of-Array (POA) irradiance, $G_{POA,t}$, on the tilted surface is the sum of the three components:

$$G_{\mathrm{POA},t} = G_{b,c,t} + G_{d,c,t} + G_{r,c,t} \tag{2}$$

Where $G_{b,c,t}$ is the direct beam irradiance incident on the collector plane at time t, $G_{d,c,t}$ is the diffuse irradiance on the collector plane and $G_{r,c,t}$ the ground-reflected irradiance on the collector plane. The calculated POA irradiance is converted into a realistic electrical power output. Meanwhile, a PV system is not perfectly efficient due to significant losses during the energy conversion process.

Losses arise from inverter inefficiency in converting DC to AC power, resistive losses in wiring, performance degradation at high temperatures, and energy reduction due to soiling. Therefore, these factors are aggregated into a single de-rating factor called the Performance Ratio (PR). For this model, a PR of 0.85 is used, signifying that 85% of the available light energy is successfully converted to usable AC power.

The power output is;

$$P_t = \frac{G_{\mathrm{POA},t}}{1000} \cdot \mathrm{PR} \cdot A \tag{3}$$

Where A is the panel area in squared meters and the division by 1000 converts W/m^2 to kW/m^2. This equation yields the final PV power generation profile in kilowatts, which serves as the foundational template for the subsequent net load simulation. Any resulting negative values (which can occur from model approximations during non-daylight hours) are set to zero to ensure physical realism. The solar PV generation profile was simulated for a fixed, non-tracking system where the substation is located. The model assumed a south-facing orientation with a shallow panel tilt of 7.38°. The R *solarR* package was used for the implementation [23]. The hourly PV profile serves as a standardised shape for PV generation which will be scaled to achieve a target penetration level at the level of each individual feeder. Let $L_i(t)$ be the hourly gross load on feeder i at hour t, and $P_{PV,\mathrm{raw}}(t)$ be the hourly solar PV system AC output from the standardised annual profile. The renewable penetration level is defined as the total annual energy generated by PV relative to the total annual energy consumed by the gross load for each specific feeder i. The total annual gross load energy for feeder i (denoted $E_{L,i}$) and the total annual energy from the raw PV profile shape (denoted $E_{PV,\mathrm{raw}}$) over the period of interest (one year) are given by:

$$E_{L,i} = \sum_{t=1}^{8760} L_i(t) \tag{4}$$

$$E_{PV,\mathrm{raw}} = \sum_{t=1}^{8760} P_{PV,\mathrm{raw}}(t) \tag{5}$$

The scaling factor λ_i that ensures the total scaled PV energy meets the target P_{target} penetration level for feeder i is given as:

$$\lambda_i = \frac{\left(\frac{P_{\mathrm{target}}}{100}\right) \times E_{L,i}}{E_{PV,\mathrm{raw}}} \tag{6}$$

Applying this feeder-specific scaling factor λ_i to the original hourly PV profile $P_{PV,\mathrm{raw}}(t)$ returns the scaled hourly PV generation $P_{PV,\mathrm{scaled},i}(t)$ for feeder i. This process is repeated for each of the three years (2022-2024). This preserves the diurnal and seasonal shape of the PV generation while adjusting its overall magnitude to meet the feeder's target annual energy contribution. To ensure generation is non-negative:

$$P_{PV,\mathrm{scaled},i}(t) = \max\left(0, \lambda_i \times P_{PV,\mathrm{raw}}(t)\right) \tag{7}$$

Therefore, the net load $P_{\mathrm{Net},i}(t)$ at feeder i with P_{target} energy penetration is given as:

$$P_{\mathrm{Net},i}(t) = L_i(t) - P_{PV,\mathrm{scaled},i}(t) \tag{8}$$

After calculating the net loads for each individual feeder, these feeder-level net loads $P_{\mathrm{Net},i}(t)$ are then aggregated upwards to their respective transformer and ultimately to the station level to form the complete net load hierarchical time series. This process ensures that the PV impact is simulated based on the specific load characteristics at the lowest level before being combined into higher-level net load series.

III. Forecast Model: Artificial neural networks (ANNs) represent a class of forecasting methods inspired by simplified mathematical models of the human brain, enabling the capture of complex nonlinear relationships between response variables and predictors [24]. At their core, ANNs consist of interconnected *neurons* organized into an input layer for predictors, an output layer for forecasts, and optional intermediate hidden layers. Simple ANNs without hidden layers are equivalent to linear regression models, where weights are optimized via learning algorithms to minimize cost functions such as mean squared error (MSE). The addition of hidden layers introduces nonlinearity through activation functions, such as the sigmoid, which combine weighted inputs and enhance robustness to outliers [25]. Weights are typically initialized randomly, constrained by a decay parameter to prevent overfitting, and refined through multiple training iterations, with results averaged for stability.

Hyperparameters, including the number of hidden layers and neurons, are often determined via cross-validation. For time series forecasting, NNAR models incorporate lagged values as inputs, analogous to linear autoregressive models [26], [27]. An NNAR(p,k) denotes p lagged inputs and k hidden neurons, while seasonal variants, NNAR$(p,P,k)_m$, include additional lags from prior seasons, m being the seasonal period of the time series. These models can replicate ARIMA structures without stationarity constraints, allowing for asymmetric cyclic patterns. The NNETAR() function from the *forecast* package is used for the implementation. The function automates lag selection for non-seasonal data or seasonally adjusted series. Forecasting proceeds iteratively, using historical data and prior predictions as inputs. External regressors are used, turning the model into a NNARX (NNAR with exogenous inputs).

IV. Forecast Reconciliation: A Hierarchical Time Series (HTS) is a multivariate time series with linear aggregation constraint [28]. Mathematically, an HTS can be represented as;

$$y_t = Sb_t \tag{9}$$

Where y_t is a vector comprising the *n* time series in all levels of the HTS at time *t*, b_t is a vector of the *m* most disaggregated series of the HTS and *S* is the summing matrix [29]. Given an HTS having a total of *n* time series out of which n_b are the bottom-level series, the reconciled forecast is given as;

$$\tilde{y}_h = SG_h\hat{y}_h \tag{10}$$

Where $\tilde{y}_h$ is the reconciled forecasts, $\hat{y}_h$ is the h-step ahead unreconciled (base) forecasts and G_h is an $n_b \times$ n matrix. The function of the G matrix is to map the unreconciled forecasts into the bottom level which are then summed up by *S* to yield the reconciled forecasts $\tilde{y}_h$. A constraint on *G* to make sure the unbiased base forecasts $\hat{y}$ results in an unbiased reconciled forecasts $\tilde{y}_h$ is given by $SGS = S$ [30]. The challenge of statistical forecast reconciliation is to finding the optimal G matrix. This can be achieved by single-level approach or by optimal forecast reconciliation approach. In the Bottom-Up (BU) approach, the forecast of the lowest level series is extracted by *G* and then aggregated by the summing matrix *S* to obtain forecast of the top-level time series.

For the BU, $G = \left[0_{n_h \times n_a}\ I_{n_h}\right]$, where *n* is the total number of series in the hierarchy, n_b is the number of the bottom-level series and the upper-level series are n_a = *n*-n_b, 0 and I are matrix of zeros and the identity matrix respectively. Building up the HTS from the most disaggregated level in BU method means that no information is lost. However, the bottom level series are usually noisy and poses forecasting accuracy challenges. Let V_h and W_h be the variance-covariance matrix of $\tilde{y}_h$ and $\hat{y}_h$with respect to the actual value $\boldsymbol{y}$ respectively. Then, $V_h = SGW_hG'S'$ and the *G* that minimises the error variance of $\tilde{y}_h$ is the one that minimises the trace of V_h which is found via optimisation to be $G = (S'W_h^{-1}S)^{-1}S'W_h^{-1}$[31]. Obtaining W_h is practically difficult and four simplifying assumptions have been presented in the literature. In the following section, $k_h > 0$;

I. Ordinary Least Squares (OLS) Reconciliation [30]: In this approach, $W_h = k_hI$, hence $G = (S'S)^{-1}S'$. This in effect makes G independent of the data and thus makes OLS reconciliation relatively faster to compute. However, the OLS method gives equal weights to all the constituent time series and does not consider inter-relationships within the HTS.

II. Weighted Least Square (WLS) Reconciliation [32]: Here, $W_h = k_h diag(\widehat{W})$ where $\widehat{W} = \frac{1}{T}\sum_{t=1}^{T} e_t\, e_t'$ and e_t is an n-dimensional vector of forecast residuals arranged in the same sequence as the data.

III. Structural Scaling (STR) Reconciliation [27]: Here, $W_h = k_h$diag$(S1)$where 1 is an *m*-dimensional unit vector. The combination weights therefore reflect the structure of the HTS as only the total source of error variance at each node is considered.

IV. Minimal Trace (MinT) [31]: Here $W_h = k_hW_1\boldsymbol{W_h} = \boldsymbol{k_hW_1}$, where $\boldsymbol{W_1}$ is the full one-step covariance matrix with the assumption that the covariance matrices are proportional to each other. Two ways of calculating $W_1$are by calculating the sample covariance (SAM) or to use a shrinkage estimator (SHR).

The R *FoReco* package was used in the implementation of the five reconciliation methods [33].

V. Addressing Negative Values in the Reconciled Forecasts: Net-load becomes negative once the power generated by the solar photovoltaic (PV) system exceeds the gross load. Since negative net-load is sometimes prohibited in non-battery-based systems (i.e., curtailment), the set-negative-to-zero (*sntz*) heuristic was applied to ensure the generated reconciled forecasts are non-negative [33]. The *sntz* heuristic is a simple post-processing step to ensure non-negative, coherent forecasts in a forecast hierarchy. It starts with reconciled forecasts from any standard method (which may include negatives) and adjusts only the bottom-level forecasts before re-aggregating via bottom-up. Let $\tilde{\mathbf{b}}_h$ be the reconciled bottom-level forecasts (potentially with negatives). The *sntz*-adjusted bottom-level forecasts are $\tilde{\mathbf{b}}_h^+ = \max(\tilde{\mathbf{b}}_h, \mathbf{0})$ and the final non-negative reconciled forecasts are $\tilde{\mathbf{y}}_h^+ = \mathbf{S}\tilde{\mathbf{b}}_h^+$. The method may however introduce slight bias compared to optimization-based methods, but it is computationally faster and often yields similar or better NRMSE in practice.

VI. Experimental Setup: Hierarchical gross Load, solar PV generation and net-load at 30% penetration level will be used in this investigation. The net-load forecasting and reconciliation strategy to be evaluated include,

A. Direct Approach (Fig. 2)

I. Form the historical hierarchical net load hierarchy from the historical hierarchical gross load and solar PV generation data.

II. Train one of the forecast models and generate hierarchical net-load forecast.

III. Apply a reconciliation method to this set of forecasts to enforce hierarchical consistency. The result is the first final forecast set.

B. Indirect Approach (Fig. 3)

I. Train one of the forecast models on the historical hierarchical gross load data and generate hierarchical gross load forecast.

II. Train the same forecast models on the historical hierarchical solar PV generation data and generate hierarchical solar PV generation forecast.

III. Subtract the generated hierarchical solar PV generation from the generated hierarchical gross load forecast to obtain the generated hierarchical net-load forecast

IV.Apply a reconciliation method to the hierarchical net-load forecast to enforce hierarchical consistency. The result is the first final forecast set.

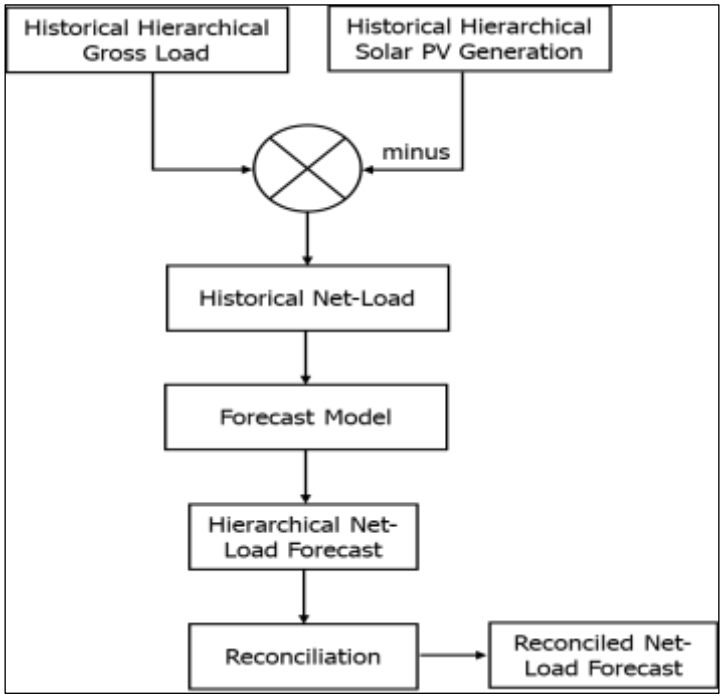

Figure 2: Direct Approach to HNLF.
Source: Authors, (2026).

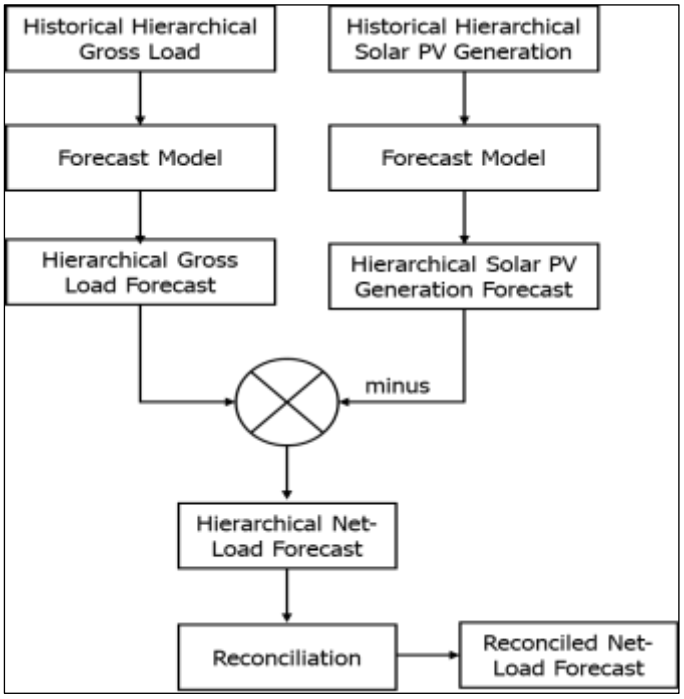

Figure 3: Indirect (Additive) Approach to HNLF.
Source: Authors, (2026).

VII. Evaluation: The final phase is the evaluation which employs a rolling forecast methodology (Fig 4), a technique designed to simulate real-world operational conditions. Instead of using a single, static train-test split, this approach iteratively creates multiple evaluation periods. In each iteration, the models are retrained on a fixed-size window of the most recent historical data (24 months) and then tested on the immediately following time period (one month). This entire process is repeated as the training and testing windows systematically slide forward through time. By aggregating the performance metrics from all iterations, this method provides a reliable assessment of a model's consistency and its true out-of-sample accuracy, ensuring that the results are not dependent on a single, arbitrary evaluation period. The hierarchical nature of the time series is an important factor while selecting metrics for evaluating forecast accuracy. Since series below aggregates to those above, the entire HTS will be on different scales, making absolute metrics not to be appropriate. Thus, this study adopts the Mean Absolute Scaled Error (MASE), Normalised Root Mean Square Error (NRMSE), Normalised Mean Bias Error (NMBE) which are scaled error metrics that enable comparison of the performances of forecasts across different aggregation levels.

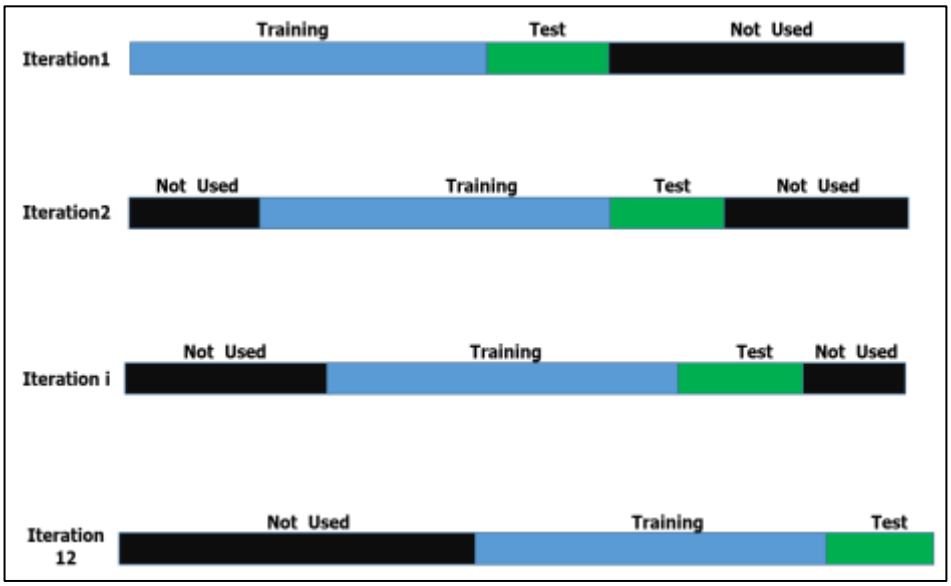

Figure 4: The Rolling Forecast Evaluation Strategy.
Source: Authors (2026).

These metrics have been used in reporting performance of HTS methods [33], [34], [35], [36]. Letting y_t be the actual values, $\hat{y}_t$ the forecasts, m the seasonal period, and n the length of the forecasts;

$$MASE = \frac{\frac{1}{n}\sum_{t=1}^{n} | y_t - \hat{y}_t |}{\frac{1}{T-m}\sum_{t=m+1}^{T} | y_t - y_{t-m} |} \quad (11)$$

Similarly,

$$NRMSE = \frac{\sqrt{\frac{1}{n}\sum_{t=1}^{n}(y_t - \hat{y}_t)^2}}{\frac{1}{n}\sum_{t=1}^{n} y_t} \quad (12)$$

Also,

$$NMBE = \frac{\sum_{t=1}^{n} y_t - \hat{y}_t}{n \times \bar{y}} \quad (13)$$

Where T is the length of the in-sample data, $\bar{y} = \frac{1}{n}\sum_{t=1}^{n} y_t$ is the mean of the actual series.When evaluating the performance of two forecasting models, statistical tests are essential to determine if one forecast is significantly more accurate than the other [37-39]. These tests typically analyse differences in loss functions, such as mean squared error (MSE) or absolute error, across a set of observations. The Wilcoxon signed-rank test is a non-parametric hypothesis test designed for comparing two related or paired samples to determine if there is a significant difference in their central tendencies [37]. Introduced as an alternative to the parametric paired t-test, it is particularly useful when the data do not satisfy normality assumptions or when the sample size is small. The null hypothesis is that the median of the differences is zero (no systematic difference in forecast accuracy), against the alternative that it is not. To determine if the strategies produced significantly different results, the Wilcoxon signed-rank test was applied. Rather than testing the final aggregated metrics, the test was performed on the paired distributions of the underlying, point-wise error components that constitute the metrics. Specifically, for MASE, the test compared the distributions of absolute errors (|actual - forecast|); for NRMSE, it compared the distributions of squared errors ((actual - forecast)²) and for NMBE, it compared the distributions of raw errors (actual - forecast).

IV. RESULTS AND DISCUSSIONS

I. Data Characteristics: Figure 5 shows the hourly profiles of the three key electrical quantities at the Station level for one full week (January 1st to 7th). The Net Load profile embodies the volatile characteristics of the gross load modulated by the solar PV profile. An indirect approach decomposes the net-load into components at the risk of summing their independent forecast errors, whereas the direct approach models the net-load, avoiding error compounding but tasking the model with learning the entangled component dynamics. The statistical profile of the grid's net load transforms significantly with increasing solar PV penetration (Table 3). While the mean and median net load predictably decrease across all hierarchical levels, this is contrasted by a sharp increase in volatility, as measured by the standard deviation. This heightened variability is a direct consequence of the *duck curve* phenomenon (Fig. 6), where deep midday load suppression creates a greater spread between the low solar-hours demand and the high evening demand [40]. This phenomenon appears to be more pronounced during the dry season than the wet season while being independent of day type (weekend or weekdays).]

Source: Authors (2026).

PV penetration also alters the predictability of net-load, as evident in the Autocorrelation Function (ACF) plot of Figure 7. The autocorrelation analysis of system net load under varying PV penetrations (0-50%) reveals a dominant 24-hour periodicity consistent with daily load cycles. At 0% PV, the ACF exhibits strong positive correlations at short lags with damped peaks at multiples of 24 hours, reflecting both short-term dependence and daily seasonality. As PV penetration increases, the diurnal cycle in the net load becomes more pronounced, with the ACF showing sharper oscillations and alternating positive (24-hour) and negative (12-hour) correlations.

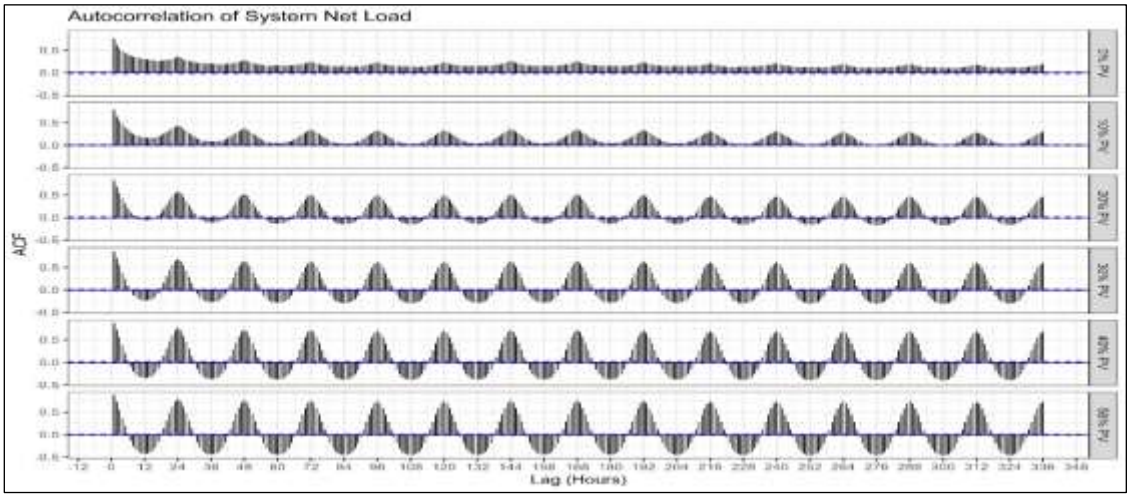

Figure 7: Autocorrelation of The System Net Load. The Correlation at The 24-Hour Lag (And Its Multiples) Is Visibly Weaker for Higher PV Penetration Levels.
Source: Authors(2026).

II. Performance of the Two Strategies: Figure 8 presents a visual analysis of the forecasting model applied to the Station Net Load. It compares a Direct forecasting strategy (Left panel, red colour), where models are trained on the Station Net Load series itself, against an Indirect strategy (Right panel, blue colour), where the Station forecast is derived from other component forecasts. The actual Station Net Load is shown in green for a single representative week. The actual net load exhibits a daily pattern in which the demand is lowest during the early morning hours and peaks in the evening. This cyclical behaviour is the primary feature that both forecasting models are attempting to capture. The Direct forecast successfully captures the overall timing and shape of the daily cycles. It correctly identifies when the peaks and troughs will occur. However, this model exhibits a bias related to the magnitude of the load. At almost every daily peak, the red forecast is noticeably higher than the green actual load. This indicates a tendency to overestimate demand during high-load periods. Conversely, during the lowest points of the day, the forecast is often just higher than the actual load, suggesting it also slightly under-estimates the lows.

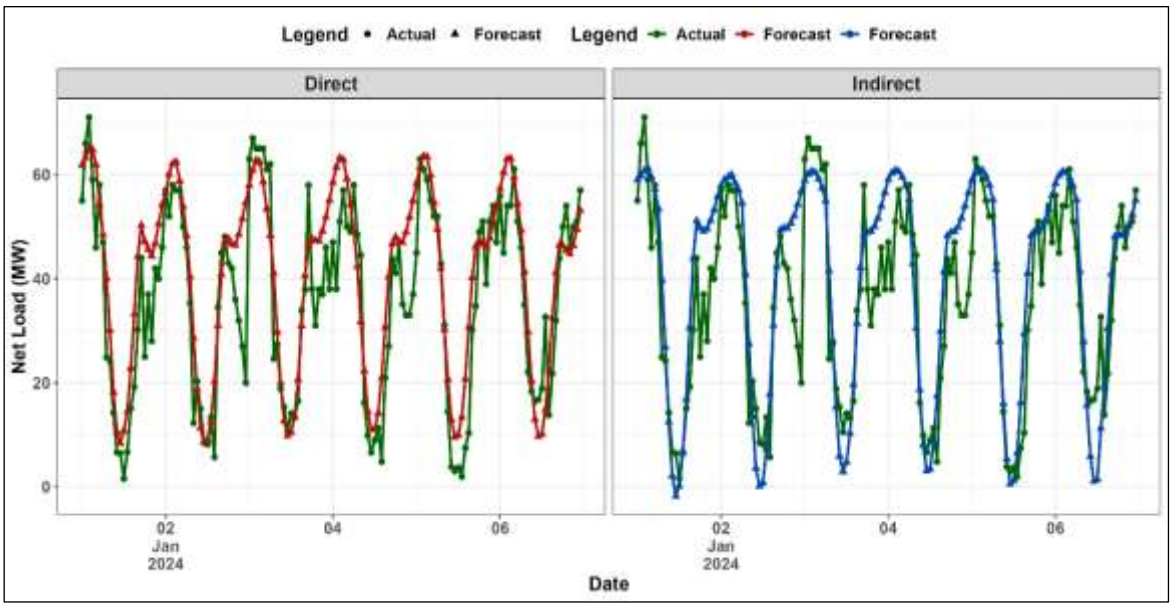

Figure 8: Time Series Plot of the Forecast of the Two Approaches and the Actual Values for the First Week of January 2024.
Source: Authors, (2026).

Like the Direct method, the Indirect forecast also does a good job of tracking the daily rhythm of the net load. However, this model also displays a consistent bias, but in the opposite direction of the Direct method. The Indirect forecast consistently fails to reach the height of the actual peaks. It underestimates demand during high-load periods. Its performance in the troughs appears often lower to the actuals compared to the Direct method. The Indirect model's forecast therefore appears smoother and more conservative. It is less responsive to the sharp peaks in the actual data, leading to its underestimation. The most important finding from this plot is that the two models have opposing systematic biases at the Station level. The Direct model over-forecasts, while the Indirect model under-forecasts. Neither model is consistently accurate in predicting the magnitude of peak load. The better model depends entirely on the business context and the cost associated with forecasting errors. If the cost of under-supplying power (e.g., needing to buy expensive power on the spot market) is very high, the Direct model's tendency to over-forecast might be preferable as a safer option.

If the cost of over-supplying power (e.g., wasted generation, selling excess at a loss) is the primary concern, the Indirect model's conservative, under-forecasting nature might be more desirable. Figure 9 displays boxplots which visualizes the distribution of forecast errors for the Direct and Indirect forecasting strategies. The Y-axis employs a symmetric logarithmic (symlog) scale, a technique necessary for visualizing distributions centred around zero that contain a wide range of values, including large outliers. This scale remains linear near the origin to allow for a clear comparison of the central tendencies, while compressing the tails to effectively display extreme errors without distortion. The Direct strategy exhibits a negative bias, as indicated by its median error being below the zero line. This demonstrates a systematic tendency to over-forecast the net load. The interquartile range (IQR), represented by the height of the box, is relatively compact which suggests that the middle 50% of its forecast errors are clustered within a tighter range, indicating a higher degree of consistency compared to the Indirect method.

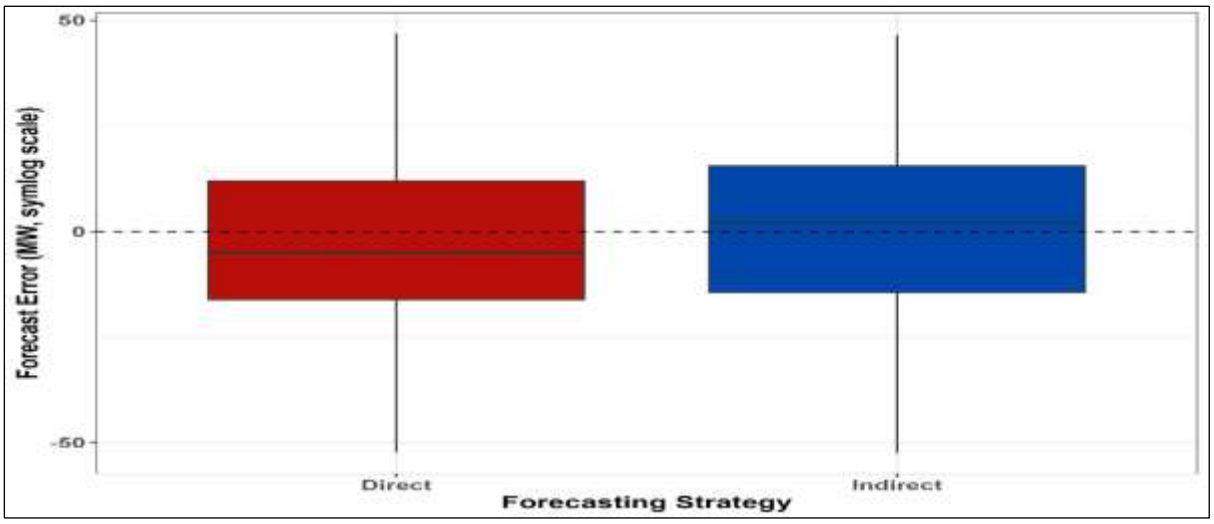

Figure 9: Forecast Error Distribution of the Two Strategies.
Source: Authors (2026).

The whiskers are also symmetrical, showing that the risk of large-magnitude errors is present for both over- and under-forecasting, though the central tendency remains biased towards over-forecasting. The error distribution of the Indirect strategy is more centred, with a median positioned slightly above the zero line. This signifies a minor positive bias, indicating a slight tendency to under-forecast the net load. This strategy displays higher forecast variance as the IQR is visibly larger than that of the Direct method, meaning its forecasts are less consistent, with the central 50% of errors covering a wider range of values. The error distribution is also asymmetrical with the upper whisker notably shorter than the lower one, highlighting a risk of large negative errors. This means the Indirect strategy is more prone to occasional, large-magnitude over-forecasting events. The plot reveals a distinct trade-off between the two forecasting strategies. The Direct method produces more consistent forecasts, but they are subject to systematic over-forecasting bias. In contrast, the Indirect method is less biased on average, but this comes at the cost of higher variance and an asymmetrical risk profile skewed towards major over-forecasting events.

The decision between the two would depend on the specific operational tolerance for predictable bias versus forecast inconsistency and the asymmetrical risk of large errors. The dumbbell plots in Figure 10-12 visualize the impact of different reconciliation methods on the accuracy and bias of the Direct and Indirect base forecasts. Each grey line connects the performance of an unreconciled *Base* forecast (grey point) to its *Reconciled* counterpart (coloured point), immediately revealing the magnitude and direction of the change. An improvement in accuracy is shown by a coloured point to the left of its grey partner, while an improvement in bias is shown by a coloured point closer to the vertical zero line. The MASE plot for both strategies showed that optimal reconciliation methods offer some degree of improvement in terms of accuracy over the base forecast while BU is the worst for both strategies. the Indirect strategy shows the most substantial improvements by the optimal reconciliation methods (Fig. 10). While the SHR method is the overall best for the Direct strategy, the STR method offered the biggest average improvements to the Indirect forecast.

These patterns are sustained in the NRMSE plot (Fig. 11), confirming the validity of the observations. The NMBE plot however tells a completely different story (Fig. 12). While the Indirect method again benefitted more from reconciliation, all reconciled forecast from the Direct strategy remain far from the zero line with reconciliation largely ineffective at correcting the large negative bias (over-forecasting) inherent in this approach. Conversely, for the Indirect strategy, BU is slightly effective at improving bias while optimal reconciliation methods largely worsening the forecast bias. These observations make it clear that the choice of forecasting strategy and reconciliation method must be driven by the primary operational objective. If the goal is maximum forecast accuracy, the plots provide evidence that the Direct strategy combined with SHR or OLS reconciliation is the superior choice. However, if the goal is to produce a less-biased forecast, the Indirect strategy combined with the Bottom-Up (BU) method is the only effective option.

Table 4 presents the results of a paired Wilcoxon signed-rank test to determine if there is a consistent, significant difference in performance between the Direct and Indirect forecasting strategies. The test is performed independently for each series at each Level of the hierarchy. The columns in the table are interpreted as follows:

I. Series: The series being evaluated.
II. Level: The hierarchical level at which the test was performed.
III. *p*_value: The probability of observing the performance difference between the two strategies if there were no actual underlying difference. A low *p*-value (less than 0.05) suggests that the observed difference is unlikely to be due to random chance.
IV. Median (Direct) / Median (Indirect): The median MASE value for each strategy. The median represents the typical performance, as it is the middle value of all error results and is not skewed by unusually large or small errors. Lower values indicate better typical performance.

V. Significance: A direct interpretation of the *p*-value. If the *p*-value is below the standard threshold of 0.05, the result is declared *Significant*, meaning there is statistical evidence of a real difference between the two strategies. Otherwise, it is *Not Significant*.
VI.Winner: This column identifies the strategy with the better (lower) median MASE, but only if the result is statistically significant. If the difference is not significant, no winner can be declared because the observed difference could be due to random chance.

Table 4: Results of a Paired Wilcoxon Signed-Rank Test to Compare the Two Strategies.

Series	Level	p_value	Median (Direct)	Median (Indirect)	Significance	Winner
Total	Station	1.27E-09	6.906	7.514	Significant	Direct
A	Transformers	1.15E-05	3.447	3.533	Significant	Direct
A1	Feeders	4.40E-87	2.362	2.848	Significant	Direct
A2	Feeders	2.08E-67	2.137	2.439	Significant	Direct
B	Transformers	2.08E-07	3.393	3.377	Significant	Indirect
B1	Feeders	4.13E-65	1.212	1.425	Significant	Direct
B2	Feeders	4.45E-32	0.511	0.599	Significant	Direct
B3	Feeders	1.49E-45	1.991	1.853	Significant	Indirect
B4	Feeders	1.0E-148	1.744	2.178	Significant	Direct
C	Transformers	1.83E-31	3.579	4.181	Significant	Direct
C1	Feeders	9.80E-04	2.020	2.204	Significant	Direct
C2	Feeders	1.40E-82	1.788	1.994	Significant	Direct
C3	Feeders	1.68E-03	1.358	1.456	Significant	Direct

Source: Authors (2026).

The result confirmed that the difference in performance between the two strategies is statistically significant for every single series analysed. All p-values are very small, indicating that the observed differences in accuracy are not due to random chance but reflect a genuine performance gap. With statistical significance established across the board, the *Winner* column clearly identifies the superior strategy based on the lower median absolute error. The Direct strategy is the overall winner, demonstrating superior performance at the highest aggregate level and for the vast majority of the individual components. At the Station level, The Direct method is significantly more accurate, with a median absolute error of 6.91 compared to the Indirect method's 7.51. The Direct strategy wins 2 out of the 3 transformer series (A and C) while the Indirect strategy shows a competitive edge for series B.

The dominance of the Direct strategy is most pronounced at the most disaggregated level. It is the statistically significant winner for 8 out of the 9 feeders. The Indirect method was only superior for the B3 feeder. The statistical analysis provides a definitive conclusion that the Direct forecasting strategy is demonstrably and significantly more accurate than the Indirect strategy for this system**.** Its superior performance is a consistent and statistically validated characteristic observed at the total system level and across almost all of its constituent parts. While the Indirect method may perform better in isolated cases, the evidence overwhelmingly supports the selection of the Direct strategy as the more reliable and accurate base forecasting approach.

V. CONCLUSIONS

The study provides an empirical answer for the direct versus indirect netload forecasting debate with insights from an hierarchical time series point of view, unlike prior studies which were often limited to a single aggregation level and reported conflicting outcomes [6], [11], [41]. This work demonstrates that for the network studied, the Direct approach yields more accurate base forecasts, potentially because a single model can better capture the non-linear interactions between load and solar PV generation that separate additive models may miss and also avoided the compounding of errors from the two component forecasts. The study also quantified the accuracy-bias trade-off inherent in the choice of reconciliation method, providing a practical framework for operational decision-making.

This research empirically demonstrates that while optimal reconciliation methods are designed to improve coherence and minimise error variance [31], they operate by preserving the unbiasedness of the base forecasts and thus cannot fix an already biased model [30]. The practical implication for grid operators is an evidence-based choice. For strategic planning where minimizing error magnitude is paramount, the Direct strategy combined with SHR reconciliation is demonstrably superior. However, for real-time operational scheduling where an unbiased forecast is critical to prevent systemic over-commitment of generation resources, the Indirect strategy with BU reconciliation presents the most viable low-bias alternative. This directly addresses the need to align forecast evaluation metrics with the specific operational decisions being made [42].

ABSTRACT

This study develops a structured maturity model to assess SMEs' readiness for the implementation of Lean Six Sigma. The model presents a tool that will assist organizations in evaluating their current maturity level before LSS deployment. A comprehensive literature review was performed to find the critical success elements, barriers, and relevant frameworks. These insights were then used to develop a four-level LSS maturity model with a scoring-based assessment instrument. The developed model was refined by expert consultations and subsequently validated using four SME case studies. Findings: The model successfully distinguished the preparedness levels of LSS among the participating SMEs. Scores ranged from Level 1 (Uncertain or Limited) to Level 3 (Understanding or Good). The tool demonstrated strong capability in identifying organizational strengths, gaps, and priorities. Practical implications: It can assist owners or managers by providing an evidence-based mechanism to assess their readiness, benchmark their performance, and plan the implementation of LSS more effectively. It aids structured decision-making and reduces the likelihood of failure at early deployment stages. Originality/value: This work is one of the first LSS maturity models focused on SMEs, along with a quantifiable scoring system, making both academic and practical contributions to improve the assessment of LSS.

I. INTRODUCTION

Manufacturing enterprises today are under high pressure to improve productivity at lower costs along with high quality, in a competitive global environment [1], [2]. In such a scenario, high-quality output is no longer an option—it is a question of survival. To achieve this, most organizations depend upon continuous improvement methods, which are effectively used in the manufacturing industries [3], and Lean Six Sigma, which combines Lean's principles of waste reduction and Six Sigma's statistical and variation control techniques, has been recognized as a structured strategy that can enhance operating efficiency and competitiveness [4], [5]. However, as far as SMEs are concerned, they face unique challenges when implementing LSS, such as limited technical knowledge, informal organization structures, and limited financial resources compared to major organizations [6-8]. Although SMEs could gain considerably from LSS, Current frameworks are generally developed for large organizations and are too complex or resource-intensive for smaller firms [9-11].

Therefore, most SMEs initiate LSS initiatives based on intuition rather than a systematic understanding of their readiness [12]. While recent studies have considered readiness evaluation as the first step for any LSS deployment process, despite this recognition, the literature suggests that there is currently no valid self-assessment instrument that would organizations to measure their maturity level. Most contributions either focus on selective factors, lack any scoring mechanisms, or remain purely conceptual without any diagnostic instruments. To take up this challenge, the present study proposes a maturity model based on self-evaluation specifically designed for SMEs concerning the implementation of Lean Six Sigma. Guided by the model, SMEs would be able to recognize their strengths, weaknesses, and areas where improvement is needed.

The model will support the SMEs in making well-grounded decisions with regard to the introduction and implementation of LSS by offering a structured diagnostic instrument. It aims at reducing reliance on external consultancy, increasing the success rate of LSS implementations, and also anticipating operational and sociocultural hurdles during transformative change. Thus, this study aims to address the following questions:

1. Under what organizational conditions can SMEs be considered ready to implement Lean Six Sigma?
2. How can the readiness or maturity of SMEs for implementing Lean Six Sigma be systematically evaluated?

This research contributes to the further development of Lean Six Sigma scholarship by proposing a maturity self-assessment model, developing and validating it, and thus offering a practical instrument to support SMEs in planning and executing LSS initiatives with improved effectiveness.

II. THEORETICAL REFERENCE

II.1 AN OVERVIEW OF SMALL AND MEDIUM ENTERPRISES AND LEAN SIX SIGMA.

LSS combines Lean's philosophy of waste elimination along with the statistical rigor of Six Sigma in pursuit of improved operational efficiency, process stability, and product [13], [14]. Despite being widely adopted by large organizations, SMEs face different challenges because of their limited financial resources, informal organizational structures, and dependence on tacit worker knowledge [15]. Amongst other researchers, [7] and [16] emphasized that the successful implementation of LSS within SMEs significantly depends upon leadership support, learning culture, internal competencies, and basic infrastructural resources. However, most of the currently existing implementation frameworks are either overly complex, resource-intensive, or intended for large-scale enterprise use and, therefore, limit their practical applicability to SMEs [9]. Encouraged by this need, recent research efforts have pushed toward recommending simple, structured, and SME-specific maturity assessment models [17], [12].

II.1.1 Obstacles and Difficulties for Small and Medium Enterprises

Although Lean Six Sigma has been effective in enhancing quality and operational performance [18], [19], SMEs frequently experience constraints that limit its successful implementation [20]. Table 1 highlights in summary form the primary barriers identified in the literature.

Table 1: Key Barriers to Lean Six Sigma Adoption in SMEs.

Barriers	Description	Sources
Resource Limitations	Some factors include limited time, budget, and manpower to undertake improvement projects	[18],[21]
Lack of LSS knowledge and skills	Employees have limited familiarity with Lean Six Sigma tools and methods	[7],[11]
Poor organizational culture	Resistance to change and inconsistency in CI practice	[10],[16]
Limited leadership commitment	Support for LSS is still more symbolic than strategic	[2], [22]
Inadequate Infrastructure	Lack of harmonization in processes, data systems, and documentation	[12],[23]

Source: Authors, (2026).

II.1.2 Important Success Elements for Small and Medium Enterprises

The effective application of Lean Six Sigma in SMEs is accomplished by some organizational enablers that support structured improvement, learning, and employee engagement. Literature also identifies leadership commitment, workforce involvement, skills development, tool usage, motivation systems, and supportive working conditions as the key enablers for LSS implementation in organizations [18],[24],[25]. The main Critical Success elements, their applicability to SMEs, and their compatibility with the dimensions of the suggested maturity model are shown in Table 2.

Table 2: Essential Components of LSS Success in SMEs.

Essential Components	Relevance in SMEs	Corresponding Maturity Model Dimension	Sources
Top management commitment	Ensures strategic support and resource allocation	Top Management & Employee Involvement	[18], [22]
Employee involvement and empowerment	Encourages participation in CI and project activities	Top Management & Employee Involvement	[7], [25]
Structured training and skill development	Builds capability to apply LSS tools effectively	Infrastructure & Training	[10], [11]
Availability and use of improvement tools	Enables systematic problem-solving and process control	Tools & Techniques	[12], [17]
Reward and recognition mechanisms	Maintains motivation and supports cultural acceptance of CI	Motivation & Recognition	[4],[18]
Fair and safe working environment	Promotes workforce stability and supports an improvement culture	Social Performance	[7],[25],[26]

Source: Authors, (2026).

II.1.3 Foundation for integrating Lean, Six Sigma, and Lean Six Sigma

Significant efforts have been made to develop frameworks and models that help apply Lean and Six Sigma principles in practice. Table 3 highlights a thorough examination of these contributions.

Table 3: List of different lean and Six Sigma models and frameworks.

Sr.no	Authors	Strengths	Limitations	Scoring System
1.	[22]	Emphasizes how crucial it is to do a readiness assessment before implementing LSS. Suggests a paradigm that combines knowledge and risk management.	Early-stage idea; framework requires additional real-world case testing.	No
2.	[11]	Offers a thorough scholarly summary of the LSS deployment variables based on a systematic review.	Theoretical, with little validation from practitioners.	No
3.	[12]	Proposes a streamlined framework for SMEs to integrate Six Sigma and Lean tools.	Validation is restricted to one case study; generalization is problematic.	No
4.	[9]	Identifies the obstacles and readiness criteria for LSS adoption in the context of SMEs.	Lacks a measurement tool that has been validated; the framework is still conceptual.	No
5.	[27]	Highlights important leadership and cultural elements while concentrating on LSS implementation in the service industry.	Limited case validation; less established manufacturing applicability.	No
6.	[28]	Highlights the obstacles and elements that make SMEs successful while implementing LSS. offers helpful advice to managers.	Mostly exploratory, with a greater emphasis on concept than prescription.	No
7.	[29]	Suggests an LSS deployment paradigm that is centered on SMEs and places a strong emphasis on flexibility and ease of usage.	The scope is restricted to Swedish SMEs and requires more extensive empirical validation.	No

Source: Authors, (2026).

An overview of current LSS implementation and readiness models indicates that, while there have been numerous studies that have made useful contributions, the most significant shortcoming is the lack of a standardized scoring system. [22] recognize the importance of readiness assessment and provide a paradigm that includes knowledge and risk management, but that remains at a conceptual level without measurable scoring. Similarly, [11] provide a systematic review of LSS deployment factors but avoid providing a measurement instrument at the practitioner level. Although models by [12], [9], [27] offer useful insights in highlighting challenges, cultural concerns, and SME-specific issues, their frameworks are mostly descriptive in nature and lack validated measurements. Even [17], [29] studies, as informative as they were in pinpointing success factors and barriers, are exploratory and contextual and thus possess limited generalizability. This is the critical gap that highlights the originality of this proposed model in this research. By converting qualitative information into measurable metrics, the scoring-based model improves objectivity, comparability, and usability for practitioners and SMEs.

III. RESEARCH METHODOLOGY AND DEVELOPMENT OF MODEL

Research shows that although Lean Six Sigma research has advanced significantly in industrialized nations [30-32], developing countries are still lacking context-specific adoption frameworks [33]. To address this gap, a practical and SME-friendly self-evaluation maturity model was created over the course of nine months using a systematic four-stage process in order to close this gap (Figure 1).

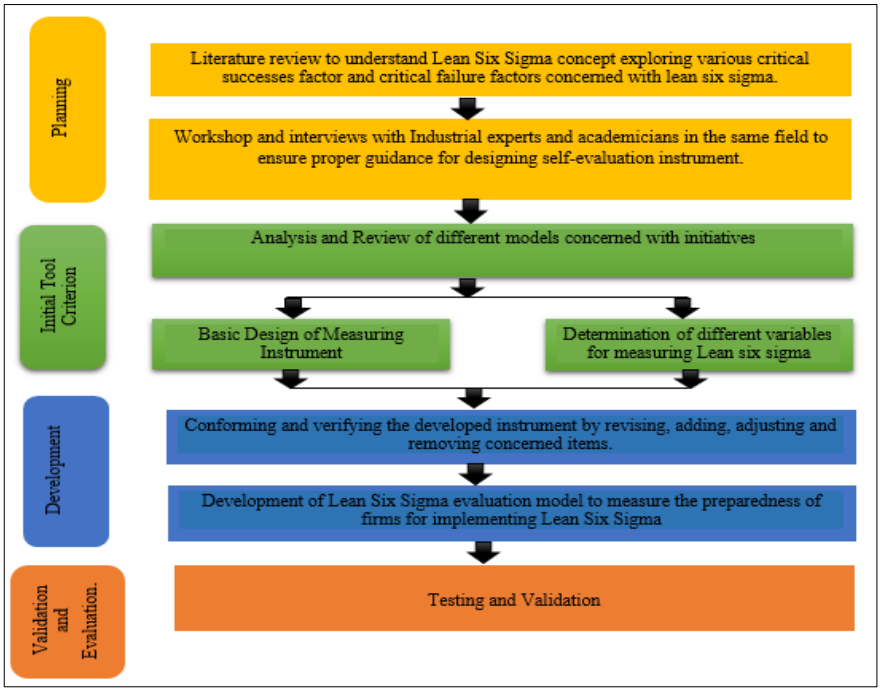

Figure 1: Research methodology.
Source: Adapted from [34].

Planning: In the beginning, five industry professionals participated in semi-structured interviews. All of the professionals who took part had carried out Lean six sigma initiatives within their firms. These professionals all had a cumulative experience in continuous improvement of between 2 and 20 years. A workshop on Lean and Six Sigma was also held, this time with three professors. Through networking and personal connections, industry professionals and academics were located. Although the workshop and interview results aren't discussed in great detail in this section, they provided a strong foundation for the preparation self-evaluation model instrument. The results revealed that there is a vital need to create a realistic instrument to assess whether businesses were ready to implement Lean and Six Sigma practices, because during the study, it was found that there was still a lot of difference between the current industrial scenario and theory related to the evaluation of Lean and Six Sigma implementation. The majority of participants mentioned challenges when implementing Lean Six Sigma into practice. Although they had a complete understanding of the company's working environment, they still faced a number of obstacles that prevented its effective implementation. Moreover, they recommended that the instrument needed to be easily usable, blend in with the SMEs environment. The preparedness self-evaluation needed to be uncomplicated, trustworthy, and resource-light, according to all of the experts.

Initial instrument creation: A preliminary list of criteria for assessing how ready a company is to apply Lean Six Sigma was created on the basis of Csfs, barriers, and existing LSS frameworks. Items were modified from previous instruments that assessed the Lean and/or Six Sigma implementation. An additional eight models (Table 4) from different sectors were also studied to extract the best practices regarding the scoring logic, design of the model, and the structure of its validation process. The draft instrument was reviewed by five industry professionals.

Table 4: Summary of the existing readiness and maturity models.

Sr.no	Authors	Focus	Inspired elements
1.	[35]	Created a self-assessment preparedness for the application of statistical procedures tailored to the food sector.	• Technique of scoring • Participation of academics and industry experts • Creation of models based on literature.
2.	[36]	Proposed a self-checking tool to assess preparedness.	• Use motivations, obstacles, and facilitators as input when creating the tool. • Completing the readiness evaluation as a team. - defining the readiness assessment's scope, such as the entire company or a particular division?
3.	[37]	Outlines a method for assessing an organization's preparedness for the fundamental ideas and components of safety change management.	• Sampling method: Developing the readiness model using Nertney's principle.
4.	[38]	Aims to examine the Swedish industry's preparedness for data analytics.	• Developing the evaluation tool using a number of preparedness capabilities. • Results of the study were used to prepare a robust model.
5.	[39]	Evaluated how well the various Industry 4.0 and smart manufacturing maturity models match the unique needs of small and medium-sized businesses.	• Rules for scoring readiness levels. - Building a solid model based on the findings of this investigation.
6.	[40]	Provide a mechanism to gauge the level of preparedness for Industry 4.0 adoption.	• Method development: Determining the level of preparedness.
7.	[34]	Proposed a maturity model for evaluating Industry 4.0 adoption	• The approach used to create the maturity model.
8.	[41]	Presented a self-assessment to help organizations measure and visualize their capabilities with respect to key elements for successful sustainability integration in the product innovation process.	• Long-term outlook on the three aspects of sustainability, with a focus on the social aspect.

Source: Authors, (2026).

Development: By updating, amending, adding, correcting, and/or eliminating some criteria and items, as necessary, this step attempted to validate the instrument. A multi-case study approach was chosen to accomplish this. This kind of approach is crucial when the subject is complicated and needs to be examined in its context [42]. Especially considering the lack of evidence on organizations' preparedness to adopt Lean Six Sigma. Employing such approach helps in the production of more trustworthy outcomes and broad conclusions. However, using this method will take a lot of time and work to complete the research.

Validation and assessment: The proposed preparedness self-evaluation model and tool were validated and evaluated throughout the fourth and final development phase. In order to reduce misunderstanding and raise the instrument's quality, queries about its functioning, item clarity, and visibility were also posed to industry specialists. An encouraging sign of the suggested tool's validity was that industrial experts said it could be used to undertake a preparedness self-evaluation for Lean Six Sigma implementation.

III.1 MATURITY LEVEL SELF-EVALUATION MODEL FOR THE IMPLEMENTATION OF LEAN SIX SIGMA

A self-evaluation maturity model has been created especially for SMEs to gauge an organization's level of readiness to apply Lean Six Sigma (LSS). The model consists of 5 components**.**

1. Commitment of top management and employees' involvement.
2. Knowledge of Tools and Techniques.
3. Infrastructure and training.
4. Motivation and Recognition
5. Social Alignment.

Each of the dimensions reflects one of the fundamental capabilities that underpin LSS implementation in SMEs, depending on which the model would be both theory-driven and practice-oriented. The following section outlines the Maturity levels, scoring mechanism, and calculation of the Lean Six Sigma Maturity Index (LSS-MI).

Table 5: Lean Six Sigma Maturity Index (LSS-MI).

Sr.no	Categories		Maturity level 1	Maturity level 2	Maturity level 3	Maturity level 4	Final Evaluation
1	**Top Management & Employees Involvement**	Does management join or attend improvement/project meetings? (e.g., project reviews, problem-solving meetings, or improvement events)?					
		Are resources (time, budget, basic tools, and key staff) allocated by top management for different projects?					
		Does top management promote a culture of learning and continuous improvement by recognizing achievements and encouraging employee contributions?					
		Are employees encouraged to share problems, ideas, or suggestions for improvement in their daily work?					
		Have employees received at least basic awareness or training on Lean, Six Sigma, or continuous improvement tools?					
2	**Infrastructure & Training**	Does the organization provide the necessary infrastructure (e.g., basic IT systems, data collection tools, process mapping tools)?					
		Are employees given awareness or basic training on Lean Six Sigma concepts and problem-solving tools?					
		Does the organization invest in training and certification for selected employees?					
		Are employees encouraged to apply learned tools (5S, DMAIC, SPC, etc.) in their daily work, with management support?					
		Does the organization have mechanisms to share knowledge from training and past projects (e.g., lessons learned, best practices)?					
3	**Tools & Techniques**	Do employees use simple quality tools (like check sheets, cause-and-effect diagrams, or basic charts) to solve everyday problems?					
		Are employees aware of Lean Six Sigma tools (e.g., Value Stream Mapping, Pareto chart, scatter plots), even if they are not using them regularly?					
		Are more structured tools and techniques (e.g., 5S, Poka Yoke, SMED, FMEA) being used in projects to improve processes?					
		Are Lean tools and some Six Sigma statistical tools (e.g., control charts, process capability, basic hypothesis					

		testing) used across most departments or teams?					
		Are advanced Lean and Six Sigma tools (both problem-solving and statistical) commonly used and integrated into daily operations?					
4	**Motivation & Recognition**	Do employees feel interested in joining improvement activities?					
		Does management say “thank you” or appreciate employees who give ideas?					
		Are small rewards (like certificates, gifts, or public praise) given for good improvement work?					
		Do employees take part in improvement work because they want to, not just for rewards?					
		Is there a regular system in place to reward and recognize employees for Lean Six Sigma efforts?					
5	**Social Performance**	Are all employees treated fairly and respectfully at work?					
		Does the company ensure that no child labor or forced labor is used?					
		Do employees have equal opportunities, without discrimination (e.g., gender, religion, caste, or background)?					
		Do employees get proper working hours, rest days, and fair treatment for overtime?					
		Does the company check workplace safety risks and take steps to prevent accidents or hazards?					

Source: Authors, (2026).

Each of the five dimensions of the maturity model is rated across four levels of maturity, reflecting the organization's capability to adopt Lean Six Sigma practices. These four levels range from minimal awareness to stable and confident deployment. The levels themselves have been adapted from classical maturity theory [43], [44] and contextualized for SMEs.

III.2 MATURITY LEVELS:

Each component is assessed across four levels of maturity, ranging from limited or uncertain adoption to full capability. The levels are described below:

Maturity Level 1: Uncertain or Limited

Organizations at this level are characterized by limited or no apparent adoption of Lean or Six Sigma. Though one or a few individuals may have former training or exposure from previous work, there is no structured implementation, no formal projects, and limited evidence of LSS-supportive behavior [45]. Resource constraints, management's lack of involvement, and low awareness among employees characteristically suppress any start [17]. This stage resembles the "Initial" level in classic maturity models in that processes are informal and at the mercy of individual effort rather than being systematically practiced [43].

Maturity Level 2: Awareness and Fair

At this stage, SMEs begin to investigate Lean and Six Sigma ideas temporarily. Basic awareness initiatives and introductory training are introduced across the departments, but systematic deployment has not been considered yet [46], [47]. In this context, organizations generally demonstrate poor standardization of processes with fragmented tools [18], [22]. This level matches the “Repeatable/Structured” phase of capability maturity, where the fundamental practices have just started to take shape but remain unstable [44].

Maturity Level 3: Understanding or Good

This level is called as ‘**Understanding or Good**’, because organizations at this level are able to comprehend and acquire new information and techniques. Compared to the previous level, this organization employs more sophisticated tools and approaches for issue resolution and has a greater understanding of LSS at the shop floor level. These organizations have moved past their own inertia in relation to LSS and have become self-learning. SMEs at this level are usually in a position to relate LSS activities to process improvements and operational performance, overcoming initial barriers including resistance from staff and absence of formal training [18],[23]. This level is an indication of increasing organizational capability and learning mindset, aligned with prevailing LSS and maturity model research.

Maturity Level 4: Capability and Certainty

This stage has been named as **'Capability and Certainty'** because organizations at this stage are better equipped to implement LSS than those at previous levels. At this stage, the organization becomes independent because the advantages are clear, and LSS begins to positively alter the organization's culture by putting in place strong infrastructure and internal training [45], [48]. Top management is involved in supporting organizational learning behaviors. SMEs in this stage generally enjoy robust leadership backing, a formal reward scheme, and wide employee engagement, allowing a self-reinforcing culture of constant improvement [17], [18]. This phase reflects the "Optimizing" stage in maturity literature, signaling institutionalized learning and strategic alignment [43].

III.3 SCORING CRITERIA:

Existing Lean Six Sigma readiness models [9],[11],[12],[23] have critical limitations; they are largely descriptive and conceptual in nature, making their practical application for SMEs limited. The present study has overcome such a limitation by adopting a scoring-based framework that converts qualitative organizational characteristics into quantifiable readiness scores. The scoring criteria are adapted from the rubric-based maturity assessment approaches commonly used in several change management and quality management models [49], [50]. Each of the 25 indicators in the proposed model is evaluated using a 0–1 scale, where 0 denotes the practice's absence, and 1 denotes its presence. This approach makes collecting evidence in SMEs easier and is consistent with the maturity evaluation's maximum score of 25. The following formula was used to determine each organization's maturity percentage:

LSS-MI= (Total Score/25) *100

The four maturity levels specified in the model were then mapped to this percentage.

Table 6: Levels of Lean Six Sigma Maturity Using Percentage Scores.

Percentage Score	Maturity Level	Interpretation
0–25%	Level 1:Uncertain or Limited	Minimal awareness; no structured LSS activity
26–50%	Level 2: Awareness and Fair	Basic awareness; inconsistent practices
51–75%	Level 3: Understanding or Good	Structured efforts; moderate tool usage
76–100%	Level 4: Capability and Certainty	Systematic, sustained LSS deployment

Source: Authors, (2026).

This structured scoring approach enhances objectivity, comparability, and practical usability for SME decision-makers.

III.4 STEPS FOR CONDUCTING SELF-ASSESSMENT.

Step 1 – Formation of the Assessment team and Model Briefing.

Performing an LSS readiness self-assessment does require the involvement of the senior management and clarity of purpose. The objective of this stage is to make the executives, managers, and owners understand why the organization is performing the assessment. A cross-functional assessment team should be assembled to perform the assessment. It should include all key operational areas represented, such as production, quality, and maintenance, among others.

Step 2: Data Collection and Preparation

Information collection by the assessment team is done based on the 25 indicators of LSS preparedness. Evidence concerning training records, tool usage, process documentation, employee involvement activities, safety practices, and leadership engagement shall be collected. All information, observations, recordings, and interviews must be impartially recorded.

Step 3: Performing Self-Evaluation for Readiness

The LSS Preparedness instrument in Table 5 is used for the self-evaluation; it has 25 indicators under five dimensions. Against each of the indicators, team members rate an entity a score of 1 (present) or 0 (absent), purely based on verifiable evidence collected in Step 3. All assessors should be asked to apply a common set of rating rules or guidelines for each item to maintain consistency and minimize subjective scoring by any assessor. Evidence may come in the form of—but is not limited to—management and employee interviews, shop-floor observations, training certificates, documented procedures, quality charts, and safety logs.

Step 4: Scoring and Determination of Maturity Level

After all the indicators have been scored, the total is summed (maximum 25). The following formula is then used to convert this score to a percentage:

LSS-MI= (Total Score)/25 *100

Based on the percentage score, each organization's level of preparedness can be determined based on the classification criteria defined in Table 6.

Step 5: Preparation of Findings and Recommendations for Action

The assessment team prepares a concise report that includes the following:

Level of maturity.
Dimension-wise performance.
Critical gaps in capacity, and
Recommended steps for addressing them.

IV. CASE STUDIES

The suggested Lean Six Sigma preparation self-evaluation technique was validated by a multiple-case study involving four SMEs in various manufacturing organizations. A LSS preparedness maturity assessment instrument was applied by each organization to determine the present maturity level through the following percentage score formula:

Percentage = (Total Score/25) × 100

A summary of these four organizations can be found in Table 7.

Table 7: Profile of Case Study Organizations.

Organization	Size	Product	Ownership	Established years
1.	SME	Manufacturer of bolts	Private	12
2.	SME	Die-manufacturing	Proprietorship	18
3	SME	Bath fitting manufacturing	Private	8
4.	SME	Automotive components	Private	19

Source: Authors, (2026).

Case 1: Bolt Manufacturing Firm

Organization 1 produces bolts for both local and export markets through semi-automated production systems. Its main products include standard fasteners, nuts, and High-Tensile Bolts. The firm scored 7/25, which is 28%, hence falling within Level 1: Uncertain or Limited. At this level, most LSS practices are absent, the infrastructure is weak, and there are only a few people with any form of LSS awareness. Top management involvement in and employee engagement with the initiative are at a minimum. Recommended improvement actions:

- Engage a consultancy firm to start basic LSS training.
- Enhance both process- and product-focused improvement activities:
- Introduce basic tools such as Scatter plots, Cause and Effect Analysis, and Pareto charts.
- Implement 5S to organize the workplace.
- Conduct periodic LSS awareness sessions for shop-floor employees.

Case 2: Die Manufacturing Firm

Organization 2 has approximately 100 employees and manufactures precision-machined parts through pressure and gravity die casting. Press tools, Sheet metal dies, forging dies, casting dies, etc., are some of the products of the company. This organization received a score of 11/25, which corresponds to 44% and positions this organization at Level 2: Awareness and Fair. The company shows initial awareness of LSS practices; however, the deployment is inconsistent and lacks a systematic structure.

Case 3: Bath Fittings Manufacturer

Organization 3 is engaged in the manufacturing of Chrome-plated bath fittings. Its products include bathroom accessories, taps, showers, etc. The company has 50 workers. The company scored 12/25, which is equivalent to 48%, and falls into Level 2: Awareness and Fair. The organization demonstrates an elementary knowledge of Six Sigma and Lean, and the application level is limited with inadequate standardization and a lack of management involvement. Improvement actions suggested for Organization 2 and Organization 3:

- Enhance the leadership and participation of the top management in the process of improvement.
- Introduce a wider set of Lean tools and basic statistical tools of Six Sigma.
- Create an official system of rewards and recognition.
- Remove organizational barriers through stronger leadership support.
- Provide external expertise to guide the LSS deployment.
- Improvement initiatives in process stability and product quality.
- Train employees in basic tools.

Case 4: Automotive Components Manufacturer

Organization 4 manufactures commercial and passenger vehicle parts. it is involved in the manufacturing of engine components, transmission parts, suspension parts, brake components, etc. It achieved the highest maturity score from the four cases, reaching 15/25 or 60%, hence placing it at Level 3: Understanding or Good. The enterprise shows stronger infrastructure, better training systems, and more concrete leadership commitment. Improvement activities are more organized, while employees show better tool awareness. Improvement actions recommended:

- Develop and document a formal project selection methodology.
- Expand the application of Six Sigma statistical methods and Lean tools.
- Institutionalize a well-structured reward and recognition system.

Cross-Case Comparison and Insights

These four cases have demonstrated that the proposed model effectively differentiates preparedness levels in SMEs for LSS: Level 1 organizations need basic awareness and infrastructure development. The organizations at Level 2 should institutionalize practices, spread training, and increase engagement at the leadership level. At Level 3, the organizations need to focus on the institutionalization of recognition systems, cross-functional learning, and the use of advanced LSS tools. By applying this maturity model, the SMEs are able to systematically evaluate their readiness, recognize capability gaps, and track their evolution into self-driven Lean Six Sigma organizations. None of the SMEs were able to reach at level 4, as this stage requires a mature organization structure, training systems, strong leadership, and frequent use of advanced tools. Typically, reaching at level 4 requires long-term investments and a sustained improvement culture, a condition that is still challenging for SMEs.

V. CONCLUSION

This research study enhances the LSS discipline by developing an integrated maturity model specifically for SMEs. The model was developed in an attempt to close the research gap, i.e., A lack of a maturity model for Lean Six Sigma, without which organizations implementing LSS cannot measure their existing level of maturity. In order to accomplish this goal, an SLR was done to explore pertinent studies on the application of Lean Six Sigma, its crucial success elements, and its hindrances. Building on these insights, the Lean Six Sigma Maturity Model was created, comprising of several maturity stages, their traits, and scores. The model was later tested and validated by interviews with subject-matter experts and subsequently applied to evaluate the current level of LSS maturity within four organizations. This model can potentially have a substantial impact on practice and knowledge. Nonetheless, it also has certain drawbacks, which are detailed in the following section, along with suggestions for additional improvement in the future.

VI. LIMITATIONS AND FUTURE DIRECTIONS FOR RESEARCH

The research done to develop the self-evaluation model/instrument has some major limitations. Comparatively few semi-structured interviews and workshops were performed. Second, in regard to the model's or instrument's use in only four organizations. Thirdly, the case studies' evaluations of social performance are restricted to the employees. It's possible that the businesses won't disclose their actual social performance regarding issues like employee maltreatment or forced labour, etc. As a result, the social performance outcomes should be interpreted with care. In order to assess whether organizations are prepared to successfully apply Lean Six Sigma, this study suggests a fresh self-evaluation model or tool. Therefore, by identifying the elements that covers a larger scope in the implementation of Lean Six Sigma, outlining problems for businesses, and suggesting the model/instrument, the study has increased knowledge in the field. It can assist practitioners in conducting a diagnostic of needs to make sure that all necessary conditions are met before beginning a Lean Six Sigma journey. It assists in the preparation phase of a Lean Six Sigma transformation, improving the likelihood that such an effort will be successful before a company invests its resources in it. This metric can be used by qualified managers to compare their organization's readiness against others because the established instrument provides a maturity score that indicates how prepared the organization is overall for launching a Lean Six Sigma initiative. The proposed methodology can also be adopted by different business activities to start their Lean Six Sigma journey, including medical, management, the hotel industry, and logistics, even though this study was done in relation to the manufacturing industry.

ABSTRACT

This article focuses on the investigation and optimization of laser cutting modes for sheet materials made of corrosion-resistant austenitic steel grade 12X18H10T. The main factors affecting the quality of the cut are examined, including laser power, speed of laser head movement, radiation frequency, and focal point position. A comprehensive analysis of the impact of these factors on surface roughness and the presence of visible defects on the cut edges is provided. The practical significance of this research lies in obtaining specific recommendations for optimal processing modes corresponding to various thicknesses of steel sheets. Applying these recommendations ensures achieving the required quality of processing. Implementation of the developed technology recommendations into serial production can significantly reduce the duration of the manufacturing cycle, eliminate the need for an additional stage of mechanical finishing of parts, and increase the operational efficiency of the used equipment.

I. INTRODUCTION

Modern machine-building production is characterized by a wide variety of material processing technologies [1-4], each of which has its own area of economic and technical feasibility. Enterprises use a range of methods for manufacturing parts with complex contours from sheet materials, including mechanical machining (milling and coordinate boring operations), stamping, waterjet cutting, and laser cutting. Each method has historically established niches of application: milling provides high precision in slots and holes, stamping is economically efficient under mass-production conditions, while waterjet cutting is indispensable for materials sensitive to thermal effects. However, within the context of medium- and small-series production tasks, especially when working with alloyed steels, laser cutting appears as the most versatile and promising method. Its advantages are comprehensive in nature and have a direct impact on both economic and operational performance indicators. Among these benefits are high productivity and speed due to non-contact interaction between the tool (laser beam) and the material, eliminating costs associated with specialized cutting tools such as mills or drills that wear out and require regular replacement. Additionally, this technology does not necessitate fabrication of complicated and expensive equipment like dies and molds, significantly reducing preparation time and expenses [5-15]. Furthermore, the ability to process large-format sheet materials without pre-cutting them into smaller blanks allows optimization of layout and minimization of waste, thus improving material utilization efficiency. In Russian Federation's rocket-space industry enterprises, corrosion-resistant steel grade 12X18H10T is widely used in critical structures operating in aggressive environments. This type belongs to the class of austenitic stainless steels. The extensive product line of components made from stainless steels produced using various techniques requires high stability and quality assurance of technological processes, particularly laser cutting [16-19]. Currently, Russian enterprises commonly employ LC MSTD FO3015 laser cutting machines, often having significant service life and experiencing natural wear of their mechanical and optical components. These factors introduce uncertainty into the process since actual beam parameters and positioning accuracy may deviate from specified values.

Moreover, accompanying technical documentation either lacks specific recommendations altogether or contains only general guidelines regarding cutting modes for different materials. Specifically, there is an absence of detailed, practice-verified settings for

12X18H10T steel at varying thicknesses. As a result, operators must empirically determine cutting parameters. Consequently, results vary: acceptable quality is achieved in some cases, whereas others exhibit substantial defects. Therefore, the lack of formalized, scientifically grounded databases for cutting regimes tailored to specific materials and machinery prevents enterprises from fully realizing the potential of laser cutting technology, ensuring high-quality products, and minimizing defective output. This underscores the urgent practical necessity and relevance of targeted research efforts in this direction. The use of laser cutting machines for sheet metal processing involves addressing several technological challenges, central among which is achieving high surface quality of cuts. Current industrial practices rely heavily on subsequent finishing operations, such as manual deburring, to eliminate visible defects and bring the part up to standard condition. However, this approach introduces negative consequences: it increases overall manufacturing lead times, raises labor intensity requiring additional human resources, leading ultimately to higher final product cost. An alternative and technologically superior path would be obtaining a finished component directly during the laser cutting stage itself, avoiding any further mechanical treatment. Achieving this goal is possible only through precise determination and strict adherence to optimal laser cutting regimes unique to each “material-thickness” combination. Thus, the objective of this study is to identify and analyze adjustable technological parameters of the laser cutting process that exert a significant influence on two key metrics: the quality of the formed cut edge (absence of burr and discoloration) and compliance with required roughness specifications according to design drawings for parts manufactured from sheet material (steel 12X18H10T).

II. MATERIALS AND METHODS

Austenitic stainless steel 12X18H10T is extensively utilized in Russian rocketry because it possesses capabilities to operate under extreme mechanical loads, thermal stresses, and aggressive environments. The chemical composition of material 12X18H10T is presented in Table 1.

Table 1: Chemical composition of steel 12X18H10T.

Element	Content, %
Carbon (C)	≤ 0.12
Silicon (Si)	≤ 0.8
Manganese (Mn)	≤ 2.0
Copper (Cu)	≤ 0.3
Nickel (Ni)	9.0–11.0
Sulfur (S)	≤ 0.02
Titanium (Ti)	0.5–0.8
Phosphorus (P)	≤ 0.035
Chromium (Cr)	17.0–19.0

Source: Authors, (2026).

Steel 12X18H10T belongs to highly carbonated (from 0.6% to 1.0%) and complex-alloyed cryogenic stainless steels. Chromium and nickel serve as primary alloying elements, preventing corrosion, providing the metal with cryogenic properties (resistance to cooling) and excellent workability. Mechanical properties of steel 12X18H10T are controlled upon release of billets and are listed in Table 2.

Table 2: Mechanical properties of steel 12X18H10T.

Parameter	Value
Ultimate tensile strength	550-650 MPa
Yield strength	225-315 MPa
Density	7.92 g/cm³
Brinell hardness	170-190 HB
Elongation	35%
Fatigue limit	530 MPa

To address the task set forth in this study, we propose investigating the effect of diverse laser cutting modes and conditions on the quality characteristics of manufactured parts. The quality of the part's edge obtained via laser cutting plays a crucial role in subsequent stages of the production process [20]. For experimental studies, we employed the LC MSTD FO3015 laser cutting system (Russia), equipped with a precise coordinate system, CNC control, and an adaptive laser head featuring a sensor for monitoring clearance from the part. This setup is depicted in Figure 2.

Figure 2: Laser Cutting Machine LC MSTD FO3015.
Source: Authors, (2026).

As a result of analyzing the design documentation used at enterprises, steel sheets made from grade 12X18H10T steel were selected for experiments, which are most commonly used to manufacture parts, namely:

• Sheet 0.8 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 1.0 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 1.5 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 2.0 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 3.0 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 5.0 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75;
• Sheet 8.0 mm thick, 12X18H10T according to GOST 19903-2015/GOST 5582-75.

The test samples used were squares measuring 20×20 mm. The processing quality requirements specify surface roughness not exceeding Ra 6.3 as per the design documentation. For visual inspection and measurement of surface roughness, the following measuring instruments were employed:

1. Portable profilometer Mitutoyo Surftest SJ-410 (Figure 3).
2. Control and measurement machine KIT-MSM-32 (Figure 4).

III. RESULTS AND DISCUSSIONS

The main parameters under investigation that affect cut quality include laser power, speed of laser head movement, emitter frequency, and lens position. These parameters will be variable during the experimentation process. During the study, it was found that these parameters have an equal effect on metal thickness values of S = 0.8 mm, S = 1 mm, and S = 1.5 mm. Therefore, it was decided to combine them into one experimental group. Parameter changes occurred through the control panel of the laser machine using the Unicut software. Dependencies of surface roughness Ra on focal distance of the lens for different sheet thicknesses are shown in Figure 5.

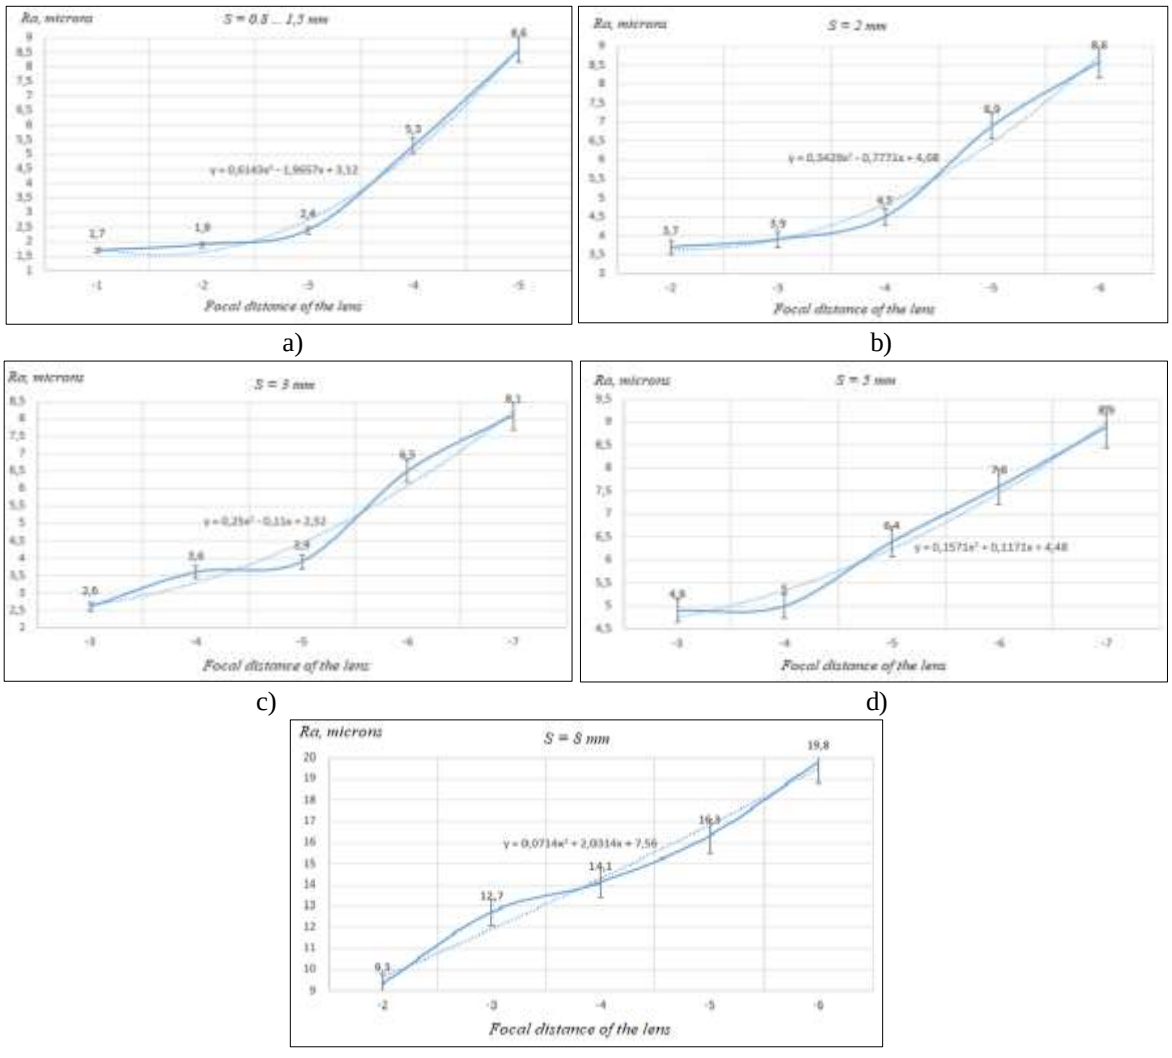

Figure 5: Dependencies of surface roughness *Ra* on lens focal distance for different sheet thicknesses:
a) for sheet thickness S = 0.8.1.5 mm; laser power P = 4000 W; laser head travel speed 7000 mm/min; frequency F = 5000 Hz;
b) for sheet thickness S = 2 mm; laser power P = 4000 W; laser head travel speed 7000 mm/min; frequency F = 5000 Hz;

c) for sheet thickness S = 3 mm; laser power P = 4000 W; laser head travel speed 7000 mm/min; frequency F = 5000 Hz;
d) For sheet thickness S = 5 mm; laser power P = 4000 W; laser head travel speed 4000 mm/min; frequency F = 1000 Hz;
e) For sheet thickness S = 8 mm; laser power P = 4000 W; laser head travel speed 2000 mm/min; frequency F = 1000 Hz.
Source: Authors, (2026).

Figure 6 shows the dependence of surface roughness Ra on the frequency of the laser emitter.

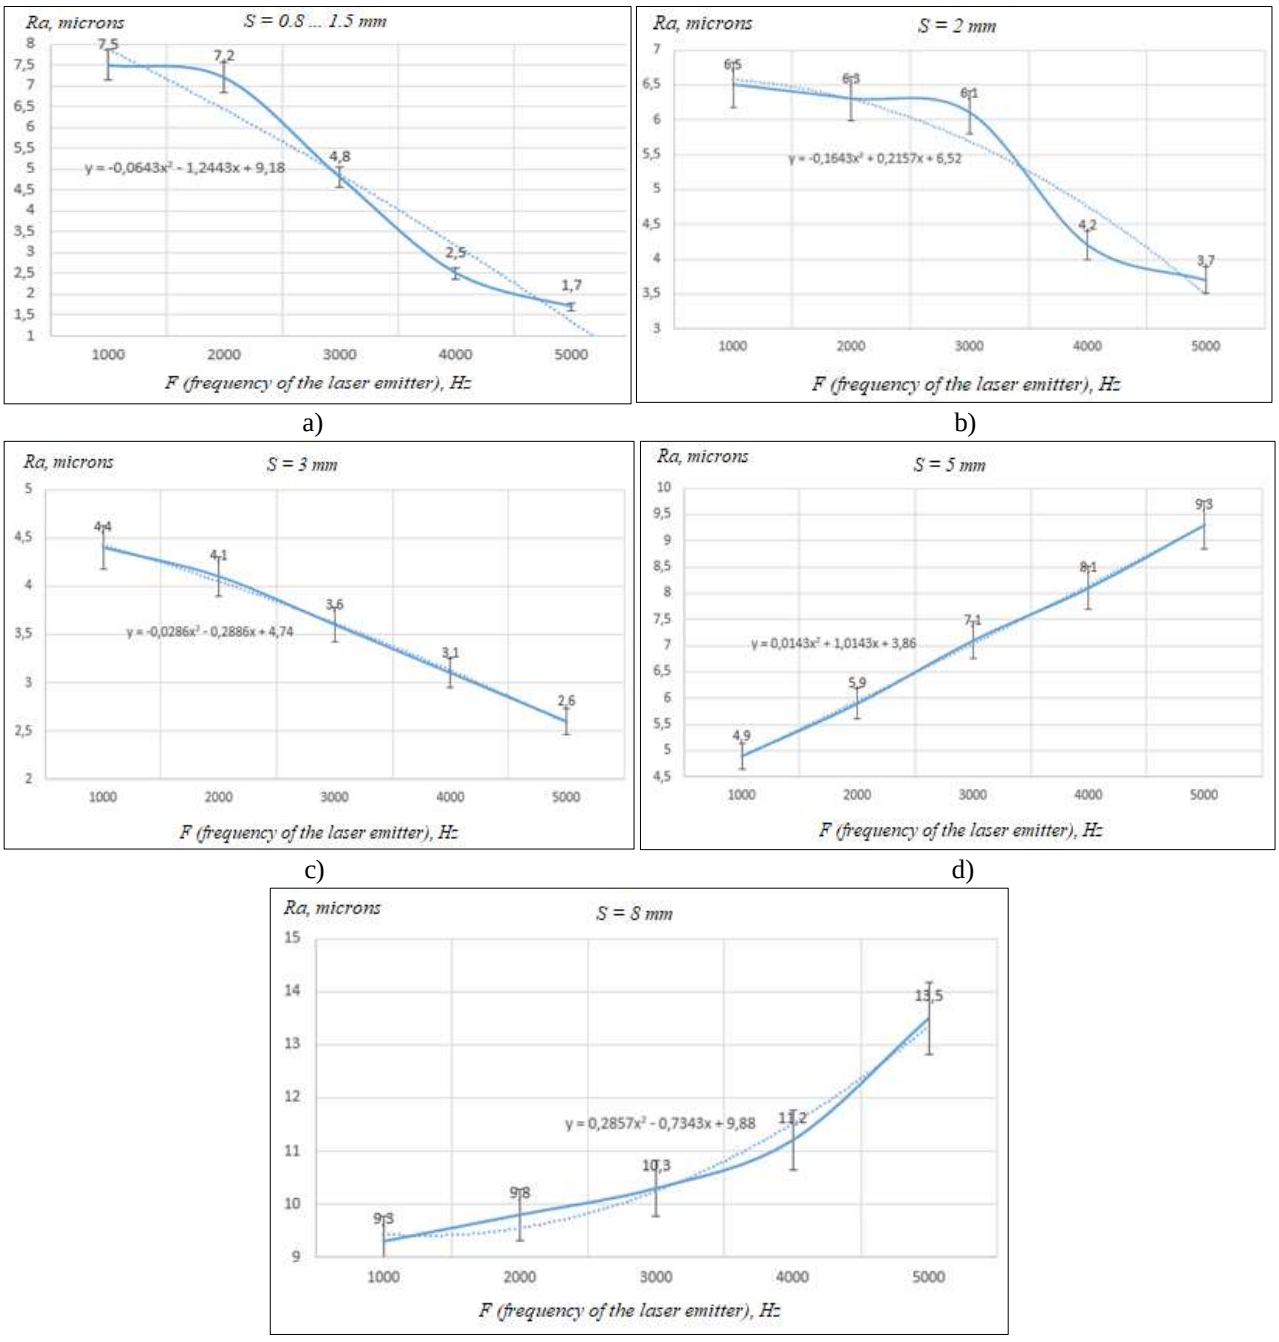

Figure 6: Dependence of surface roughness Ra on laser radiation frequency for:
a) sheet thickness S = 0.8...1.5 mm; laser power P = 4000 W; laser head speed = 7000 mm/min; lens position (focus) = -1.0;
b) sheet thickness S = 2 mm; laser power P = 4000 W; laser head speed = 7000 mm/min; lens position (focus) = -2.0;
c) sheet thickness S = 3 mm; laser power P = 4000 W; laser head speed = 7000 mm/min; lens position (focus) = -3.0;
d) sheet thickness S = 5 mm; laser power P = 4000 W; laser head speed = 4000 mm/min; lens position (focus) = -4.5;
e) sheet thickness S = 8 mm; laser power P = 4000 W; laser head speed = 2000 mm/min; lens position (focus) = -6.0
Source: Authors, (2026).

Dependences of surface roughness Ra on the speed of laser head movement for different thicknesses of cut sheets are shown in Figure 7.

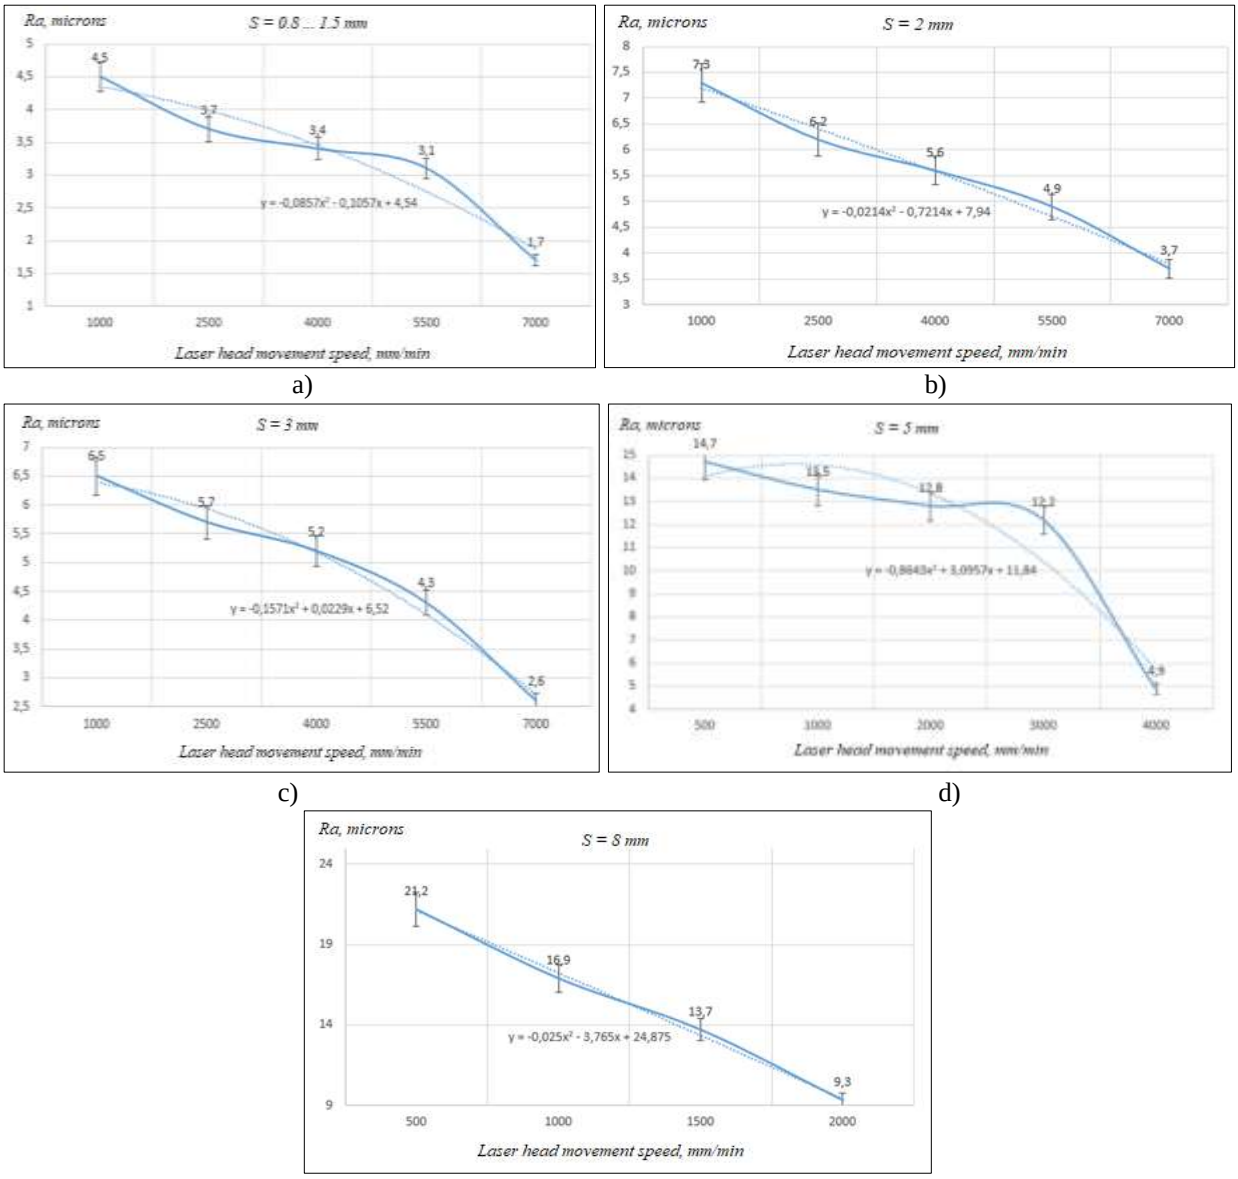

Figure 7: Dependence of surface roughness Ra on laser head movement speed at:
a) sheet thickness S = 0.8.1.5 mm; laser power P = 4000 W; laser emitter frequency = 5000 Hz; lens position (focus) = -1.0;
b) sheet thickness S = 2 mm; laser power P = 4000 W; laser emitter frequency = 5000 Hz; lens position (focus) = -2.0;
c) sheet thickness S = 3 mm; laser power P = 4000 W; laser emitter frequency = 5000 Hz; lens position (focus) = -3.0;
d) sheet thickness S = 5 mm; laser power P = 4000 W; laser emitter frequency = 1000 Hz; lens position (focus) = -4.5;
e) sheet thickness S = 8 mm; laser power P = 4000 W; laser emitter frequency = 1000 Hz; lens position (focus) = -6.0
Source: Authors, (2026).

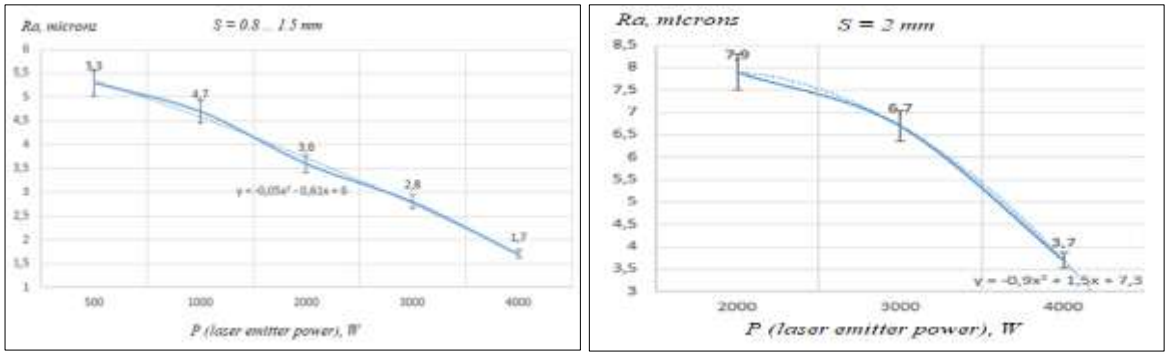

Figure 8: Dependence of surface roughness Ra on laser emitter power at:
a) sheet thickness S = 0.8.1.5 mm; laser head movement speed = 7000 mm/min; laser emitter frequency = 5000 Hz; lens position (focus) = -1.0;
b) sheet thickness S = 2 mm; laser head movement speed = 7000 mm/min; laser emitter frequency = 5000 Hz; lens position (focus) = -2.0.
Source: Authors, (2026).

In Figure 8, the dependencies of surface roughness Ra on the laser emitter power are presented. It should be noted that further experiments to reduce the laser power were not carried out when the sheet thickness was 2 mm (see Fig. 8, b), because with a further reduction in laser power, the material did not penetrate. For the same reason, no experiments were conducted to reduce the laser power for sheets thicker than 3 mm, as reducing the laser power by more than 5% resulted in insufficient penetration during one pass. As an example, Figure 9 shows images of processed surfaces after cutting sheets of 5 mm and 8 mm thickness. During visual inspection, such defects as scale formation and heat-affected zones have been identified, i.e., changes in color—from straw yellow to blue and violet along the cut line. This is particularly critical for stainless steel components since chromium can burn off in the heat-affected zones, thereby reducing corrosion resistance.

IV. CONCLUSIONS

The work performed has yielded comprehensive scientific-practical results in optimizing the modes of laser cutting of corrosion-resistant austenitic steel grade 12X18H10T using the LC MSTD FO3015 equipment. Quantitative relationships between technological parameters and quality characteristics of cuts have been established. Analysis of these relationships allows us to draw the following conclusions:

1. The optimal focus position value is found to be a critical parameter determining the geometry of the cut. For thin sheets (0.8-1.5 mm), the optimum value is -1.0 mm (surface focus), providing minimum surface roughness Ra of 1.7 microns. As the thickness increases, it becomes necessary to shift the focus deeper into the material (-4.5 mm for 5 mm, -6.0 mm for 8 mm) to ensure uniform energy input across the depth of the cut.
2. Non-linear dependencies of the optimal laser emitter power on material thickness have been revealed. For sheet thicknesses up to 2 mm, it is possible to reduce the power down to 2000 W without compromising quality, whereas for 3 mm or greater, even a slight decrease in power (to 3000 W, which represents a drop of only 25%) leads to incomplete cuts and sharp deterioration in edge quality.
3. It has been proven that increasing the speed of the laser head movement up to 7000 mm/min improves processing quality when cutting thin sheets, while for thicker ones (5-8 mm), optimal speeds range from 2000 to 4000 mm/min. Further increase in speed causes dross formation and degradation of surface quality in terms of roughness.
4. The frequency of the laser emitter exerts its most significant influence on thin sheets, where high-frequency mode (5000 Hz) ensures process stability. For thicknesses of 5-8 mm, low frequency (1000 Hz) proves optimal, promoting more effective melting and removal of material.It has been determined that a 4 kW laser emitter configured with air has the following application areas for cutting sheet materials made of 12X18H10T:

thicknesses of 0.8-2.0 mm: high-quality cutting with parameters meeting design documentation requirements;
thicknesses of 3.0-5.0 mm: limited applicability requiring subsequent mechanical treatment;
thicknesses over 5 mm: technologically unfeasible due to unsatisfactory edge quality and geometric accuracy.

For sheet thicknesses ranging from 0.8 to 2.0 mm, the recommended optimal regimes include:

laser emitter power: 4000 W;
laser head travel speed: 7000 mm/min;
frequency: 5000 Hz;
lens focal distance: -1.0...-3.0.

Under these conditions, expected surface roughness values fall within the range of Ra 1.7-3.7 microns. For thicknesses from 3.0 to 5.0 mm, recommendations include:

reducing speed to 2000-4000 mm/min;
shifting the focus to -4.5...-6.0 mm;
using pulsed mode with a frequency of 1000 Hz.

Mandatory subsequent mechanical finishing.Implementation of these recommended regimes enables elimination of manual dross removal operations, shortening of the manufacturing technology cycle, reduction of operator subjectivity, and increased utilization efficiency of the equipment.

ABSTRACT

With the ongoing rise in global energy demand, grid-connected photovoltaic (PV) systems are increasingly recognised as a viable and sustainable energy alternative. These systems primarily operate using one of two distinct topologies: the two-stage (DC-DC-AC) configuration, in which the voltage from solar panels is initially boosted by a DC-DC converter before being converted to AC through an inverter. While functional, this design presents inherent drawbacks, including increased system size, higher costs, and reduced efficiency due to multiple conversion stages. To address these challenges, the single-stage (DC-AC) topology has been developed, directly linking solar panels to the inverter and eliminating the need for a DC-DC converter to enhance overall system efficiency. This study aims to identify the optimal topology for grid-connected PV systems by offering a comprehensive comparative analysis of power loss, system efficiency, and MPPT algorithm performance across these two configurations in a 150 kW grid-connected PV system under varying irradiance conditions. The simulation results underscore the superiority of the single-stage topology, demonstrating its streamlined design, cost-efficiency, and improved energy performance. Consequently, this analysis provides a valuable framework for engineers and researchers in selecting optimised configurations for grid-connected PV systems.

I. INTRODUCTION

Due to the increasing global need for electrical energy, solar photovoltaic (PV) technology is recognised as a cost-effective solution for power generation across various sectors, including residential energy systems, small off-grid applications, and large infrastructure projects [1]. The power output of photovoltaic panels must be controlled, as it depends on external conditions such as temperature and solar irradiation. Maximum Power Point Tracking (MPPT) techniques are used to ensure that PV panels produce the maximum possible power [2]. Incremental Conductance (IncCond) and Perturb and Observe (P&O) are two of the most extensively utilised algorithms for grid-connected systems, owing to their clarity and simplicity of implementation [3]. Grid-connected PV systems use two topologies. The first is a two-stage topology, as shown in Figure 1, which uses a DC-DC converter to boost the photovoltaic voltage and track the maximum power point of the solar panels. In the second stage, a single-phase or three-phase inverter injects the electricity produced by the solar PV system into the grid and ensures its synchronization [4].

The two-stage topology has certain drawbacks, despite its benefits in controller design. Additional stages increase system complexity, which reduces overall system dependability [5]. As the number of circuit stages increases, power losses also increase, lowering the overall efficiency of energy transfer. As shown in Figure 2, a system that relies solely on the inverter is known as a single-stage topology. It is designed to eliminate the drawbacks of the two-stage topology [6].

The primary objective of this paper is a comparative study of system efficiency, power loss, and the performance of Maximum Power Point Tracking (MPPT) methods between single-stage and two-stage topologies for a 150 kW solar photovoltaic (PV) power plant. This study provides valuable insights to support informed decision-making in the design and implementation of grid-connected PV systems. The paper is organised as follows: Section 2 details the design of the solar PV array. Section 3 discusses the modelling of the DC-DC boost converter. Section 4 describes the MPPT methods used in the analysis. In Section 5, the control technique of the grid-connected inverter is explained. Section 6 presents the simulation process and compares the results obtained. Finally, Section 7 concludes the study by summarising the key findings and their implications.

II. PV POWER PLANT MODELING AND SIZING

The PV array represents the entire energy-generating system[7], consisting of multiple modules connected in series or parallel to produce high levels of current, voltage, and power. In this study, the PV system includes 365 solar panels arranged into 73 strings, with each string containing five panels. Table 1 outlines the characteristics of the PV modules under standard test conditions (STC).

Table 1: PV module characteristics.

The Parameter	The Value
Rated maximum power (P_{max})	415 W
Voltage at P_{max}	72.9 V
Current at P_{max}	5.69 A
Open-circuit PV voltage	85.3 V
Short-circuit PV current	6.09 A
The number of cells	128

Source: Authors, (2026).

Figure 3 displays the PV array design with the single-diode model, which is frequently used to study the behavior and performance of PV cells [8]. The I_{PV} can be determined by using the following equation[9]:

$$I_{PV} = I_{ph} - I_0\left[exp^{\frac{V_{pv}+I_{pv}R_s}{\alpha V_t}} - 1\right] - \frac{V_{pv} + I_{pv}R_s}{R_{sh}} \quad (1)$$

In this equation, I_{PV} represents the PV output current, and V_{PV} denotes the PV output voltage. The parameters include R_{sh} the shunt resistance, and R_s, the series resistance. I_{ph} is the current generated by solar irradiation, while V_t refers to the thermal voltage. Additionally, I_0 is the diode saturation current, and α stands for the ideality factor of the junction[3].
Figures 4 and 5 display the characteristics of the photovoltaic power plant under varying solar irradiance levels of 300, 600, 800, and 1000 W/m². These figures illustrate how irradiance affects key performance metrics, including output voltage (V_{PV}), power (P_{PV}), and current (I_{PV}).

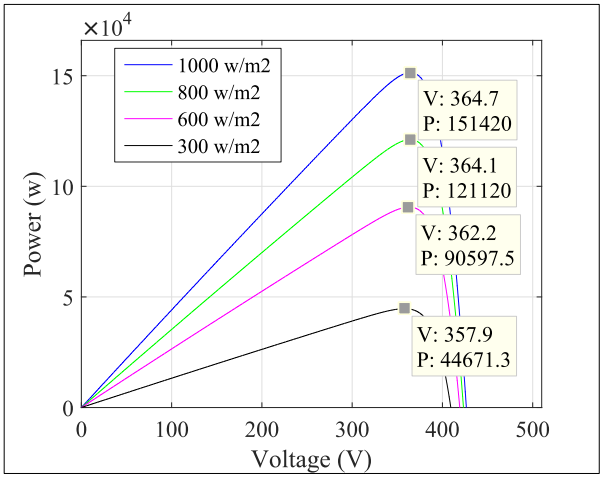

Figure 4: The power-voltage characteristic curve.
Source: Authors, (2026).

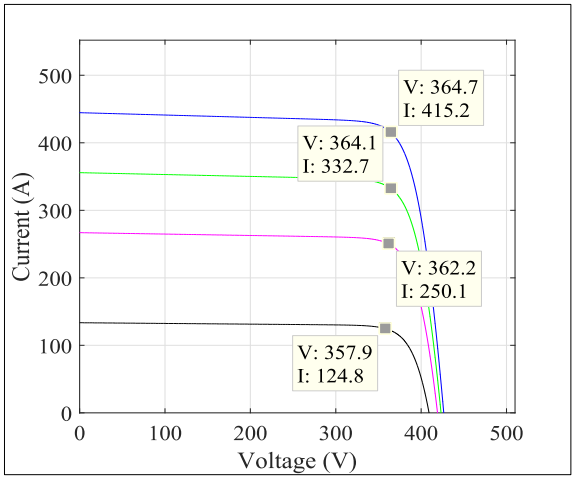

Figure 5: The current-voltage characteristic curve.
Source: Authors, (2026).

At maximum irradiance (1000 W/m²), the PV system achieves a voltage of 364.7 V with a power output of 151.42 kW, and a corresponding current of 415.2 A. As irradiance decreases to 800 W/m², the system voltage remains relatively stable at 364.1 V, but power and current reduce to 121.12 kW and 332.7 A, respectively. At 600 W/m², the voltage is 362.2 V, power output is 90.60 kW, and current is 250.1 A. Lastly, under the lowest irradiance of 300 W/m², the voltage drops slightly to 357.9 V, with power output at 44.67 kW and current at 124.8 A.

III. MODELLING OF THE DC–DC BOOST CONVERTER

The Boost Converter, as shown in Figure 6, consists of key components including an inductor, a power switch (typically a MOSFET or IGBT), a diode, and input/output capacitors for voltage filtering [10]. These components work together to boost the input voltage to a higher output level. In this system, the Maximum Power Point Tracking (MPPT) algorithm dynamically adjusts the converter's duty cycle (D) to continuously track the Maximum Power Point (MPP) of the PV array, optimizing power extraction under varying irradiance conditions [11]. The relationship between the output voltage (V_{out}) and input voltage (V_{pv}) is represented by the following equation [12]:

$$V_{out} = \frac{V_{pv}}{1 - D} \quad (2)$$

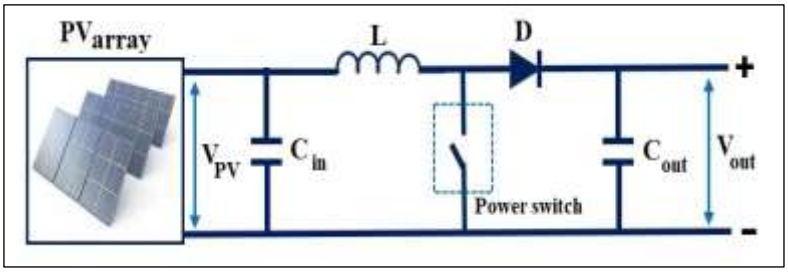

Figure 6: DC-DC boost converter.
Source: Authors, (2026).

To design the boost converter for efficient elimination of current and voltage ripples, the following equations are used [13]:

$$C_{in} = \frac{D}{8 \times f^2 \times L \times 0.1} \tag{3}$$

$$L = \frac{D(1-D)^2 \times R}{2 \times f} \tag{4}$$

$$R = \frac{P_{MPP}}{V_{grid}} \tag{5}$$

IV. INCREMENTAL CONDUCTANCE MPPT ALGORITHM

This algorithm is based on the slope of the PV system's voltage and power curvese is zero at the Maximum Power Point (MPP) [14], allowing the MPP to be tracked by comparing the incremental conductance ($\frac{\Delta I}{\Delta v}$) to the instantaneous conductance ($\frac{I}{v}$), as shown in Equation 6 [15]. This comparison indicates which side of the MPP the PV array is currently operating on[16] . Figure 7 the flowchart of the Incremental Conductance (IncCond) method.

$$\frac{dp}{dv} = \frac{dVI}{dv} = I + V\frac{\Delta I}{\Delta v} \tag{6}$$

$$\frac{\Delta I}{\Delta v} \begin{cases} = \dfrac{-I}{v} \; At\ MPP \\ > \dfrac{-I}{v} \; Left\ of\ MPP \\ < \dfrac{-I}{v} \; Right\ of\ MPP \end{cases} \tag{7}$$

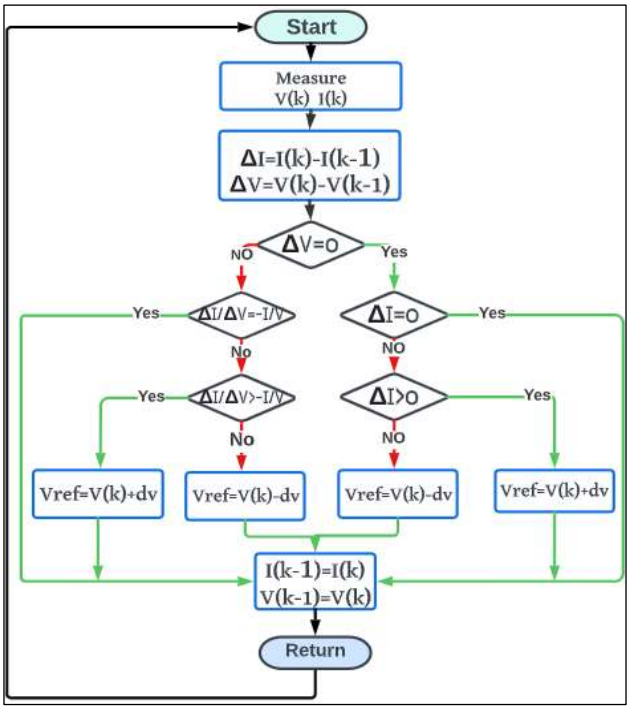

Figure 7: Flow chart of IncCond Method.
Source: Authors, (2026).

V. CONTROL STRATEGY OF PV INVERTER

The control strategy for the PV inverter consists of two main control loops. The first loop employs a proportional-integral (PI) controller to maintain the DC-link voltage at either the nominal reference voltage or the maximum power point (MPP) voltage[17], as determined by the MPPT algorithm in a single-stage configuration. The output of this loop is the reference for the active current. Meanwhile, the reactive current reference is typically set to zero to achieve a power factor close to unity[10].

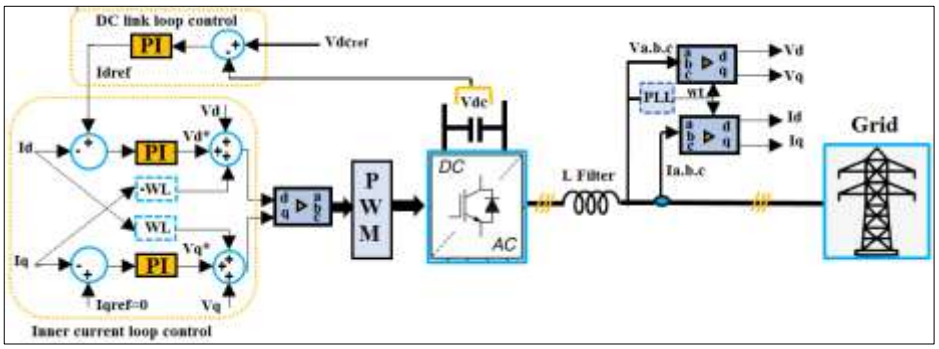

Figure 8: Control structure of the three-phase inverter.
Source: Authors, (2026).

To synchronise the inverter's output with the grid, a phase-locked loop (PLL) is used [18]. The PLL provides the phase angle required for the park transformation, which converts the grid's three-phase instantaneous voltages and currents into the dq reference frame[19]. Within this frame, inner PI controllers generate active and reactive voltage references based on the desired power output[20]. The dq-to-abc transformation then uses these active and reactive voltage references to create a reference voltage, Vabc, which is fed into the PWM generator. This generator produces the switching pulses for the inverter[4]. Figure 8 illustrates the concept of dq-control for a three-phase PV inverter.

VI. SIMULATION RESULTS AND DISCUSSION

In this section, for comparison, the performances of the two topologes. The simulations shown in Figures 9 and 10 are run, and their parameters are listed in Table 2.

Table 1: Simulation parameters.

The Parameter	The Value
U_{grid}	220 V
frequency	50 Hz
L_{Filter} , R_{Filter}	0.09 H 1.1Ω
L_{boost}	3 mH
C_{boost}	1100 µF
C_{DC}	120000 μF

Source: Authors, (2026).

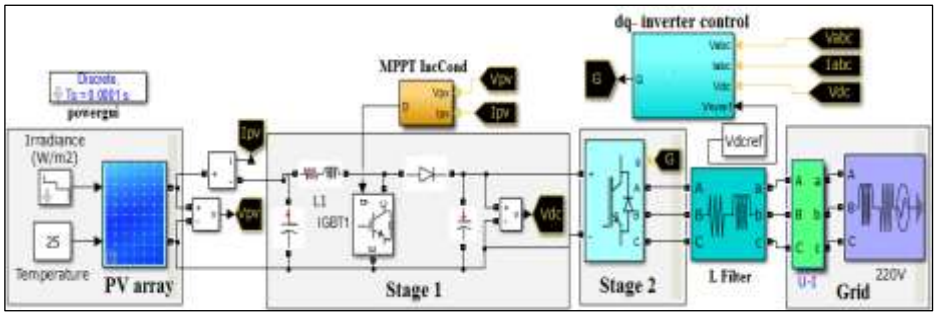

Figure 9: Simulation model of the two-stage topology.

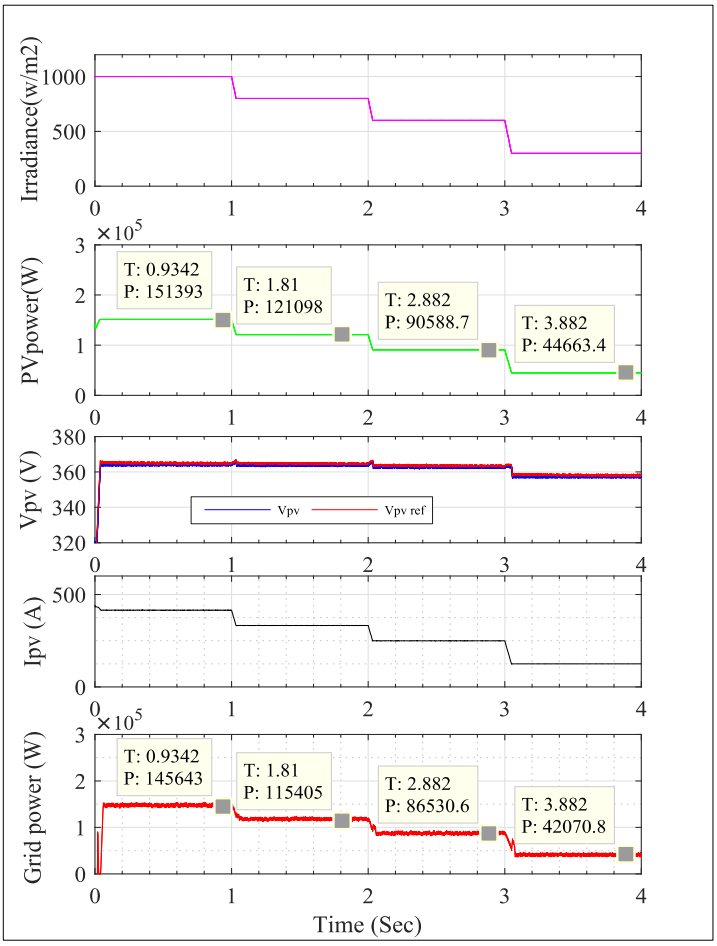

Figure 11 : Single-stage topologies Simulation result.
Source: Authors, (2026).

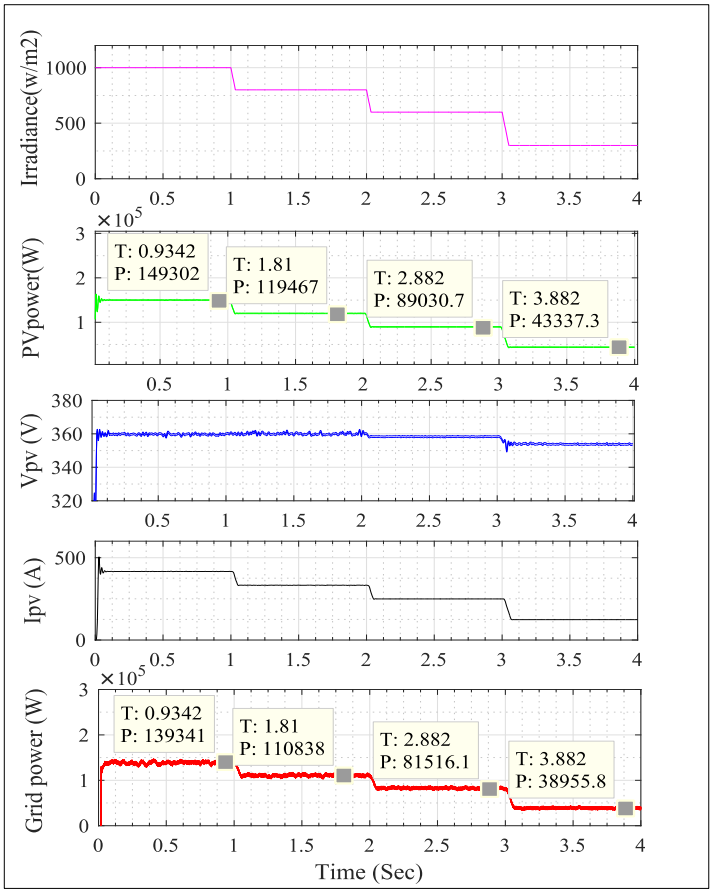

Figure 12: Two-stage topologies Simulation result.
Source: Authors, (2026).

The simulation results presented in Figures 11 and 12 illustrate key performance metrics, including voltage, current, and power output for the PV array, as well as the power injected into the grid for both single-stage and two-stage topologies. At maximum irradiance (1000 W/m²), the PV panels in the single-stage system generated an output power of 151.393 kW, with 145.643 kW successfully injected into the grid. In comparison, the two-stage system's PV panels produced a slightly lower output of 149.302 kW, of which 139.341 kW was injected into the grid due to additional conversion losses. As irradiance decreased, the single-stage topology maintained its efficiency advantage. At 800 W/m², the PV panels in the single-stage system generated 121.098 kW, with 115.405 kW reaching the grid, while the two-stage system produced 119.467 kW and injected 110.838 kW. This trend persisted at 600 W/m², with the single-stage topology producing 90.5887 kW and injecting 86.5306 kW, compared to the two-stage system's output of 89.0307 kW and grid injection of 81.5161 kW. At the lowest irradiance level (300 W/m²), the single-stage system generated 44.6634 kW, injecting 42.0708 kW into the grid, whereas the two-stage system generated 43.3373 kW with only 38.9558 kW reaching the grid.

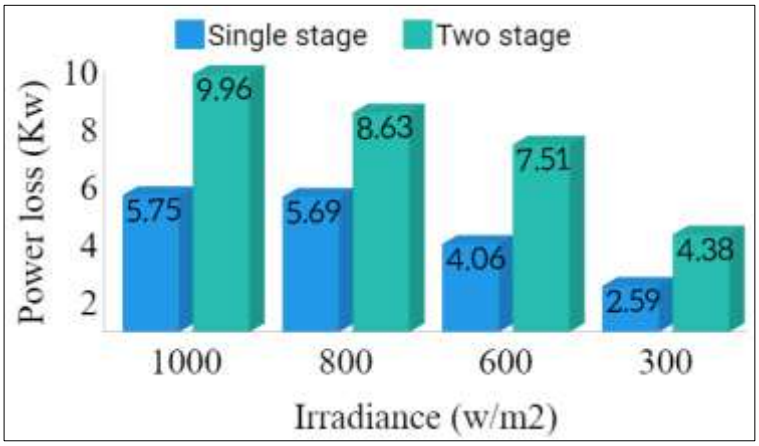

Figure 13: Quantitative Comparison of Single-Stage Two-Stage Power Losses.
Source: Authors, (2026).

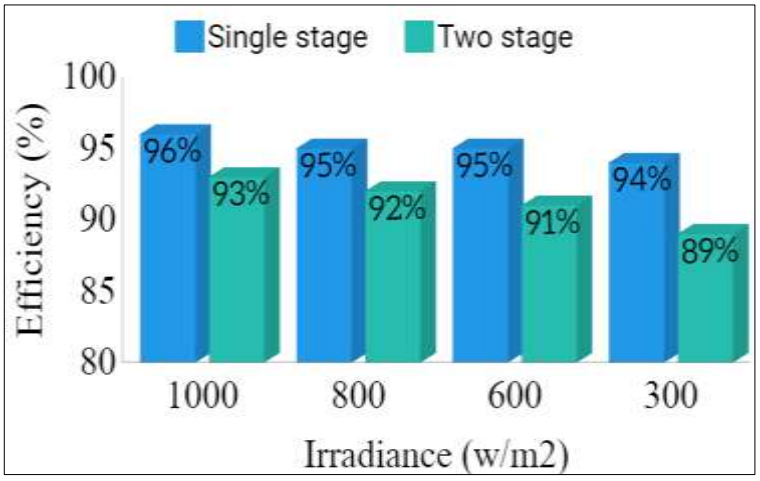

Figure 14: Quantitative Comparison of Efficiency in Single-Stage and Two-Stage Topologie.
Source: Authors, (2026).

The histogram columns in Figures 13 and 14 provide a visual, quantitative comparison between the two topologies, emphasizing the disparity in power losses at various irradiance levels. Power losses in the two-stage system reached 9.96 kW, 8.63 kW, 7.51 kW, and 4.38 kW at irradiance levels of 1000 W/m², 800 W/m², 600 W/m², and 300 W/m², respectively. In comparison, the single-stage topology showed lower losses of 5.75 kW, 5.69 kW, 4.06 kW, and 2.59 kW at the same irradiance levels. This reduction in power loss is attributed to the direct connection between the solar panels and the inverter in the single-stage design, eliminating the DC converter stage losses present in the two-stage system. The histogram effectively highlights these differences, reinforcing the efficiency advantage of the single-stage topology, which recorded efficiencies of 96%, 95%, 95%, and 94% under irradiance levels of 1000 W/m², 800 W/m², 600 W/m², and 300 W/m², respectively, as opposed to the two-stage system's efficiencies of 93%, 92%, 91%, and 89%. These results collectively support the single-stage configuration as a more efficient and economically viable choice for grid-connected PV systems, given its capacity to reduce power losses and enhance energy transfer efficiency.

VI. CONCLUSION

This study offers valuable insights into the optimisation of grid-connected photovoltaic (PV) systems through a comprehensive comparative analysis of single-stage and two-stage topologies within a 150 kW power plant framework. The findings reveal that the single-stage architecture significantly reduces power losses compared to its two-stage counterpart, resulting in enhanced overall efficiency. Furthermore, the Maximum Power Point Tracking (MPPT) algorithm exhibited superior performance in the single-stage configuration, successfully achieving a higher and more accurate maximum power point across varying solar irradiance conditions. This improvement underscores the efficacy of employing an inverter directly for maximum power tracking, as opposed to relying on a DC-

DC converter. Additionally, the single-stage topology presents multiple advantages, such as its compact size and cost-effectiveness, providing essential guidance for engineers and researchers in selecting the most optimal configurations for grid-connected PV systems.

ABSTRACT

This project focuses on the experimental investigation of microstructural and mechanical behavior of sintered stainless steel 316 (SS316) under various processing and compositional conditions. SS316 metal powder with 99% purity and a particle size range of 30–45 microns were utilized in both advanced and conventional sintering techniques. The first phase involved Spark Plasma Sintering (SPS) at 950°C, with a pressure of 40 MPa and a dwell time of 10 minutes, producing dense and compact specimens. In the second phase, the metal powder was sintered using a conventional furnace after cold pressing at 10 kg/cm². Corrosion testing was conducted for 7 days in distilled water, seawater, and sodium hydroxide solutions to study degradation behavior. In the third phase, SS316 powder was reinforced with ceramic and non-metallic additives such as alumina, zirconia, hydroxyapatite, and silicon in different weight ratios (25–30%), followed by sintering in a muffle furnace at 900°C. This research aims to compare the microstructure, corrosion resistance, and mechanical performance of pure and reinforced SS316 under different sintering environments, offering insights into material selection for biomedical, structural, and corrosion resistant applications.

I. INTRODUCTION

Stainless Steel 316 (SS316) is a widely used austenitic stainless steel known for its excellent corrosion resistance, mechanical strength, and biocompatibility. It is extensively applied in marine environments, medical implants, and industrial processing due to its high chromium, nickel, and molybdenum content. In powder metallurgy, sintering of metal powders enables the fabrication of complex shapes and tailored microstructures with reduced waste and energy consumption [1] [2]. Biomedical implants and medical devices have become essential components of modern health care, offering significant improvements in comfort, mobility and overall life expectancy. As medical needs continue to expand, there is a growing demand for materials that can perform safely and reliably inside the human body. The creation of such materials requires careful control over physical, chemical and mechanical characteristics, since each implant must operate under complex biological conditions [3] [4]. Advances in material science directly influence the progress of implant manufacturing, leading to the design of components that are stronger, more compatible with human tissue and capable of long-term performance. The search for improved biomaterials therefore remains a central focus in current research, particularly in the development of metals and composites that combine mechanical strength with biological acceptance [5] [6]. Spark Plasma Sintering (SPS) provides significant processing advantages such as rapid heating and sintering, high densification within a short time, and minimal grain growth, making it highly suitable for fabricating advanced metallic materials [7] [8].

SS316 is an ideal candidate for such processing due to its excellent corrosion resistance, high strength, good ductility, and inherent biocompatibility, which make it suitable for structural and biomedical applications [9] [10]. Furthermore, the incorporation of ceramic and silicon-based reinforcements enhances the performance of SS316 by improving surface hardness, increasing wear resistance, and introducing beneficial bioactivity, particularly when hydroxyapatite is used as a reinforcing phase. These combined advantages make SPS-processed and reinforced SS316 a promising material system for high-performance engineering and biomedical applications [11] [12] [13]. Powder metallurgy is a manufacturing route in which metallic powders are compacted and subsequently consolidated through controlled heating to form dense, functional components. During the sintering stage, atoms migrate across particle boundaries, promoting strong interparticle bonding, reducing voids, and improving overall mechanical integrity [14]. Owing to its capability to achieve intricate geometries and customized material characteristics, this approach has become an essential method for producing high-performance parts across various engineering sectors [15].

SS316 is valued for its excellent durability, corrosion tolerance and compatibility with biological environments. Its alloying elements, namely chromium, nickel and molybdenum, provide strong resistance to localized corrosion, particularly pitting and crevice attack in chloride rich conditions such as seawater. These characteristics make SS316 a preferred material for demanding structural and biomedical applications [16] [17]. SS316 finds widespread use in marine, chemical and biomedical environments due to its reliable performance in corrosive conditions. The material can be effectively consolidated through powder metallurgy routes, and it responds well to the addition of reinforcing phases, making it a versatile option for developing advanced composite structures [18] [19].

Spark Plasma Sintering is an advanced consolidation method in which a pulsed direct current is applied together with external pressure to compact powders quickly and efficiently. The process is known for achieving very high density within a short duration, supported by extremely fast heating rates, lower required sintering temperatures and minimal grain coarsening. These features make SPS an effective technique for producing refined and high-performance materials [20].

Previous investigations show that the use of Spark Plasma Sintering can lead to stainless steel components with finer microstructural features and enhanced mechanical properties when compared to materials produced through conventional sintering routes. This improvement is attributed to the rapid and controlled consolidation conditions provided by the SPS process [8]. Conventional sintering is carried out by heating pressed metal powders in a furnace for a prolonged duration so that atomic diffusion can occur and the particles can join together. This approach often results in enlarged grains and may not always achieve full densification, particularly when very fine powders are used. In the case of SS316, reported processing temperatures typically fall between 900°C and 1200°C, and the resulting microstructure as well as the final properties are strongly influenced by both the selected temperature and the time for which the material is held at that temperature [2]. Microstructural features in sintered materials can be examined using Scanning Electron Microscopy, which offers detailed surface imaging at very high resolution. When combined with Energy Dispersive X Ray Spectroscopy, this technique also allows the identification of the elements present in different regions of the sample.

Together, these analytical tools make it possible to observe phases, detect pores and study the distribution of constituent elements, providing valuable insight into the quality of sintering and the uniformity of composite materials [21]. Sintered SS316 exhibits mechanical characteristics such as hardness, strength and ductility, all of which depend on factors like residual porosity, grain refinement and the conditions used during consolidation. Its resistance to corrosion in chloride rich and alkaline media is one of its major advantages, although material degradation can still occur when localized attack begins or when the protective surface film loses stability. These behaviors are important for evaluating the performance of SS316 in demanding service environments [22]. Improvements in consolidation conditions along with the addition of suitable reinforcing phases can lead to noticeable gains in the mechanical and corrosion related performance of the material [23]. The addition of ceramic phases to stainless steel, including materials such as alumina, zirconia and hydroxyapatite, is known to enhance properties like hardness, resistance to wear and stability at elevated temperatures. Hydroxyapatite also provides bioactive characteristics, which makes it attractive for medical related uses.

Reports in the literature indicate that incorporating ceramic content in the range of twenty to thirty percent can improve overall performance while still retaining the corrosion resistant nature of the steel matrix [24]. Silicon can act as an additional reinforcing phase because it offers high hardness and effective heat conducting ability. Its inclusion in the metal matrix contributes to improved strength and supports better overall structural performance [25]. This study explores the sintering behavior and performance of SS316 using both advanced and conventional approaches. While traditional furnace sintering is cost-effective, SPS offers rapid densification and improved control over grain structure due to its high heating rate and applied pressure. Additionally, combining SS316 with ceramic materials such as alumina, zirconia, hydroxyapatite, and silicon may enhance its hardness, corrosion resistance, and applicability in biomedical and high-temperature environments [26]. The outcomes of this work have relevance across several industrial sectors. In the biomedical field, SS316 composites reinforced with hydroxyapatite offer potential for bone implant and orthopaedic applications due to their biocompatibility and enhanced performance.

In marine environments, the excellent corrosion resistance of SS316 makes it suitable for underwater and offshore components. Aerospace and defense applications can benefit from high-strength, wear-resistant sintered composites that contribute to lightweight structural designs. Within the energy and nuclear sectors, SS316 is already widely deployed for reactor components, and improved composite versions can further enhance resistance to stress, wear, and corrosion under demanding service conditions.

The primary objective of this study is to fabricate SS316 sintered pellets using both SPS and conventional sintering techniques and to investigate how variations in particle size and sintering parameters influence the resulting density, microstructure, and mechanical properties of SS316. The work further aims to analyze the effects of ceramic and silicon-based reinforcements on the characteristics of the sintered composites. Additionally, corrosion behaviour is evaluated by subjecting the sintered SS316 specimens to different environments, including water, seawater, and NaOH. Comprehensive microstructural characterization is carried out using Scanning Electron Microscopy (SEM) coupled with Energy Dispersive X-ray Spectroscopy (EDX), and the hardness of both pure and reinforced SS316 samples is assessed to understand their performance enhancement.

II. MATERIALS AND METHODS

The primary raw material used in this work was SS 316 powder, selected for its corrosion resistance and suitability for consolidation through powder metallurgy routes. Table 1 shows the powder specifications used in the research work. The metal powder served as the main matrix for all specimens. To prepare composite variants, several reinforcing substances were incorporated. Alumina was employed for its high hardness and chemical stability. Zirconia was selected due to its toughness and compatibility with the steel matrix. Hydroxyapatite, which contains calcium and phosphate groups, was included to introduce bioactive characteristics that are valuable for biomedical applications. Silicon powder was added as an additional strengthening phase because of its hardness and ability to assist in heat transfer during processing. Ethanol was used during the mixing stage to assist in uniform blending of the powders and to act as a temporary binder. All powders were stored in sealed containers prior to use to prevent moisture absorption and contamination.

Table 1: Powder specifications.

Property	**Value**
Purity	99%
Particle size	30-45 microns
Gross weight	270 grams
Net weight	250 grams
Density	8.0 g/cm^3
Melting point	1400-1450°C

The preparation of the sintered samples followed a systematic sequence beginning with the weighing of the required quantities of SS 316 powder and the selected reinforcement materials. Table 2 represents the parameters used in the SPS study. Each powder mixture was prepared according to the intended composition, ensuring that the chosen percentages of alumina, zirconia, hydroxyapatite and silicon were accurately maintained. Ethanol was added in small amounts to aid in achieving a uniform distribution of the reinforcing particles throughout the steel matrix.

Table 2: SPS parameters used in this study.

.**Parameters**		**Value**
Sintering temperature		950°C
Applied pressure		40 MPa
Heating rate		100°C/min
Holding time		10 min

The powders were blended using a ball mill operated at controlled speed to prevent excessive heat generation or unwanted structural changes in the powder particles. The fig. 1 shows the powders used in this study. The milling process continued until a visually homogeneous mixture was obtained. The blended powders were then dried at moderate temperature to remove traces of ethanol before compaction.

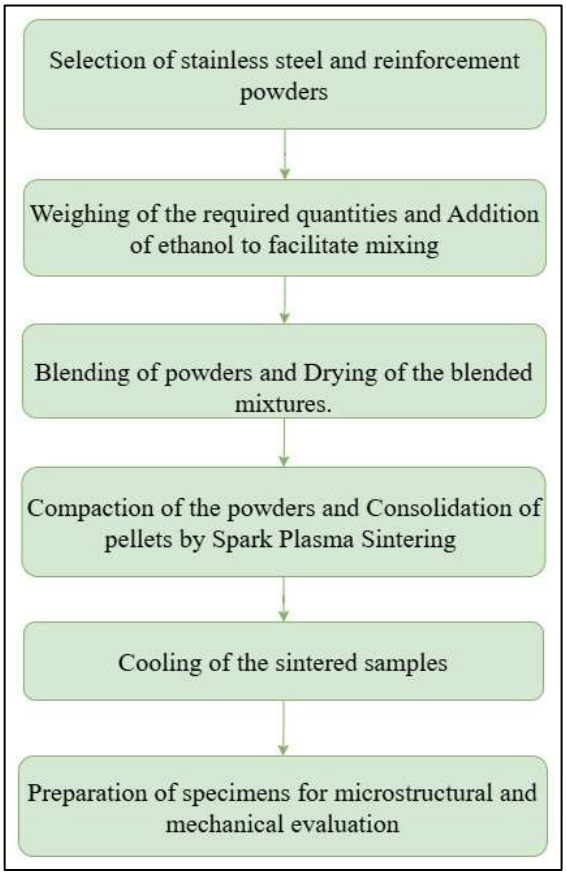
For pellet formation, the dried powder mixtures were placed into a steel die and compacted using a hydraulic press. A constant load was applied to produce green pellets with adequate strength for handling. These compacted samples were then subjected to thermal consolidation. A portion of the specimens was processed using SPS, where current assisted heating and pressure were applied simultaneously [26]. Another portion was consolidated by the traditional furnace sintering route, where pellets were placed in a controlled atmosphere furnace and heated at the target temperature for the selected holding time. After cooling, the samples were removed, labelled and stored for testing. Figure 2 shows the flowchart of the research work.



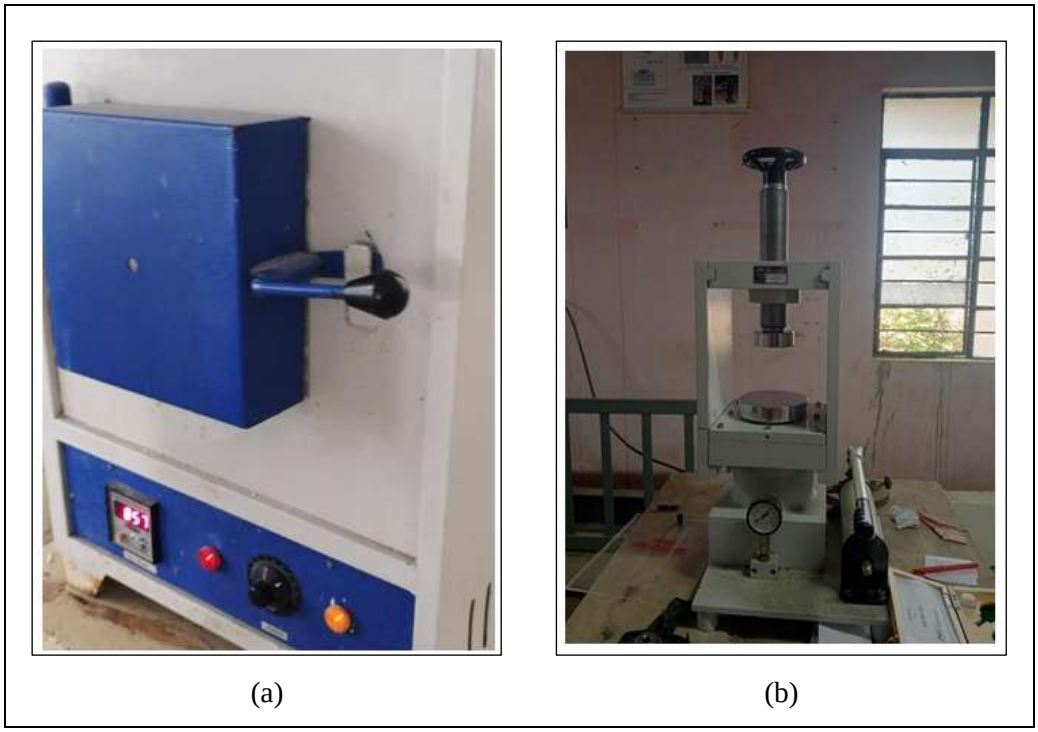


Figure 2: Flowchart of the work.

A Spark Plasma Sintering system manufactured by Fuji was employed for the rapid consolidation of the prepared powders. This equipment is capable of reaching temperatures well above 1000°C and can apply pressures to 40 MPa [8]. Figure 3 represents the SPS image used for this study. The system allows the simultaneous application of electrical current and mechanical load, enabling fast heating and effective densification of the compacted samples.

Figure 3: SPS Instrument.

A muffle furnace was used for the conventional sintering route. Figure 4 (a), (b) represents the muffle furnace and manual pellet press used in this study. This furnace provided controlled and uniform heating for extended durations, allowing pellets to be consolidated through traditional thermal treatment. The heating chamber offered stable temperature distribution, which is essential for consistent microstructural development.

(a) (b)

Figure 4: (a) Muffle furnace and (b) Pallet press.

The preparation of the pellet using SPS began with the measurement of 10g of SS 316 powder. The selected quantity was placed in a clean container and transferred into the die set that belongs to the Fuji Spark Plasma Sintering system. Figurer 5 shows the pellet made from the sintering. The sintering operation was carried out under controlled settings. These conditions were selected to promote rapid consolidation while preventing unnecessary grain growth. After the heating cycle, the pellet was allowed to cool inside the chamber. The final compact had a diameter of approximately 10 mm and a thickness of 4 mm. Once the pellet was released from the die, it was weighed, and any unutilized powder was collected for reuse.

(a) (b)

Figure 5: (a) Pallet with die and (b) Pallet.
Source: Authors (2026).

The surface of the sintered pellet was prepared to make it suitable for microstructural evaluation. A series of abrasive papers was used in sequence beginning with grade 0/3, followed by 0/2, 0/1 and finally E 120. This progression helped in removing surface irregularities and oxidation products. After the sanding stage, the specimen was transferred to a double disc polishing unit. Alumina paste was applied to the rotating surface of the polishing machine, and the pellet was gently pressed against the disc until a smooth and reflective finish was obtained. The polished specimen was rinsed thoroughly with clean water to remove any remaining abrasive particles. The resulting surface exhibited a bright mirror like appearance, which ensured clear microscopic imaging. The polished pellet produced through SPS was forwarded for microstructural and elemental examination. The SEM was used to observe pore distribution, grain boundaries and the overall surface features of the material. The same instrument was equipped with an energy dispersive X ray unit which enabled the identification of the elements present in the examined regions. This allowed verification of the chemical uniformity of the SS 316 sample. A separate set of pellets was prepared using the traditional route.

One gram of SS powder was placed inside a steel die and compressed using a manually operated press. A load of 10 g/cm2 was applied for 30 seconds to form compact samples. Three pellets were produced in this manner. Each compact had an average thickness of 3 mm and a diameter of 10 mm. The green pellets were placed inside a muffle furnace and heated to 900°C for 10 minutes. Once the heating cycle was completed, the furnace was switched off and allowed to cool naturally for 12 hours. This slow cooling reduced thermal stress in the samples. Three individual pellets were immersed in different media to evaluate their corrosion behaviour. One beaker contained distilled water, the second contained seawater, and the third contained a mixture prepared by dissolving 1.3g of sodium hydroxide in 30 mm of water. The pellets remained in these media for 8 days. Their mass and visible surface condition were recorded before and after the exposure period. Three composite formulations were prepared shown in Table 3.

Table 3: Composite sample details.

Mixture No.	Sample composition	Time Held
Mixture 1	75% SS316 + 25%	60 seconds
Mixture 2	70% SS316 + 30%	120 seconds
Mixture 3	70% SS316 + 30%	120 seconds

Source: Authors (2026).

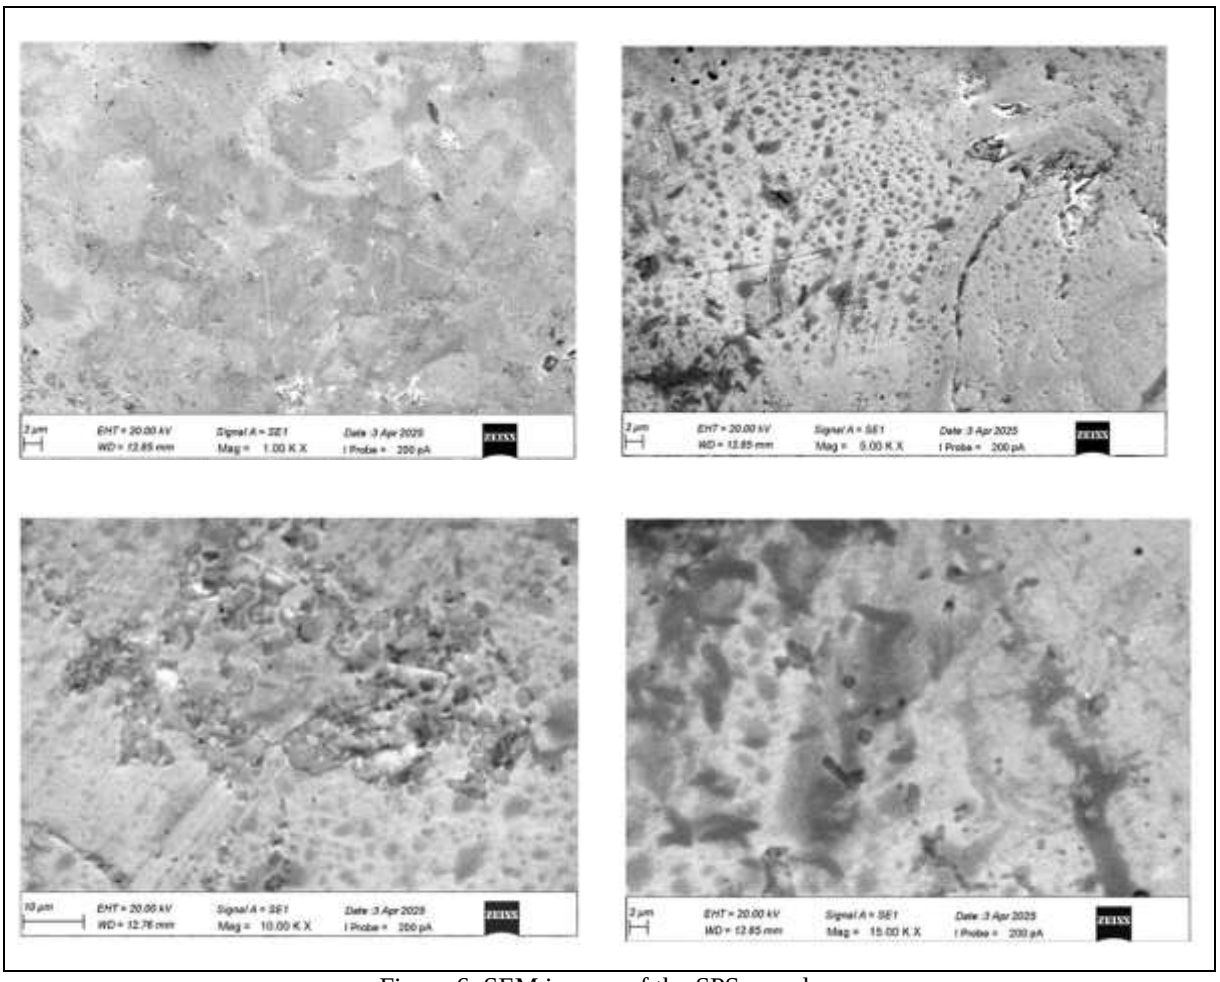
Ethanol was added during mixing to help distribute the additives uniformly. The powders were blended manually in a grinding bowl until a consistent mixture was obtained. The prepared mixtures were pressed into pellets using the manual press. A load of 15 kg/cm2 was maintained for each pellet. The holding time was 60 seconds for the mixtures with ceramic additives and 120 seconds for the mixture that contained silicon. This ensured adequate green strength for handling [27]. All composite pellets were heated in the muffle furnace at 900°C for 15 minutes. They were then allowed to cool slowly inside the furnace for 12 hours. This natural cooling prevented cracking and maintained structural stability [20]. After processing, all composite pellets were submitted for hardness measurement. The cold compaction of powder mixtures was carried out using a manually operated pallet press. This press generated the required load to form green pellets with sufficient strength for further processing. The die set used in the press ensured that all samples were produced with identical size and shape. Surface preparation of the sintered specimens was performed using a double disc polishing machine.

This device enabled the removal of surface irregularities and produced a smooth finish suitable for microstructural examination. A series of abrasive papers was used during this process, including grades ranging from coarse to fine such as 0/3, 0/2, 0/1 and E 120. Each grade allowed gradual refinement of the sample surface before final polishing. Microstructural analysis was carried out using a scanning electron microscope equipped with an energy dispersive X ray system. The microscope provided high resolution imaging to observe features such as grain structure, pore distribution and reinforcement dispersion. The attached energy dispersive system enabled elemental analysis of selected regions, helping to confirm the presence and distribution of ceramic and silicon-based phases in the composite samples. Mechanical characterization was performed using a hardness testing machine. This instrument applied a controlled load to the polished specimen surface and measured the resulting indentation, providing an indication of the resistance of the material to localized deformation. Hardness values were used to compare pure SS pellets with those containing reinforcing phases.

III. RESULTS AND DISCUSSION

The SS 316 powder that was processed through the SPS route produced a compact pellet with clear evidence of effective consolidation. The rapid heating combined with the applied pressure resulted in strong bonding among the particles, and the final compact retained its shape without visible cracks or structural distortion. The compact had a diameter of 10 mm and a thickness of 4 mm after sintering. The recorded mass of 2.532g after the heating cycle indicated that the loss of material during the process was very small. The sintering temperature was maintained at 950°C, with an applied pressure of 40 MPa and a holding duration of 10 minutes.
These measured values point to a high degree of densification. Fig 6 represents the SEM image of the samples. The consistency in dimensions before and after processing suggests that the applied pressure and controlled temperature cycle enabled the SS 316 particles to rearrange and bond efficiently. The absence of significant mass reduction further confirms that the consolidation took place without major oxidation, evaporation or powder ejection.

Such results illustrate the capability of the SPS method to produce dense metallic pellets in a relatively short processing time when compared with conventional thermal treatments [28]. The overall outcome demonstrates that the selected sintering conditions were suitable for stainless steel grade, producing a compact with adequate density and structural stability. This provides the basis for further characterization such as microstructural analysis and hardness evaluation. The surface of the Spark Plasma Sintered SS 316 pellet was examined using SEM. The micrograph displayed a compact structure in which the particles had fused effectively, resulting in a surface with very little visible porosity. The arrangement of grains appeared consistent across the observed area, and the boundaries between adjacent grains were clearly identifiable [29]. The limited enlargement of these grains is expected, as the SPS technique employs rapid heating and a short exposure time at the peak temperature. This prevents excessive diffusion and restricts the growth of the individual grains. The surface did not show noticeable cracks, voids or defects, indicating that the consolidation process produced a stable and well bonded structure [30].



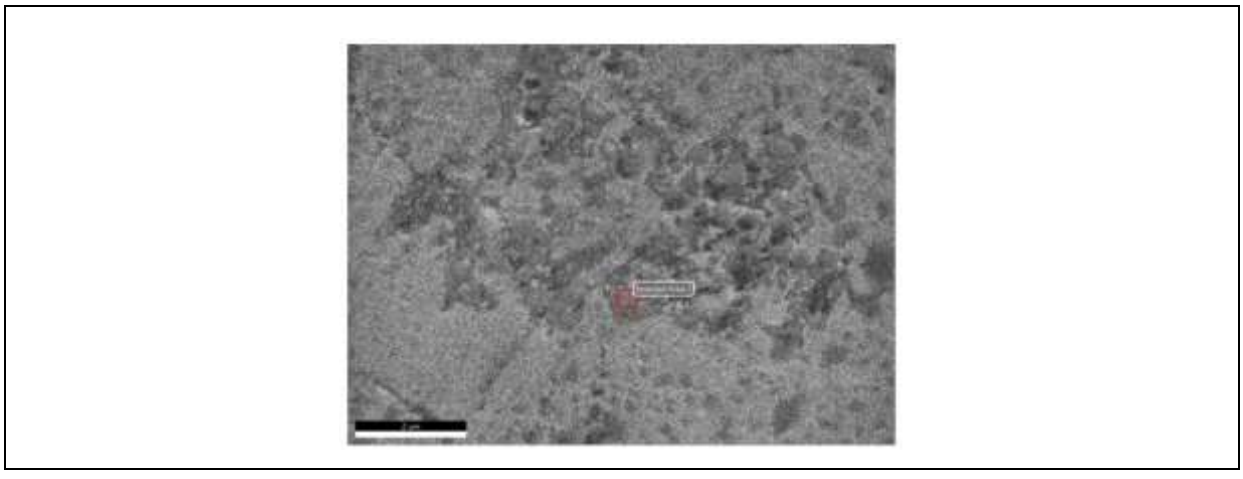


Figure 6: SEM images of the SPS samples.
Source: Authors (2026).

The microstructural features revealed through the microscopy confirm the advantages often associated with the SPS process. The presence of fine grains and the absence of large pores suggest that the material experienced efficient densification while avoiding the high degree of diffusion that typically occurs during long furnace treatments. The controlled grain size and dense structure are expected to have a positive influence on the mechanical performance of the pellet, particularly its hardness and resistance to surface deformation. Furthermore, the refined surface features and minimal oxidation indicate that the material will likely maintain favourable corrosion behaviour when exposed to aggressive environments [31]. Overall, the observed microstructure supports the conclusion that the chosen processing conditions were effective for producing a well consolidated SS sample.

Energy dispersive X ray examination was carried out at two selected regions of the Spark Plasma Sintered pellet. Figure 7 and 8 represents the EDX area 1 and 2 with the elemental mapping. The spectra from both regions presented clear and well resolved peaks corresponding to the elements that are normally present in stainless steel grade three hundred and sixteen. In the first region, elements such as carbon, oxygen, aluminium, silicon and titanium were detected in addition to the major constituents chromium, manganese, iron and nickel [1]. The presence of oxygen is attributed to slight surface oxidation during polishing, which is commonly observed in stainless steels when exposed to air. The second region displayed a composition dominated by chromium and iron, with smaller contributions from carbon and manganese.

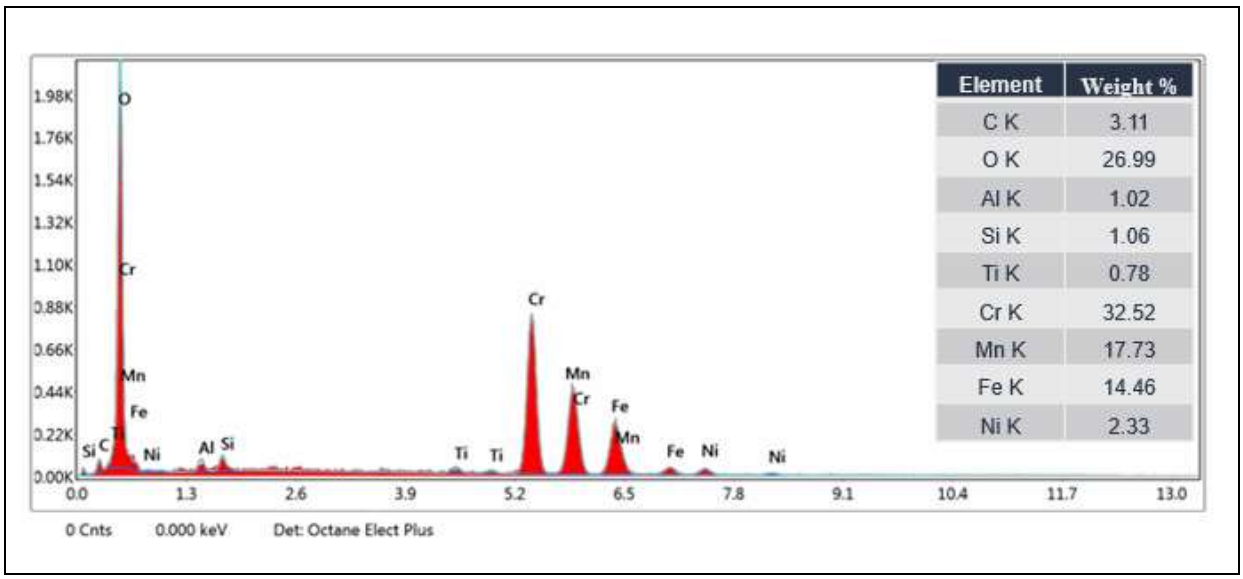

Figure 7: EDX area 1.
Source: Authors (2026).

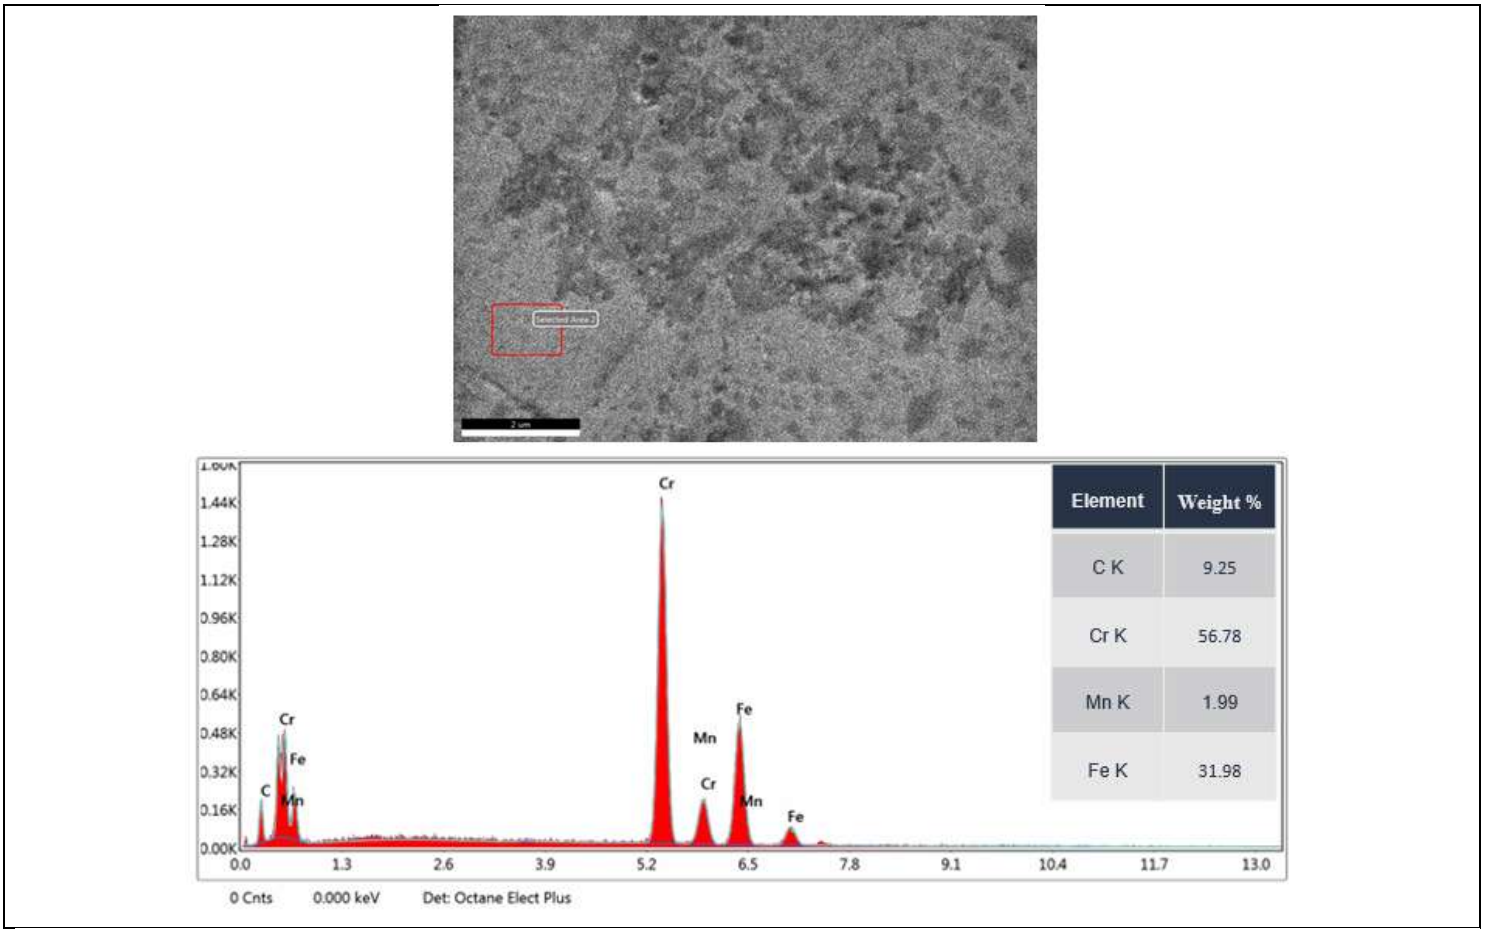

Figure 8: EDX area 2.
Source: Authors (2026).

The elemental concentrations observed in both regions fall within the expected range for stainless steel grade three hundred and sixteen. The detection of chromium, manganese, iron and nickel in appropriate proportions confirms that the alloy composition remained stable throughout the sintering process. The occasional presence of aluminum, silicon and titanium in the first region is attributed to minor traces left during surface preparation and does not indicate contamination of the bulk material [2]. The consistency in the distribution of the primary alloying elements across the examined regions demonstrates that the SPS method facilitated proper mixing and retention of the chemical composition. The process conditions prevented oxidation of the internal structure and avoided any loss of metallic constituents. The uniform chemical profile also supports the microstructural observations, showing that the rapid heating and controlled atmosphere of the sintering technique help maintain the integrity of the stainless steel powder during consolidation [7]. The combined results from both microstructural and elemental evaluation confirm that the sintered pellet preserved its intended composition.

No foreign substances or undesirable phases were detected, showing that the preparation and processing steps were performed without introducing impurities. The even distribution of chromium and iron, in particular, indicates that the corrosion resistant nature of the alloy is expected to be maintained in the final compact. These findings reinforce the reliability of the SPS route for producing dense SS 316 samples with stable chemical characteristics. Three pellets were produced through cold pressing followed by furnace sintering. All samples had a diameter of 10 mm and a thickness of 3 mm after compaction. Their appearance after the thermal cycle revealed slight variations that reflect the influence of traditional sintering conditions [23]. The first pellet maintained a stable shape and displayed a faint brown surface tint. This colour change is commonly associated with mild surface oxidation that forms during heating in a muffle furnace. The second pellet showed a very small reduction in size, suggesting a moderate level of shrinkage due to particle rearrangement and bonding during the heating stage. The third pellet exhibited a slightly uneven surface, indicating that the particle fusion was not completely uniform. Such surface roughness is typical when fine SS 316 powders are sintered without applied pressure [32].

The long cooling period of nearly 12 hours inside the furnace allowed the samples to return to room temperature gradually. This slow cooling helped reduce thermal stresses and promoted steady phase development within the material. It also prevented cracking, which is sometimes observed when metallic pellets are cooled abruptly. The visual and dimensional characteristics of the pellets confirm the expected behaviour of SS 316 during conventional furnace sintering. Compared with the Spark Plasma Sintered pellet, these samples show evidence of lower densification, as indicated by minor shrinkage and surface irregularities [33]. The appearance of oxidation on the surface also aligns with the furnace atmosphere, which does not offer the same level of control as vacuum based sintering processes. Overall, the results demonstrate that while conventional sintering can produce reasonably compact pellets, the degree of densification and surface quality is influenced strongly by furnace atmosphere, heating duration and absence of external pressure. These observations highlight the contrast between rapid current assisted consolidation and traditional thermal processing.

III.1 CORROSION BEHAVIOUR

The pellets produced through the conventional sintering route were immersed in three different media to examine their corrosion behaviour. The weights recorded before and after the 8-day exposure period is listed in Table 4. All samples showed a measurable reduction in mass, although the extent of loss differed depending on the environment.

Table 4: variation of weights.

Environment	Initial weight (g)	Final weight (g)	Change (g)	Remarks
Distilled Water	58.598	52.246	6.352	Minor expected
Sea Water	62.278	56.455	5.823	Possible pitting
NaOH Solution	65.911	61.181	4.73	Alkaline corrosion

Source: Authors (2026).

The pellet placed in distilled water lost 6.352 grams during the test. Distilled water contains no dissolved salts or aggressive ions, so the weight loss is attributed mainly to mild surface reactions and the removal of loosely bonded oxides. The pellet exposed to seawater lost 5.823 grams. Although the total mass loss is slightly lower compared with distilled water, the surface of this pellet is expected to show signs of localized attack caused by chloride ions. The sample immersed in the sodium hydroxide solution lost 4.73 grams. The alkaline nature of the medium often leads to the formation of surface films that can either protect or deteriorate depending on the material [34]. The reduction in mass in this case indicates that the film was unable to fully prevent the reaction between the pellet and the solution. The general trend observed in the weight measurements aligns with the expected behaviour of SS 316. The sample in distilled water experienced only mild degradation, confirming that SS 316 is largely stable in neutral environments. The seawater sample was subjected to chloride ions, which are known to disrupt the passive oxide layer that protects stainless steel.

This can lead to localized pits even if overall mass loss appears moderate [35]. The presence of such ions makes seawater a more aggressive medium despite the slightly lower numerical weight change [20] [36] . The specimen in the sodium hydroxide solution reacted with the alkaline medium. Although SS 316 shows some resistance in alkaline solutions, prolonged contact can still weaken the passive film and produce surface dullness or localized thinning. The mass loss recorded for this pellet indicates that the reaction rate was not negligible. These findings demonstrate that the corrosion resistance of the conventionally sintered pellets varies significantly with the nature of the environment. Neutral water causes minimal damage, seawater introduces the possibility of pitting through chloride action and the sodium hydroxide solution encourages surface layer disruption. The results also highlight the influence of sintering method on corrosion performance, since pellets produced without external pressure and rapid heating tend to contain surface irregularities that can further accelerate attack.

III.2 COMPOSITE SAMPLES OF REINFORCED STAINLESS STEEL

Three composite pellets were produced by introducing different reinforcing phases into stainless steel. The first composite, labelled C1, contained 75 % SS and 25 % of a combined mixture of alumina, zirconia and hydroxyapatite. This sample developed a uniform surface after sintering and showed no visible cracking. The second composite, labelled C2, contained 70 % SS and 30 % SS of the same ceramic mixture. This pellet also displayed a smooth surface but showed signs of increased rigidity due to the higher ceramic content. The third composite, labelled C3, was prepared with 70 % SS and 30 % silicon powder as shown in Table 5. This sample appeared dense but revealed a slightly brittle character after sintering, which is consistent with the presence of silicon rich phases that tend to limit ductility [27] [37] [38].

Table 5: Composite weight percentage with sintered temperature.

Sample ID	Composition	Sintered Temp	Time	Pressure	Remarks
C1	SS316 (75%) + Al_2O_3, ZrO_2, HA (25%)	900°C	15 min	15 kg/cm²	Clean surface
C2	SS316 (70%) + Al_2O_3, ZrO_2, HA (30%)	900°C	15 min	15 kg/cm²	Slightly brittle
C3	SS316 (70%) + Silicon (30%)	900°C	15 min	15 kg/cm²	Dense and hard sample

Source: Authors (2026).

The applied load for all compactions was fifteen kilogram per square centimeter, ensuring that the green pellets had enough strength to withstand handling and the subsequent thermal treatment. Hardness values were obtained for each of the composite pellets to evaluate the effect of reinforcement on mechanical strength. The data are summarized in Table 6.

Table 6: Hardness results.

Sample ID	Composition	Hardness (HV)	Remarks
C1	SS316 (75%) + Al_2O_3, ZrO_2, HA (25%)	539.3	Moderate hardness
C2	SS316 (70%) + Al_2O_3, ZrO_2, HA (30%)	380.3	Higher ceramic effect
C3	SS316 (70%) + Silicon (30%)	281.5	Possibly highest

Source: Authors (2026).

The pellet with 25% ceramic reinforcement, C1, recorded a hardness of 539.3 HV. This value indicates that the addition of the ceramic blend contributed significantly to resistance against localized deformation. The second pellet, C2, which contained a higher proportion of ceramic reinforcement, showed a hardness of 380.3 HV. Although still higher than unreinforced stainless steel, the reduction compared with C1 suggests that an excessive number of ceramic particles may have influenced the bonding between the steel matrix and the reinforcement, leading to reduced compactness [36] [39]. The third sample, C3, which contained silicon as the reinforcing phase, recorded a hardness of 281.5 HV. This lower value reflects the influence of silicon, which, although beneficial for strength improvements in some alloys, can form brittle phases during sintering that do not contribute positively to indentation resistance. The slightly brittle nature observed in C3 further supports this behaviour.

The comparison of the hardness values shows that the ceramic mixture of alumina, zirconia and hydroxyapatite was more effective in improving the mechanical resistance of the SS matrix compared with silicon. The moderate hardness obtained for C1 suggests an optimal balance between ceramic content and matrix consolidation, whereas the decreased hardness in C2 indicates that increasing ceramic content beyond a certain level may introduce porosity or reduce the bonding efficiency [40]. The silicon reinforced pellet exhibited the lowest hardness among the composites, implying that the structure formed during sintering may not support strong load transfer between the matrix and the reinforcing particles [41]. These results emphasize the importance of reinforcement type and composition in determining the final mechanical properties of powder consolidated materials [34].

IV. DISCUSSION

The results obtained from the Spark Plasma Sintered sample demonstrate the effectiveness of this consolidation technique in producing dense metallic pellets with refined microstructural features. The compact exhibited a smooth surface, limited porosity and clearly defined grain boundaries. Such features indicate efficient bonding between the SS 316 particles and suggest that the material would display strong mechanical behaviour, particularly in hardness and resistance to surface deformation [28]. The controlled thermal cycle of the SPS process appears to have played a major role in achieving these favourable characteristics. In contrast, the pellets prepared through the conventional furnace route displayed small variations in appearance and surface quality. Slight shrinkage, mild oxidation and uneven surface regions were observed.These outcomes are consistent with the nature of furnace sintering, where slower heating rates and the absence of applied pressure limit the extent of densification.

Even so, the pellets retained sufficient structural integrity to proceed with corrosion and mechanical evaluation. Their behaviour under different chemical environments provides valuable insight into the performance of SS 316 when processed using a more traditional approach. The composite samples developed with ceramic and silicon reinforcements displayed noticeably different hardness values, confirming that the type and amount of the reinforcing phase strongly influence the final mechanical response. The combination of alumina, zirconia and hydroxyapatite contributed to higher hardness compared with the silicon-based composite, demonstrating the effectiveness of ceramic additions in improving load bearing capability. The slight brittleness observed in the silicon reinforced material suggests that the formed structure may not support strong stress transfer within the matrix.

The corrosion test results further highlight the importance of processing technique and reinforcement content in determining the chemical stability of the pellets. Differences in mass loss among the samples immersed in distilled water, seawater and sodium hydroxide solutions show that the method of sintering influences surface quality and passive layer formation. The interaction of reinforcement phases with aggressive media will also help identify which composite formulation offers the most favourable balance between mechanical strength and environmental resistance. Taken together, the findings show that SPS provides superior densification and microstructural refinement, ceramic reinforcements enhance hardness and environmental exposure reveals the durability of the produced materials. These observations create a clear connection between processing conditions, microstructure and final performance.

V. CONCLUSIONS

The investigation shows that stainless steel 316 processed through powder metallurgy responds strongly to the choice of sintering technique and reinforcement strategy.

The SPS route delivered the most favourable outcome, producing a compact with very high density, smooth surface finish and a fine microstructure with minimal porosity. Elemental analysis confirmed that the chemical composition remained stable, indicating that the rapid current assisted heating preserved alloy integrity. These results position the SPS method as the most effective route in this study. The furnace sintered samples displayed moderate bonding and predictable mass loss during corrosion testing. Among the exposure conditions, seawater produced the most pronounced degradation due to chloride activity, while distilled water showed minimal effect. The alkaline solution caused surface film changes but lower mass loss compared with the salt environment.

The reinforced composites demonstrated clear variations in hardness. The mixture containing twenty five percent ceramic reinforcement produced the highest hardness value, indicating improved resistance to deformation. The silicon-based composite displayed lower hardness and a slightly brittle character, showing that reinforcement type has a significant impact on mechanical response. Future work should extend the mechanical evaluation to tensile and compression behaviour, explore thermal and electrical properties and optimize sintering conditions for even greater densification. Additional characterization through X ray diffraction, transmission electron microscopy and biological testing for hydroxyapatite-based composites will help establish the full potential of these material systems.

ABSTRACT

Drones that are equipped with artificial intelligence and interconnected with the Internet of Things have revolutionized the monitoring, maintaining and managing of power infrastructure over the last decade. This Paper provides an overview of the background of the Drone of Things and basic components-and sets the stage for exposure that is much more detailed than what has been discussed on Artificial Intelligence applications in the electric power sector up to this point. Examining the cases highlights the significance of Artificial Intelligence enabled Drone of Things systems, particularly in enhancing infrastructure inspection, predictive maintenance, disaster response, energy theft detection and planning sites for renewable energy. This paper discusses fundamental Artificial Intelligence approaches utilized in practical applications such as computer vision, machine learning, deep learning, and natural language processing. This paper also addresses possible challenges to their implementation-such as regulation, integration, and the accuracy of Artificial Intelligence algorithms-and the limitations of Artificial Intelligence -enabled Drone of Things systems. In the future, new developments in 5G, edge computing, swarm intelligent systems, and advanced sensing systems will provide a wide range of new ways that Artificial Intelligence powered Drone of Things systems can be utilized in the electric sector. The following analysis gives an in-depth look into how Artificial Intelligence enabled Drone of Things are important for operation optimization, reliability enhancement, and providing safety to power systems. Those technologies will lead to many advances and improvements in the management and distribution of electricity in the energy sector over the coming years.

I. INTRODUCTION

A power sector in profound and exciting change with the advent of convergence of drones, Internet of Things (IoT) and Artificial Intelligence (AI). This powerful synergy is giving life to the Drone of Things (DoT), or rather, the network of intelligent and interconnected drones that revolutionize how we manage, maintain and optimize power infrastructure [1].

Imagine drones mapping a continent. They fly meters and miles to scan transmission lines when all the signs of distress and fatigue can be detected consciously. They can detect hazards such as vegetation intrusion and even predict possible equipment failure, sometimes before it happens. This is the power of AI-powered DoT (AI-DOT) in the power sector [2], [3].

I.1 THE CONVERGENCE OF DRONES, IOT AND AI

It combines drones, IoT and AI technologies to create a complete power infrastructure management system [4], [5]. Each of these technologies plays a key part in building an all-in-one and intelligent system to manage power infrastructure. Drones have grown from basic remote-controlled gadgets to advanced machines that gather data. High-resolution cameras, thermal imaging sensors, light detection and ranging (LiDAR) technology and even corona discharge detectors are among their capabilities, making them indispensable for monitoring the power grid. They can reach inaccessible and dangerous spots such as high-voltage transmission towers, dense forests and offshore wind farms, thus saving people from risking themselves.

They can obtain an accurate and detailed perspective of the power assets through visual data that is not feasible to gather from the ground [5]. The backbone of this smart system is the IoT, which connects a significant network of devices and sensors that can be embedded in various places in the power grid. The network offers real-time information concerning constant performance, environmental conditions, as well as hazards within the system. Secondary substations might contain temperature, vibration or oil level sensors etc. In the event of their weather stations, they can have wind speed, temperature, and humidity level measurements. This information with the visual information gathered by the drones makes an exhaustive digital twin of the physical grid.

An integrated view of its health and performance is offered. AI has a major influence on this networked system. Complex formulas sift through massive amounts of information from drones and IoT devices spotting patterns, differences, and oddities that might signal upcoming problems. In other words, AI can detect small shifts in a transformer's heat pattern that could mean it's about to fail, or even a slight curve in a power line tower that could lead to disaster. This allows for fixing things before they break and planning repairs in advance, which stops expensive power outages and ensures people get electricity they can count on [6].

I.2 THE DRONE OF THINGS (DOT) IN THE POWER SECTOR

The merging of drones, IoT, and AI leads to the idea of the DoT, a system of smart drones working together. This has a big impact on how power systems work. Drones aren't just remote-controlled devices anymore. They're now smart helpers that can choose what to gather and what AI programs should look at.They can adapt their flight paths in real time to focus on areas of concern, communicate with other drones to coordinate inspections or even return to base for recharging or data transfer without human intervention [1-6]. In the power sector, DoT is transforming various aspects of operations, including:

- DoT offers an autopilot inspection of power lines, towers, substations and any infrastructure required. These drones will be able to sense symptoms of corrosion, damage and vegetation encroachment, among other hazards useful for maintenance planning and assessment of potential risks.
- The AI powered DoT, on the distribution equipment will predictively maintain the devices because it analyzes data from drones and sensors IoT to identify possible equipment failures that may occur. A proactive approach reduces downtime, lowers repair costs and enhances reliability of power supply.
- In case of any power cut or natural calamity, DoT can be immediately deployed to assess the damage and identify the cause of the problem and guide the repair crews to the affected areas. The rapid capability of this deployment reduces downtime and allows for quicker power restoration.
- DoT can be used for security surveillance of power infrastructure to detect vandalism, access by unauthorized people and other security threats.

I.3 ADVANTAGES OF AI-POWERED DOT IN POWER SYSTEMS

The adoption of AI-powered DoT in the power sector offers numerous advantages:

- **Improved Efficiency and Productivity:** DoT automates tasks that were earlier time-consuming and labour-intensive, including inspecting power lines and equipment. This significantly improves efficiency and productivity by reducing man-hours and inspection time, hence generating cost savings.
- **Improved Safety:** It ensures that droids can reach dangerous or inaccessible regions, thus minimizing risks to human workers. It enhances safety and reduces chances of accidents.
- **Accurate and Reliable Systems:** AI algorithms can analyze data much more accurately than humans, with more accurate detection of faults, thus much higher reliability for power systems. The chances of a power outage become much lower and therefore maintain greater supply stability.
- **Data Insights:** Artificial intelligence will be able to draw insightful inferences from the data and hence enable proactive maintenance, optimal utilization of resources, better planning of things, which ultimately will manifest as better decisions and thus improved efficiency in operational activities.
- **Reduce Downtime and Outages:** Predictive maintenance and rapid response capabilities of AI-powered drones minimize downtime, thereby averting costly power outages. This is also instrumental in building reliability into the power supply while reducing the economic impact of disruptions.
- **Environmental Benefits:** DoT can therefore help in the environmental sustainability through the following ways: Maximizing the generation of renewable energy and reducing reliance on fossil fuels. For example, drones inspect solar panels for any damage or soiling that helps maximize optimal energy production.

The confluence of drones, IoT, and AI opens an era for intelligent management and maintenance of power infrastructure. The DoT or Drone of Things is a promise that stands poised to yield improvements in efficiency, safety, accuracy, and data-driven decisions in the areas of power sectors. Based on this technology, the power sector will finally be able to optimize operations, reduce costs, and improve reliability to help build a more sustainable future.

II. AI-DRIVEN DRONE APPLICATIONS ACROSS THE POWER VALUE CHAIN

AI-DoT are transforming the power sector by enabling efficient and intelligent automation across the entire value chain, from generation to distribution.

II.1 GENERATING PLANTS

II.1.1 Solar Farm Inspection

AI-DoT are revolutionizing solar farm inspections by providing rapid, accurate and comprehensive assessments of vast arrays of solar panels. Let's delve into the technical aspects of how these drones are enhancing efficiency and optimizing energy production. Fig.1 shows the block diagram of overall AI-DoT system for Solar Farm Inspection [7], [8].

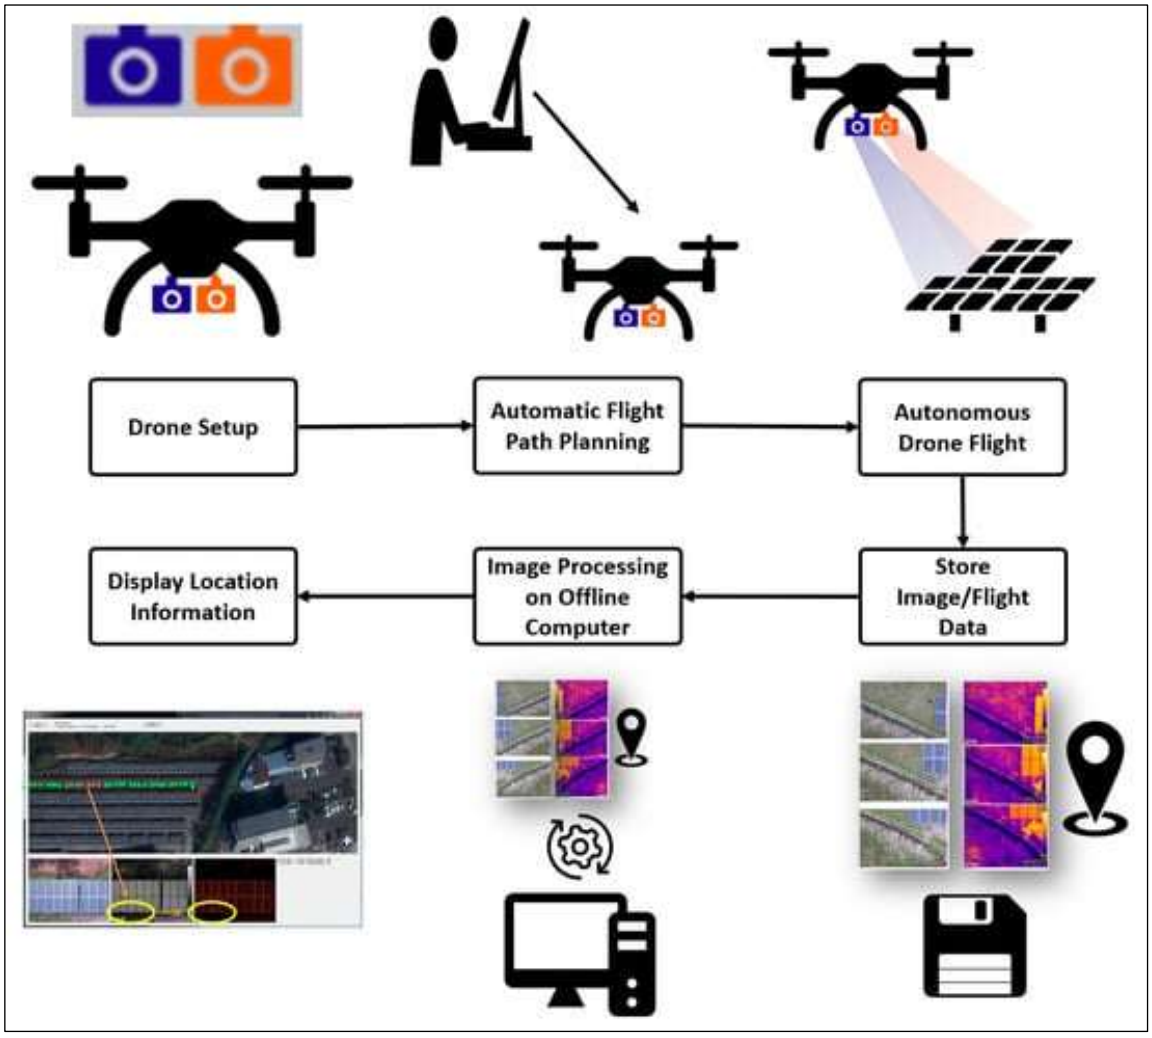

Figure 1: Block diagram of overall AI-DoT system for Solar Farm Inspection.

II.1.1.1 Panel Defect Detection

The advent of high-resolution imaging owing to drone technology has changed the whole narrative of maintaining solar energy plants. The drones come equipped with high power cameras enabling them take clear images of the solar panels even at an individual level. The pictures are then processed by complex AI systems with most relying of Convolutional Neural Network (CNN) technologies to inspect the images as though a human inspector was being used. These systems are capable of identifying numerous defects that can cause poor performance of a solar panel without any human interaction. Like an AI detective going through each panel with a clear lens, it can detect minute cracks that can cause failure down the line or internal separation of the panels(delamination). The AI will also detect thermal hot spots on the solar panels, which are pronounced areas with high temperatures that either indicate electrical faults or cell damage and can excessively lower energy production or even cause a fire.

Loses due to these structural elements are not the only obstacles that this AI has outsmarted as it has the ability to measure as well the soiling on the panels worn towards the hostile external environment hardening process making energy generation difficult. This automated analysis is not just looking for an issue, but rather determining how best to deal with it. The AI produces a comprehensive report on each damage with its exact location and severity allowing the maintenance team attend repairs and schedule clean ups accordingly. Principle of focusing on most damaging issues is adopted so that costs and time take in implementing maintenance measures is reduced. In the long run, this ensures harnessing more energy, minimizing stand-by time of the solar farms and facilitating better management of the solar farms. Fig.2 shows the Image of overall PV power plant followed by automatically planned flight path and location of defective PV modules respectively [9].

II.1.1.2 Soiling Analysis

Picture drones that have been designed to accommodate advanced cameras which can see beyond the capacity of the human eye. This is the potential of multi-spectral and hyper-spectral imaging which is changing knows and manages soiling of solar panels. These technologies enable the use of drones to obtain images in several light wavelengths revealing the composition of the soiling that would have remained concealed. Multispectral cameras take a picture only in a handful of selective bands of the electromagnetic spectrum like the red, green and blue visual bands with extra bands outside that are seen in. With this characteristic, they are able to differentiate between some basic types of soiling such as dust and plant materials. Hyperspectral cameras, in comparison, take pictures in hundreds of wavelength bands to give a clearer view of the soiling than a 'seeing' camera. Thus, enabling specific things to be determined such as types of dust, pollen, or even faces from birds.

AI analysis tools do the rest and provide details on the soiling level and soiling type of every individual panel. It's like having a dirt analysis of every solar panel in your system. Such information is critical in the effective management of cleaning operations. The areas that get affected the most will be cleaned eliminating wastage of time and resources. In addition, the evaluation is useful in looking for the right cleaning solution in as much as different types of soiling may call for different cleaning approaches. For example loosening dried grime of bird stools will require a different technique from dry wing surfaces. Through this targeted style of cleaning, solar farm owners can appreciate the necessity of the cleaning exercise and as such, keep the cleaning practice productive and the energy output high while curbing energy losses that arise from excessive cleaning[10], [11].

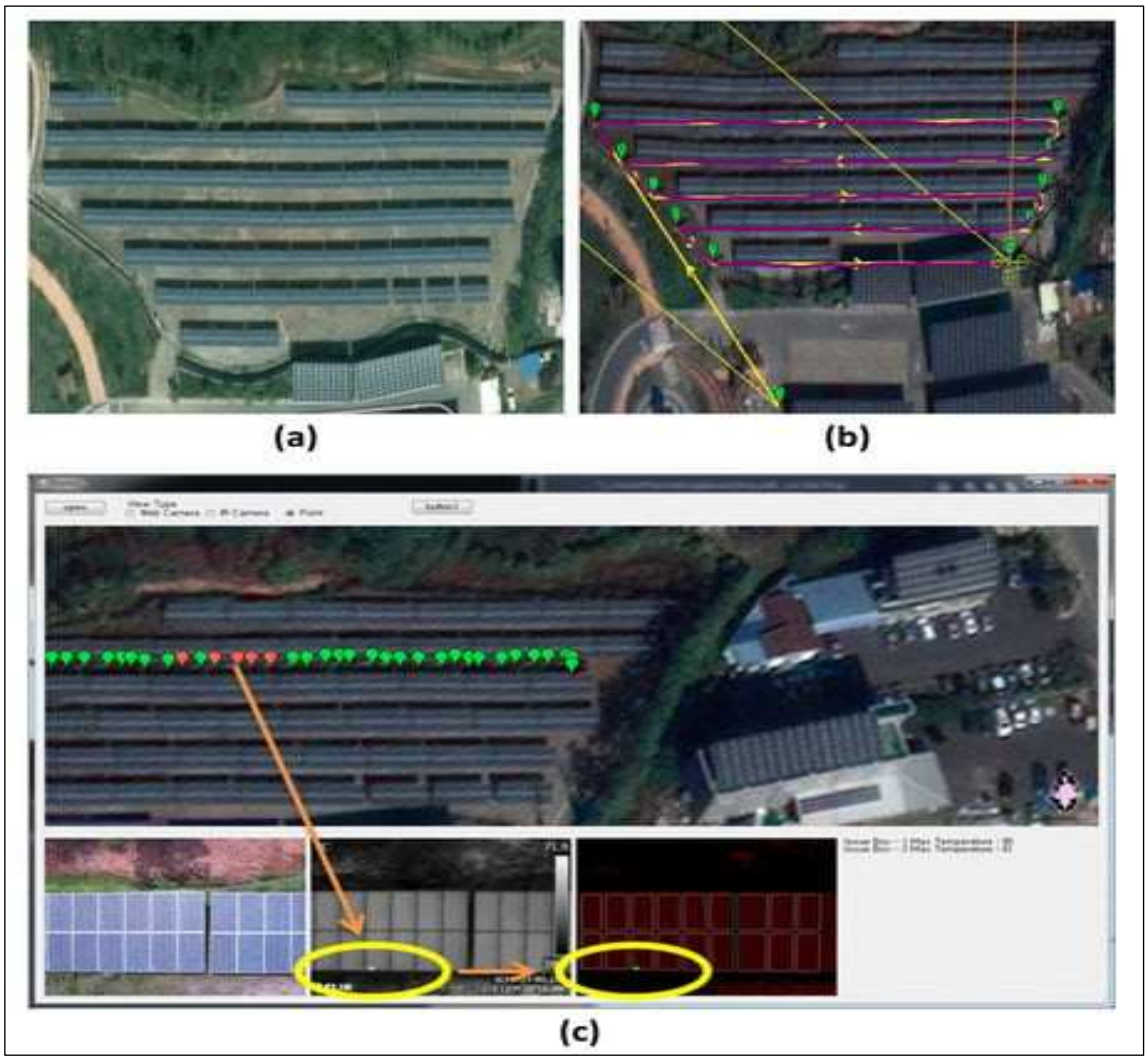

Figure 2: (a) Image of overall PV power plant; (b) image showing the automatically planned flight path; and (c) the final result showing the location of defective PV modules.
Source: [10].

II.1.1.3 Vegetation Management

Drones equipped with LiDAR sensors and high-resolution cameras are revolutionizing the management of solar farms by literally adding a new perspective to it. These technologies facilitate the production of realistic 3D models of the solar farm and its immediate environment, which assists in the understanding of vegetation management in great detail. LiDAR entails the transmission of laser beams and measuring how long it takes for those beams to reflect back from any object to form a 'point cloud' of the surface represented. Thus, this data when incorporated with an image of high resolution it becomes possible to mould the three-dimensional model of the solar farm's profile, including its landscape, overgrowth and solar panels[12], [13]. Analyzing such models for, among other things, vigorous growth around the solar array ie where trees, bushes or other plants are growing up to the edge of the solar panels is performed by AI.

Each leaf, even that of a small shrub shading a few millimeters of the panel can reduce its energy production significantly, or in some cases destroy entirely the panel. Thanks to this feature, the AI also suggests which areas are the most important for receiving attention on the suppression of foliage growth. This is a more effective way of managing vegetation as most of it is directed towards the target only. Vegetation management is simplified as maintenance crews now only go out to cut back or remove offending shading vegetation. In addition, this helps in capitalizing on solar energy within the solar farm in a more effective way by addressing potential shading issues that might arise in future and ensuring renewed efficiency of the solar farm. Fig.3 shows the LiDAR point cloud colored by Sitemark followed by Visual orthomosaic and contour lines based on the colored LiDAR point cloud [14], [15].

Source: [15].

II.1.2 Wind Turbine Inspection

AI-powered drones are transforming wind turbine inspections, enabling safer, faster and more accurate assessments of these towering structures. Let's delve into the technical aspects of how drones are enhancing the efficiency and safety of wind turbine maintenance [16]. Fig.4 shows the Wind turbine drone inspection system and Fig.5 summarise the flowchart of the automated wind turbine damage suggestion system.

Figure 4: Wind turbine drone inspection system.
Source: Authors (2026).

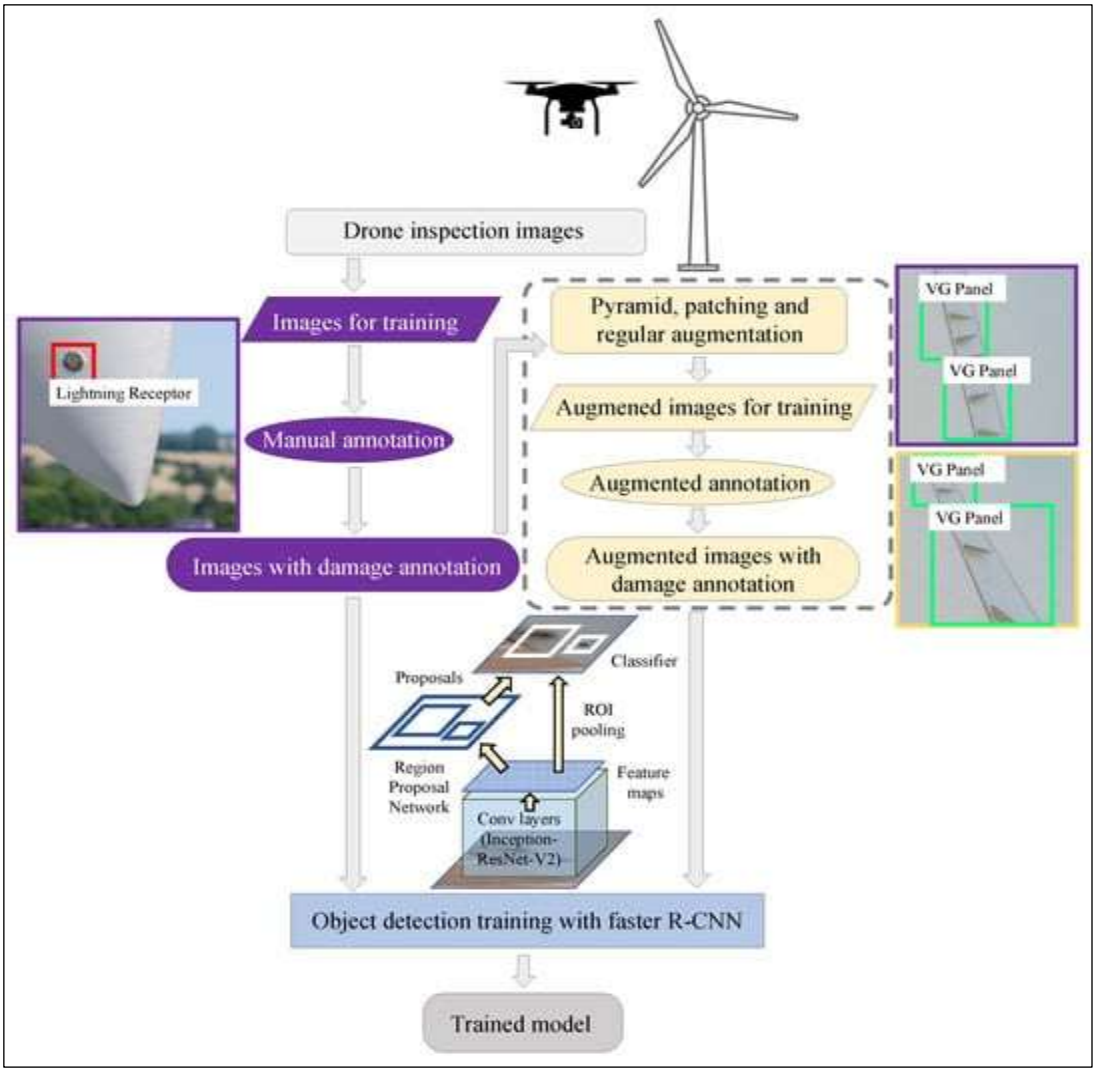

Figure 5: Flowchart of the automated wind turbine damage suggestion system.
Source: [17].

II.1.2.1 Blade Damage Assessment

The ability to obtain high resolution images through drones is altering the process of wind turbine blades inspections. These drones are fitted with sophisticated cameras capable of imaging the entire blade surface, including the tip, the leading and trailing edges. This form of imaging then undergoes high level processing in visual computing packages including the semi-automated Convolutional Neural Networks that play a role of a blade inspector. Such systems of artificial intelligence are proficient in damage assessment. They are able to spot defects such as cracks which if not treated may widen resulting to a breakage of a blade. They are also able to assess the level of blade wear at distinct areas such as the leading edge where blades face erosion due to rain, hail and dust. In addition, the AI system can also assess the extent of other damages such as burn marks, delamination and structural damages that are caused due to lightning striking the turbine.

Even more specialized algorithms deal with the leading edge of blades, the area most prone to erosion, in order to assess the type and the amount of damage inflicted is erosion. Blades can also be analyzed by Drones equipped with LiDAR sensors that can build 3D models of the blades. This allows a better understanding of the geometric construction of the blades, which improves damage evaluation. The AI then architectural powers reports after processing the images and the 3D model whereby the report includes the exact location and the level of seriousness of each defect. This way they are able to guide the maintenance teams on which repairs need to be done first, thereby avoiding the low-cost repairs that may lead to failures and addressing the most important issues to extend the life of the wind turbine [17].

II.1.2.2 Gearbox and Generator Monitoring

Consider a drone as a flying doctor who has a medical toolkit, in this case, listening to the heartbeat of the wind turbine. What this means in laying terms is advanced sensor integration and AI-based monitoring gearbox and generator health. Today, drones are also fitted with sensors that are able to take the status of these major elements and gather lots of information about their condition. To this end, there are vibration sensors, which are placed in the gearbox and the generator to measure the shakes within the apparatus like the sound of a stethoscope. These shakes are likely to change due to wear and tear, misalignment, or other issues. Temperature sensors, which are fitted in sensitive areas, such as the bearings and gears, are analogous to thermometers.

For instance, a bearing may be worn out or run dry and causing excess heat. Last but not least, the use of acoustic sensors is similar to the use of very keen-sounding microphones to listen into the inner workings of the sounds captured. An abnormal sound could signify the presence of a loose component or a chipped gear within the gearbox or the generator. When this information is processed, that is when the true enchantment occurs, as the sensor data gets analysed with the help of AI algorithms in real time. The AI assumes the role of the turbine operator, continuously monitoring the condition of the equipment. It does this by looking for abnormalities, or departures from the norm – excessive vibrations, elevated temperatures, etc.

Additionally, and in the case of machines such as i.e. wind turbines, which have huge amounts of history and utilization, the AI can forecast failure scenarios and adjust repair times accordingly based on previous machine learning. This means that it becomes possible to replace systems without waiting for a breakdown to avoid losses due to downtime and to increase the service life of the turbine. This strategy aiming to minimize down time in turbines maintenance using sensor data and information from AI's calculations is cutting across and changing the corporate marketing of wind turbine maintenance [17].

II.1.2.3 Lightning Protection System Checks

Its impressive capital assets demand that the integrity of the lightning protection system of a wind turbine be upheld. More recently, drones have been incorporated in the safety assessments increasing the range, depth and efficiency of inspection of the lightning protection system. Visualize the drone as a small flying electrician, inspecting every possible part of the system with intensive focus. The drone's high-resolution camera is capable of looking at the lightning receptors, the down conductors connecting the lightning to the ground currents and the ground itself. The drone's inspective abilities extend to advanced observations such as signs of damage, corrosion and loose fittings that can potentially render the system ineffective. However, the inspection does not end up there. Additional significance is also added to the drone by using thermal cameras which are capable of measuring the temperatures of different regions and thus identifying the presence of hot spots within the lightning protection system. Hot spots are variations in temperature that are areas of trouble within the system.

Hot spots are not always visible, yet they are the most common suspects that usually cause the system from properly dissipating the electricity into the ground [17]. In order to improve the inspection further, a special sensor installed on the drone can be used to check electrical values of the grounding system. It's like examining the power lines to see whether they are efficient and in a good condition. It can be estimated that if the reading was found to be high at this point, the high resistance would suggest the existence of a fault in the grounding system which could lead to damage to the turbine if struck by lightning. Finally, all this visual, thermal and electrical data is processed by AI. The AI behaves like a doctor who studies the health state of the lightning protection system and looks for possible reasons of its malfunction. This comprehensive and automated approach to inspection ensures that the lightning protection system is functioning optimally, providing reliable protection for the wind turbine and maximizing its operational lifespan.

II.1.3 Hydroelectric Dam Inspection

Drones with AI seem to be real helpers when it comes to checking hydroelectric dams and doing a wide range of quick and thorough assessments of important infrastructure. Let's get into the details of how drones improve safety and performance at hydroelectric dams.

II.1.3.1 Concrete Crack Detection

This is where concrete structures such as bridges, dams, buildings etc., require proper inspection and maintenance to make it safe and long-lasting. Traditionally, this was a laborious manual visual inspection that takes up considerable time with a high possibility of human error. However, the development in AI-based DoT is transforming this into a safer and more efficient and accurate technique of concrete crack detection. The high-resolution cameras in the drones capture images of the surface of concrete from various angles, and thus provide a panoramic view of the structure. This enables them to cover extensive coverage quickly, thus saving much inspection time. These images are then analyzed for cracks by sophisticated computer vision algorithms often based on CNNs. AI algorithms can be trained on massive images with cracks labeled so that there will be identification and classification of the cracks based on size, shape and direction. Accuracy is also ensured by arming the drones with LiDAR sensors to create 3D models of the structure.

The surface representation of the detailed crack detection would be much more precise, especially in complex or hard-to-reach areas. The 3D models and images will then be analyzed by the AI algorithms that automatically identify the crack existence and generate reports with considerable detail about them. The reports contain precise location information and assessments of the severity, which would help engineers prioritize the necessary repair and maintenance work. This technology has various advantages. It ensures safety because it can reach areas which are inaccessible by humans by opening it up for the drones to inspect; thereby, reducing the necessity of inspection at a height or confined space. It enhances efficiency through automated inspection that tends to be far faster than the traditional methods. Accuracy is also enhanced since AI algorithms can decipher cracks almost invisible to the naked eye. For example, it provides factual opinions rather than judgments by humans. It may also save time, during the inspection process and be much accurate.

AI-based DoT for concrete crack detection has vast applications within the industrial sector. This can be applied in both bridge inspections, dams, and tunnels to detect weaknesses in the structure before they eventually cause failure. It can be applied for the inspection of buildings ensuring safety and sustainability in high-rise buildings, historical buildings, and other buildings. It can be applied for construction monitoring purposes to identify issues related to concrete beginning from the construction phase even post-construction. AI-powered DoT is changing the way we find cracks in concrete. It's making it safer, faster, and more accurate to check on and keep up with important infrastructure. It is an important technology for keeping concrete structures safe and making sure they last a long time. Its goal is to make the built environment better, stronger, and more sustainable. There are a lot of good things about this technology. Drones can cover large areas quickly and effectively, which is much faster than traditional methods.

It is also accurate because the AI algorithms can find small signs of leaks that people might not see. The repair is done faster, which protects against more damage and saves money in the long run. The most important thing is that the tool saves a lot of water because it can find leaks early and stop them from losing more water. This serves as excellent environmental use since it reduces water wastage as well as protects the surrounding ecosystems from damage brought about by leakages. AI-powered DoT for water leakage identification has several applications. The tool can be used for pipeline inspections, among others such as water distribution networks, oil and gas pipelines or sewage systems. It can be used for leak detection in the dams and reservoirs so that possible damages are avoided along with saving the neighboring communities from destruction. In agriculture, it will detect leaks in irrigation canals so that water will not be wasted and efficiency increases. And generally, it will use in monitoring water bodies so that areas of water loss could be determined to manage our precious water resources well. Fig.6 shows the AI powered DoT for concrete crack detection system.

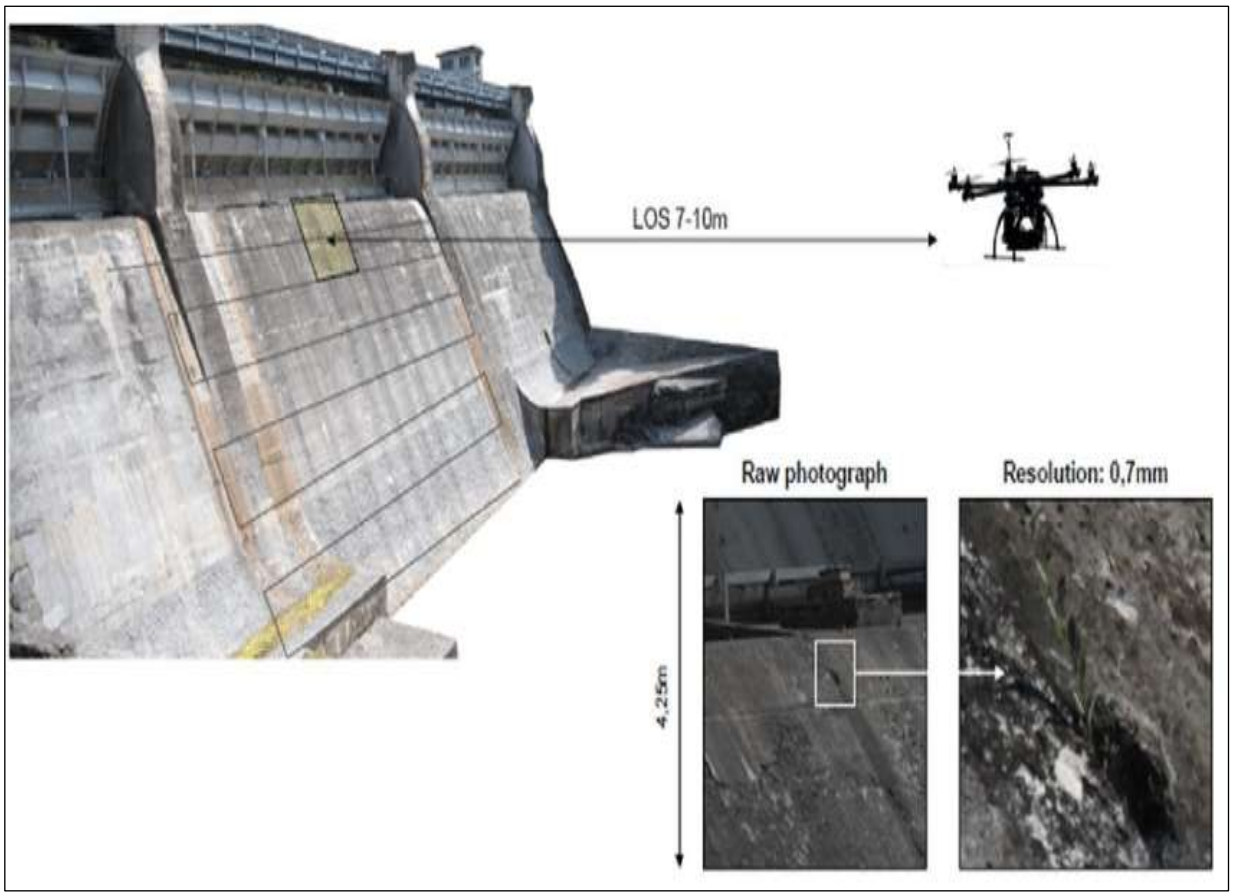

Figure 6: AI Powered DoT for concrete crack detection system.
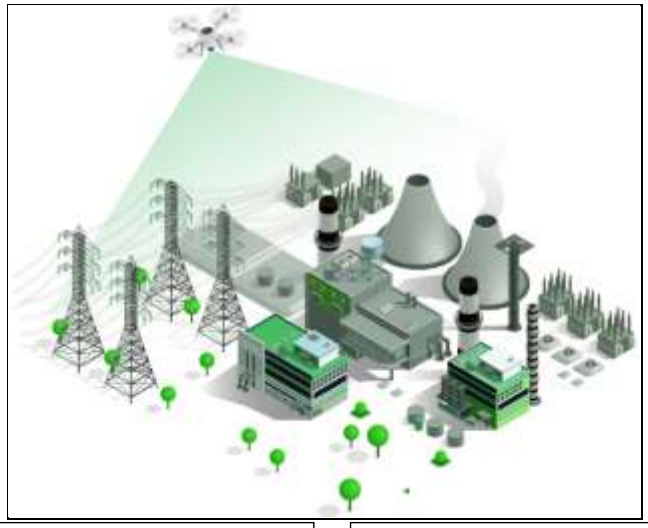
Source: [18].

II.1.3.2 Sedimentation Monitoring

It has presented one of the major challenges in the management of water resources and hydroelectric power generation due to the buildup of sediment within reservoirs and the waterways. The accumulation decreases the capacity of a reservoir, degrades water quality and in extreme cases can stop the flow in hydropower turbines, thus reducing their efficiency. Initially, manual surveys and sampling of water were the core monitoring activities on sedimentation, which were very costly and time-consuming and offered very little information. However, a Drone of Things powered by AI would revolutionize the whole process much more efficiently, much more accurately, and far more comprehensively. Just imagine drones carrying sonar or LiDAR like underwater surveyors. They fly over the water and send sound waves or laser pulses down through the surface to map the underwater topography. This produces an incredibly detailed 3D map of the reservoir bed showing depth and distribution of sediment. Such drones also carry multispectral cameras capturing images of the water in different wavelengths of light.

This would help analyse the quality of the water and enable the team to identify areas with high sediment concentration, almost like taking an X-ray of water. The real power of this technology lies in the AI algorithms that analyse the data collected by these drones. These can suitably measure the volume of sediment in a reservoir, explain how it is spread, and then continue with fluctuations in levels of sedimentation over a given period. All this makes possible an estimate of the effect of sedimentation in capacity on the reservoir and identifying other sources of erosion such as soil erosion from neighboring areas. There are many advantages of this approach. With a DoT, one can cover vast areas very quickly and efficiently in order to collect data from quite some points in the reservoir and provide much more information on sedimentation patterns compared to the older methods. The AI algorithms will also better analyse such data compared to manual methods and facilitate further accurate assessments. Regular monitoring identifies sedimentation problems early on; and timely intervention measures save the reservoir's capacity and hydropower generation from significant losses.



The automated methodology cuts down the necessity to have costly and time-consuming surveys done manually. Hence, it has important cost-saving benefits. Moreover, the technology will help identify sources of erosion as well as sediment pollution through observing patterns in sedimentation. This is essential for environmental protection and the management of water resources. An AI-powered DoT is to be used for sedimentation monitoring of reservoirs, ensuring an appropriate water storage capacity, managing water quality and sustainable resource management of water. One can use it to monitor the effects of sedimentation on hydropower generation, thereby allowing the operators to plan maintenance or dredging operations that would optimize energy production. It can further be used in monitoring environmental changes, source identification of sediment pollution, and assessment of the impacts of sedimentation on aquatic ecosystems. It can even be used in flood control, monitoring sedimentation in rivers and floodplains to assess flood risk and work out mitigation measures.

II.1.4 Thermal Power Plants

While renewable energy sources are gaining prominence, thermal power plants continue to play a significant role in electricity generation. AI-powered drones are proving to be valuable tools for inspecting and maintaining these facilities, ensuring their safe and efficient operation. Fig.7 shows the AI Powered DoT for thermal power plant inspection system.

II.1.4.1 Chimney Stack Inspection

This drone flies hundreds of feet in the sky. In the foreground stands a gigantic industrial chimney stack. Such inspection is reality nowadays with the advent of AI-powered Drone of Things or simply DoT for short. These drones, mounting high resolution cameras and thermal imaging sensors, revolutionize how to inspect and maintain these critical structures venting exhaust gases and pollutants emanating from power plants and industrial facilities. A comparison between the features and systems above with classical approaches such as scaffolding or rope access techniques yields that cost-effectiveness is combined with minimum safety risk for the inspectors. AI-powered drones end the risks of flying this way by offering a safer and more efficient alternative. It can quite easily access

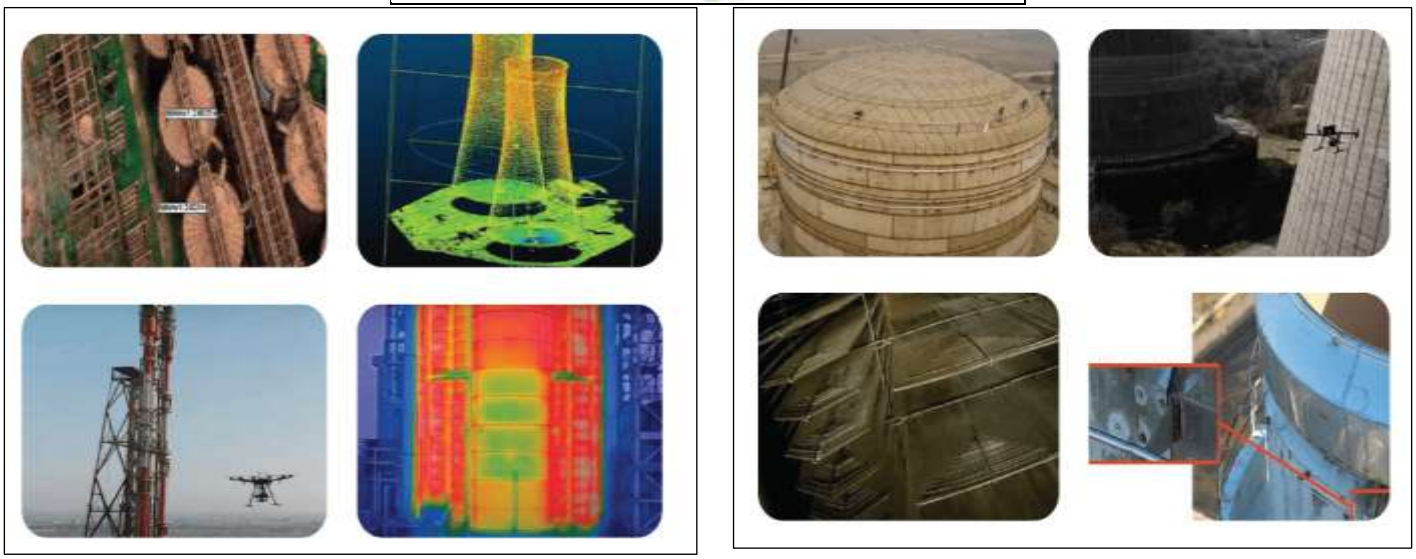


Figure 7: AI Powered DoT for thermal power plant inspection system.
Source: [19].

Inaccessible areas and capture highly detailed images of the chimney's interior and exterior surfaces, encompassing the condition of the brickwork, mortar joints and attached platforms or ladders. The drones' thermal cameras pick on temperature differences that allow it to detect problems such as the possible failure of insulations, structural damage, as well as areas where heat is leaking out and which generally hinder efficiency. It is the advanced computer vision algorithms in analysing the visual and thermal images that pose the power with this technology. The AI algorithms will automatically identify all possible defects including crack, spalling (where concrete flakes off), corrosion, as well as blockages. They can even estimate the degree of these defects, which is priceless information when it comes to prioritizing repair work. The AI system then produces comprehensive reports with detailed visual documentation, thermal maps and precise location information for any defects found. This means engineers and maintenance teams can rapidly assess the chimney stack's condition and plan necessary repairs in advance[19].

This technology has a number of benefits. There is improved safety: because inspectors would not have to climb tall constructions or work at heights to inspect. Efficiency is improved by making inspections automated, hence much faster than other methods. Lastly, accuracy is improved in that AI algorithms can detect minor defects that, through human inspection, would be missed. Further, it reduces the cost of inspection as it does not require scaffolding, rope access or specialized equipment. Lastly, it provides detailed documentation that is very helpful for maintenance planning and regulatory compliance. AI-based DoT chimney stack inspection is widely employed in several sectors of business. This process may be utilized for inspecting the chimney stack in thermal power plants to ensure efficient and safe working. Stacks mounted in industrial plants, refineries etc can be scanned to study the emission of smoke and dust as part of environmental pollution. Ancient buildings with old chimneys and towers also can find support in this technology to ensure their safety and durability.

II. 1.4.2 Cooling Tower Inspection

Regular inspection is required for cooling towers, which are considered the means of dissipating excess heat in power plants and other industrial processes. Traditionally, it involved manual inspection, an agonisingly slow, dangerous and limited process. Drones with AI are fresh in this game and remain safer, faster, and comprehensive when inspecting a cooling tower than any other inspection method in existence. With a high-resolution camera that has a thermal imaging sensor, this drone manages to see every nook and cranny inside the cooling tower as it creates very specific images of the shell, the fill material, the drift eliminators, the piping and even nozzles. It ends up creating a total visual analysis of the structure and its parts that might exist internally and externally. Thermal cameras can detect temperature changes, thereby exposing issues such as blockages, leaks or inefficient cooling, along with even damage not visible to the naked eye. In general, there is true magic in high-tech vision algorithms analysing detailed visual and thermal images.

This AI can itself automatically identify such defects as cracks, corrosion, damage to the fill material, and even biological growth. It also rates the level of severity of these defects, thereby providing essential prioritization for various types of maintenance. The AI will generate reports containing high detail visual documentation and thermal maps, as well as the correct location of any issues that may be detected. This allows engineers and the teams responsible for the maintenance to quickly determine the condition of a cooling tower and what is needed as far as repairs or cleaning. In comparison with other methods, this has a lot of advantages: it is safer because inspectors do not have to climb tall structures or go into confined spaces; it is efficient by being automated, meaning the inspection might be much faster compared to traditional methods; and it is more accurate by having AI algorithms look for defects that are nearly not noticed during inspection on the human body. It also reduces inspection costs since the requirement for scaffolding, rope access, or specialized gear is eliminated and by locating and remedying defects impacting cooling effectiveness, it can help optimize the performance of the cooling tower along with total operational efficiency.

II.1.4.3 Coal Stockpile Volume Estimation

Estimation of the amount of coal in stockpiles is still essential for power plants to manage fuel supplies and work effectively. This used to be done by traditional measurement and estimation through aerial photos, which is a quite inaccurate procedure and time-consuming as well. The use of drones in measuring coal stockpile volume is changing with AI. These drones are equipped with LiDAR sensors that work based on the principle of how laser pulses are emitted and measured by the time travelled after its reflection from the coal pile. It generates a very dense 3D point cloud and, in essence, gives a digital representation of the stockpile's surface. To eliminate errors, the GPS and inertial measurement unit of the drone puts this point cloud precisely within a real-world coordinate system. Noise and outliers are usually in the raw LiDAR data and this is filtered by AI algorithms for clean and accurate representation of the surface.

Then, the AI classified the points in the point cloud into either ground or stockpile to separate the coal pile from the surrounding terrain. AI develops a 3D surface model of the stockpile of coal as portrayed in filtered and classified data. A volumetric algorithm used by specialized software computes the volume of coal stockpile on the basis of such a 3D model. Multiplication of the volume with the bulk density of coal, found from the lab test or history, will yield an estimate for the actual mass of coal. The 3D models developed can be visualized and analysed with the help of specialized software to gain insights into the shape and volume distribution of the stockpile. The AI system automatically generates reports containing all volume calculations plus other relevant data that can be linked to any given inventory management system, and such data facilitates timely tracking and analysis [19].

II.2 TRANSMISSION SYSTEM

II.2.1 Autonomous Inspection and Monitoring of Transmission Systems

Power transmission systems inspection and maintenance are becoming new faces of AI-driven drones; their activities help run processes more efficiently, safely and reliably. Here's a closer look at how intelligent aerial robots is revolutionizing the monitoring of transmission lines, towers, and substations [6].

II.2.1.1 Transmission Line Inspection

The inspection of power transmission lines, those critical pathways delivering electricity from power plants to our homes and businesses, is revolutionized with AI-powered drones. Traditional inspection methods are slow, expensive and very limited in access to remote areas and difficult terrain. Drones with advanced sensors and AI algorithms improve efficiency and enhance safety while providing a much more complete solution. They will take cameras with higher resolutions that will provide high-resolution images of the transmission lines, including the conductors-that is, the wires-themselves, insulators that support the wires and supporting structures. All these will give a visual record of the line's condition, thus making it possible to identify the possible problems. They also have thermal cameras that can spot variations in temperature along the lines. These can highlight hot spots which are an indication of loose connections, corrosion or other issues that could lead to a loss of power or even fires.

Real 'power' lies in those AI algorithms that look at the visual images and the thermal images together. Such algorithms can automatically detect many types of anomalies, including broken conductors, damaged insulators, vegetation creeping onto lines, and loose or missing hardware. This automation does not involve the manual inspection of every single image but instead saves time and is more accurate. Subsequently, with a reasoned conclusion, the AI system generates comprehensive reports along with visual images documenting all the anomalies detected, including thermal maps and the precise location of those anomalies. The maintenance teams would quickly be able then to estimate the condition of the transmission lines and work on a priority list of problems, first those most crucial. This technology has many positive factors. It speaks of safety as it does not require labourers to climb high towers or have access to places that may be hazardous.

It ensures efficiency as inspection is automated, which saves much time from inspection procedures compared with the conventional methods. It also promotes precision because AI algorithms can identify defects that may have been missed by human inspectors. Lastly, it reduces downtime since proactive maintenance becomes effective and prevents costly interruptions in electricity supply. The last is that inspection costs are avoided, and the helicopters, ground patrols or any other special gear can be excluded. AI-powered drone inspections have a number of applications, such as routine inspection, emergency response after the storm or some other event, vegetation management, and construction monitoring. This technology is quite fundamental to the reliable delivery and efficient transmission of electricity with increased sustainability and resilience in the energy grid. Figure 8. Shows the DoT inspecting a power line(a), a close-up image of a healthy insulator(b), and a close-up image of a damaged insulator with cracks(c) respectively [20].

II.2.1.2 Tower and Substation Inspection

Inspection of transmission towers and critical substations controlling electricity always requires high vigilance for ascertaining the reliability and safety of our power grid. Traditionally, inspections were done through manual climbing of towers as well as close-up observation of substation equipment. Though this practice was time-consuming and not cost-free, it also posed a hazard to workers. However, AI-powered drones transform that very landscape with a safer, more efficient, and more all-inclusive approach towards checking the towers and substations. With LiDAR sensors, these drones function as flying 3D scanners that create highly accurate 3D models of towers and substations. It helps inspectors to scan the very structures virtually from all sides and capture their very precise dimensions and geometry in detail. High-resolution cameras mounted on drones take extremely detailed images of each and every aspect of the substation, from the insulators and steel structures to the conductors and other equipment at the substation. Another layer of information which can be added to the thermal cameras installed on the drones is temperature variation detection in equipment and connections, indicating possible overheating or even not tightened connections.

The real power though is realized with advanced computer vision algorithms which analyse not only visual and thermal data but also LiDAR data. AI algorithms work like expert inspectors to automatically identify nearly any defect or anomaly. They can detect structural issues such as corrosion, cracks, and loose bolts in towers and on substation equipment. They may also report equipment irregularities such as overheated transformers, cracked insulators, and malfunctioning circuit breakers. In addition, they can detect development encroaching too close to towers or substation equipment, potentially damaging them or interfering with their operation. The AI system then produces comprehensive reports, which also include detailed visual documentation, thermal maps, 3D models and precision location information for any item found. This allows engineers and maintenance teams to quickly assess the towers and sub-stations so that restoration work is prioritized to address the most critical issues right away [21]. This technology offers many benefits. Firstly, safety is increased because workers are not asked to climb tall towers or to approach high-voltage equipment.

It increases efficiency due to automated inspection processes that would definitely be much faster than by people alone. Accuracy is improved in these inspections as the AI algorithms can detect minor defects that might be unnoticed by human inspectors. This also saves on inspection costs because of no manual climbing, special equipment and no need for extended time schedules; by promoting proactive maintenance, it prevents costly repairs and outages from popping up without warning. With these visual, thermal, and LiDAR data sets, more comprehensive insights about the tower and substation conditions are brought into the decision-making process for maintenance. AI-powered drones inspect towers and substations for routine monitoring, assessment after storm damage, security surveillance and construction monitoring. This technology is indispensable in the quest to ensure reliability and resilience of the power grid while bringing the energy future one step closer to being cleaner and more reliable.

II.2.2 Distribution System

AI-powered drones are revolutionizing how we inspect and maintain the vast network of power distribution lines that bring electricity to our homes and businesses. These drones, equipped with advanced sensors and AI algorithms, offer a safer, more efficient and more comprehensive solution compared to traditional methods like ground patrols or helicopter inspections[22].

II.2.2.1 Power Line Inspection

AI-powered drones are changing the process of inspecting power lines. The lines that provide the electricity to our homes and businesses are inspected using advanced cameras and thermal imaging sensors by these drones. Flying electricians, these drones carry out meticulous examinations of each line in distribution. Detailed images taken include the wires, the insulators and even the supporting structures for all lines. The thermal cameras will measure temperature variations and highlight probable problem spots like loose contacts or corrosion. But what is the real magic - advanced computer vision algorithms are used to analyse those pictures. The AI can recognize a very broad spectrum of anomalies - damaged equipment, vegetation overgrowth, violation of rights of way, including the exact pinpointing of where the power outages happened so that crews can regain power to those areas efficiently.

This auto-analysis saves time and ensures accuracy as compared to human inspections. The AI then produces reports that are fully detailed with visual documentation, thermal maps and location information for any issues that are identified. This makes it easier for maintenance teams to quickly evaluate the situation and prioritize repairs so that critical problems are addressed first [21]. This technology provides the following: safety that is eliminated since workers may not require climbing poles, nor enter hazardous areas during inspections, reduces cost to be many times faster for inspections. Improves in precision given the AI could find and pick out better defects often missed by even the expert human inspectors and reduces downtimes because it uses proactive measures for maintenance - no probable chance of discontinuity within the electricity supplies. This further saves the cost of inspections due to the removal of ground patrols, specialized equipment or extended downtimes.

II.2.2.2 Grid Mapping and Planning

AI-powered drones level the playing field, as it were, when it comes to mapping and planning distribution networks. High-resolution cameras, LiDAR sensors and thermal imaging cameras mounted on drones might be said to constitute 'flying surveyors' gathering a treasure trove of data regarding the grid as well as its surroundings. They create very sophisticated models of the 3D network, identify poles and transformers and can even detect problems such as damaged equipment or vegetation encroachment. Then, it goes through advanced AI algorithms, creating a full digital twin of a distribution network. Digital twin provides an in-depth evaluation of the grid mapping of the connection between elements, the analysis of sag and clearance over the power line and even identification of specific locations with a risk from vegetation. But not just in mapping- planning and optimizing the grid is much easier through AI-powered drones.

They can analyze load patterns and predict future demand. Based on this, they can highlight the areas that require expansion or up-gradation within the grid. They can also decide the location of new transformers and substations by working on terrain, population density, and load patterns and also with that new focus towards renewable energy, these drones would be able to scan the possibility of incorporating photovoltaics and wind energy into the grid, as well as the best locations for their incorporation. It has some advantages. It enhances accuracy, efficiency and safety while costs are reduced in comparison to traditional methods. However, the most important thing is that it gives data-driven decision-making opportunities in planning and optimizing grids with valuable insight. This increases the resilience of the grids that can better adapt to future challenges: increasing demand and renewable energy sources [15].

II.2.2.3 Last-Mile Delivery

AI-powered drones change not only the way we inspect and maintain power infrastructure but also the way we respond to emergencies and ensure speedy repairs, particularly in remote and challenging locations. And so, when talk is about "last-mile delivery," AI-powered drones are the game-changers. Imagine a critical piece of equipment fails in a remote power substation high up in the mountains. Using traditional methods, getting a spare there might take hours or even days, leaving people without power for extended periods and causing immense economic loss. That's where AI-powered drones come in. They can be sent over to the location fast, where that essential spare part could be dropped directly into the substation, finding easy routes over treacherous terrains and thus reducing downtime. This reduces disturbances to customers and saves on costs incurred in repairing losses and unproductive time. Besides, when nature does its thing, like destructive weather conditions rendering roads impassable, drones become a very important asset. They can help give a bird's eye view of the disaster situations, and this gives the fastest possible way of establishing the damage areas and which areas require urgent repair. They can carry vital equipment also and hand-over needed machinery to restoration teams in inaccessible areas so they can restore electricity and all crucial utilities much quicker than would otherwise be the case.

III. AI APPROACHES FOR DOT APPLICATIONS

III.1 COMPUTER VISION

Computer vision is thus providing drones with smart eyes that can let them see the world, look at things, and understand what they are seeing. In essence, it involves data extraction with meaningful information taken from images and videos captured by cameras mounted on drones. This creates opportunities to apply drones to a variety of power infrastructure management applications. In many cases, the images from the drone are not suitable for analysis without some fine-tuning. That's where image processing comes into play. It's basically optimizing a photo before uploading it to social media. Such techniques as noise reduction, contrast adjustment, and sharpening enhance the quality of images so that the computer may identify and analyze the relevant features[23-26]. Once prepared, computer vision algorithms are further used to identify parts of specific interest. For power lines, that would mean identification of insulators, transformers, vegetation, and even the power lines themselves.

Algorithms such as YOLO, Faster R-CNN, and SSD are well-suited at that because they can quickly and precisely locate those parts in that image. Beyond object detection, computer vision also helps in separating images into meaningful regions. For example, it is an outline of different parts of a picture. Example: It can isolate the damaged portion by using Mask R-CNN and U-Net algorithms if the image of a broken insulator is captured by a drone. This enables one to establish the amount of damage and therefore order repair. Another massive component of computer vision would be image classification. In this case, the classing of an image into a certain pre-defined class is done. For instance, an algorithm may classify a picture of power line conditions as "normal", "minor damage" or "severe damage." This enables one to understand the situation much faster on the site. Computer vision allows features to be extracted from images, such as edges, corners, and textures. These can further allow the identification of patterns or anomalies that may imply a trouble.

For example, changes in the texture of one of the elements of a power line could indicate corrosion. Computer vision can thus generate 3D models for the components of the power infrastructure by combining various images captured from different angles. The detailed and wide scope view offered by such a model helps in an effective inspection and analysis process. For the case of power line inspection, computer vision allows a drone to automatically detect most kinds of defects, ranging from broken insulators, to damaged conductors, encroaching vegetation, to rust. This really accelerates the inspection process and minimizes the possibility of human error. Besides, computer vision is used in monitoring substations; identifying possible dangers; damages created after storms; even tracking vegetation near power transmission lines. The computer vision is one critical technology that empowers the drones to effectively monitor and manage the power infrastructure. It allows drones to see and perceive the world around them by providing great insights to increase power systems efficiency, reliability, and safety.

III.2 MACHINE LEARNING

Machine learning is giving a brain to drones, which enables it to learn and adapt as it goes. Drones need not be programmed for every situation because they themselves can analyze data, determine patterns and make decisions when equipped with machine learning. This learning capability is revolutionizing how we maintain and manage power infrastructure[27-29].

In machine learning, the most common technique used is supervised learning where an algorithm is trained on a set of labeled data. It may be considered as giving the drone lots of examples of what good equipment is and what bad is, and subsequently letting it learn to discern the difference. Through this, the drone will be able to decide outcomes, such as how much useful life remains in a transformer or what condition the power line is in. It is further divided into regression, which predicts a continuous value like temperature, and classification, which predicts a categorical value like "good", "fair" or "poor."

Unsupervised learning deals with unlabeled data. Here the algorithm is asked to find hidden patterns and structures in the data. For instance, it can analyze the pattern of drone flight patterns and determine anomalies such as when a drone flies from its usual route. This might appear as a problem that requires further investigations. Techniques for unsupervised learning include: Clustering where similar data points are often grouped together and dimensionality reduction simplifies the data reducing the number of variables. Reinforcement learning is really teaching a dog new tricks through rewards and punishments. It learns based on interaction with the environment and receives feedback for its actions. In drone usage, it could be related to optimizing routes during inspection: the algorithm will test different routes, which it learns are most efficient and effective based on the feedback it receives.

The scope of applications of machine learning in power infrastructure management is broad. For example, a drone scanning sensor data to predict equipment failure before its event occurrence allows for proactive maintenance without having costly outages and ensuring reliability in the grid. Another application of machine learning could be anomaly detection, where it detects the deviation in patterns within sensor data or images, which are usually unusual and might signal a problem. This implies that there are irregular changes in temperature inside a transformer, abnormal vibrations on a power line or even shady activities that might indicate energy theft. Further, machine learning can optimize the operation of drones. For example, it can decide on optimal flight paths, schedule inspections and also rationalize resource use. This way, drones are optimized in order to maximize potential impact on power infrastructure management.

III.3 DEEP LEARNING

Deep learning is kind of advanced artificial intelligence inspired by the human brain. It is developed through artificial neural networks - very complex structures, modelled closely to how our brains operate when processing information. The networks have many layers in them, and hence, they can learn deep and complex patterns and representations from gigantic sets of data. This makes deep learning particularly suited for processing unstructured data such as images and videos, which are also abundant in the drone-based inspection of power infrastructure [30], [31]. Among the primary architectures for deep learning are Convolutional Neural Networks (CNNs). CNNs are designed precisely to process grid-like data, such as images. They are highly competent in object detection, image classification and segmentation tasks. This means they are applicable for visual data analysis captured by drones during power line inspections. For example, a CNN can be trained for recognizing different power line components: insulators, conductors, and towers, then detecting possible anomalies or defects that may exist.

Another basic architecture is Recurrent Neural Networks (RNNs). RNNs are best suited to sequential data, like time-series data from drone sensors. This really makes them valuable for predictive maintenance and anomaly detection. For instance, an RNN could analyse vibration data collected over time from a transformer and learn to predict potential failures based on slight changes in the vibration patterns. GANs represent a quite recent development within deep learning. They include two collaborating neural networks: the first builds new data while the other attempts to say whether its generated or real. Based on this innovative architecture, GANs can efficiently produce synthetic data that might closely resemble true data, and in terms of DoT, can be adopted to generate datasets for other AI models, especially for scenarios of scarce or pricey real world data. Some of the following benefits of deep learning can be leveraged for drone-based power infrastructure management: it enables much more accurate and robust image analysis especially in difficult conditions such as low illumination, or complicated backgrounds.

This is important for dependable classification and detection of defects. Deep learning also automatically performs feature extraction; and the task requires no time-consuming effort of manual feature engineering, again requiring significant domain expertise. Deep learning also stands out in data fusion-the process of integrating data coming from different sources to get an even better view of the power infrastructure. For example, it can integrate camera visual data, infrared thermal data and LiDAR data to create an even more detailed 3D model of a power line and identify risks more accurately. In essence, deep learning equips drones with a higher level of intelligence than simple algorithms, allowing them to analyse complex data, learn from experience, and make decisions. This increases the efficiency, accuracy and reliability of power line inspections, predictive maintenance and other critical tasks in power infrastructure management. With the power of deep learning, we are moving toward a more resilient and sustainable power grid.

III.4 NATURAL LANGUAGE PROCESSING

NLP is that subset of AI focused on enabling computers to understand and interpret the human language and eventually generate it. It is essentially teaching a computer how to read, write and talk-to bridge the gap as they communicate with each other. The DoT relies on NLP for automated, task-related use involving human languages-for the generation of reports and communication[32-34].

Another impressive technique applied in NLP is text summarization- the reduction of very extensive data sets to more concise summaries. This is highly applicable in DoT where tremendous amounts of data are collected by the drones during the inspection. Human operators gain better understanding and take appropriate actions on the information provided by automatically generated key findings and recommendations summarizing inspection reports from NLP algorithms. Sentiment analysis is another useful NLP technique. This would determine the emotional tone of a text and thus may be useful to find the public sentiment over the proposed route of the power line or to analyse customer feedback.

Machine translation translates reports and other documents from one language to another for further effective communication and collaboration across various regions and countries. Speech recognition endows the ability to perceive and understand voice commands in drones for more intuitive yet effective control. It can be especially useful, especially when manual control cannot be achieved or even is impossible. Natural language generation helps the drones to produce human-readable reports from the data it has collected. This automatically made report writing since the effort and time of human operators will be spared in the process. DoT uses NLP mainly for report generation purposes. It can automatically create a report of a very detailed inspection findings and recommendations as well as visual representations of data. Of course, it saves time and eliminates human error or variation in reporting. NLP allows drones to make use of the natural language to communicate with the human operators, thus enabling more effective cooperation and troubleshooting. Using NLP, apart from answering the given questions, it can be used in the retrieval of information where drones can fetch the respective meaningful information from various documents and databases to further aid the decisions to be made, problems solved etc.

There are, however, a number of considerations to be taken into consideration when applying NLP in DoT; importantly data quality, which is critical since NLP models rely mostly on training based on the available data assuming that such data would be right and representative. Model explainability is also crucial for building trust and making the decisions the AI system makes transparent and understandable. Ethical considerations, such as addressing potential biases in algorithms, are also paramount to ensure that AI is used responsibly in the management of power infrastructure. Finally, resources needed for computational machines must be brought in because training and deploying NLP models, especially deep learning models, can require significant computing power. With effective use of NLP and other AI approaches, DoT can significantly enhance power infrastructure monitoring, maintenance, and management to improve efficiency, reliability and safety toward making the power grid more resilient and sustainable.

IV. IMPLEMENTATION CHALLENGES AND CONSIDERATIONS

Implementing AI-powered Drone of Things (DoT) systems in the power sector comes with its own set of challenges and considerations[35-38]. Here's a breakdown:

IV.1 REGULATORY FRAMEWORKS AND AIRSPACE RESTRICTIONS

It is an excellent benefit when it comes to using drones in the case of power line inspection, but with unmanned aircraft comes a great deal of regulatory considerations. Just as manned aircraft fall under a very complex web of rules designed to ensure safety and security, drones, too, require such regulation in place. Regulations vary from country to country but are far more strict for operations beyond the line of sight of the visible work, where the aircraft flies out of the operator's line of sight. This is the kind of operation often called upon in the inspection of long stretches of power lines in less expensive and efficient ways. The activity is very time-consuming, as most of it involves careful planning and attention to definite requirements for obtaining all permits and licenses for BVLOS operations. Another issue is airspace restriction. The power infrastructure sprawls over vast geographic distances, for example areas adjacent to airports, military bases or any other sensitive point at which the flights of drones may be either restricted or generally prohibited. In this regard, their flight paths may have to be changed or some alternative means applied for inspection purposes.

One needs to properly plan crossing these restrictions and coordinate duly with authorities while, in some cases, obtaining special permissions. Besides such deep concerns about safety and security, even very elementary privacy issues have to be factored in. For instance, even normal applications like line inspections with drones would provoke privacy issues over data collection over some private properties. Responsible acquisition of data will require guidelines and clear-cut protocols that ensure proper consent, anonymization of sensitive data and transparency over uses of collected data. It would be basically important to find a balance between the benefits of drone inspection and their corresponding infringement on privacy rights so that the said technology would also be done ethically and accepted by the public. In summary, though, drones may become a very potent tool for inspection of power infrastructure, but their operation is to be done in tandem with a framework of regulations and ethics. Understanding of drone regulations, airspace restrictions and privacy considerations becomes very important in safe and responsible and effective power sector deployment.

IV.2 INTEGRATION WITH EXISTING POWER INFRASTRUCTURE AND DATA SYSTEMS

Integration of advanced AI-powered DoT systems in the existing power grid infrastructure is beyond the simple plugging in of new technology into existing hardware and software networks of managing the power grid. Another major impediment the new DoT systems may face is compatibility with the existing infrastructure with regard to data formats and communication protocols. This could turn out to be an enormous job on translation of data, establishment of secure communications, and initiation of data flows between these disparate systems. Without compatibility, precious data from drones may not flow effectively into the power grid management systems. Another important challenge is that several power companies are holding onto older legacy systems, which, although working correctly, may not be suitable for the quantity of information being churned out by modern AI and drone technologies. They will probably not have sufficient processing speed, storage capacity, or flexibility to integrate with those new systems.

Upgrading and adapting these legacy systems, although possible, can both be expensive and time-consuming and require a lot of investment and potentially disrupt working patterns. In addition, DoT systems produce a large amount of data. Inspection by drones with high-resolution cameras and various sensors would generate significant amounts of data. Such data needs a robust infrastructure for storage, processing and analysis. This would demand enough storage capacity but also includes efficient data processing pipelines and analytics platforms that could extract meaningful insights from otherwise raw data. Without proper data management, the valuable information collected by drones might get lost in the flood of data, thus hindering the potential benefits of the DoT system. Integration of AI-DoT systems into the existing power infrastructure will require careful planning and consideration regarding compatibility issues, legacy systems, and data management challenges. Building solutions that overcome these challenges can be true aids in unlocking the real potential of DoT technology and its successful implementation in the power sector.

IV.3 ACCURACY AND RELIABILITY OF AI ALGORITHMS

The quality of the algorithm used will determine how effective AI-powered drone inspections would be. Algorithms may be strong but not a hundred percent accurate always and in many cases, performance is also influenced by lots of variables. The quality of training data is another such major variable. Because the AI algorithm learns from the input data, if that input data happens to be wrong or incomplete, the outputs made and decisions taken by the algorithm will be untrustworthy. For instance, taking the training of an algorithm with images of pristine power lines, the same algorithm, while facing tiny defects or anomalies on real world power lines, fails to detect them. Thereby, it is essential that the training data prepared should be the right way with diversity, representativeness, and accurate labelling for reliable AI models.

Environmental factors also greatly influence the precision of the AI algorithm, especially those using computer vision. Weather conditions, lighting and image quality can all affect how well an algorithm could interpret visual data. For instance, an algorithm trained on clear, sunny images may find difficulty identifying defects in images captured under foggy or overcast conditions. Other problems include insufficient illumination or casting shadows. This means missing information and a rating which might be incorrect, so correcting this issue demands developing algorithms insensitive to variations in environmental conditions that could get relevant information from poor-quality images. The algorithm itself should be resilient. In addition to quality and the quality of its data, an AI algorithm needs to be reliable under unexpected events or a change in conditions.

It needs to have the ability to handle noisy data, learn about new situations and gracefully recover from exceptions. Testing and validation must be exhaustive to establish consistency and accuracy over a variety of scenarios. This will involve testing the algorithms against different datasets, simulating various environmental conditions, and comparing their performance with established benchmarks. It is only when one gets the accuracy and dependability of AI algorithms will they be able to perform any operation using drones for checking the power lines. They should focus on the proper quality of training data that does not have environmental factors working as obstacles and test and verify them properly to ensure it's robust and reliable. Considering these requirements, we will be able to design trustworthy AI systems with accuracy, enhancing the safety and efficiency in the management of the power infrastructure.

IV.4 DATA SECURITY AND PRIVACY CONCERNS

With the advent of AI-powered drones in power infrastructure inspections comes a critical responsibility: the protection of the sensitive data that these drones collect. That information not only is very detailed about the power grid itself but may also accidentally capture images of private property and individuals. Protecting such information from unauthorized access, misuse and breaches is important. Data breaches can be very crucial because they might expose critical infrastructure to sabotage or disrupt operations, which affects sometimes national security. Cyberattacks launched against DoT systems can steal sensitive information, tamper with inspection results, or even hijack a drone control system. To this effect, proper cybersecurity will involve efficient encryption, access controls and intrusion detection systems and prevent unauthorized access into the system. Regular security audits and vulnerability assessments are also provided to identify potential weaknesses in the system. This is aside from security and there's the critical aspect of data privacy. Clear policies and procedures should make sure that the data which is collected is used correctly and stored without violating individuals' rights as well as privacy regulations.

It relates to obtaining any kind of consent for collecting data, anonymising sensitive information or restricting a certain amount of access from people who are only authorized. Observing data protection principles enhances public confidence and ensures the ethical use of DoT technology. Lastly, determination of clear data ownership is necessary. Determination of the ownership of the information obtained by DoT system-the power company, a technology provider or third parties-would have legal operational implications. Clear ownership in place will ensure that the data managed are kept secure and under control of those best placed to comply with applicable requirements. Determination of the right ownership also will resolve every possible argument over the data at hand. In conclusion, data security and privacy concerns have to be met in a responsible and effective manner before AI-powered drones can take to the skies in the power sector. Data protection, strict security measures, and respect for ethical ways of handling data will give us the power to use these technologies in our favour, while keeping sensitive information secure and under public confidence.

IV.5 LIMITATIONS OF AI-DOT SYSTEMS IN HARSH ENVIRONMENTS

The AI-based solution is extremely promising, though environmental interference is the reason that leads to its decreased efficiency, so DoT systems in particular are of a real necessity to further continue the scope of research and development in areas where it improves the level of robustness and adaptability.

IV.5.1 Weather Woes

Strong winds, heavy rain and snow conditions pose a severe restriction to drone activities. Strong winds may make flight unstable and the picture blurred. Rain and snow may reduce the visibility and affect the functionality of onboard sensors. Sometimes extreme weather even makes it dangerous to deploy drones and therefore inspections have to be rescheduled. This may result in increasing latency in identification of potential issues and risk of power outages.

IV.5.2 Electromagnetic Interference (EMI)

Power infrastructure itself can induce EMI which might interfere with the communication system of the drone or its sensor data readings. The high voltage power lines and electrical substations are sources of electromagnetic fields that have impact on the navigation, communication signals and sensor data in the drone. This might result in inappropriate data collection or loss of communication with the operator and even cause safety hazards if it starts interfering with the flight control.

IV.5.3 Terrain Problems

Power lines are hard to navigate and operate over in difficult and remote terrain, such as mountains or forests. The obstructions due to trees, cliffs and undulating terrain may cause obscurations that will make it impossible for the drone to keep a clear line of sight with the lines under inspection, hence making it impossible to carry out optical inspections. The support of Global Positioning System (GPS) navigation may be weak in such environments. Also, poor access to these areas can be challenging to launch, recover, or provide support for maintenance on the drones. Overcoming these limitations would require continued research and development on:

- **Making more robust drones:** Design drones that are more resistant to weather, have stronger communication systems, and advanced sensors that can work well even in challenging environments.
- **Enhancement of Algorithms:** It may focus on enhancing AI algorithms that are less susceptible to environmental interference and which could robustly extract meaningful information from noisy or incomplete data.
- **Improvement of Navigation and Control Systems:** Advanced navigation and control systems which can operate reliably in GPS-denied environments and challenging terrain.

The AI-DoT systems thus can be extended to make them operational even in highly demanding environments through the resolutions of these challenges. The approach towards integration of AI powered DoT systems in power sector calls for multi facets of solution for various associated challenges and considerations discussed earlier. This will require more collaboration, investment, development in research and commitment to best ethical AI practices.

- **The Way of Collaboration:** DoT technology requires collaboration of multiple stakeholders for its effective deployment. Power companies, technology providers and the regulatory bodies need to join hands to develop industry standards, share best practices and address problems related to regulatory hurdles in the implementation of DoT. Such collaboration will ensure safe, responsible and beneficial application of DoT systems toward both the power industry and the public.
- **Infrastructure Investment:** Huge investments in infrastructure would be necessary to support DoT systems. This includes the need for strong data management systems that can handle the vast data generated by drones, development of strong cybersecurity measures to secure sensitive information, and developing AI algorithms that can provide accurate analysis and reliable predictions. Investment in training and development for personnel is also needed so that the workforce may deliver the operating and maintaining skills associated with these systems.

Continuous research and development needs to be applied in AI so that this area remains highly evolved while developing its systems with strong robustness, reliability and accuracy of the AI-DoT. That means designing better and advanced AI algorithms as well as advancing the capabilities of hardware components and sensor types on the drones. Environmental adversities pose another threat that is bound to happen with any developed system or structure; the only antidote for continuous innovation so DoT stays abreast.
Ethical considerations come to the forefront, so ensuring the responsible use of AI builds public trust and makes way for the acceptance of DoT technology. There must be consideration of issues surrounding data privacy, algorithmic bias and even job loss. Thus, clear ethical guidelines have to be developed; the public has to be assured by means of openness; public discourse has to be made an integral part of confidence-building in this technology. By embracing the multi-faceted approach, the power industry will better overcome all the challenges associated with AI-DoT systems and tap into this transformative technology for full expression. It is bound to lead to safer, more efficient and more reliable power infrastructure for the industries and communities that it shall service.

V. FUTURE TRENDS AND OPPORTUNITIES

The Drone of Things is rapidly evolving, driven by advancements in AI, communication technologies and sensor capabilities. Here are some key future trends and opportunities that will shape the future of AI-DoT in power infrastructure [39-42]:

V.1 IMPACT OF 5G AND EDGE COMPUTING ON DOT PERFORMANCE

This integration of 5G networks and edge computing could be taken as the future direction to revolutionize DoT system capabilities in terms of real-time data processing and autonomous drone operations. Envision a drone flying through networks of power lines inspecting them and taking in images as well as sensor data from the flight. All captured data in 5G can be transferred nearly in real time to a central control center where AI algorithms could analyze it for defects or anomalies. It's just about real-time transfer; the bandwidth is high and the latency is low. An immediate analysis can occur due to faster response times. This would alert the operators, who would immediately take necessary actions and thus prevent an outage. Such a response capability would be very crucial in an emergency situation because the damage caused could be minimized with prompt assessment and action and quick restoration of power supply. In this scenario, with edge computing, the power processing has brought it one step closer to where the data originated from. No longer need it travel its way through to distant servers located in a cloud for analysis; this can be done within the drone itself or at an edge server located nearby.

That again reduces latency and makes possible near-real-time decision-making. For instance, the drone can automatically change its flight path to take a closer look at a potential defect or even raise an alert if it identifies a critical problem. Increased autonomy in this regard improves efficiency but also allows drones to operate in remote or challenging environments where communication with a central control center might be unreliable. This powerful combination unlocks new possibilities for DoT systems. It allows operators to make immediate decisions to react to potential problems before an outage can occur. It enhances the situational awareness of these systems through the steady stream of real-time data regarding the health of the grid. It enables operators to use resources more effectively by allowing drones to be more autonomous and to make adjustments based on changed conditions. Basically, 5G and edge computing are making drones change from data-gathering robots to the smarter agents of analysis on their own in real time, which marks a tremendous stride toward that future of utilizing drones much more integrally in establishing reliability, resilience and sustainability within power infrastructure.

V.2 DEVELOPMENT OF SWARM INTELLIGENCE FOR COORDINATED DRONE OPERATIONS

Imagine a fleet of drones as taking off not necessarily as separate units but rather as a collective swarm, like a flock of birds or a school of fish. This is the vision about swarm intelligence where numerous drones work in cooperation and interactive communication as if a single coherent entity acting with a common purpose. This methodology could be used to change the way we look at and maintain our critical infrastructure in power line inspection. A swarm of drones allows dividing and conquering where different parts of the power grid will be inspected simultaneously instead of relying on one drone to cross large distances. This saves much time for inspection thus enabling frequent and comprehensive review. Also, the concerted movements of the swarm leave no part untouched hence perfect coverage with reduced chances of missing possible faults. This is particularly helpful in inspecting power lines that traverse difficult terrain or remote areas where access might be limited and coverage hard for a single drone. Cooperative properties of swarm intelligence also open avenues for the execution of more complicated tasks. For instance, in coordinated maintenance, drones may change insulators, particularly damaged ones.

During emergencies, a swarm can quickly assess damage, identify weak points and transmit updates to response teams, facilitating fast and efficient rehabilitation. However, significant advancements in drone technology are necessary to fully realize the potential of swarm intelligence. Communication: Drones must be able to communicate perfectly with each other and share information about their location, findings and tasks. This could require robust and reliable communication networks, perhaps using 5G or mesh networks. Advanced algorithms have to be developed in order for the swarm to coordinate and work together without collision or conflict. The inspiration for this draws from nature, studying coordination of movements of insect or animal swarms, and applies these principles to drone technology. Conclusion Swarm intelligence brings a paradigm shift to the ways drones can execute power line inspection and maintenance in much more effective, total and adaptive ways. In achieving this stable and sustainable energy future, wherein power grid reliability and resilience improvement rest on core-drone swarms cohesively working together, ends.

V.3 ADVANCED SENSING SYSTEMS FOR ENHANCED DATA ACQUISITION

The future of DoT in power line inspection lies in the expansion of the sensory capabilities of these aerial robots. Although high-resolution cameras provide useful visual information, equipping drones with advanced sensors unlocks a new dimension of data acquisition, allowing for more comprehensive and accurate assessments of power infrastructure. For example, hyperspectral cameras capture more information than even a normal camera by penetrating the spectrum of the entire electromagnetic spectrum. That is, the cameras "see" in more detail than the naked eye and can detect little variations in light that identify hidden defects or stress in power line components. For instance, a hyperspectral camera is able to detect signs of corrosion or material degradation invisible to an ordinary camera. In LiDAR sensors, detection and ranging work by transmitting laser pulses into the air and measuring their return, which allows the development of sophisticated 3D maps over the surroundings. This serves the purpose in evaluating whether vegetation has started encroaching into space, pointing out trees whose branches and roots could have reached areas that may jeopardize overhead lines, or in more abstract terms, helps to give clear and accurate models of infrastructure in the form of geometric data to base maintenance on or to test scenarios that would require considerable amounts of resources and times to assess on site.

New, more advanced thermal imaging technologies have been developed to improve the inspection capability. Sensors in these technologies detect the heat signatures, which prove very helpful in identifying overheated components as well as loose connections, signs of potential failure. These are especially helpful in transformers, insulators, and other electric components, where temperature variations may point out the problems. With such advanced sensors integrated with AI algorithms, the whole inspection process of drones reaches another dimension. Data collected from such sensors will be further analyzed by AI to reveal any kind of hidden patterns or anomalies that go unnoticed through a human's eye and insight.In other words, AI-based algorithms will inspect hyperspectral data to indicate minute levels of corrosion; LiDAR data for 3D modeling of vegetation overgrowth, and thermal image interpretation of overheating of components. Advanced sensors' powers combined with AI's analysis ability might well lead to a more informed understanding of the power infrastructure status, which ensures better planning in maintenance, quicker response to potential concerns, and therefore a more efficient, stronger power grid.

V.4 POTENTIAL OF AI-DOT FOR GRID OPTIMIZATION AND RESILIENCE

Undoubtedly, the use of AI drones for both inspection and maintenance is quite beneficial, nevertheless it has other applications as well. This Advanced Intelligent Technology, AI-DoT, is therefore expected to revolutionize the operational capabilities of the grid as well as increase the stability of power systems, resulting in a better energy system than the present. Drones constantly operate using multiple sensors and artificial intelligence to enhance the security level of the power system. In addition, these devices are capable of transmitting data in regards to the power flow, voltage levels and environmental parameters active within the grid in real time, thus creating a more detailed and working picture of the grid’s operation. This data can help understand the range of potential threats, including but not limited to high line loading, transient voltage excursions and dangerous weather patterns. In turn, successful tackling of these issues would allow grid controllers to avert load shedding, improve the operational efficiency of the grid and enhance the management of electricity supply.

The focus of additional enhancements of grid systems with AI-DOT will also touch the aspects of improvement of efficiency of grid management. What is the proper way to achieve this? The situation will be analyzed using statistical and historical evidence. The AI algorithms will be driven to recognize the changes and they will help predict how much the natural loads will increase, which would help the operator in properly allocating the power supply to the system while reducing the outflows of energy. This will also lower the operation cost incurred in the electric system and help reduce adverse effects that are created by the generation of power. In addition to that, AI-DoT will aid in bringing in more resources such as solar and wind energy into the power grid management by keeping track of the resources and adjusting the power grid accordingly. There’s also the backbone of the AI-DoT, which serves the same purpose as any operating system in a cloud-managed service and adds a layer of power network resilience.

VI. CONCLUSION

As detailed in this paper, AI powered drones are set to revolutionize the management and delivery of electric power services. The invention of Drone of Things is in the process of taking place where the demand of power essences has shaped management of power infrastructure using artificial intelligence and drones. Application advantages are many especially in AI-DoT. Tasks such as inspection and maintenance, which would have required manual labor, replace with automation hence improving efficiency. Drones operate in locations that pose a risk to human workers or where it may be too difficult to reach. The knowledge of how to process large amounts of information in a very short time is also an asset of AI. You can be sure that even the tiniest defects will stand out in the images as AI brings modern technology in defect detection. Thus leading to predictive maintenance which focus on performing maintenance activities when the system is likely breaking down averting loss due to service outages hence increasing grid reliability. The AI-DoT has increasing pace of innovation in power sector, further research and development efforts will be required to exploit the full potential of AI-DoT.

This includes development of AI algorithms for complex data processing in changing environments, improvements in drones and many different specific types of sensors used on them, as well as sociological issues associated with data handling and bias in AI solutions. Also, new uses of this technology like grid optimization, emergency response, infrastructure planning, and similar will generate larger revenue for AI-DoT. AI-DoT is more than just an opportunity for improvement in technology; it provides us with an entirely different way of handling and controlling the power system. And in doing so, we are preparing the grounds for a stronger and more integrated power grid in the future. AI equipped drones are not only the tools; they are the active contributors for an advanced, better, cleaner operational energy environment. With the greater demand of electric energy as an essential commodity, it is unavoidable that AI-DoT will be paramount in lessening the pressure on the prevailing infrastructure.

Traditional drying.

ABSTRACT

Drying is useful for extending the shelf life of a food product by preventing spoilage, making it a crucial step in the *Rengginang* production process to reduce the water content to a safe level. Traditional drying methods, which rely on sunlight, have several limitations, such as dependence on weather, long processing times, and the risk of contamination. This study aims to evaluate the effectiveness of drying rice crackers using thermal energy from rice husks from a technical and ergonomic perspective. The study was conducted to design a dryer using worker anthropometric data and two 360-minute drying scenarios: one using a rice husk-based dryer and one using direct solar drying. The results show that the height of the top and bottom shelves in the drying room is 1285.39 mm and 617.64 mm, based on anthropometric data of standing eye height and gripping hand height. The maximum height of the control device and the height of the door handle are 1649.01 mm and 876.98 mm, based on anthropometric data of standing hand reach and elbow height. The dimensions of the shelves for placing *Rengginang* have a length and width of 711.96 mm and 525.49 mm, respectively, based on anthropometric data of elbow reach and front reach of the gripping hand. The use of a rice husk energy dryer resulted in an average drying temperature of 69.06°C with a range of 51.29-81.90°C, and the initial moisture content of *Rengginang* of 48.27% was successfully reduced to 8.78%. When dried directly in the sun, the moisture content only dropped to 29.21%. This difference indicates a significant influence of technical conditions on drying performance, such as heat distribution and air ventilation. From an ergonomics perspective, drying efficiency contributes to reduced work duration, heat exposure, and worker physical strain. Optimal drying can reduce the risk of musculoskeletal disorders and improve work comfort. Ergonomics thermal engineering results in effective utilization of rice husk energy, including technical aspects and the design of tools and work processes that are appropriate for worker posture.

I. INTRODUCTION

Traditional food, as a small business, plays a vital role in supporting the rural economy in Indonesia, particularly in Lombok. One popular product is *Rengginang*, a traditional snack made from sticky rice that requires a drying process as a crucial step in its production. In general, the drying process for *Rengginang* is still traditionally carried out by drying it directly in the sun. This method is highly dependent on weather conditions and takes a long time. It also carries the risk of contamination and inconsistent product quality. Direct sun drying carried out in open areas causes losses such as insect infection, uncontrolled and long drying, dust and dirt contamination, and food is susceptible to microbiological contamination by fungi and pathogens as a result of unhygienic conditions in open environments [1], [2].

Rengginang, as a wet food, is also susceptible to contamination by dust, dirt, and microbiological agents such as mold if left in the open for too long. *Rengginang* are traditional rice crackers made from coarsely ground glutinous rice, dried, and then fried until crispy. Although Lombok is located in a tropical region with almost constant sunshine, the temperature is not optimal for the drying process. This is indicated by the long drying time, which automatically stops when the weather is cloudy or rainy. Direct sunlight results in an average drying temperature of 29.44°C [3]. On the other hand, agricultural waste such as rice husks has significant potential as a renewable alternative energy source.

II. THEORETICAL REFERENCE

Lombok Island is an agricultural region where most farmers grow rice as a staple crop. For example, in 2024, according to data from the Central Statistics Agency (BPS), rice production reached 785,918 tons of dry milled grain on Lombok Island, one of Indonesia's agricultural regions [4]. The by-product of processing rice is 20% in the form of rice husks [5], [6]. Theoretically, the potential for rice husks on Lombok Island for 2024 is 157,184 tons [7]. Improper processing of rice husks, which are the main by-product of rice production, causes environmental impacts such as solid waste [8]. The calorific value of rice husk from several research results which have a calorific value equivalent to half the calorific value of coal includes11-15,3 MJ/kg [9], net calorific value 12-16 MJ/kg [10], 13-19 MJ/kg with an average of 18 MJ/kg [11], heat heating value 18.14 ± 0.04 MJ/kg [12]. Rice residue in the form of rice husk and rice straw is used as biofuel to supplement or replace fossil fuels. It has an acceptable calorific value, good thermal characteristics, and low gas emissions in both oxidizing and inert atmospheres, making it a sustainable biomass option for economic and environmental growth [12], [13].

The use of rice husk biomass can be considered as a substitute for fossil fuels, the demand for which is increasing, and the price is increasing, especially for rural communities with small-scale agriculture. Fuel demand is influenced by fuel prices and population growth, which impact economic stability and environmental protection [14]. Rice husks are a biomass waste abundant in agricultural areas, but their use as an energy source for small businesses remains very limited. Proper processing of rice husks can produce an efficient and environmentally friendly drying fuel. Designing a rice husk-based dryer requires consideration of technical and thermal aspects as well as the comfort and safety of business operators. These technical and thermal aspects can be addressed through an energy conversion process using a heat exchanger to convert ambient air into heat. The use of a heat exchanger with rice husk energy can produce a drying temperature between 73 and 119°C, and a mixture of rice husk energy and solar energy produces an average combustion chamber temperature of 347.3°C [15], [16].

Rice husk is suitable for energy use as biomass fuel because of its high silica content, and is superior to rice straw [17]. A heat exchanger can increase the temperature during the drying process by converting biomass energy into thermal energy. A heat exchanger implements the heat transfer process between two fluids at different temperatures separated by a wall without mixing. It can also be used to recover waste heat to reduce the need for additional heating [18-20]. Occupational comfort and safety aspects influence the productivity levels of workers involved in outdoor work due to heat exposure. High heat exposure results in low productivity for outdoor workers, particularly in tropical climates. 60% of workers experience a decrease in productivity when exposed to high heat (WBGT >28°C or temperature >35°C), 30% in indoor or outdoor industries during heat stress conditions, with a decrease in productivity of 2.6% for each degree above the wet bulb temperature of 24°C (WBGT), and a significant economic burden due to work-related heat stress [21-23].

Outdoor workers have a number of risk factors, namely heat stress and heat-related conditions, which affect health, well-being, and productivity, as well as work-related injuries, reduced psychomotor performance, loss of concentration, reduced alertness, loss of coordination, fatigue, and affect productivity and sectoral economies, especially in areas that are highly susceptible to heat [24-27]. Therefore, an ergonomics thermal engineering approach is needed, namely a multidisciplinary approach that integrates the principles of energy efficiency (thermal) and operator comfort and safety (ergonomics) in tool design. Ergonomics assessment is important to increase productivity and reduce risks in physical work [28]. Current ergonomics interventions have had an impact on reducing musculoskeletal disorders (MSDs) complaints widely [29]. The decline in performance that influences the decline in work productivity is the impact of various complaints, both physical and psychological [30].

The Occupational Safety and Health Administration (OSHA) provides recommendations regarding ergonomic measures to prevent sources of disease, namely (1) engineering, such as the design of work tools and work stations; (2) management engineering, such as work organization. These recommendations reduce musculoskeletal disorders in workers to avoid the risk of work injuries [31]. Ergonomics thermal engineering, such as the use of cross ventilation, shade nets, and tool design at optimal heights, has been proven to reduce heat loads and the risk of worker fatigue [32]. Thermal comfort for outdoor applications has more than 20 indices, human psychological states, and other parameters, but most of the models are based on physiological and psychological levels [33].The combination of rice husk-fueled dryer design and worker-oriented design is known as ergonomics thermal engineering. This approach is expected to produce a dryer design that is not only energy efficient and uses renewable fuels but also ergonomic in its use. Thus, the application of appropriate technology based on ergonomic thermal engineering can increase productivity, product quality, and the sustainability of small businesses such as *Rengginang* production at the household level.

III. MATERIALS AND METHODS

The study was conducted using an ergonomics thermal engineering approach. The ergonomics approach was implemented through the participation of workers from small *Rengginang* (rice crackers) businesses who dry the product. The study used worker anthropometric data, a Nordic Body Map (NBM) questionnaire, percentile tables, and materials such as rice husks, *Rengginang* (rice crackers), drying equipment, a drying device with a vertical shelf-shaped drying chamber, and two biomass furnaces. The dryer design was based on user participation, with dimensions based on worker anthropometric data and readily available dryer materials. This ensured the dryer was appropriate for the needs of small *Rengginang* businesses.

The dryer was designed for rice husk energy, and the dryer dimensions were based on workers' anthropometric data. Female workers were first subjectively assessed for musculoskeletal complaints about their work posture during the *Rengginang* drying process.

Musculoskeletal complaints were measured using the Nordic Body Map (NBM) questionnaire. The Nordic Body Map (NBM) measures and identifies muscle and skeletal complaints in various parts of the worker's body due to their work posture. This tool is handy in the initial assessment of ergonomics risks, especially in work environments that require physical activity, such as lifting, bending, prolonged sitting, or repetitive movements. This questionnaire is standard and widely used in ergonomics research due to its low cost, worker involvement, and ease of data collection.

The Nordic Body Map questionnaire was used to identify MSDs symptoms in workers related to ergonomics risks, measuring the risk of injury in human-machine interaction activities [34], [35]. The ergonomic approach was limited to dryer design, while the thermal approach was carried out through direct sunlight drying tests and a drying device. *Rengginang* samples weighing approximately 5 kilograms were used for testing in the drying chamber, and approximately 1 kilogram for testing in direct sunlight. Ergonomics analysis was conducted by comparing them with related research results, while thermal analysis was performed by measuring the ambient and drying chamber temperatures and moisture content. Temperature measurements in the dryer were performed using a K-type thermocouple and a data logger. The dryer design used in this study is a modification and application of Patents IDS000004448 and IDS000005388 [36], [37].

The measurement of workers' anthropometric data was adjusted to the dryer design's needs. The subjects were 25 female workers taken from one of the traditional *Rengginang* businesses in Mataram, Lombok, Indonesia. Measurements include eye height in a standing position, namely for the height of the top shelf, the height of the hand gripping for the height of the bottom shelf, the height of the hand reach in an upright standing position for the maximum height limit of the control device, the height of the standing elbow for the height of the door handle, the width of the elbow span for the maximum length of the tray, and the front reach of the hand gripping for the maximum width of the tray. Anthropometric data were then calculated using percentile values. In this case, the 5th percentile ensures that all subjects can use the dryer design if implemented in the prototype. The 5th percentile is shown in Equation 1.

$$\text{Percentile } 5 = \bar{x} - (1.65\ \delta) \tag{1}$$

The 5th percentile is calculated based on the mean value ($\bar{x}$) and standard deviation (δ) from measurement data. Standard deviation (δ) as in Equation 2, where x_i is the measurement data, $\bar{x}$ is the mean of the measured data, and n is the number of measured data.

$$\delta = \sqrt{\frac{\sum(x_i - \bar{x})^2}{n-1}} \tag{2}$$

Dryer testing was conducted to dry *Rengginang* by measuring the ambient temperature, drying chamber temperature, and outlet temperature. The testing time was 360 minutes to avoid over-drying and ensure stable drying results. Furthermore, the traditional drying process for *Rengginang* in the sun can take 6–12 hours, depending on the weather, and a 360-minute test is a realistic representation. The calculation of the %wb (wet basis) moisture content of *Rengginang* uses several equations. The wet moisture content (wb) is calculated based on the total weight.

$$\text{Initial Water Mass} = \text{Initial Material Mass x Initial Material Moisture Content} \tag{3}$$

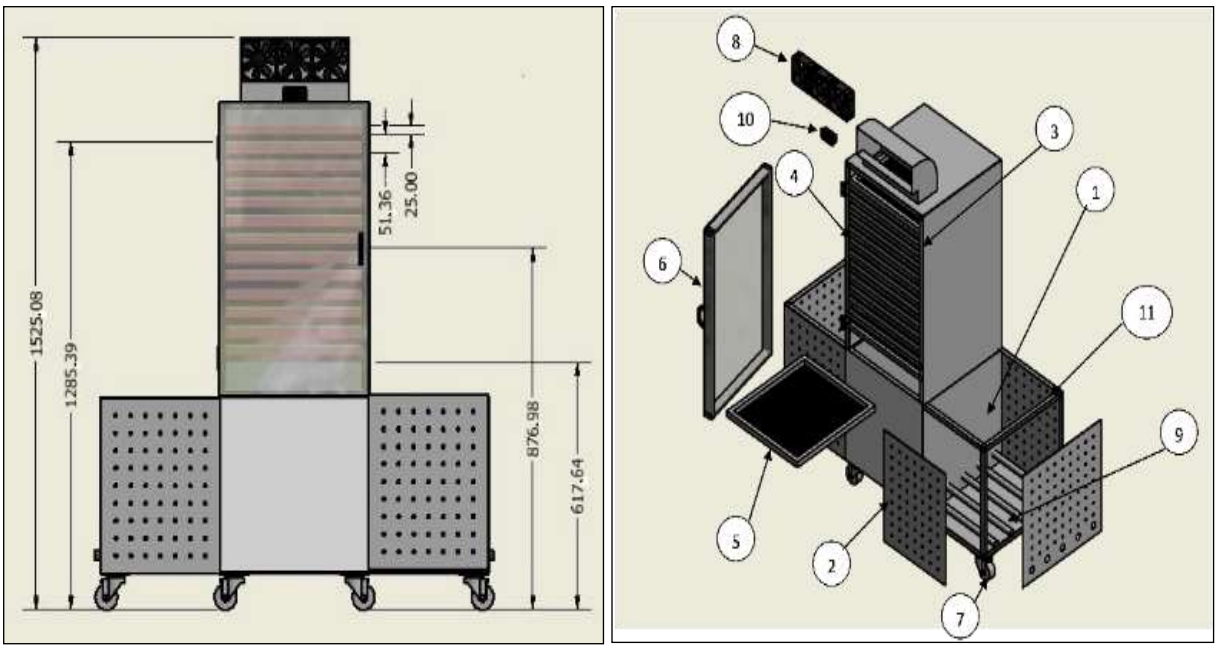
$$\text{Dry Mass} = \text{Initial Material Mass} - \text{Initial Water Mass} \tag{4}$$

$$\text{Final Water Mass} = \text{Final Material Mass} - \text{Dry Mass} \tag{5}$$

$$\text{Final Moisture Content (wb)} = \frac{\text{Final Water Mass}}{\text{Final Material Mass}} \text{ x } 100\% \tag{6}$$

In the research, the results of the dryer design have not been tested on humans or workers, only limited to the use of workers' anthropometric data.

IV. RESULTS AND DISCUSSIONS



The results of measuring the level of musculoskeletal complaints using the Nordic Body Map questionnaire on several workers who carried out the *Rengginang* drying process found that after work, the average was 55. This total score has a moderate risk level and requires corrective action. The total individual score from the measurement of musculoskeletal complaints using the Nordic Body Map 50-70 has a moderate risk level and requires improvements to the work tools used [30]. Musculoskeletal complaints in workers are caused by unnatural working postures and exposure to the heat of the sun due to work being carried out in open areas during the *Rengginang* drying process, as shown in Figure 1. Figure 1 is based on the guidance of a student's final assignment that has not been published [38]. Figure 1 shows the work process carried out with an unnatural posture.

Figure 1: The worker's posture when drying *Rengginang*.
Source: [38].

Work processes carried out in unnatural postures can result in musculoskeletal complaints with symptoms including pain in the upper and lower back, neck, shoulders, hands, wrists, elbows, knees and ankles, as well as an increased risk of work injuries [31], [39], [40]. An ergonomics approach to small-scale *Rengginang* production was applied through worker participation, namely the use of anthropometric data. The results of anthropometric data measurements from 25 workers obtained an average standing eye height of 137.732 cm with a standard deviation of 5.572 and a 5th percentile value of 128.539 cm. The average hand grip height was 66.888 cm with a standard deviation of 3.105, and the 5th percentile value was 61.764 cm. The average hand reach height was 177.732 cm with a standard deviation of 7.776, and the 5th percentile value was 164.901 cm. The average standing elbow height was 94.86 cm with a standard deviation of 4.341, and the 5th percentile value was 87.698 cm. The average elbow span width was 75.9 cm with a standard deviation of 2.851, and the 5th percentile value was 71.196 cm.

The average front reach of the grasping hand is 57.90 cm with a standard deviation of 3.241, and the 5th percentile value is 52.549 cm. The application of the 5th percentile from the results of anthropometric data measurements is used as a maximum dimension requirement for the dryer design in this study. The height of the top and bottom shelves in the drying chamber is 1285.39 mm and 617.64 mm, based on anthropometric data of standing eye height and grasping hand height. The maximum height of the control device and the height of the door handle are 1649.01 mm and 876.98 mm, based on anthropometric data of the hand reach height and standing elbow height. The dimensions of the rack, which is used to place the *Rengginang*, have a length and width of 711.96 mm and 525.49 mm, respectively, based on anthropometric data of the elbow reach width and the front reach of the hand gripping. These results are applied to the design of the dryer as presented in Figure 2. Based on the design in Figure 2, the application is in the form of a prototype drying tool with a *Rengginang* drying process as shown in Figure 3.

(a) (b)

Figure 3: Drying of *Rengginang*: a) rice husk energy dryer, b) direct sunlight.
Source: Authors, (2026).

The drying process for *Rengginang* using a dryer designed with an ergonomics thermal approach, as shown in Figure 3(a), can be carried out indoors. This ensures workers are not exposed to the sun's heat and allows for a more natural working posture, as seen from the use of vertical racks in the drying room. The energy source uses rice husk biomass. The dryer is also equipped with solar cells to drive a fan, ensuring heat transfer occurs through forced convection. This is in line with the research of Duque-Dussán et al., which shows that hybrid solar dryers that combine solar and mechanical drying principles are equipped with biomass burners and photovoltaic systems, allowing for completely independent drying [41]. A shelf adapted to anthropometric data makes it easier for operators to retrieve/insert trays without bending. Furthermore, the resulting product is more hygienic because the drying process takes place in a closed drying room.

Workers no longer have to monitor the dried product, and it doesn't need to be turned over. Ergonomics interventions through engineering have resulted in a significant reduction in ergonomics risk factors and reduced rates of musculoskeletal disorders among workers [42]. Ergonomics approaches are effective in reducing postural loads and can be seen as an opportunity for farmers to increase attention to health and well-being in farming [43]. Figure 3(b) shows the direct sun-drying process carried out in an open space. This leaves the dried product vulnerable to dust and other dirt, and workers exposed to the sun's heat. Furthermore, the drying temperature is suboptimal because it uses ambient temperature. Figure 4 shows the results of temperature measurements for the *Rengginang* drying process using rice husk energy dryers and direct sunlight.

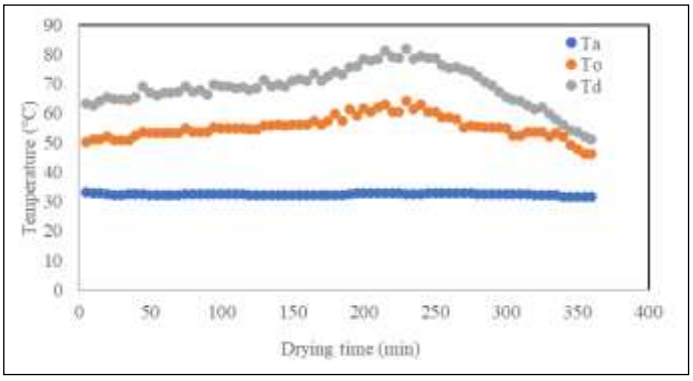

Figure 4: Distribution of drying temperature of *Rengginang* with a dryer and direct sunlight.
Source: Authors, (2026).

The average ambient temperature (Ta) used to dry *Rengginang* was 32.42°C, with a range of 31.54-33.04°C. Temperature measurements were taken from the first 5 minutes to 360 minutes, from 9:00-15:00 WITA. This is in line with Sarmad et al., who found that solar radiation intensity varies from 9:00-15:00 and increases from morning until reaching its maximum value at 13:00 [44]. The use of a dryer powered by rice husk energy resulted in an average drying temperature (Td) of 69.06°C with a range of 51.29-81.90°C. This temperature range resulted from using rice husk in the furnace for only one filling and without adding any additional rice husk mass. Furthermore, the lower initial temperature resulted from the rice husk undergoing a prior evaporation process. The moisture content of rice husk is 6-10%, and there is a drying zone in the biomass, namely the process of evaporating the water content before further heating occurs [45-47]. When rice husks are converted into charcoal, high temperatures are generated. Test results also show that the outlet temperature of the drying chamber (To) remains quite high, averaging 55.29°C and ranging from 46.2 to 64.11°C. The drying temperatures inside and outside the drying chamber were 113.02% and 70.54% higher, respectively, compared to ambient temperature. At these temperatures, Figure 5 shows the decrease in the mass of the dried *Rengginang*.

Figure 5 shows a comparison of the decrease in *Rengginang* mass during the 360-minute test between the rice husk dryer and direct sun drying. The average mass of *Rengginang* in the rice husk energy dryer was 1086 g on each rack, while direct solar drying was 1086 g. The use of the rice husk energy dryer showed a faster decrease in *Rengginang* mass during 360 minutes compared to direct sun drying. This is influenced by the higher temperature used in the rice husk dryer. The rice husk dryer produced a final mass of 616.2 g, while direct sunlight drying produced 794 g. *Rengginang* initial moisture content is 48.27% wb. The moisture content %wb (wet basis) is the percentage of moisture content in a material calculated based on its wet weight.

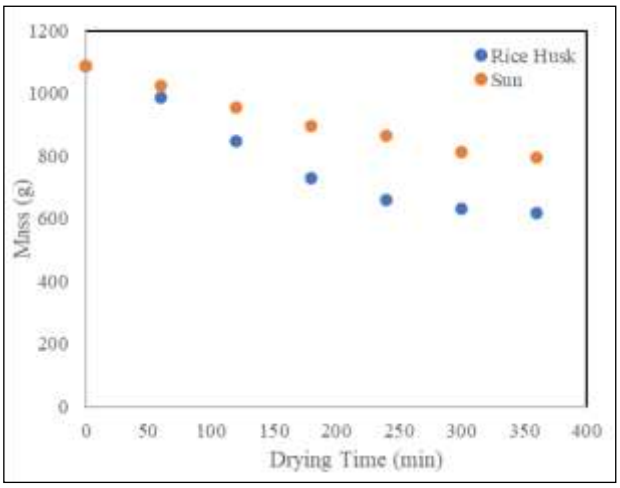

Figure 5: Comparison of drying *Rengginang* using rice husk dryer and direct sunlight.
Source: Authors, (2026).

In this study, drying *Rengginang* for 360 minutes showed that drying using rice husk energy accelerated the reduction in the product's water content compared to conventional solar drying. Comparison data for drying using rice husk energy and direct sun drying are presented in Table 1.

Table 1: Comparison of data on rice husk energy dryer and direct sun drying.

Parameter	Rice husk energy dryer	Direct sun drying
Mass of initial materials (g)	1086	1086
Initial moisture content of material (%)	48.27	48.27
Final material mass (g)	616.2	794
Final moisture content (wb) (%)	8.83	29.25
Drying time (minutes)	360	360

Source: Authors, (2026).

Based on Table 1, the rice husk energy dryer significantly reduced the initial moisture content of *Rengginang* by 48.27% to 8.83% in 360 minutes. This value is within the ideal moisture content limit for *Rengginang* products ready for frying (<12%). The water content of *Rengginang* according to SNI 01-4307-1996 regarding rice crackers is a maximum of 12% [48]. This demonstrates that the rice husk energy dryer is operating optimally, with stable and efficient heat distribution and airflow. Meanwhile, sun direct drying yielded a final moisture content of 29.25% within the same drying time. This indicates that the drying process is not optimal due to differences in heating temperature and uneven air circulation. Table 1 shows how drying performance is highly dependent on technical conditions such as temperature, airflow, and heat distribution. Rice husk energy dryers provide stable heat and can be used at any time (independent of the weather), thus offering advantages in terms of time and quality. In addition, rice husks' abundant availability can reduce waste through their use in drying energy. Vast expanses of rice fields have the potential to utilize rice husk waste as a biomass raw material to support renewable energy [49]. Meanwhile, sun direct drying often requires more than a full day to reduce the moisture content to less than 12% due to its high dependence on weather, humidity, and direct sunlight.

Ergonomics studies have shown that these differences in performance have direct implications for workers' physical workload and duration of heat exposure. More energy-efficient rice husk drying means shorter labour time to achieve the final result, thus reducing exposure to high temperatures and lowering the risk of muscle fatigue and heat stress. This is particularly relevant in traditional food processing activities such as *Rengginang*, which are generally carried out manually in high-temperature environments. Conversely, sun direct drying shows suboptimal drying, which extends the work duration and increases static loads due to the need to regulate and monitor the dryer for longer periods. Furthermore, this inefficiency can impact the frequency of stirring and tray rearrangement activities, as well as increase muscle fatigue in the arms, back, and lower legs due to unnatural working postures. Therefore, an ergonomics thermal engineering approach in designing traditional rice husk energy dryers is not only technically superior but can also provide significant ergonomics benefits, such as reducing prolonged heat exposure, shortening work cycles, reducing the risk of musculoskeletal disorders, and increasing work comfort. This application, which is centered on humans as workers, is in line with research results that state humans remain important for adaptability and innovation, so human-machine integration is a crucial factor [50].

The importance of an ergonomics approach in evaluating the performance of drying equipment so that technological innovation prioritizes process efficiency and the long-term safety and health of workers.

V. CONCLUSIONS

Drying *Rengginang* using rice husk energy for 360 minutes can increase the ambient temperature and optimally reduce the moisture content. The initial moisture content of 48.27% can be reduced to 8.83% when using rice husk energy, while under direct sunlight conditions, the reduction only reaches 29.25%. This indicates that factors such as drying temperature, air circulation, and rice husks influence the drying duration. From an ergonomics perspective, drying time impacts not only product quality but also workers' physical workload. Fast and effective drying can reduce heat exposure, repetitive manual activities, and the risk of musculoskeletal disorders. Conversely, suboptimal drying can potentially extend work time and increase physical fatigue. Utilizing rice husk energy as a heat source not only offers promising efficiency and sustainability but also contributes to increased work comfort if supported by ergonomic tools and process design. The practical implications of these results encourage the need to integrate technical and ergonomics approaches in the development of small and medium-scale food drying systems.

ABSTRACT

The selection of portable retinographs has become a significant challenge in teleophthalmology and clinical services that depend on fast and accurate capture of fundus images. The wide variety of models available on the market, each with distinct technical and operational characteristics, requires a structured evaluation based on multiple criteria. This study aimed to apply the Analytic Hierarchy Process (AHP) method to support multi-criteria decision-making in choosing the portable retinograph best suited to clinical practice needs. Criteria such as image quality, portability, battery life, cost, technical support, and compatibility with digital systems were defined. Based on the hierarchical structuring of the problem and the elaboration of paired comparison matrices, the relative weights of each criterion and the performance of the evaluated alternatives were calculated. The results objectively revealed the most appropriate model according to the priorities established by the experts. It was concluded that AHP proved to be effective, transparent, and replicable, making it a valuable tool for decision-making processes involving medical technology.

I. INTRODUCTION

Fundus photography is an essential procedure for detecting and monitoring ocular pathologies such as diabetic retinopathy, glaucoma, vascular occlusions, and macular diseases [1]. With the expansion of teleophthalmology programs and primary care screening, portable fundus cameras have come to play a central role, enabling examinations outside hospital environments and contributing to early diagnosis in remote populations or those with limited access to specialists [2]. The growth of the portable fundus camera market has brought a variety of models differing in cost, image resolution, battery life, ergonomics, and integration with information systems [3]. This diversity makes the selection process complex, especially when budget constraints and specific operational needs are involved. Decisions based solely on the lowest price or isolated features may compromise exam quality and the effectiveness of the service [4]. In this context, multicriteria decision-making (MCDA) methods emerge as alternatives capable of systematizing judgments and balancing conflicting criteria [5]. Among them, the Analytic Hierarchy Process (AHP), developed by Thomas Saaty, stands out for its ability to organize complex problems into hierarchical structures and transform subjective judgments into consistent mathematical values [6]. The objective of this study is to apply the AHP method to select the portable fundus camera most suitable for the needs of an ophthalmology clinic or telemedicine program. To achieve this, relevant decision criteria were defined, the problem hierarchy was constructed, and pairwise comparisons between criteria and alternatives were carried out, allowing the calculation of relative weights and the identification of the best option. The specific objectives include identifying the decision criteria, structuring the hierarchical model of the problem, applying AHP to the available alternatives, and assessing the consistency of the judgments made.

II. RELATED WORK

The application of multicriteria decision-making methods to the selection and management of health technologies has been widely discussed in the literature, particularly in the context of acquiring medical equipment [7]. Within the use of Multicriteria Decision Analysis (MCDA) for medical equipment management, the AHP stands out as one of the most suitable methods to support evaluation, selection, and investment-prioritization tasks in resource-constrained environments [8]. In this scenario, AHP has become established as a tool capable of reducing uncertainties and providing greater transparency to decisions involving multiple technical, economic, and operational criteria [9],[10]. In more specific studies, various authors have proposed AHP-based models to directly support the selection of medical devices. One application of AHP elicited user needs for acquiring a computed tomography scanner, demonstrating that the method enables the integration of preferences from different stakeholders into a structured model for the procurement of diagnostic imaging equipment [11]. Along similar lines, [12] developed a multicriteria methodology based on AHP to select the most ergonomically suitable ultrasound device, considering criteria related to technical performance and the well-being of healthcare professionals.

Other works reinforce the use of AHP as the core of decision-support tools for hospital procurement. A model for weighting criteria for selecting medical equipment based on AHP highlighted its ability to structure and prioritize factors such as cost, maintenance, reliability, and technical support [13],[14]. More recent studies have advanced toward integrated frameworks that combine AHP with other methods—such as TOPSIS, VIKOR, and PROMETHEE—with the aim of increasing the robustness of decisions and incorporating sensitivity-analysis scenarios in the selection of complex medical devices [15]. In the specific domain of imaging technologies and diagnostic services, [16] employed AHP to rank radiology departments, demonstrating the method's potential for capturing aspects of quality, efficiency, and technological availability in the evaluation of diagnostic imaging services. The performance of two portable retinal cameras—one smartphone-based and the other smartscope-based—was assessed for capturing fundus images, highlighting the growing role of portable devices in ophthalmologic practice and their integration with OCT examinations [17].

A recent review addressed the advancement of portable devices in ophthalmology and their implications for screening diseases such as diabetic retinopathy and age-related macular degeneration [18]. Although these studies do not directly apply AHP to the selection of portable fundus cameras, they highlight the growing relevance of these technologies and the need for structured evaluation methods [19]. In light of these works, the present study contributes by applying AHP specifically to the selection of portable fundus cameras, articulating technical criteria (image quality, digital compatibility), operational criteria (portability, battery life), and organizational criteria (cost, technical support). Unlike broader approaches to selecting medical equipment or other imaging devices, this article focuses on the specific context of teleophthalmology and clinical ophthalmic practice, filling a gap in the literature by proposing and testing an AHP model for the comparative selection of different commercial portable fundus-camera models.

III. LITERATURE REVIEW

III.1 ANALYTIC HIERARCHY PROCESS (AHP) METHOD

The Analytic Hierarchy Process (AHP) was developed by Professor Thomas L. Saaty in the early 1970s and later consolidated in a classical work dedicated to the method [20]. It emerged as a response to the need to structure and quantify subjective judgments in complex decision-making processes in which different qualitative and quantitative criteria must be considered jointly and in a comparable manner [21]. Since then, it has become one of the most widely used multicriteria decision-making methods, applied in fields such as healthcare, engineering, logistics, public management, and technology selection [10]. AHP is based on three fundamental principles: decomposition, comparative judgments, and priority synthesis [22]. Initially, the problem is decomposed into a hierarchical structure that facilitates understanding of the decision process. The upper level contains the overall objective; the intermediate levels contain the criteria and subcriteria; and at the base of the hierarchy are the alternatives. To illustrate this organization, it is recommended to include a figure representing the hierarchical structure of the problem, such as a vertical diagram containing the objective, criteria, and alternatives [23], as shown in Figure 1.

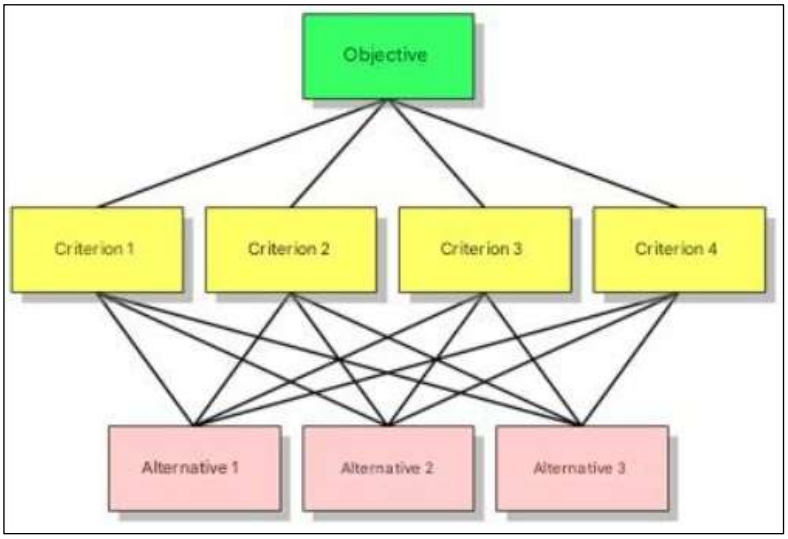

Figure 1: Hierarchical structure of the AHP.
Source: [6].

After the problem has been structured, the stage of comparative judgments begins. The elements at each level of the hierarchy are compared pairwise using Saaty's Fundamental Scale, which ranges from 1 (equal importance) to 9 (extreme importance), including their reciprocal values. This scale enables the intuitive capture of the relative preference between two elements. To reinforce this understanding, it is recommended to include a Table 1 with Saaty's Fundamental Scale, containing descriptions and examples.

Table 1: Saaty scale used in the pairwise comparisons.

	Element 1	**Element 2**	**…**	**Element D**
Element 1	1	a_{12}	…	a_1D
Element 2	$1/a_{21}$	1	…	a_2D
⋮	⋮	⋮	⋮	⋮
Element D	$1/aD_1$	$1/aD_2$	…	1

Source: [6].

The comparisons are organized into square matrices, from which the priority vector is extracted, typically through the principal eigenvector associated with the largest eigenvalue λmax. This vector mathematically represents the weight of each element in relation to the objective [24] ,[25]. An essential aspect of the method is the verification of the consistency of the judgments made. Because human comparisons may naturally present inconsistencies, a specific procedure was established to assess the quality of these comparisons [26]. This process involves calculating the Consistency Index (CI) and the Consistency Ratio (CR), which relates the CI to a reference value known as the Random Index (RI). When the CR is equal to or less than 0.10, the judgments are considered to have acceptable coherence, indicating that the comparisons follow a logically consistent pattern [27]. Another important contribution of AHP is its ability to integrate judgments from multiple experts. When more than one evaluator is involved, judgments can be aggregated using the geometric mean, preserving independence and valuing collective expertise.

This step is particularly relevant in technological decision-making in healthcare, where shifts in priorities can significantly impact the final choice [28]. Several studies demonstrate the versatility and potential of AHP when applied to complex technological systems. Different authors have used the method in areas such as software selection, educational platform choice, and supplier evaluation in the healthcare sector, highlighting its ability to handle multiple—and often conflicting—criteria. These examples show that AHP is well suited for decision-making processes that require a balance between technical, operational, and economic factors, which supports its application in the analysis and selection of portable fundus cameras [29]. Thus, AHP stands out for its robustness, its ability to handle structured subjectivity, and its methodological clarity, which allows individual perceptions to be transformed into rational, measurable, and justifiable decisions [30].

III.2 PORTABLE FUNDUS IMAGING TECHNOLOGIES

Portable fundus cameras emerged as an alternative to traditional tabletop fundus imaging systems typically used in clinics and hospitals. These devices employ miniaturized optical systems combined with high-resolution digital sensors, enabling the capture of retinal images without pupil dilation or with minimal dilation, depending on the model [31] ,[32]. Among the leading globally recognized manufacturers are the Optomed Aurora, the Volk Pictor Plus, the Remidio Fundus on Phone, and compact models from Topcon, which—although more robust—offer versions with increased portability. These devices show significant differences in image quality, ergonomics, battery life, and integration with telemedicine software. Despite their advantages, challenges remain, such as balancing optical quality and portability, the high cost of some models, and the need for integration with electronic health record systems. Current trends point toward devices with enhanced connectivity, integration with artificial intelligence algorithms for automated pathology detection, and greater operational autonomy [33].

IV. METHODOLOGY

This study is characterized as applied research, quantitative and descriptive in nature, using the multicriteria AHP method for selecting portable fundus cameras. The methodological application followed a structured sequence beginning with a clear definition of the problem: selecting the most suitable device among the models available on the market. Next, the evaluation criteria were defined based on the literature and expert analysis: image quality, portability, battery life, cost, technical support, and compatibility with electronic record systems. The problem was then organized into a hierarchical structure composed of the objective at the top, the criteria at the intermediate level, and the evaluated alternatives at the base. Three representative market alternatives were considered: a model with high optical precision (A), an intermediate model with good cost-benefit ratio (B), and an ultracompact smartphone-based model (C). For each criterion, experts performed pairwise comparisons using Saaty's scale. The resulting matrices enabled the calculation of relative weights for the criteria and the priorities of the alternatives. The consistency ratio was calculated for all matrices to verify the reliability of the judgments. The analysis was carried out using automated spreadsheets developed in Excel, allowing extraction of eigenvectors, consistency indices, and the final ranking of alternatives.

IV.1 DATA COLLECTION AND PROCESSING

Data collection was conducted exclusively through documentary research and analysis of technical information provided by the manufacturers of the selected devices. This procedure is widely used in studies applying the AHP method, as it allows the gathering of objective data on characteristics, specifications, and functionalities of the evaluated alternatives, serving as the basis for building the comparisons. Pairwise comparisons between criteria and between alternatives were defined based on the analysis of the collected technical information, using Saaty's Fundamental Scale (1–9). The assigned values were organized in electronic spreadsheets (Microsoft Excel®), which were also used for calculating eigenvectors, normalization processes, verification of consistency indices, and obtaining the model's final priorities.

The data processing followed these steps:

• Construction of the judgment matrices
• Normalization of the matrices
• Calculation of priority vectors
• Calculation of the largest eigenvalue (λmax)
• Calculation of Consistency Indices

$$CI = \frac{\lambda \max - n}{n-1} \quad (1)$$

• **Calculation of the Consistency Ratio (CR):**

$$CR = \frac{CI}{RI} \quad (2)$$

Where RI is the Random Index presented by Saaty (1980). Only matrices with CR ≤ 0.10 were considered consistent, according to the classical recommendation in the literature [6],[20].

IV.2 DEFINITION OF CRITERIA

The definition of criteria considered three sources:

(i) specialized literature on teleophthalmology and diagnostic technologies;
(ii) international guidelines on ophthalmic image quality;
(iii) technical opinion of the interviewed experts.

The literature highlights that criteria such as image quality, technical support, portability, and digital compatibility are decisive in the adoption of portable diagnostic equipment [34]. Accordingly, six central criteria were defined for the analysis:

• **C1 – Image quality:** directly associated with diagnostic accuracy.
• **C2 – Portability:** fundamental for remote screenings.
• **C3 – Battery life:** relevant in fieldwork and regions without electrical infrastructure.
• **C4 – Cost:** including acquisition and cost-effectiveness.
• **C5 – Technical support and maintenance:** critical for operational continuity.
• **C6 – Digital compatibility:** integration with EHR, PACS, and telemedicine systems.

The choice of these criteria aligns with recommendations from technology assessment studies and the guidelines of the American Telemedicine Association.

IV.3 DETERMINATION OF WEIGHTS

To determine the weights of the criteria, the pairwise comparison method was applied according to the Fundamental Scale [35]. The study compared each criterion with the others in terms of relative importance, resulting in the matrix presented in Table 3. The weights (priority vector) were obtained through:

1. **Normalization of the AHP matrix:**

$$a'_{ij} = \frac{a_{ij}}{\sum_{i=1}^{n} a_{ij}} \quad (3)$$

1. **Calculation of the weight vector (w_i):**

$$w_i = \frac{1}{n}\sum_{j=1}^{n} a'_{ij} \quad (4)$$

2. **Mathematical validation using the principal eigenvector:**

$$A\mathrm{w} = \lambda_{\max}\mathrm{w} \quad (5)$$

The final weights, presented in Table 4, highlighted the predominance of **C1 (0.30)** and **C5 (0.20)**, a finding consistent with previous studies on technology decision-making in clinical settings. The consistency of the judgments was verified by calculating the Consistency Ratio (CR), which in this study resulted in **CR = 0**, indicating full coherence of the comparisons.

IV.4 APPLICATION OF THE AHP METHOD

The application of the Analytic Hierarchy Process (AHP) in this study followed a structured set of steps that allowed the transformation of experts' subjective judgments into quantitative measures used to select the portable fundus camera most suitable for the clinical context. The process began with defining the alternatives, constructing the judgment matrix for the criteria, calculating the relative weights, assessing consistency, and, finally, synthesizing the overall priorities of the evaluated devices.

Initially, three commercially representative models of portable fundus cameras were selected based on their technical relevance and widespread use in teleophthalmology services. These models are presented in Table 2.

Table 2: Portable fundus camera models analyzed.

Commercial Model	Manufacturer	Main Features
Optomed Aurora	Optomed	High resolution, advanced ergonomics, suitable for teleophthalmology.
Volk Pictor Plus	Volk	Good image quality, widely used in screening.
Remidio Fundus on Phone	Remidio	Smartphone-attached system, extreme portability, and high digital integration.

Source: Authors, (2026).

Next, the six evaluation criteria were defined, representing the most relevant factors for choosing the device: image quality, portability, battery life, cost, technical support, and integration with electronic systems. Each criterion was described based on the literature and the evaluators' experience, as shown in Table 3.

Table 3: Evaluation Criteria.

Code	Criterion	Description
C1	Image Quality	Sharpness, resolution, and diagnostic capability of the fundus.
C2	Portability	Weight, size, and ease of transport.
C3	Battery Life	Continuous operating time without recharging.
C4	Cost	Purchase price and cost-effectiveness.
C5	Technical Support and Maintenance	Access to maintenance, training, and manufacturer assistance.
C6	Compatibility with Electronic Systems	Ability to integrate with EHR, PACS, and telemedicine platforms.

Source: Authors, (2026).

With the criteria defined, the pairwise comparison matrix was constructed using Saaty's Fundamental Scale (1 to 9). The experts assessed the relative importance of each pair of criteria, resulting in the matrix presented in Table 4.

Table 4: Pairwise Comparison Matrix of the Criteria.

	C1	C2	C3	C4	C5	C6
C1	1,00	2,00	3,00	2,00	1,50	3,00
C2	0,50	1,00	1,50	1,00	0,75	1,50
C3	0,33	0,67	1,00	0,67	0,50	1,00
C4	0,50	1,00	1,50	1,00	0,75	1,50
C5	0,67	1,33	2,00	1,33	1,00	2,00
C6	0,33	0,67	1,00	0,67	0,50	1,00

Source: Authors, (2026).

From this matrix, the priority vector (normalized principal eigenvector) was calculated, determining the weights of the criteria presented in Table 5.

Table 5: Relative Weights of the Criteria.

Criterion	Description	Relative Weight (wi)
C1	Image Quality	0.30
C2	Portability	0.15
C3	Battery Life	0.10
C4	Cost	0.15
C5	Technical Support and Maintenance	0.20
C6	Digital Compatibility	0.10
Sum		1.00

IV.5 ANALYSIS OF FUNDUS CAMERAS

The analysis of portable fundus cameras considered the three selected models (Table 1), evaluated across the six established criteria. The selection of these models was based on commercial availability, relevance in teleophthalmology programs, and established use in clinics and research, following recommendations from international studies. The models exhibited distinct characteristics, allowing for a robust multicriteria evaluation. The Optomed Aurora stood out for its high image quality and exemplary technical support; the Volk Pictor Plus demonstrated a balance between portability and cost; while the Remidio Fundus on Phone excelled in digital integration and extreme portability. Performance evaluation used scores from 1 to 9 (Saaty Scale), which were subsequently normalized and aggregated using the criteria weights. This procedure follows the additive synthesis process:

$$\text{"Overall Score of the Alternative"}\ A_k = \sum_{i=1}^{n} \quad (w_i \cdot p_{ik}) \tag{6}$$

V. RESULTS AND DISCUSSION

The results obtained through the application of the AHP method provided a clear understanding of the relative importance of each criterion in the selection of a portable fundus camera and the influence of these weights on the final ranking of the evaluated alternatives. Analysis of the pairwise comparison matrices revealed that the image quality criterion (C1) emerged as the most relevant in the decision-making process, corresponding to the highest weight among the analyzed criteria. This outcome is consistent with clinical practice, where diagnostic accuracy depends directly on the resolution and sharpness of the captured images. Next, the technical support and maintenance criterion (C5) stood out as an essential element to ensure the operational continuity of the equipment, reduce downtime, and provide qualified user assistance. The cost (C4) and portability (C2) criteria presented intermediate weights, reflecting their relevance, although they do not surpass the importance attributed to diagnostic quality and specialized support. The battery life (C3) and compatibility with electronic health record systems (C6) criteria had a lower relative impact on the decision, suggesting that, while relevant, they are perceived as secondary influencing factors compared to the technical aspects central to ophthalmic practice. These results reinforce patterns described in similar studies, where technological and support criteria carry greater weight in the acquisition of medical equipment. After defining the criteria weights, the alternatives were evaluated. The experts assigned scores from 1 to 9 to each model for each criterion, as presented in Table 6.

Table 6: Model Scores by Criterion (1–9 Scale).

Model / Criterion	C1	C2	C3	C4	C5	C6
A – Optomed Aurora	9	7	8	4	9	8
B – Volk Pictor Plus	8	8	7	5	8	7
C – Remidio Fundus on Phone	7	9	6	7	7	9

Source: Authors, (2026).

These scores were normalized and combined with the relative weights of the criteria, resulting in the overall priorities presented in Table 7.

Table 7: Overall Priorities of the Alternatives.

Model	**Description**	Overall Priority
A	Optomed Aurora	0,340
B	Remidio Fundus on Phone	0,334
C	Volk Pictor Plus	0,326

Source: Authors, (2026).

The analysis of the overall priorities highlights a significant balance among the evaluated models, indicating that all exhibit competitive performance. However, the Optomed Aurora (Model A) stood out as the most suitable alternative, achieving an overall priority of 0.340. This superior performance is primarily due to the combination of excellent image quality (C1) and robust technical support (C5), which are precisely the most influential criteria in the AHP model. Model C (Remidio FOP) achieved a very close score (0.334), benefiting mainly from its high portability and excellent digital compatibility. Model B (Volk Pictor Plus) obtained an overall priority of 0.326, favored for its good balance between image quality, portability, and cost, although it did not excel in the criteria deemed most critical by the experts. The consistency of the matrices was verified to ensure the reliability of the judgments. Considering the largest calculated eigenvalue ($\lambda max = 6.0$), the following was obtained:

$$CI = 0 \tag{7}$$

$$RI\ (n = 6) = 1{,}24 \tag{8}$$

$$CR = 0/1{,}24 = 0 \tag{9}$$

The CR value of 0 indicates perfect consistency in the pairwise comparisons, fully meeting the parameters defined by Saaty. This ensures that the experts' judgments were coherent and that the developed model is mathematically stable and reliable. The sensitivity analysis showed that small variations in the criteria weights did not significantly change the final ranking of the alternatives. This result highlights the robustness of the applied AHP model, reinforcing the reliability of the selection made. It is observed that technical and operational criteria, particularly those related to product quality and after-sales support, tend to exert a decisive influence on the selection of medical technologies. The integration of expert judgment, mathematical modeling, and structured analysis allowed the conclusion that the Optomed Aurora is the most suitable alternative for teleophthalmology services and clinical practice, offering the best balance between technical performance, specialized support, and operational applicability.

VI. CONCLUSION

This study aimed to apply the AHP method to support the selection of a portable fundus camera in the context of clinical practice and teleophthalmology, simultaneously considering multiple technical, operational, and economic criteria. Based on the definition of six main criteria—image quality, portability, battery life, cost, technical support, and digital compatibility—and the evaluation of three representative commercial models, it was possible to structure the problem into a clear hierarchy, develop pairwise comparison matrices, calculate relative weights, and synthesize the overall priorities of the alternatives. The results showed that image quality (C1) and technical support and maintenance (C5) were the most influential criteria in the decision-making process, followed by cost (C4) and portability

(C2), while battery life (C3) and digital compatibility (C6) had a relatively lower impact. This hierarchy is consistent with ophthalmic practice, where diagnostic reliability and the operational continuity of equipment are central factors for providing safe and effective care. Prioritization of technical and support criteria also aligns with previous studies on medical equipment selection using AHP or MCDA. In the synthesis of overall priorities, all three analyzed models demonstrated competitive performance. However, the Optomed Aurora (Model A) was identified as the most suitable alternative, with an overall priority of 0.340, closely followed by the Remidio Fundus on Phone (Model C) and the Volk Pictor Plus (Model B). This result indicates that, although the equipment is technically competitive, the combination of excellent image quality and robust technical support distinguishes Model A in the considered use context. The closeness of the scores also suggests that local decisions—such as budget constraints, regional availability of technical support, or institutional telemedicine strategies—may justify the selection of other models in specific scenarios, highlighting the usefulness of AHP as a tool adaptable to the priorities of each service. Consistency verification of the judgments, with a consistency ratio (CR) equal to zero for the criteria matrix, ensured the internal coherence of the comparisons and the mathematical stability of the adopted model. Sensitivity analysis indicated that moderate variations in criteria weights did not alter the ranking of alternatives, suggesting robustness of the solution obtained. These findings support the literature that identifies AHP as a transparent, auditable, and suitable method for supporting health technology acquisition decisions, particularly when multiple stakeholders and criteria must be considered in an integrated manner. The main contributions of this study are: (i) proposing and applying a specific AHP model for the selection of portable fundus cameras, adapted to the demands of teleophthalmology services; (ii) empirically demonstrating that image quality and technical support tend to prevail over strictly economic criteria in the decision-making process; and (iii) providing a replicable methodological framework that can be adjusted to include other models, additional criteria, or different expert profiles. From a practical perspective, the model can be incorporated into clinical engineering processes, procurement committees, or telemedicine programs to support purchase decisions in a systematic and justifiable way. However, some limitations should be acknowledged. The number of experts involved was limited, which may restrict the generalizability of the judgments, although internal consistency was satisfactory. In addition, the study considered only three commercial models, not covering the full spectrum of portable fundus cameras available on the international market. Important criteria such as life-cycle costs, real-world performance indicators (e.g., non-diagnostic exam rates, operator learning curve), and user experience metrics (usability, ergonomics) were not explicitly included in the model. For future research, it is recommended to expand the number of experts and devices evaluated, including fundus cameras from different price ranges and technological generations. Incorporating hybrid approaches, such as fuzzy AHP or integration with methods like TOPSIS, VIKOR, or PROMETHEE, may allow better handling of uncertainties and more complex preference scenarios. It is also suggested to include criteria related to integration with artificial intelligence algorithms for automated retinopathy detection and the evaluation of field clinical indicators, in order to bring the model closer to the real needs of remote ophthalmology screening and diagnostic programs. In this way, the present study constitutes an initial step in developing a systematic approach for selecting portable fundus cameras, paving the way for more comprehensive and integrated decision-support models in ophthalmic technologies.

ABSTRACT

Increasing industrial competitiveness demands stable and continuously monitored production processes. This work presents a Non-Conformance Detection System based on Fuzzy Logic, applied to quality control in manufacturing. Using the PPM (Parts Per Million) indicator, the system evaluates process performance and identifies the risk level of non-conformities. Scenarios with PPM between 20 and 11,000 were analyzed, covering conditions from ideal to critical situations. The fuzzy model, composed of triangular and trapezoidal membership functions, expert rules, and centroid defuzzification, showed smooth transitions and greater sensitivity compared to deterministic methods. The results confirm its practical applicability in the automotive industry, assisting in risk identification, rapid decision-making, and continuous process improvement.

I. INTRODUCTION

Quality control in industrial manufacturing systems has been a recurring theme since the advent of mass production in the Industrial Revolution, when the standardization of processes and products became essential to meet the growing market demand. In recent decades, with globalization, Industry 4.0, and the increased complexity of production processes, fault detection and non-conformity prevention have become critical factors for the competitiveness and sustainability of organizations [1]. The problem under study is directly related to the non-detection of non-conformities in industrial manufacturing processes, which can lead to rework, waste of resources, increased costs, and, above all, compromised customer satisfaction. The literature points out that the absence of effective monitoring mechanisms can lead to the repetition of errors and the loss of reliability of the production system [2]. The current demands of Industry 4.0 require increasingly precise, flexible, and sustainable processes. The absence of effective fault detection mechanisms compromises productivity and quality, negatively impacting the competitiveness of companies. In this sense, the adoption of techniques based on Artificial Intelligence and Fuzzy Logic is highly aligned with the needs of the sector, as it allows for the handling of uncertainties and variabilities common in industrial processes. In this context, several methodologies and theories have been used to minimize such problems. Among the most relevant approaches are statistical process control techniques, Lean Six Sigma methodologies, and, more recently, intelligent systems based on computational intelligence [3], [4]. Among these techniques, fuzzy logic stands out for its ability to handle imprecise and uncertain information, offering a model closer to human decision-making. The objective of this dissertation is to develop a system for detecting nonconformities in industrial manufacturing processes, based on fuzzy logic to integrate process signals and quality criteria, reducing the non-detection rate and the response time of inspections.

II. INDUSTRIAL MANUFACTURING SYSTEM

Production systems are defined as socio-technical systems responsible for transforming inputs into products through structured and organized processes [5]. Production involves interrelated technical and human functions, based on systems theory and cybernetics, considering human, social, technical, and organizational subsystems integrated into the environment [6]. Value creation requires organized processes and operations such as machining, assembly, testing, and transportation, performed by people and equipment [7]. With the development of the Toyota Production System, a holistic approach to Lean Production Systems (LPS) emerged, combining strategic principles, operational methods, and tools aimed at eliminating waste and continuous improvement [5]. These systems guide all processes towards the customer and seek the systematic reduction of activities that do not add value [8]. Manufacturing has evolved through four industrial revolutions: mechanization; adoption of new energy sources and combustion engines; automation with electronics and computing; and, more recently, Industry 4.0, marked by cyber-physical systems, IoT, cloud computing, and cognitive resources [9]. Companies aligned with Industry 4.0 are considered "smart," with flexible, precise, digitized, and logistically integrated systems[10]. Digital transformation occurs in four stages—digitization, virtualization, connectivity, and autonomization—leading to new scenarios of human-machine cooperation in smart factories [5].

II.1 INTELLIGENT MANUFACTURING SYSTEM

Intelligent manufacturing is an advanced production model that uses information technologies, sensors, data analysis, and intelligent systems to optimize all stages of a product's life cycle, from design to final integration. Its goal is to increase the efficiency, quality, and competitiveness of companies in dynamic markets [11]. The advancement of automation, driven by the evolution of machines and computers, has led to the emergence of concepts such as flexible cells, computer-integrated manufacturing, and, finally, intelligent manufacturing. Since the 1990s, international programs—especially in Japan, the USA, and Europe—have driven research and cooperation to develop this new productive paradigma [12]. Smart manufacturing integrates communication technologies, data science, systems engineering, and automation to connect people, machines, and processes. This integration occurs through detection, interconnection, analysis, learning, and autonomous decision-making, allowing the optimization of three central elements (people, management, and technology) and five fundamental flows (information, logistics, capital, knowledge, and service) [13]. According to [14], smart manufacturing relies heavily on data, sensors, and advanced analytics, integrating Operational Technology (OT) and Information Technology (IT). According to [12] organizes the concept into six fundamental pillars:

1) Manufacturing technologies and processes – including additive manufacturing, new materials, hybrid processes, and smarter robots.
2) Materials – use of new materials, biomaterials, and resource recovery at the end of the life cycle.
3) Data – massive collection and advanced analysis, basis for predictive models and knowledge preservation.
4) Predictive engineering – creation of digital models to predict future behaviors and support strategic decisions.
5) Sustainability – development of sustainable products and processes, valuing remanufacturing, reuse, and impact reduction.
6) Resource sharing and networking – cooperation between companies to share equipment, software, and knowledge.

Artificial Intelligence is essential in SMI, enabling real-time monitoring, automated decision-making, intelligent scheduling, and increasingly advanced human-machine integration [11]. In Industry 4.0, SMI uses service-oriented architecture (SOA) and platforms connected via the Internet, forming an integrated ecosystem where technical, managerial, and organizational processes operate collaboratively, flexibly, and reconfigurably.

II.1.1 Sistema de Manufatura Flexivél

A flexible manufacturing system (FMS) can be defined as a computer-controlled production system capable of processing a variety of part types, characterized by the ability of production to be adapted to the production of multiple parts, small or medium batches, and there are several flexible manufacturing systems categorized according to the target process being improved. These categories are addressed below [9]:

a) Variant flexibility: Ability to manufacture or assemble more variants of a product. (Product flexibility)
b) Quantity flexibility: Ability to adapt the production system to fluctuating volumes.
c) Technology flexibility: The ability of the manufacturing and assembly system to be used for a range of technologies.
d) Successor flexibility: Ability to use equipment or parts also for future products.

II.2 QUALITY IN THE INDUSTRIAL MANUFACTURING SYSTEM

Quality in industrial production involves the ability of a production system to generate goods that meet or exceed technical standards, requirements, and customer expectations, from conception to delivery [15] and [16]. This concept encompasses conformity, reliability, and continuous improvement throughout the production process.

II.2.1 Quality Management System (QMS)

The Quality Management System (QMS) promotes the standardization of processes with a focus on continuous improvement and customer value [15]. Implementing a QMS means documenting procedures, monitoring performance, and correcting deviations systematically, ensuring that all products meet the established requirements.

II.2.2 Evolution towards Industry 4.0 and Quality 4.0

The transition to Industry 4.0 has transformed quality approaches: integrated systems and connectivity have become fundamental, characterizing what is now called Quality 4.0 [16]. Technologies such as automation, intelligent sensors, and real-time data analysis allow for greater efficiency and reliability [17]. Digital integration enables preventive actions and data-driven decisions, increasing the competitiveness of the industry.

II.2.3 Quality Tools and ISO 9001

The implementation of ISO 9001:2015 requires the establishment of an effective QMS, capable of documenting processes, reducing failures, and ensuring conformity [18]. In the Brazilian context, the application of tools such as PDCA, 5S, and statistical methods proves essential to reduce costs, rework, and improve customer satisfaction [19].

II.2.4 Quality Tools

Quality tools are essential instruments for monitoring, analyzing, and improving processes in industrial environments. Below are the main ones:

a) Pareto Diagram

The Pareto Diagram organizes defects in descending order of frequency, allowing the identification of the most relevant causes according to the Pareto principle, which indicates that a few factors are responsible for the majority of problems. Thus, prioritizing the main causes allows for a greater impact on process improvement [20]. Diagram is shown in the figure 1.

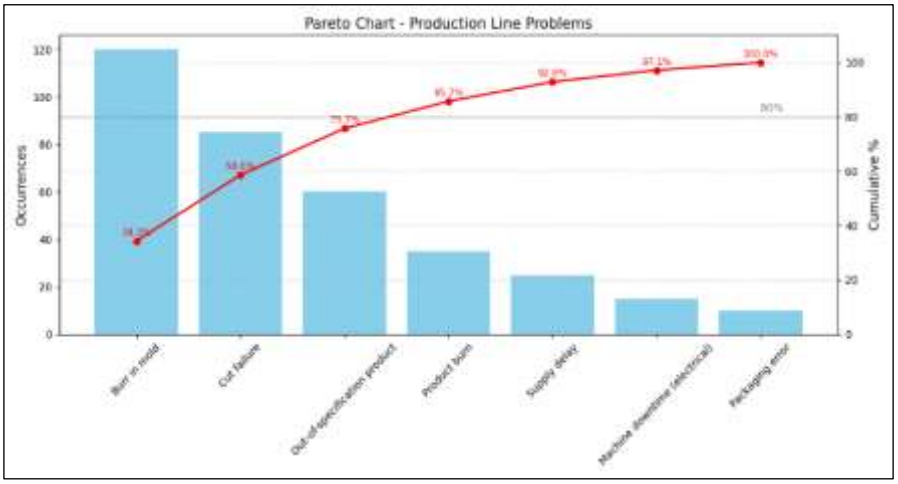

Figure 1: Pareto Diagram.
Source: Authors, (2026).

b) Control Chart

The Control Chart is used to monitor the stability of a process over time. It presents upper and lower control limits, as well as a centerline. When the points remain within these limits, the process is considered stable; values outside the limits indicate a need for intervention [21]. The control chart is shown in the figure 2.

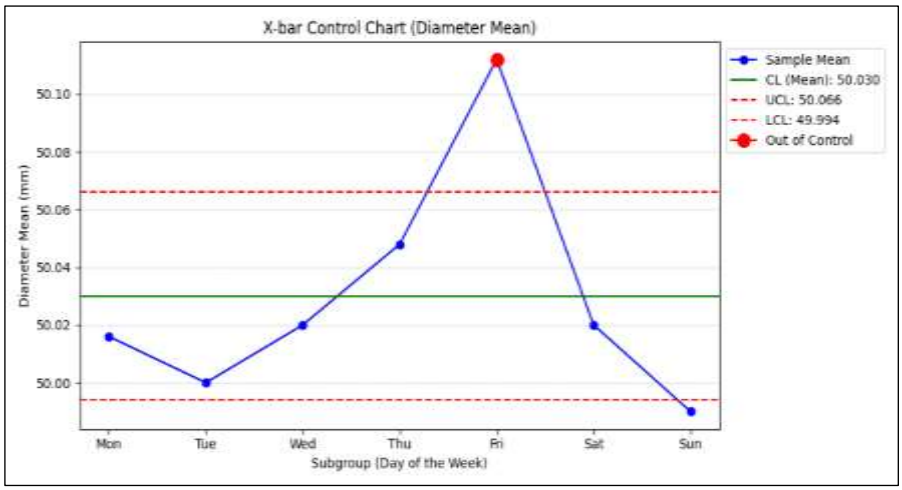

Figure 2: Iron bar production.
Source: Authors, (2026).

c) Ishikawa Diagram

The Ishikawa Diagram, or cause-and-effect diagram, assists in the systematic identification of the possible causes of a problem, organizing them into categories such as methods, machines, manpower, materials, measurements, and environment. This facilitates understanding the origins of a nonconformity [22]. The Ishikawa Diagram is shown in the figure 3.

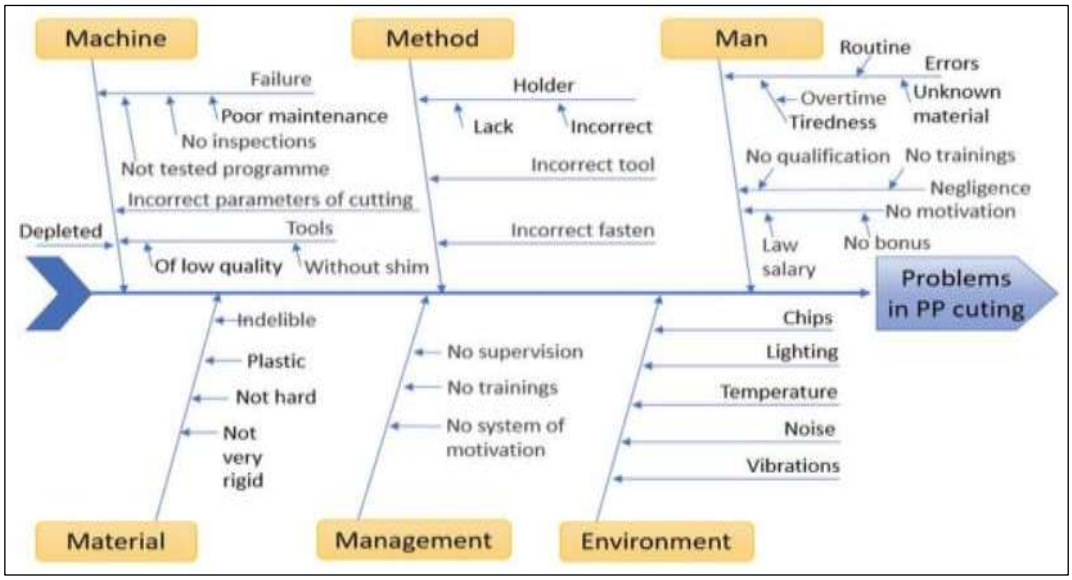

Figure 3: Ishikawa diagram for polypropylene cutting.
Fonte: [22].

d) Flowchart

Finally, the flowchart graphically represents the steps of a process, allowing you to visualize the logical sequence of activities, identify critical points, and support operational improvements. This tool is fundamental for standardizing procedures and understanding the production flow clearly. The figure below shows an example of a flowchart.

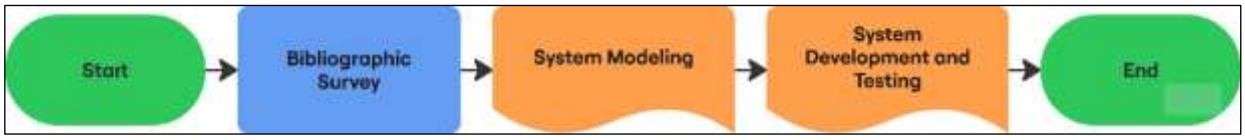

Figure 4: Methodological flow.
Source: Authors, (2026).

II.3 TÉCNICAS DE INTELIGÊNCIA ARTIFICIAL

This topic will cover the most commonly used techniques in industrial processes. Fuzzy Logic, Simple Linear Regression, Decision Trees, and Artificial Neural Networks are widely used in intelligent systems for decision support, process control, and modeling of industrial phenomena.

II.3.1 Fuzzy Logic

Fuzzy Logic allows working with imprecision and subjectivity, representing variables by degrees of membership between 0 and 1. Unlike traditional Boolean logic, it allows an element to partially belong to several sets. This approach is applied in different stages of manufacturing, such as temperature control, defect reduction, and injection parameter adjustment. The operation of a fuzzy system involves three fundamental steps: fuzzification, which converts numerical values into linguistic terms; inference, which applies "If-Then" rules defined by experts; and defuzzification, which transforms the fuzzy result into a precise numerical value. The most common membership functions are triangular, trapezoidal, and Gaussian, with the triangular function being the most used due to its simplicity and computational efficiency [23]. The linguistic variable is a variable whose elements are names of fuzzy sets. Its main function is to provide a way to characterize the complexity of phenomena and the lack of clarity. This allows the treatment of more complex systems to be analyzed using traditional mathematical terms [24]. The most common forms of fuzzy membership functions are: triangular fuzzy, trapezoidal fuzzy, and Gaussian fuzzy. See figures 5, 6, and 7, respectively.

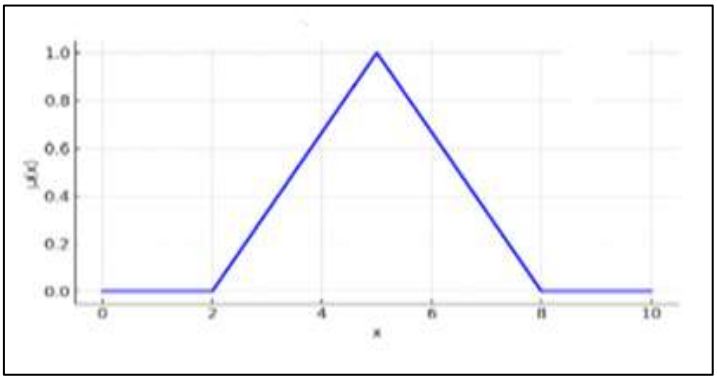

Figure 5: Fuzzy Triangular Membership Function.
Source: Authors, (2026).

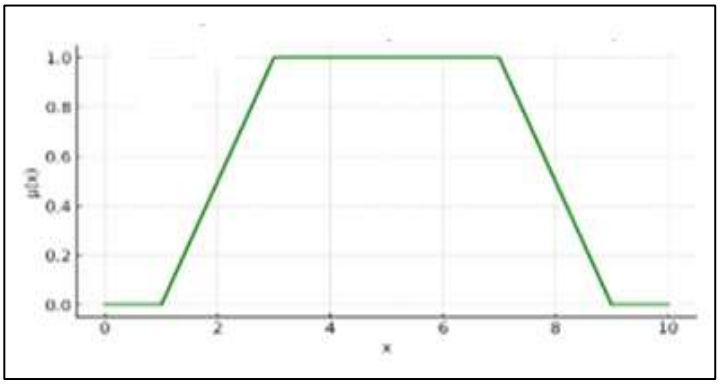

Figure 6: Fuzzy Trapezoidal Membership Function.
Source: Authors, (2026).

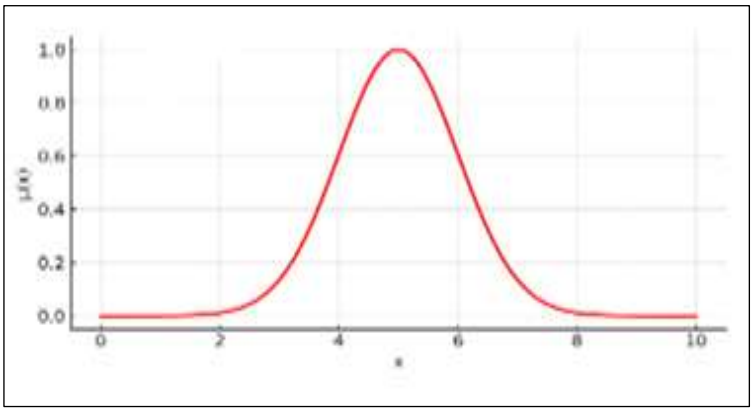

Figure 7: Fuzzy Gaussian Membership Function.
Source: Authors, (2026).

II.3.2 Simple Linear Regression

Simple linear regression models the relationship between two variables one explanatory and one response using a straight line defined by the intercept (α) and slope (β) parameters. This model allows for predicting future behaviors and identifying trends, being widely applied in production processes, demand forecasting, costs, or operational performance. The error term (ei) represents the random variation not explained by the equation. Despite its simplicity, this technique is effective when there is a linear correlation between the variables and provides a clear interpretation of how changes in x affect y. Figure 8 shows the graph of a linear function [25].

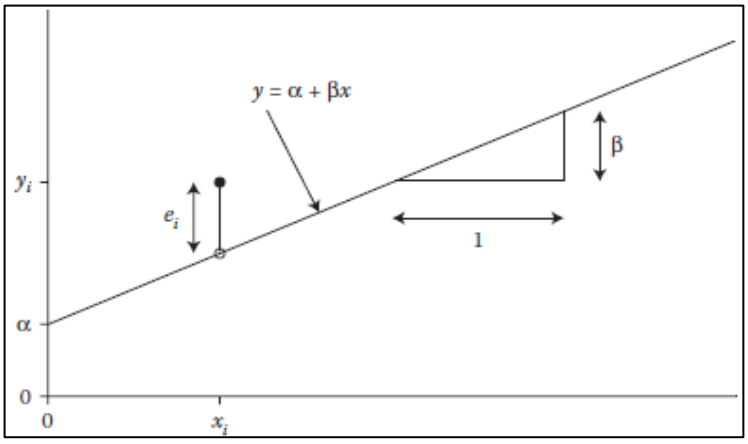

Figure 8: Simple linear regression model.
Source: [25].

II.3.3 Decision Tree

A Decision Tree is a supervised learning method used for classification or regression. It functions like a flowchart, where each node represents a decision test, each branch is a result, and each leaf indicates a class or prediction. Among its main advantages are ease of interpretation, low computational cost, and the ability to handle imperfect or redundant data. The construction of the tree involves the recursive partitioning of data until stopping criteria are met, followed by a pruning step, which avoids overfitting and improves the generalization of the model. This type of technique is widely used in medical applications, risk analysis, quality analysis, and industrial decision-making. Figure 9 depicts an example of a decision tree designed for classification, obtained by running the J48 (C4.5) algorithm applied to the Weka "contact lenses" dataset [26].

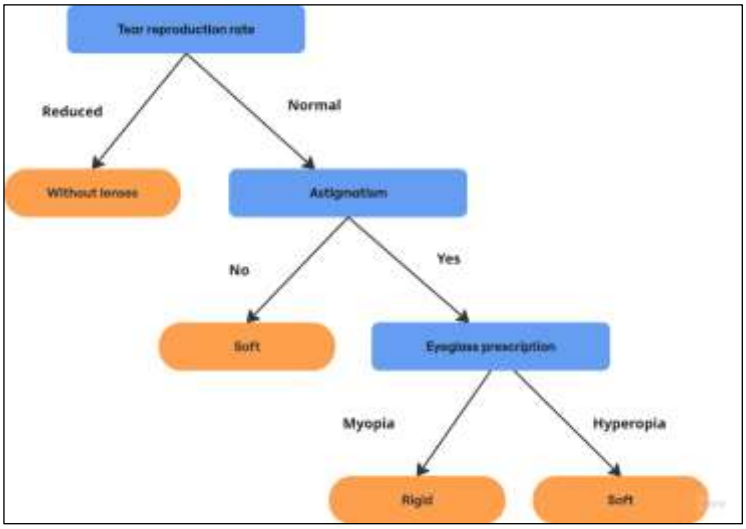

Figure 9: An example of a decision tree.
Source: Authors, (2026).

II.3.4 Artificial Neural Networks

Artificial Neural Networks are models inspired by the functioning of the human brain and are capable of learning complex patterns. They are formed by layers of interconnected artificial neurons that process information by multiplying inputs by weights and applying activation functions. The learning process occurs through backpropagation of error, adjusting the weights to improve accuracy. ANNs are especially effective in problems that require pattern recognition, time series prediction, complex classification, and decision-making based on large volumes of data. Due to their flexibility, they are widely used in computer vision, industrial automation, intelligent control, and predictive systems [27]. Figure 10 shows the neuron function.

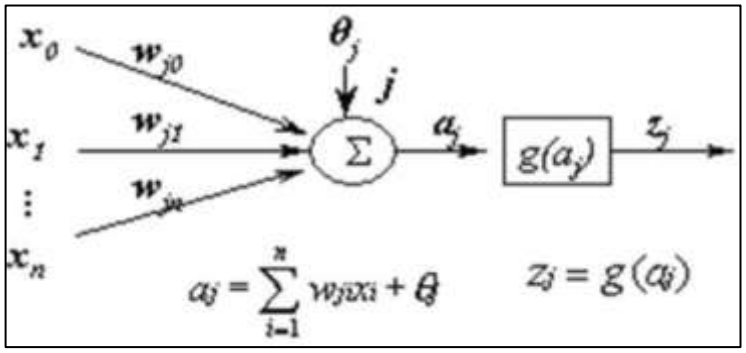

Figure 10: Neuron function.
Source: [27].

III. MATERIALS AND METHODS

For the development of the proposed system, the following computational tools and resources were used:

a) Programming language: Python;
b) Development environment: Visual Studio Code (VS Code);
c) Python libraries: NumPy, Matplotlib, and scikit-fuzzy (for fuzzy modeling and inference);
d) Auxiliary software: Miro (for creating flowcharts and modeling diagrams);
e) Simulation environment: Windows 11 operating system.

The use of the Python language is justified by its wide application in scientific research and the availability of libraries specialized in fuzzy logic and data analysis, which facilitates the implementation of intelligent systems and the handling of large volumes of information. The use of the Visual Studio Code (VS Code) IDE is justified because it is the most widely used IDE for software and embedded projects in the world. The methodology proposed in this dissertation is based on applied and experimental research, since its objective is the development and validation of a computational system aimed at detecting nonconformities in industrial manufacturing processes. The applied nature of the study is justified by seeking a solution to a real problem in the industrial area, which is the early identification of failures in the production process through monitoring the Parts Per Million (PPM) indicator. In addition, the research has an experimental and exploratory character, as it involves the conception, implementation, and evaluation of a computational prototype based on fuzzy logic, developed to simulate typical conditions of an industrial environment. The experimental approach allows testing the system's behavior in the face of different input scenarios, making it possible to analyze its inference and response capacity in nonconformity situations. The technique used in the methodology of this dissertation is the computational intelligence technique Fuzzy Logic.

Fuzzy logic is a theory proposed by Lofti Zadeh in 1965, which is based on sets that have degrees of membership and are encoded in unit intervals; that is, they have a membership function whose values are compatible with these sets in degrees of membership from 0 to 1, differing from classical logic theory, since the data are complex, that is, a piece of data has membership in a set, "all or nothing", which is based on sets whose inclusion is resolved in degrees of "true or false", 0 or 1, all or nothing; unlike fuzzy logic, where a piece of data is part of a set to a certain extent, to a higher degree (0), sometimes to a medium degree (0.5) or can increase or decrease its vagueness, and may even be empty [28].

III.1 RESEARCH STAGES

The development of this dissertation was structured in three main stages. These are:

a) Bibliographic survey

This stage consisted of conducting theoretical and documentary research on the main concepts related to industrial quality, process control, performance indicators (especially the Parts Per Million KPI), as well as the fundamentals of fuzzy logic and its applications in decision support systems. Academic sources, scientific articles, dissertations, and books addressing the topic were consulted in order to support the conceptual and technical development of the proposed system.

b) Fuzzy system modeling

In this phase, the input and output parameters of the fuzzy system were defined, based on variables relevant to the evaluation of the quality of the production process. The modeling involved the elaboration of membership functions, the definition of fuzzy rules (e.g., If cost LOW and benefit HIGH then cost-benefit HIGH), and the structuring of the inference mechanism, in order to approximately represent human reasoning in making decisions about the conformity or non-conformity of the process. The Miro software was used to design the flowcharts representing the system's operational logic and data flow, contributing to the visualization of the decision-making process.

c) System Development and Testing

After modeling, software was developed in Python, using the Visual Studio Code (VS Code) IDE, to implement the non-conformity detection and KPI monitoring system Parts Per Million (PPM). The program was structured to collect and process simulated production data, apply the fuzzy model, and return a monitoring graph of the indicator, allowing the user to identify failure trends and make corrective decisions more quickly. Computational simulation tests were performed, in which different data scenarios were entered into the system to evaluate its robustness, coherence of fuzzy inferences, and reliability of results. This step was essential to verify the adherence of the proposed model to the expected behavior in a real industrial environment.

Figure 11 shows the research steps represented in a methodological flow adopted to achieve the established objectives.

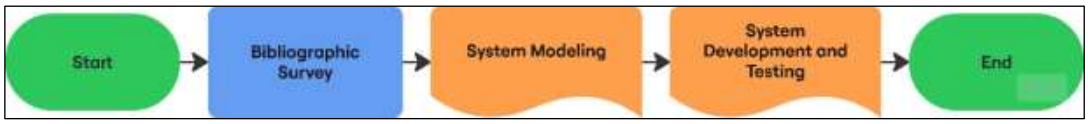

Figure 11: Methodological flow.
Source: Authors, (2026).

The system validation was performed in a simulated manner, using datasets representative of an industrial manufacturing process. The simulations allowed us to verify the consistency of the fuzzy system outputs in relation to the input conditions and to analyze the correlation between the KPI PPM (Parts Per Million) values and the compliance levels identified by the model. The results were evaluated based on performance criteria related to the accuracy in detecting non-conformities, the stability of the inferences, and the clarity of the information presented in the monitoring graph. This analysis made it possible to verify the viability of the system as a decision support tool in production processes.

III.2 FUZZY SYSTEM DEVELOPMENT

This topic presents all the steps used in the implementation of the fuzzy system based on Fuzzy Logic to monitor the Parts Per Million (PPM) indicator in manufacturing processes in the automotive supply chain. The objective is to transform numerical process data into an intelligent risk interpretation, capable of adaptively anticipating nonconformities. The introduction of this fuzzy system allows for the evaluation of quality levels even in imprecise scenarios or with natural process fluctuations, something that traditional methods cannot adequately represent.

III.2.1 General system architecture

The application was structured in a logical flow composed of four main steps:

a) Input: actual value of the PPM indicator collected in the industrial process.
b) Fuzzy processing: composed of fuzzification, rule base, and inference.
c) Defuzzification: transformation of the fuzzy result into a numerical index.
d) Output: Risk Index (0 to 100), indicating the degree of compliance of the process.

The system architecture can be represented as shown in figure 12.

Figure 12: System architecture flowchart.
Source: Authors, (2026).

III.2.2 Definition of the fuzzy input variable – PPM

The PPM indicator is widely used in industry to measure the number of defective parts in relation to the total produced. Table x abaixo presents the limits for PPM indicators according to the IATF 16949 standard.

Table 1: Limits for PPM indicators – IATF 16949 standard.

Level	PPM Range	Interpretation
Excellent	0 – 100 ppm	Very capable process
Good	100 – 500 ppm	Proper control
Acceptable	500 – 1.000 ppm	As expected, but with caution.
Warning	1.000 – 5.000 ppm	It requires investigations and corrective actions.
Bad	> 5.000	Process out of control.
Critic	>10.000	High risk – possible customer account suspension.

Source: Authors, (2026).

Based on this classification, six fuzzy sets were defined for the PPM:
Unit: parts per million (PPM). Universe considered: 0 20,000 PPM (sufficient to cover >10,000).

a) **Excellent:** 0 – 100 ppm (Very capable process)
b) **Good:** 100 – 500 ppm (Proper control)
c) **Acceptable:** 500 – 1.000 ppm (As expected, but with caution.)
d) **Warning:** 1.000 – 5.000 ppm (It requires investigations and corrective actions.)
e) **Bad** > 5.000 ppm (Process out of control)
f) **Critic:** > 10.000 ppm (High risk – possible customer account suspension)

Each set represents a region of the PPM space with smooth transitions between boundaries, a fundamental characteristic of fuzzy systems.

III.2.3 Membership functions of the PPM variable

The membership functions were defined to reflect industrial logic, using triangular and trapezoidal functions.

a) **Excellent:** — trapezoidal: (a=0, b=0, c=25, d=100) - High relevance in very low PPMs; decreases down to 100.
b) **Good:** — triangular: (100, 300, 500) - Peak at 300, base 100–500.
c) **Acceptable:**— triangular: (500, 750, 1000) - Peak at 750, base 500–1000.
d) **Warning:** — triangular: (1000, 3000, 5000) - Peak at, base 1000–5000.
e) **Bad** — triangular: (5000, 7500, 10000) - Peak at 7500, base 5000–100000.
f) **Critic:** — trapezoidal: (10000, 11000, 12000, 12000) - Starts to increase from 10k, becomes strong above 15k.

III.2.4 Fuzzy output variable – Risk index (0–100)

The output variable does not represent PPM values. It represents a fuzzy interpretation of the current process risk. For this reason, the output is defined on a universal scale of 0 to 100, widely used in risk analysis systems. Output universe: 0 …100 (0 = zero risk; 100 = maximum/critical risk). Fuzzy output sets (with triangular/trapezoidal shapes):

a) **Very Low** — tri (0, 10, 20)
b) **Low** — tri (10, 25, 40)
c) **Moderate** — tri (30, 50, 70)
d) **High** — tri (60, 75, 85)
e) **Very high** — tri (80, 90, 95)
f) **Critical** — trap (90, 95, 100, 100)

III.2.5 Construction of fuzzy rules

The rules were constructed based on a direct interpretation of the PPM classification table:

IF 0 ≤ PPM <= 100 It is **Excellent** → Risk Index Is **Very Low**
IF 100 ≤ PPM <= 500 It is **Good** → Risk Index Is **Low**
IF 500 ≤ PPM <= 1,000 It is **Acceptable** → Risk Index Is **Moderate**
IF 1,000 ≤ PPM <= 5,000 It is **Alert** → Risk Index Is **High**
IF PPM >= 5,000 It is **Bad** → Risk Index Is **Very High**
IF PPM >= 10,000 It is **Critical** → Risk Index Is **Critical**

These rules ensure that the system responds gradually, avoiding abrupt jumps in the ranking.

III.2.6 Fuzzy Inference Process

The Mamdani inference method was used, a method traditionally employed in industrial applications due to its robustness and interpretability.

AND operator used: minimum (typical in Mamdani).
Implication: clipping of the consequent's moiety by the degree of activation (minimum).
Output Aggregation: maximum (take union / sup) between the clipped sets.
Flow for a specific PPM:

a) Calculate the PPM membership level in each input set.
b) For each rule, obtain the activation level = membership of the antecedent.
c) Clip the MF of the corresponding output set at the activation level.
d) Aggregate (max) all clipped output MFs to obtain the aggregated fuzzy MF of the risk index.

III.2.7 Defuzzification

To transform the output fuzzy set into a numerical value, the following method was used:

Centroid – Center of Gravity (COG)
This method calculates the "center of mass" of the resulting area, providing a final risk index between 0 and 100.

IV. RESULTS AND DISCUSSIONS

This topic presents the results obtained from the implementation and testing of the fuzzy system developed for detecting nonconformities in industrial manufacturing lines. The results were organized, interpreted, and compared with industrial quality control practices, especially the use of metrics such as PPM (Parts Per Million), widely used for monitoring process performance. Obtaining real PPM data for the project was not possible due to the difficulty of accessing industrial information, which is usually confidential. To enable testing and maintain methodological consistency, simulated data were used, realistically constructed to represent different process situations. This approach allowed the system to be validated and its operation demonstrated, making the use of simulated data a necessary and justifiable alternative. The simulations were performed using PPM values obtained or defined in representative industry scenarios: 20, 150, 400, 800, 2500, 6000, and 11000. Each value was processed by the fuzzy system, resulting in an aggregate risk level and indicating the probability of the process exhibiting compliance, intermediate risk, or severe non-compliance.

The tests were conducted with the objective of verifying the fuzzy system's ability to:

a) Interpret PPM levels reported by the production process;
b) Add expert knowledge through fuzzy rules;
c) Automatically classify the degree of non-compliance risk;
d) Indicate recommended actions for each situation.

IV.1 IMPLEMENTAÇÃO COMPUTACIONAL DO SISTEMA FUZZY

This topic presents the implementation of a fuzzy system to monitor the PPM indicator in a production process in the automotive industry. The development was carried out in Python, chosen for its simplicity, readability, versatility, and large ecosystem of libraries, which facilitates prototyping and maintenance. The IDE used was Visual Studio Code, a lightweight, free, and highly extensible editor that offers features such as debugging, support for multiple languages, Git integration, and a built-in terminal. After defining all the implementation steps in topic 3.2.3, the execution of the system developed in Python is presented. Figure 13 exemplifies the behavior of the input variable in the system, demonstrating that the PPM variable has six membership functions (PFs), two trapezoidal (Excellent and Critical) and four triangular (Good, Acceptable, Alert, and Bad).

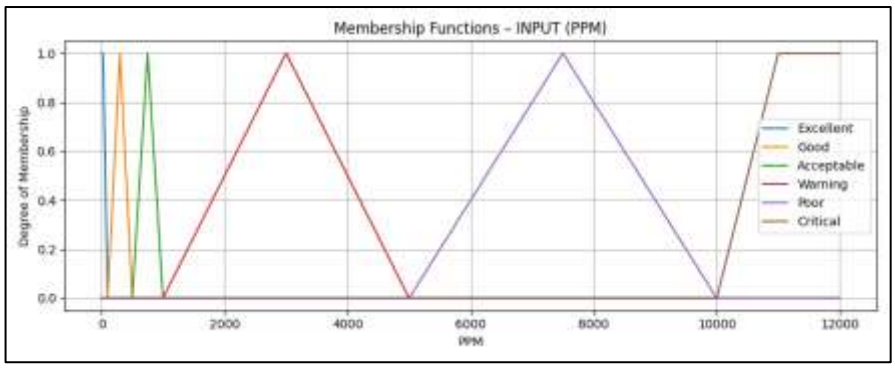

Figure 13: Input membership functions.
Source: Authors, (2026).

Figure 14 illustrates how the output variable is admitted in the proposed fuzzy system, considering that the Risk Index output variable, related to the PPM input, also has six membership functions (PFs), one trapezoidal (Critical) and five triangular (Very low, Low, Moderate, High, Very High).

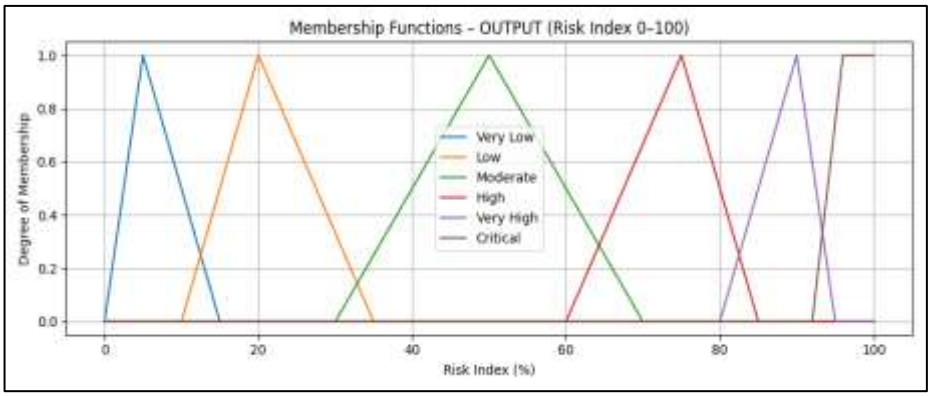

Figure 14: Output membership functions.
Source: Authors, (2026).

IV.1.1 How the fuzzy system works

As discussed earlier in topic IV, the operation of the developed fuzzy system was tested with simulated PPM input values, reflecting real industrial process values. The simulated values were a vector with the values [20, 150, 400, 800, 2500, 6000, 11000], thus covering all possible scenarios of an industrial process. Below, all tests with the aforementioned input values will be presented.

a) For PPM = 20

In Figure 15, it can be observed that the value PPM = 20 belongs almost entirely to the "Excellent" set, showing a high degree of membership. The other sets ("Good", "Acceptable", "Alert", "Bad", and "Critical") have zero membership, indicating that the process is exclusively framed within the best quality condition.

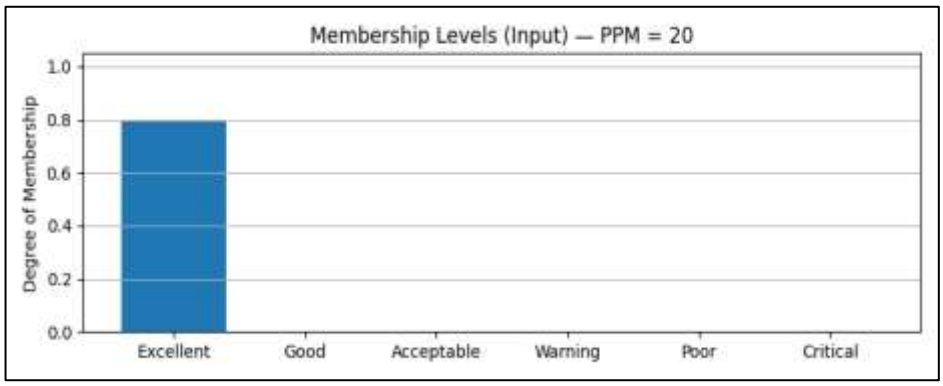

Figure 15: Degree of membership for PPP = 20.
Source: Authors, (2026).

In Figure 16, only the rule associated with the "Excellent" set is activated. The strength of this rule is equivalent to the degree of relevance calculated in the input, demonstrating that the system exclusively uses knowledge related to high-performing processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as low-risk.

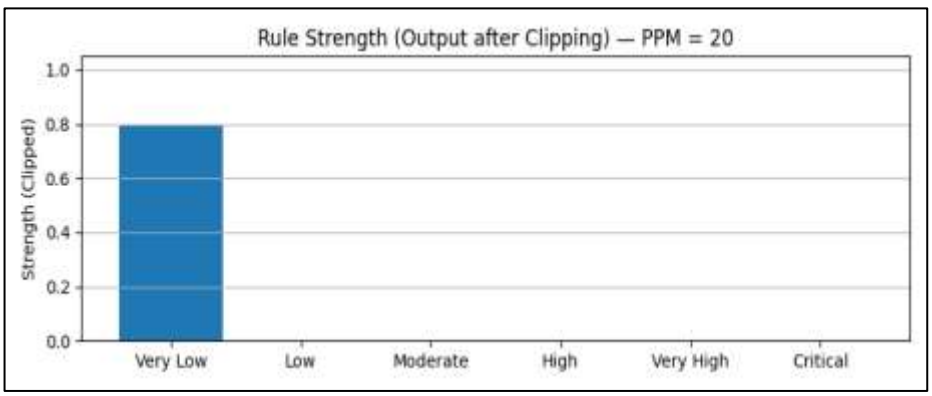

Figure 16: Rule strength for PPP = 20.
Source: Authors, (2026).

In figure 17, the graph shows that the output surface is predominantly shaped by the "Very Low Risk" set, resulting in an aggregate curve concentrated at the beginning of the risk axis. The dashed line indicates the defuzzified value, which approaches a small value, representing an extremely low risk index.

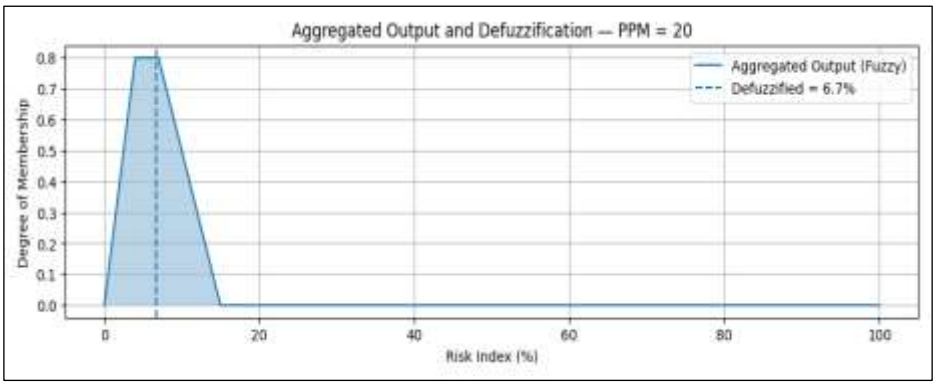

Figure 17: Aggregate output for PPP = 20.
Source: Authors, (2026).

b) For PPM = 400

In Figure 18, it can be observed that the value PPM = 400 belongs to the "Good" set, presenting a membership degree of 0.50. The other sets ("Excellent", "Acceptable", "Alert", "Poor", and "Critical") have zero membership, indicating that the process is exclusively framed within the best quality condition.

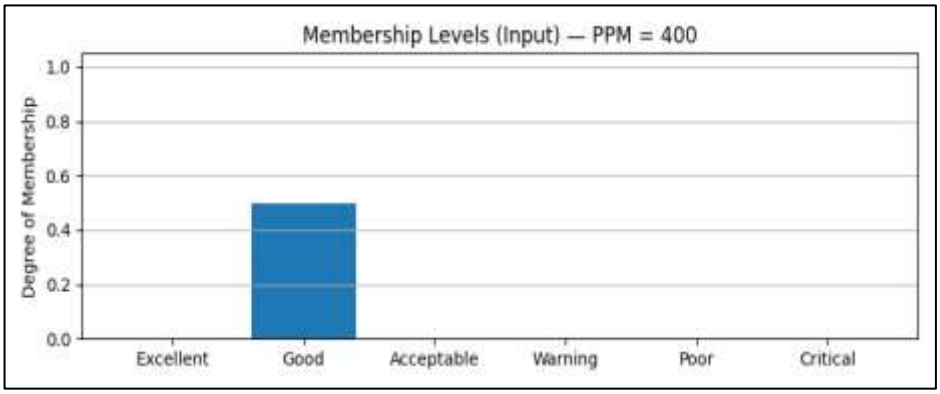

Figure 18: Membership degree for PPP = 400.
Source: Authors, (2026).

In Figure 19, only the rule associated with the "Low" set is activated. The strength of this rule is equivalent to the degree of membership calculated in the input, which demonstrates that the system exclusively uses knowledge related to high-performance processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as low risk.

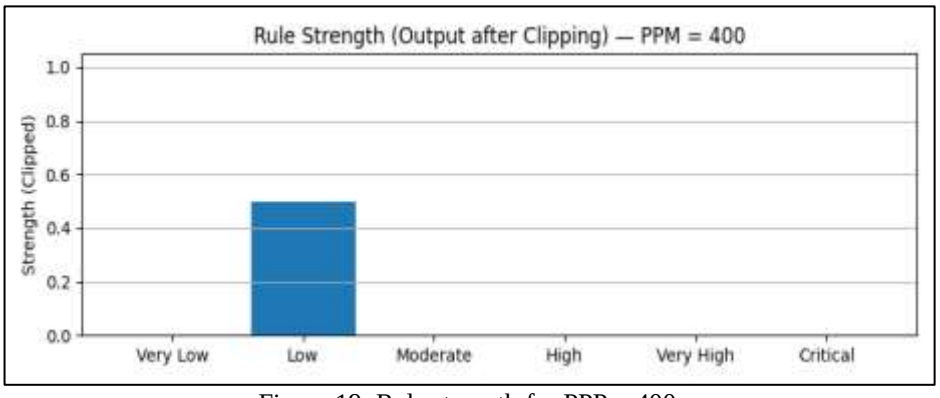

Figure 19: Rule strength for PPP = 400.
Source: Authors, (2026).

In figure 20, the graph shows that the output surface is predominantly shaped by the “Low Risk” set. The dashed line indicates the defuzzified value, which approaches a small value, representing an extremely low risk index.

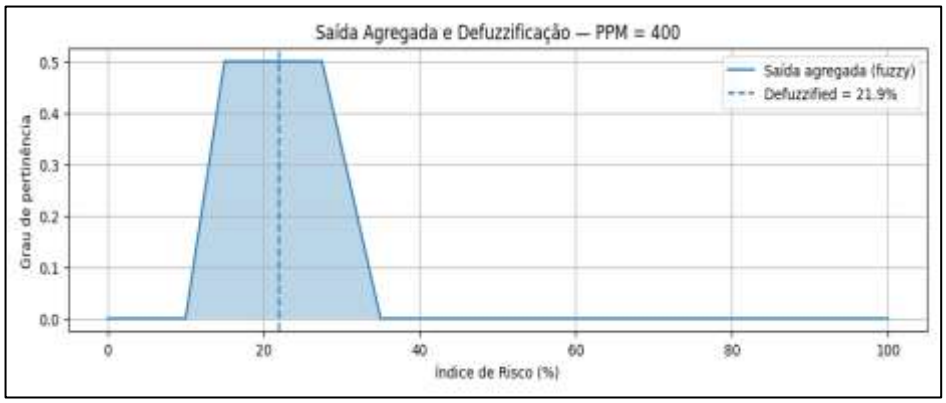

Figure 20: Aggregate output for PPP = 400.
Source: Authors, (2026).

c) For PPM = 800

In Figure 21, it can be observed that the value PPM = 800 belongs entirely to the "Acceptable" set, presenting a membership degree of 0.80. The other sets ("Excellent", "Good", "Alert", "Bad" and "Critical") have zero membership, indicating that the process is exclusively classified as acceptable.

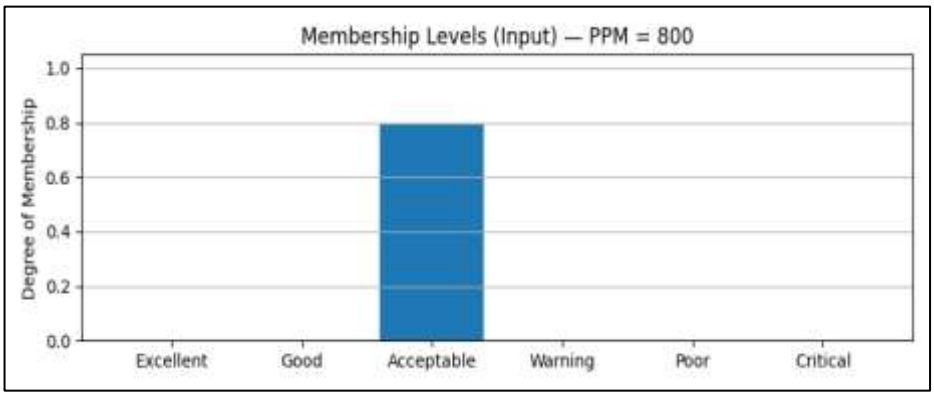

Figure 21: Membership degree for PPP = 800.
Source: Authors, (2026).

In Figure 22, only the rule associated with the "Moderate" set is activated. The strength of this rule is equivalent to the degree of relevance calculated in the input, which demonstrates that the system exclusively uses knowledge related to high-performance processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as moderate risk.

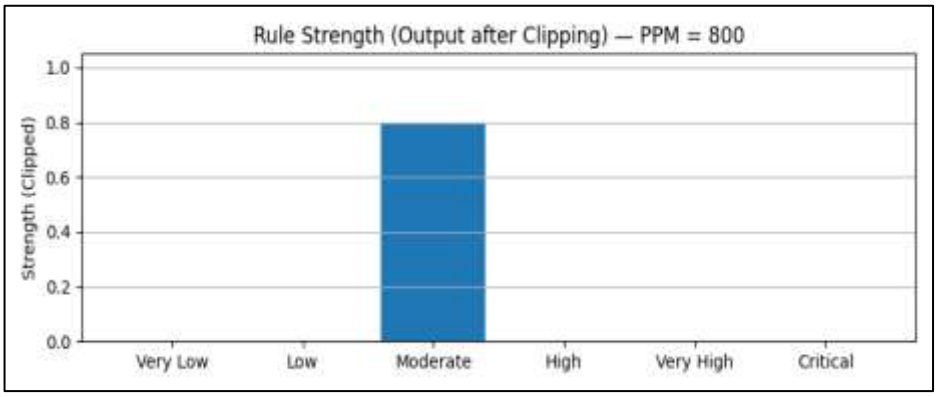

Figure 22: Rule strength for PPP = 800.
Source: Authors, (2026).

In figure 23, the graph shows that the output surface is predominantly shaped by the “Moderate” set. The dashed line indicates the defuzzified value. The system interprets that the process is within expectations, but with clear warning signs.

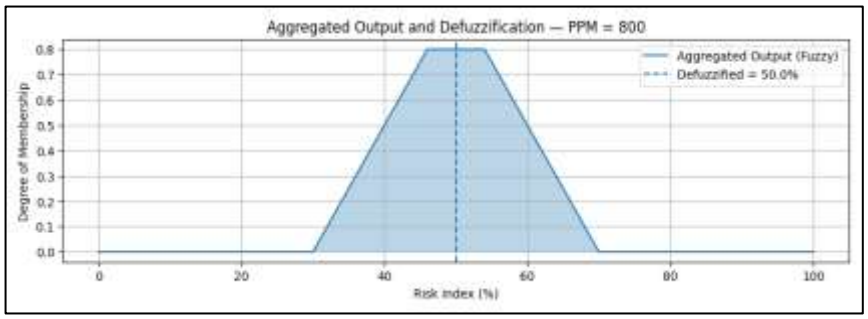

Figure 23: Aggregate output for PPP = 800.
Source: Authors, (2026).

d) For PPM = 2500

In Figure 24, it can be observed that PPM = 2500 belongs mostly to the “Alert” set, with a membership degree of approximately 0.75. The other classes (“Excellent”, “Good”, “Acceptable”, “Bad”, “Critical”) have a membership close to zero.

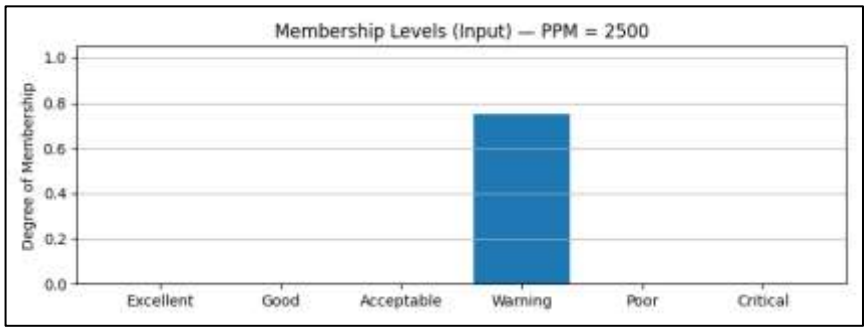

Figure 24: Membership degree for PPM = 2500.
Source: Authors, (2026).

In Figure 25, only the rule associated with the "High" set is activated. The strength of this rule is equivalent to the degree of membership calculated in the input, which demonstrates that the system exclusively uses knowledge related to high-performing processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as High risk.

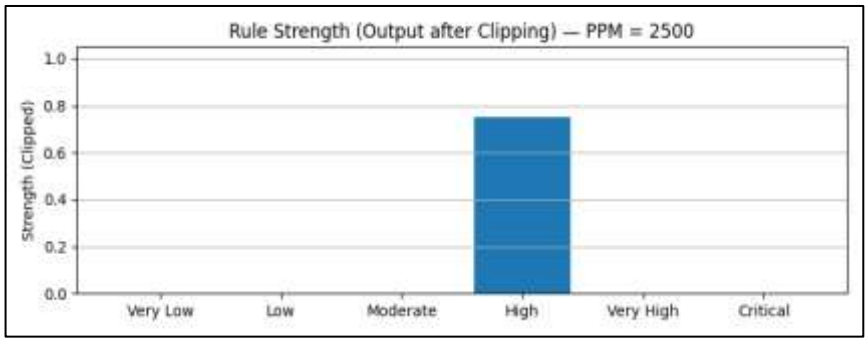

Figure 25: Rule strength for PPP = 2500.
Source: Authors, (2026).

In Figure 26, the graph shows that the output surface is predominantly shaped by the "High" set. The dashed line indicates the defuzzified value. The system interprets this as the process being in a high alert/risk zone.

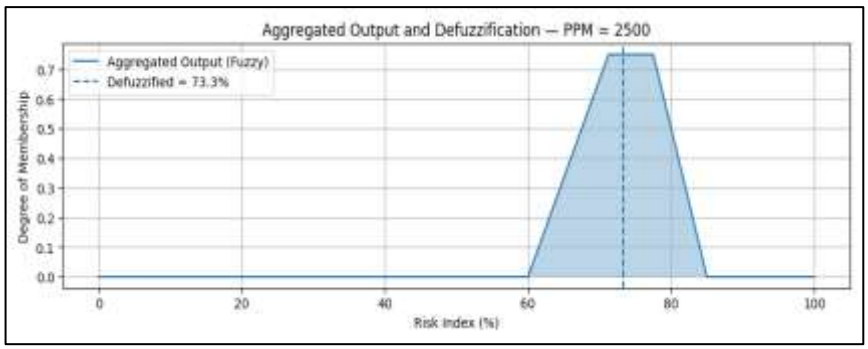

Figure 26: Aggregate output for PPP = 2500.
Source: Authors, (2026).

e) For PPM = 6000

In Figure 27, it can be observed that PPM = 6000 belongs mostly to the "Poor" set, with a membership degree of approximately 0.40. The other classes ("Excellent", "Good", "Acceptable", "Alert", "Critical") have zero membership. The system considers that PPM = 6000 is clearly a value outside the acceptable level, but it is not yet extreme.

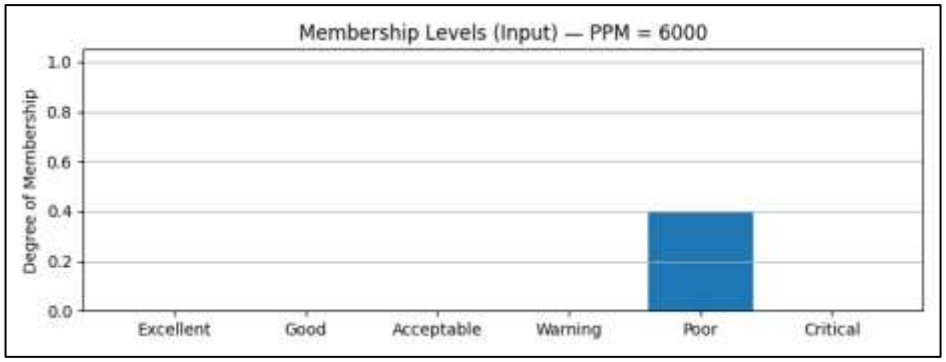

Figure 27: Membership degree for PPM = 6000.
Source: Authors, (2026).

In figure 28, only the rule associated with the "Very High" set is activated. The strength of this rule is equivalent to the degree of relevance calculated in the input, which demonstrates that the system exclusively uses knowledge related to high-performing processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as Very High risk.

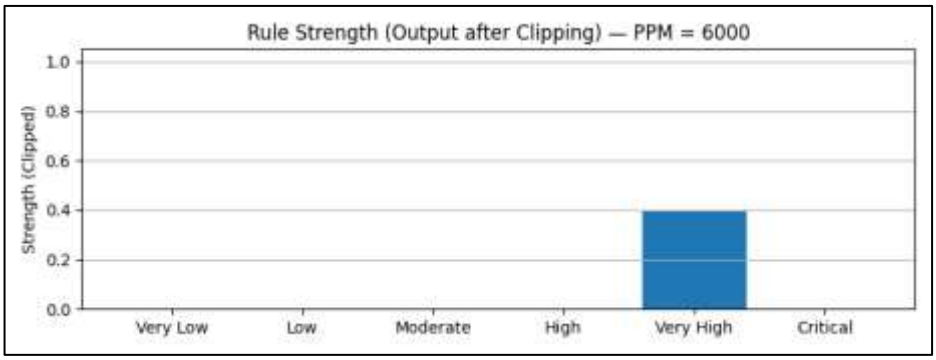

Figure 28: Rule strength for PPP = 6000.
Source: Authors, (2026).

In figure 29, the graph shows that the output surface is predominantly shaped by the "Very High" set. The dashed line indicates the defun zzified value. The system interprets this as the process being in a very high risk zone.

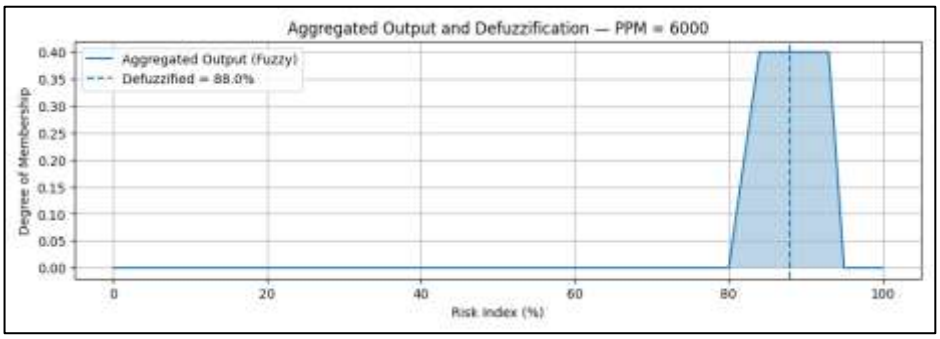

Figure 29: Aggregate output for PPP = 6000.
Source: Authors, (2026).

a) For PPM = 11000

In Figure 30, it can be observed that PPM = 11000 belongs entirely to the "Critical" set, with a membership degree of approximately 1.0. The other classes ("Excellent", "Good", "Acceptable", "Bad", "Critical") have zero membership. There is no ambiguity: the entry is at the maximum plateau of the critical set.

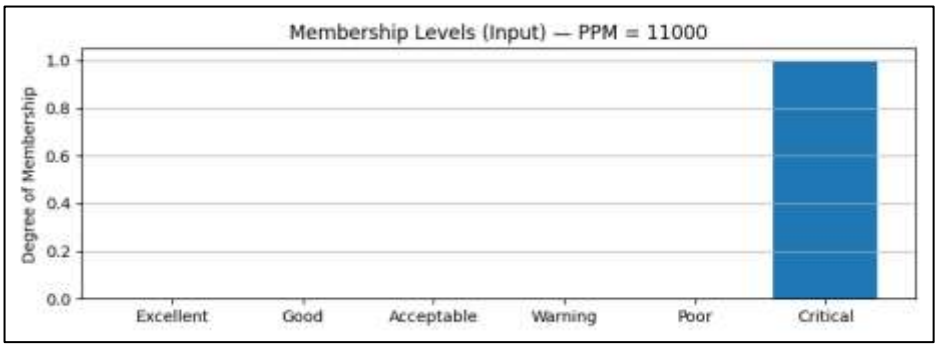

Figure 30: Membership degree for PPM = 11000.
Source: Authors, (2026).

In Figure 31, only the rule associated with the "Critical" set is activated. The strength of this rule is equivalent to the degree of relevance calculated in the input, demonstrating that the system exclusively uses knowledge related to high-performance processes to generate its output. No other rule contributes to the final calculation, reinforcing the natural classification of the process as Critical risk.

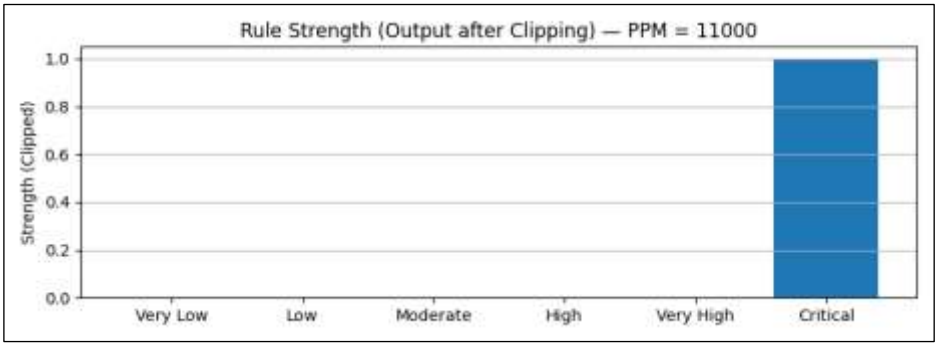

Figure 31: Rule strength for PPP = 11000.
Source: Authors, (2026).

In Figure 32, the graph shows that the output surface is predominantly shaped by the "Critical" set. The dashed line indicates the defuzzified value. The system interprets that the process is in the Critical risk zone.

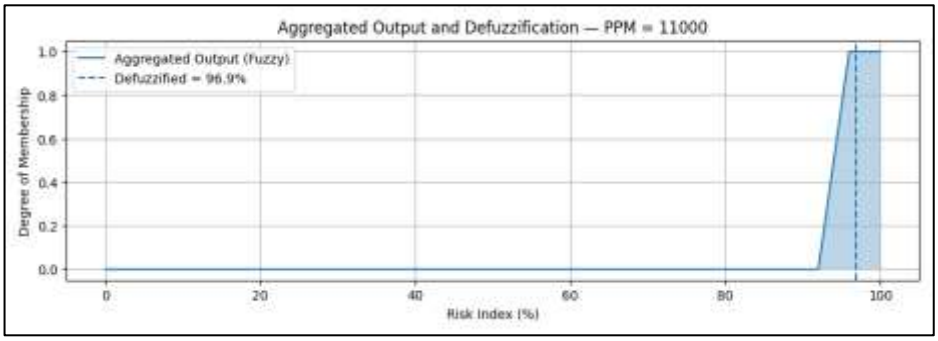

Figure 32: Aggregate output for PPP = 11000.
Source: Authors, (2026).

IV.1.2 Results and discussion

According to the analysis of the results, the developed fuzzy system was able to:

a) Faithfully represent the expected behavior of industrial processes.

- Extremely low values (such as PPM = 20) were correctly classified as a stable situation, aligning with a robust process, with minimal variability and adequate control.For intermediate values, such as 150 and 400 PPM, the
- system does not present binary responses, but rather gradual degrees of risk, which more realistically represent the uncertainty and the transition between stability and attention.

b) Provide sensitivity to the process, even in "gray" regions.
In the real industrial scenario, a process with 400 to 800 PPM may not be considered completely out of control, but it certainly requires monitoring. The fuzzy system managed to capture this, classifying them as:

- 400 PPM → moderate risk
- 800 PPM → high risk

This differentiation is essential to avoid both false alarms and excessive complacency.

c) Handling Severe Scenarios Well

In tests with high values (2500, 6000, and 11000), the system reacted appropriately, raising the belonging function in the maximum risk categories, ensuring that clearly unstable processes were classified as "critical." This behavior reflects industrial logic, in which PPM above 2000 generally indicate:

– process out of control;
– raw material, setup, or calibration problems;
– systemic failures or equipment wear.

In environments where standards such as IATF 16949 or ISO 9001 are applied, processes with very low PPM indicate maturity and stability, while high values require immediate corrective actions. The fuzzy system demonstrated the ability to simulate this logic, but with greater flexibility, because:

a) it does not depend exclusively on fixed limits;
b) it incorporates human knowledge through linguistic rules;
c) it allows smooth transitions between risk ranges.

This means that the fuzzy model can behave like an expert, evaluating real process conditions. The tests performed demonstrated that the fuzzy system is capable of detecting increasing levels of non-conformity in a coherent, continuous manner, aligned with the real needs of industrial manufacturing. The interpretation of each PPM range confirmed that the system:

a) reproduces the behavior of a quality expert,
b) provides gradual and reliable diagnoses,
c) assists in operational and strategic decision-making,
d) can replace or complement traditional SPC systems.

Below is a summary of the tested values, aggregated outputs, and recommended action by the fuzzy logic:

Table 2: Summary of tested values, aggregated outputs, and action recommended by fuzzy logic.

PPM	Active Relevance Set	Fuzzy System Interpretation	Resulting Risk Index	Recommended Action in the Industry
20	Excellent (≈1.0)	Process in excellent condition.	Very Low Risk	No action required.
150	Good (≈0.50), Excellent (≈0.00)	Partially belonging to the "Good" group.	Low Risk	Perform periodic checks.
400	Acceptable (≈1.0)	The process was fully classified as "Acceptable".	Moderate Risk	Monitor trends; initiate corrective actions.
800	Alert (≈1.0)	Process reaches alert level. System identifies high risk.	High Risk	Review machine, process parameters, calibration, and training. Initiate action plan.
2500	Poor (≈1.0)	Process clearly inadequate. Strong activation of the “Poor” category.	Very High Risk	Stop the process for corrections; perform maintenance.
6000	Poor (≈1.0) → near critical	The process is still within the "Bad" category, but close to the "Critical" threshold.	Very High Risk / Trending Towards Critical	Immediate action: Block the batch, conduct root cause analysis, and implement urgent correction.
11.000	Critical (≈1.0)	Full relevance in "Critical". System indicates maximum severity.	Extreme Risk	Complete shutdown; process audit; emergency actions; rework.

Source: Authors, (2026).

Thus, the application of the developed system demonstrates that fuzzy logic is a powerful and suitable tool for implementing intelligent non-conformity detection systems.

V. CONCLUSIONS

This dissertation presented the development and validation of a Non-Conformance Detection System for Industrial Manufacturing Processes based on Fuzzy Logic, capable of analyzing process performance using the PPM (Parts Per Million) indicator and providing intelligent diagnoses of the risk level associated with product quality. The results obtained demonstrated that the fuzzy system is capable of interpreting input values continuously, flexibly, and in line with industrial reality, providing understandable classifications such as low, moderate, high, critical risk, or widespread failure. The fuzzy approach proved particularly useful for processes where binary interpretation (accept/reject) is insufficient, allowing the system to represent uncertainties, gradual transitions, and intermediate scenarios with greater sensitivity. The development of the fuzzy system, with simulation in various scenarios, fulfills the general and specific objectives that comprise this dissertation, as it demonstrated excellent capacity to:

a) Correctly classify all tested PPM ranges (20, 150, 400, 800, 2500, 6000 and 11000), reflecting the expected behavior of an industrial process under different compliance conditions;
b) Provide continuous and realistic responses, avoiding abrupt changes common in traditional deterministic systems;
c) Represent expert knowledge through fuzzy rules and linguistic terms;
d) Assist in industrial decision-making, intuitively identifying situations ranging from full stability to systemic failure.

This behavior confirms that the system is suitable for manufacturing monitoring, internal audits, improvement programs, and operational control.

ABSTRACT

The advancement of digital technologies has significantly transformed industrial processes, shaping the Industry 4.0 scenario, in which cyber-physical systems, IoT, Big Data, and Artificial Intelligence (AI) enhance productivity efficiency and flexibility. In this context, the manufacturing of electronic meters faces challenges such as operational complexity, demand variability, the need for traceability, and data integration across the production chain. Therefore, the adoption of intelligent solutions that support production planning and control in an agile and precise manner becomes essential.

This study aims to develop an intelligent model for the productive planning of electronic meters, integrating Industry 4.0 resources to improve decision-making and optimize operational flow. The model seeks to minimize bottlenecks, forecast material requirements, improve machine utilization, and increase planning reliability. The methodology was structured in four stages: mapping the production process and identifying critical variables; real-time data integration via IoT and MES systems; development of AI models based on machine learning; and the construction of a system capable of simulating scenarios and generating production plans. Tests using historical and real data were conducted. The results indicated higher accuracy in forecasts, reduced idle times, and better balance between capacity and demand. The model proved adaptable to different scenarios, demonstrating its potential to support companies in adopting more dynamic and efficient processes aligned with Industry 4.0.

I. INTRODUCTION

Industry 4.0 has established itself as one of the pillars of digital transformation in the industrial environment, driving integration between advanced technologies, real-time data, and intelligent production processes [1-3]. Characterized by the use of cyber-physical systems, connectivity via the Internet of Things (IoT), Big Data, advanced automation, and Artificial Intelligence (AI), this new industrial era provides significant gains in efficiency, flexibility, and analytical capacity [4-7]. In this scenario, the competitiveness of companies is directly related to the adoption of tools capable of improving decision-making and promoting Operational Optimization at all levels of production.

One of the sectors that most demands such advances is the manufacture of electronic meters, whose production process involves a wide variety of components, high precision requirements, and a constant need for traceability [8-10]. Production planning in this type of environment presents complex challenges, marked by demand variation, diversity of meter models, and the need to integrate information from different stages of the production chain. Traditional planning strategies, based on fixed rules or manual analysis, are limited in the face of growing operational complexity [11],[12]. Thus, there is a need for intelligent and adaptive solutions capable of dealing with dynamic and variable environments. The application of AI in this context offers significant opportunities for analyzing large volumes of data, forecasting scenarios, identifying bottlenecks, and supporting real-time decision-making, thereby increasing productivity and quality levels [13-15]. The proposal to develop an intelligent model for the production planning of electronic meters represents a significant contribution to the field, as it integrates essential Industry 4.0 technologies with advanced AI methods geared toward optimization. The innovation of this model lies in its ability to combine data collected by IoT sensors, Manufacturing Execution Systems (MES), and analytics platforms to create a more autonomous, responsive, and efficient production environment.

In addition, the use of machine learning algorithms enables more accurate predictions about production times, future demand, resource availability, and operational performance, resulting in more reliable production plans that are aligned with market needs [16-18]. The relevance of this topic is reinforced by the competitive pressures faced by the industrial sector, which demands rapid customer response, cost reduction, and increased overall efficiency. By incorporating elements of Industry 4.0 into the planning process, companies now have tools capable of transforming raw data into strategic information, promoting more assertive decisions and reducing uncertainty. The proposed model also contributes to improving traceability, increasing process reliability, and reducing waste, which are fundamental aspects for lean and sustainable production [19], [20]. Thus, this work presents an innovative approach that integrates intelligent planning, digital technologies, and Operational Optimization, demonstrating how Industry 4.0 can enhance productive performance and strengthen competitiveness in the electronic meter sector.

II. THEORETICAL REFERENCE

II.1 APPROACH TO INDUSTRY 4.0 AND ITS DEGREES OF MATURITY

Industry 4.0 represents a milestone in the evolution of production systems, characterized by the integration of advanced digital technologies, intelligent automation, and massive data analysis [21-23]. For manufacturers of electronic meters, whose production requires a high degree of precision, traceability, and reliability, the adoption of these concepts becomes not only strategic but fundamental to ensuring competitiveness and quality in an increasingly regulated and demanding market [24]. The application of Industry 4.0 in this sector generally occurs gradually, following different degrees of maturity. The first stage, known as initial digitization, involves replacing manual processes with computerized systems. For electronic meter manufacturers, this may include the digitization of production orders, electrical test records, calibration, and quality inspections. Although there is still no significant integration between systems, this stage lays the foundation for further advances, reducing errors and improving the traceability of components and batches [25]. In the second stage of maturity, data connectivity and integration emerge.

Here, welding machines, SMT (Surface Mount Technology) devices, test benches, and optical inspection systems are integrated into an MES (Manufacturing Execution System) [26]. This connection allows production data—such as cycle times, failures, welding parameters, and electrical test results—to be collected automatically and analyzed in real time. At an electronic meter manufacturer, this stage enables rapid detection of deviations, reducing rework rates and ensuring greater consistency in the performance of the equipment produced. The third stage corresponds to intelligent automation and the use of advanced technologies such as artificial intelligence, machine learning, and cyber-physical systems. At this level, electronic meter assembly lines become capable of automatically adjusting machine parameters according to observed conditions. For example, algorithms can predict failures in welding equipment, anticipating maintenance needs. In addition, computer vision systems can enhance the inspection of electronic boards, identifying micro-defects that would go unnoticed by the human eye. The analysis of historical data also makes it possible to predict variations in energy consumption in the meters, optimizing the final calibration.

At the highest level of maturity, the factory reaches an autonomous and fully integrated stage, in which production flows, internal logistics, inventory management, and quality control operate in a synchronized manner. Digital twins — digital replicas of production processes — allow scenario simulations, testing of new meter models, and validation of production parameters even before physical manufacturing. Continuous communication between ERP, MES, and IoT devices ensures a highly efficient and adaptable operation [16],[17]. For the electronic meter manufacturer, this results in shorter response times, significant cost reductions, and greater reliability in measurements and calibrations. Thus, the evolution through the maturity levels of Industry 4.0 is not merely a technological modernization, but a profound transformation of production processes. In companies that manufacture electronic meters, this journey represents the key to elevating quality standards, increasing competitiveness, and meeting the demands of a sector driven by precision, safety, and continuous innovation.

II.2 PRODUCTION PLANNING AND CONTROL FOR ELECTRONIC METERS

Production Planning and Control (PCP) plays a strategic role in the electronic meter industry, a segment that demands high precision, regulatory compliance, and complete product traceability. The complexity involved in manufacturing these devices—which include electronic boards, sensors, power supplies, communication modules, and calibration systems—makes PCP essential to ensuring operational efficiency, final quality, and on-time delivery [27-30]. The PCP process begins with long-term planning, which involves demand forecasting, production capacity analysis, and the definition of supply strategies. For electronic meter manufacturers, this stage is particularly sensitive, as demand fluctuations can occur due to public tenders, large utility projects, or technology replacement cycles.

Good planning must consider these variables, adjusting production capacity, the allocation of skilled labor, and the availability of critical inputs, such as microcontrollers and communication components, which are subject to variations in the global market. As part of medium-term planning, PCP transforms forecasts into master production plans, defining which meter models will be produced in each period. This includes balancing assembly lines, defining economic batches, and sequencing operations. Since many electronic meters have variations in communication modules (such as Wi-Fi, PLC, or RF) and advanced features, PCP must optimize production to minimize setup changes and maintain process fluidity. The operational stage, or production control, involves daily monitoring of the shop floor. At this point, the PCP monitors indices such as SMT line efficiency, soldering machine availability, functional test results, and rework rates. Integrated systems, such as MES and ERP, are widely used to record production data in real time, enabling quick decisions when deviations arise. For example, if a batch of boards shows recurring failures in electrical tests, the PCP can intervene by adjusting process parameters, reallocating resources, or engaging product engineering [16-18].

Another essential aspect is materials control, since the production of electronic meters depends on specific components that are often difficult to replace on the international market. PCP must ensure adequate stock levels, avoiding interruptions in production and preventing excess obsolete items. Techniques such as MRP (Material Requirements Planning) and ABC analysis assist in this management, ensuring that critical components receive priority [31]. Quality control is also part of PCP, as meters must comply with national and international metrological standards and regulations. Planning must allow adequate time for calibration, inspections, functional tests, and certifications, avoiding bottlenecks that compromise delivery times [32],[33]. Finally, PCP plays a crucial role in aligning production, engineering, purchasing, and logistics. In the electronic meter industry, where product reliability is essential for energy security and accurate consumption measurement, a well-structured PCP ensures not only efficiency but also business sustainability and full compliance with market requirements.

II.3 REAL-TIME DATA INTEGRATION VIA IOT

The research aims to improve this current system to encompass the development of an intelligent system for production planning, which is based on monitoring production events, which indicated actions to be taken to follow the planning carried out, integrating resource management and B.O.M, which is currently done by Jundsoft Software, optimizing business rules with new Design Patterns. As can be seen in Figure 2, the service layer has APIs developed for communication with the equipment and, therefore, continuously collects data from this equipment directly into the database.

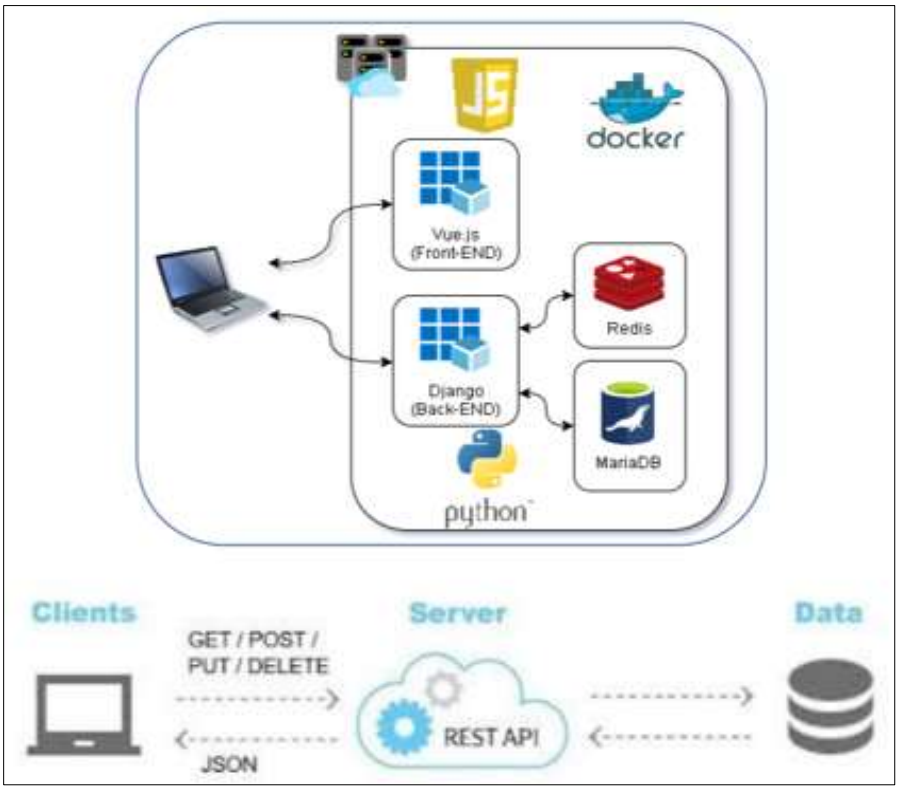

Figure 1: Draft of the Software Architecture for Intelligent MES System.
Source: Authors, (2026).

II.3.1 Traceability Device

This research aims to integrate software stacks (service layer API) with hardware stacks (Traceability Device), which in turn is connected to equipment that generally has RS232 serial communication. Therefore, the device will be the interface for communicating with the equipment and connecting them to the internal network, moving the equipment from stage 1 maturity to stage 2, where there is connectivity, for collecting data from each piece of equipment on a pilot line, which will be used to validate the collection. Some devices in this pilot production line do not have connectivity and will receive a traceability device for data collection, as shown below:

• Parameterization device:

This prototype device will be responsible for configuring the product's memory, recording the serial number, and checking other quality parameters to ensure that the product complies with the customer's purchase order requirements (verification according to the production order). This system should operate automatically, without the need for operator selection. Based on the production order number, the system will consult via API which configurations and checks should be performed on the product. As these configurations are made based on customer parameters, the name of the device is Parameterization.

• PIMA Asynchronous Serial Output Device:

This device will be a functional test prototype of the product's communication protocol. It will be responsible for ensuring that the product will function and communicate correctly, and for ensuring that the serial code is recorded in the memory (performed on the parameterization device). This step will be performed after the product is permanently closed, ensuring that there will be no cover exchange error, or that the mechanical closing process did not damage the product. To know what should be tested, the system will consult via API from the production order number what should be the correct serial number of the production sequence, which communication protocol, and other optional items to be verified.

II.4 MANUFACTURING EXECUTION SYSTEMS (MES)

Manufacturing Execution Systems (MES) play a central role in modern industrial operations management, acting as the bridge between strategic planning carried out by corporate systems, such as ERP, and operational activities on the factory floor. The main objective of an MES is to ensure that production is carried out efficiently, traceably, and in line with quality, time, and cost specifications. An MES collects real-time data from machines, operators, and processes, allowing managers to monitor production performance minute by minute. This data includes indicators such as productivity, downtime, material consumption, batch quality, and cycle time for each stage of the process. Based on this information, the company can quickly identify bottlenecks, anomalies, or deviations, making corrective decisions that increase efficiency and reduce waste. This continuous monitoring capability makes MES essential in highly technological environments, such as automated lines, electronic device assembly, and processes that require precision and repeatability.

In addition to monitoring, MES also controls production, managing manufacturing orders, guiding operators with digital instructions, and recording each step of the process, ensuring full traceability. Another relevant point is quality control, as MES integrates inspection tools, automatic collection of test results, and application of sampling plans. This ensures that non-compliant products are quickly isolated and that quality standards are strictly met [26]. In addition, MES contributes to the management of resources, including operators, machines, tools, and materials, optimizing their use. When fully integrated with ERP and automation systems, it becomes a pillar of Industry 4.0, enabling decisions based on real and reliable data. Thus, Manufacturing Execution Systems represent an indispensable tool for organizations seeking productivity, quality, and competitiveness in a constantly changing market.

III. MATERIALS AND METHODS

III.1 METHODOLOGY AND ACTION STRATEGY:

The study will be developed through research, by surveying existing data, collecting information at the factory with managers, administrators, and technicians in order to ensure the development of the project in accordance with the real needs of the company. This project will be developed by a team of developers, engineers, and technicians who will be assigned well-defined responsibilities in each phase of the project. To plan, execute, and manage this project, PMBOK principles will be adopted as shown in Figure 2. In this project, five groups of processes stand out.

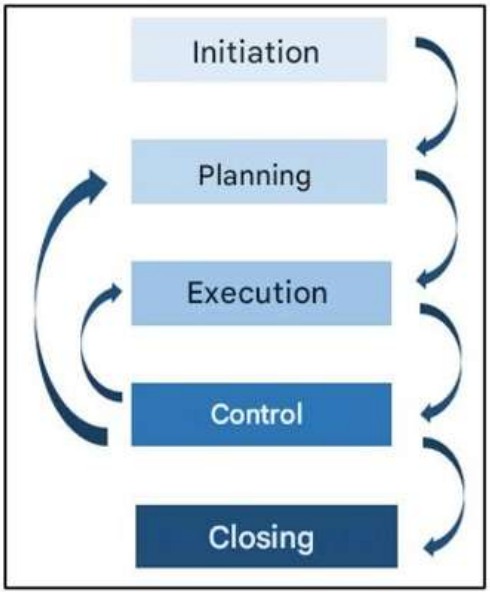

Figure 2: PMBOK management model.
Source: Authors, (2026).

• **Initiation:** In this phase, the project's needs will be listed to begin the development stages. Relevant data for the project's development will also be collected here, such as scope, risks, costs, participants, and schedule.
• **Planning:** The planning will be organized into a timeline according to the activities to be carried out. Frequent meetings are expected so the team can align ongoing work and determine ways to improve the process with agility. For this purpose, daily discussions are intended, enabling faster decision-making, value delivery to the customer, and participation from the project sponsor.
• **Execution:** The project will be executed by professionals with expertise in software, electrical, electronic, automation, and mechanical areas. This phase will also include the coordination of resources according to the project's progress and stage.
• **Control:** Project control will be performed to ensure that the objectives are achieved. This will be done through schedule analysis and meetings with team members and the project sponsor.
• **Closure:** In this stage, the client is expected to receive: reports, acceptance terms, maintenance and operation manuals (and other documents required by the Institute and the Company), as well as the new products developed. In addition, as the software development method, the incremental methodology will be used, in which each activity cycle will develop an integral part of the software, making it possible to measure the following phases of the process according to Figure 3.

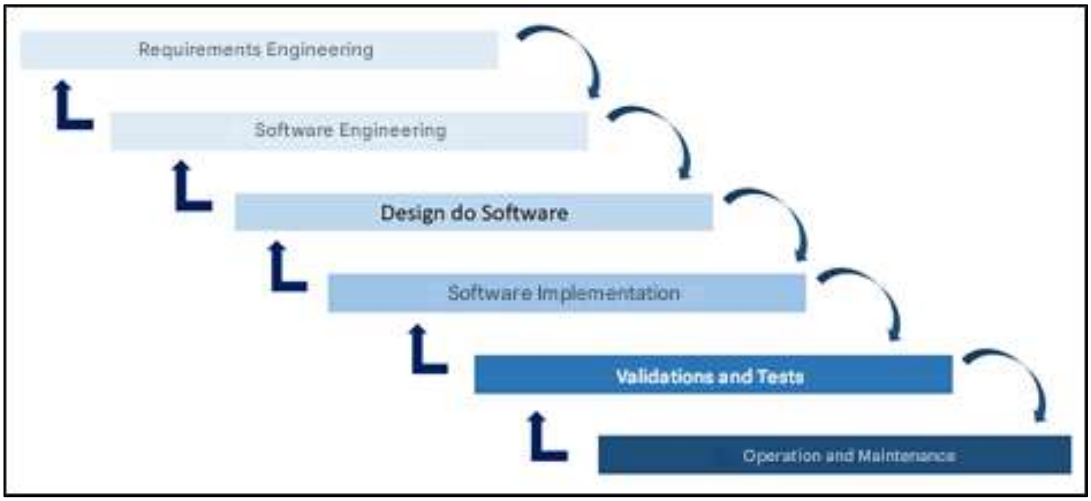

Figura 3: Ciclo incremental do Software.
Source: Authors, (2026).

• **Requirements Engineering:** In this stage, the needs related to the software—specifically the module to be developed—will be defined so that the solution meets the company's scenario, considering visual, behavioral, action-related, criteria-based, and operational limitations.
• **Software Engineering:** In this stage, diagrams and documentation regarding the module and the implemented functionalities will be developed. This document should address the software design, describing limitations, use cases, functionalities, technologies, and the technical definitions of the functional and non-functional requirements.
• **Software Design:** In this stage, the software design will be developed based on the user interaction interfaces, visual identity definitions, element layout, actions, behaviors, and company standards, taking operational limitations into account.
• **Software Implementation:** In this stage, the process of creating, defining, and executing the coding of the functionalities specified in the requirements document will be carried out, along with strategies to achieve the module to be delivered.
• **Validation and Testing:** This stage is characterized by activities that perform validations and tests to approve the application and the developed module. Functionality, integrity, security, unit, and installation tests will be executed as methods to assess product quality, support bug fixes, and carry out code refactoring processes.
• **Operation and Maintenance:** This stage will involve code refactoring and adjustments that may be necessary due to new requirements or technological updates. This includes carrying out coding activities during this phase.

III.2 TOOLS FOR PROJECT DEVELOPMENT

To develop this project, support tools will be needed to carry out scenario projections, technical drawings, simulation models, and coding of the items listed in Table 1.

Table 1: Types of tools involved in the research.

Tool	Concept	Application in the project
Proteus VSM	Software that allows the creation of circuits, simulation, and layout design for analog and digital applications, including microcontrollers.	It will be used for the development of electronic boards and connections.
Solid Works	Software designed for the creation of three-dimensional virtual mechanical prototypes. It also allows for the simulation of the functioning of parts, assemblies, movements, among others.	In the project, the software will be used to model mechanical parts and devices. From three-dimensional prototypes, 2D drawings will be generated and forwarded to the machining process.

PMBOK Guide	It is a set of project management practices organized by the PMI institute and is considered the basis of project management knowledge by professionals in the field.	It will be used to manage the project, from the initial stage to completion.
Visual Studio Code	Source code editor developed by Microsoft for Windows, Linux, and macOS. It includes support for debugging, built-in Git version control, syntax highlighting, and intelligent code completion.	Development environment.
MySQL Workbench	Client for executing SQL queries, system administration, and database modeling, creation, and maintenance through an integrated environment.	Development environment for queries, data structures, and logical models.
Astah Community	Class, Use Case, Sequence, Communication, State Machine, Activity, Component, Deployment, and Composite Structure Diagram Designer. Used in Software Engineering.	Class project diagrammer and requirements diagrams.
Draw io	Online graphic editor that allows you to develop drawings, graphics, and other designs without the need for expensive and heavy software. It provides resources for creating any type of design and has a section dedicated to information architecture.	Architecture project diagrammer and flowcharts.
Trello	Collaboration tool that organizes projects into boards. At a glance, Trello shows what is being worked on, who is working on what, and where something is in a process.	Activity manager.
Github Desktop	Application that allows you to interact with GitHub using a GUI instead of the command line or a web browser, with which you can upload, extract, and clone remote repositories.	Code versioning.
UX Prototyper - Justinmind	Justinmind is a prototyping tool for websites, software applications, and mobile applications that can work with Windows and Mac, or with iOS and Android. There is a free version that you can work with very well.	Design interface prototyper.
Barcode reader for meter tracking	Industrial scanner for reading 1D and 2D barcodes from 15 cm to 15 m	It will be necessary to track the item by station and identify through data where the product is located, whether it has been rejected or not, in addition to adding the completed stage information to the block body according to the line layout.

III.3 TECHNOLOGIES FOR PROJECT DEVELOPMENT

The technologies that will be used and applied in the project meet the needs of supplying the technology presented as the scope of the project, Internet of Things (IoT), Intelligent Systems, and Artificial Intelligence.

Table 2: Technologies applied in the research process.

Technology	Concept	Application in the project
Vue.js	Vue.js is an open-source JavaScript framework focused on developing user interfaces and single-page applications.	JavaScript framework for building user interfaces.
Vue Router	Vue Router is the official router for Vue.js. It integrates deeply with the core of Vue.js to make it easy to build Single Page Applications with Vue.	Library for page routing.
Vue-118n	Vue I18n is a plugin for internationalization in Vue.js. It easily integrates localization features into your Vue.js application.	Library for internationalizing Vue.js applications.
VueUse	It is a collection of hundreds of essential Vue composition utilities for interacting with various browsers, sensors, animations, and state APIs.	Hooks library for Vue.js.
Quasar or Naive UI	It is an open-source framework based on Vue.js for building applications with a single code base. It can be deployed on the web as SPA, PWA, SSR, in a mobile application using Cordova for iOS and Android, and in a desktop application using Electron for Mac, Windows, and Linux.	Vue.js component framework.
Echart	It is an open-source JavaScript visualization tool that can run fluently on desktops, web apps, and mobile devices.	Data visualization library for creating graphs.
Moment.js	It is a very popular JavaScript library that facilitates working with dates and times in projects developed in this language. With it, you can perform tasks such as manipulating, formatting, and validating dates more simply and efficiently.	Library for manipulating dates and times.
Axios	Axios is a library for making HTTP requests and handling data communication between the frontend and backend in web applications. It provides a simple and flexible API for making asynchronous API calls, such as getting data from a RESTful API, sending data to a server, or updating data in real time.	HTTP client for communicating with the back end.
FastAPI	It is a web framework first released in 2018 for building HTTP-based service APIs in Python. It is used to build APIs with Python 3.8+ based on standard Python type hints. FastAPI is based on Pydantic and uses type hints to validate, serialize, and deserialize data.	Web framework.
SQLAIchemy	It is a cross-platform framework that has quickly become one of the most widely used object-relational mapping tools in the Python community, the language for which it was developed. It provides full SQL flexibility,	ORM library for interacting with databases in Python.

	obtaining a complete set of well-known enterprise-level persistence patterns that are designed for efficient, high-performance database access.	
Redis	It is used by companies that need high-performance tools due to the processing of huge volumes of data, such as Twitter, or applications with real-time updates, such as betting sites.	In-memory database for caching.
Celery	It is a robust, simple, and flexible distributed system that allows you to execute large numbers of messages asynchronously. It is a task queue focused on real-time processing, in addition to supporting task scheduling.	Library for executing asynchronous tasks.
Websockets	WebSocket is a technology that enables bidirectional communication over full-duplex channels on a single Transmission Control Protocol socket. It is designed to run on browsers and web servers that support HTML5, but can be used by any application client or server.	Bidirectional communication protocol over HTTP.
Pydantic	Pydantic Python is a powerful library for Python developers, offering features such as data validation, automatic type conversion, data serialization and deserialization, and automatic documentation.	Library for data validation in Python.
Pytest	Pytest is a Python testing framework that originated from the PyPy project. It can be used to write various types of software tests, including unit tests, integration tests, end-to-end tests, and functional tests. Its features include parameterized tests, fixtures, and assertive rewriting.	Testing framework for Python.

IV. RESULTS AND DISCUSSIONS

The execution of planning, coordination, and technical structuring activities throughout the period resulted in significant advancements in both administrative organization and the consolidation of the technical foundation required for system development. The main outcomes achieved include: validation of the technical scope with the company; alignment of execution and delivery schedules; structuring of the development team after a rigorous selection process; establishment of versioning and collaboration guidelines via GitHub; strategic prioritization of the Technical Sheets module; and practical immersion in the partner company's manufacturing environment, enabling full understanding of production flows and critical process points. From these results, several relevant conclusions were drawn. First, the complexity of the company's industrial processes requires a highly integrated and flexible approach capable of adapting to the demands of traceability, compliance, and automation. Second, replacing manual processes with integrated digital modules represents not only an operational necessity but also a concrete opportunity for gains in efficiency, standardization, and reliability. It was also found that the integration among the research's technical teams was essential for advancing technical definitions, demonstrating that multidisciplinary collaboration is a key factor for the project's success.

Among the deliverables produced in this activity, the following stand out:

• Technical diagram and mind map of the functional structure of the Technical Sheets module;
• Functional mockups of the SIPE system interfaces;
• Restructured schedule based on the new team composition;
• Individual and consolidated technical reports with documentary and visual evidence from technical visits;
• Versioned repositories with code documentation on GitHub;
• Initial architectural definitions involving the use of technologies such as FastAPI, Kafka, MariaDB, and ClickHouse;
• Technical visit reports mapping industrial processes and integration points with the integrated system.

In terms of investigation and experimentation, the activity validated the technical feasibility of digitizing and automating the Technical Sheets generation process, based on a critical review of the documents currently used by the company. The analysis of production flows—especially in the meter assembly, plastic injection, and metrological laboratory sectors—provided practical input for refining system requirements. Industrial communication technologies such as MQTT, HTTP, RS-232, RS-485, and IEC 62056-21 optical interfaces were also examined, confirming the feasibility of integration between physical devices and management systems. The activity significantly contributed to increasing the knowledge of the professionals involved regarding Industry 4.0 enabling technologies, particularly in industrial process automation, digital traceability, system integration, real-time data management, and information security. Coordinators and developers participated in practical training and immersion activities within the factory processes, gaining applied knowledge about digitizing technical documents, API modeling, structuring hybrid databases (OLTP and OLAP), scalable backend architecture, and interoperability standards with industrial ERPs. This continuous learning strengthened the team's technical capabilities and raised the project's overall technological maturity, aligning it with the principles of Industry 4.0.

The results obtained in the seventh month can be analyzed across three dimensions: qualitative, quantitative, and organizational. Each provides important insights into understanding the impact of the activities carried out and the added value brought to the project. In the qualitative dimension, progress was significant. User experience improved substantially with the redesign of the sidebar and the implementation of the sheet preview feature. The system became more intuitive, reducing learning curves and increasing operational efficiency. Additionally, standardization through templates brought greater reliability to the recorded information, reducing human error and strengthening traceability within production processes From a quantitative perspective, the numbers also demonstrate progress. More than twenty parameterized templates were created during the month, forming a solid foundation for different application scenarios. The average time required to complete the sheets was reduced by approximately thirty percent, showing the direct impact of automation and standardization on the team's daily routine. Furthermore, fifteen critical inconsistencies identified in previous cycles were corrected, reinforcing the maturity of the validation process and improving system reliability, as shown in Figure 4.

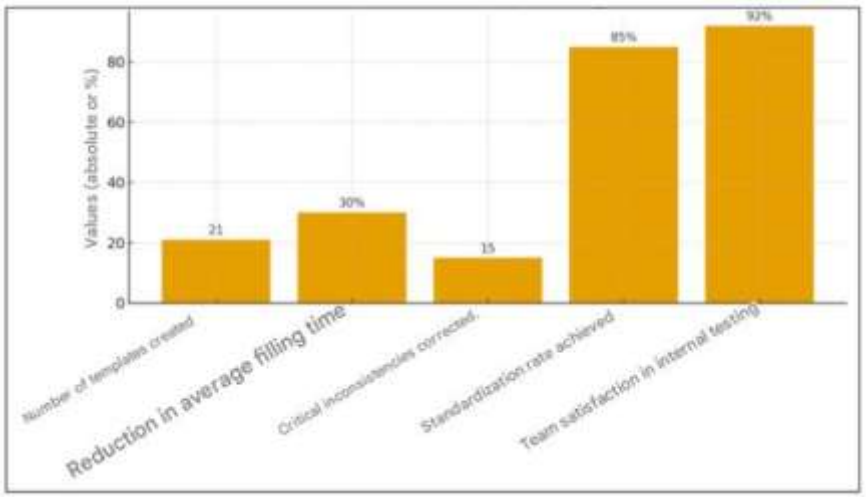

Figure 4: Quantitative performance indicators for the Technical Data Sheet module in the 7th month.
Source: Authors, (2026).

Following the implementation of product traceability, which was the focus of phase 1 of development, this new phase aims to elevate the system to a more comprehensive MES level, with greater control over production flow and production order management. This includes real-time monitoring of the production plan, allowing the system to actively interact with the equipment, determining what should be produced, reducing dependence on production operators, improving process quality, and applying stricter control over the production plan and quantities produced. To interact with production systems and equipment, various documents will be transferred to the SIPE system to avoid ambiguity and errors in data entry, such as labels, laser markings, and proper product configuration according to customer specifications. Figure 5 shows the hierarchical levels of industrial systems, organized in a pyramid ranging from machines (physical level) to ERP (corporate level). It shows the expected reaction times at each layer and the types of events managed, such as failures and rejections. This structure facilitates integration between the shop floor and management systems.

IV.1 TECHNOLOGICAL INNOVATIONS

The SIPE System features process innovation, being a new solution for the company, for the Western Amazon region, and for Brazil. The main innovations include:

a. IoT-based traceability devices;
b. Intelligent production planning system with real-time data interpretation;
c. Artificial intelligence algorithms for dynamic production replanning;
d. Dashboards integrated with Business Intelligence (BI);
e. Integration via microservices and APIs for modularity and scalability;
f. Predictive production control based on industrial data analysis.

The system uses a simple yet powerful design approach, utilizing modern development SDKs for easy maintenance and improvement. All system functions and transactions are performed on the server side, using a REST API to interact with equipment for data collection and control. The following figure shows the SIPE system architecture diagram using Vue.js on the front end, Django (Python) on the back end, MariaDB database, Redis cache, and containerization with Docker. Communication between client and server occurs via REST API using data in JSON format, ensuring scalability, modularity, and performance in industrial applications. In Figure 6, the diagram is presented that connects template versions to an active workflow with sequential levels, where each level defines the minimum number of approvers and who is allowed to approve by role or by individual. Decisions are recorded per level, with a full audit trail. The setup sheet inherits the dynamic structure and directly references the original technical sheet, preserving traceability between the approved specification and the configuration executed on the production line. In this stage, a set of unit and integration tests was also conducted to validate the robustness of the Technical Sheet approval module and the derivation of the Setup Sheet. The focus was on ensuring logical consistency, data integrity, and performance under load, covering the following main scenarios:

• **Workflow:** Execution of scenarios with multiple approval levels, including approvers defined by role or by specific user. Chain rejections and alternative flows were simulated to validate system behavior in cases of partial quorum or lack of consensus.
• **Validations:** Tests for duplicate approvals by the same agent, status transitions (pending → approved/rejected), and automatic blocks when the minimum number of approvers was not reached. Business rules were validated with audit records for each event.
• **Setup Sheet:** Verification of correct data inheritance from the approved Technical Sheet, tests for submission of configuration parameters, and checklist registration. Traceability between the original Technical Sheet and the executed Setup was audited.
• **Integration and Performance:** REST endpoints related to the workflow and the Setup Sheet were subjected to moderate-load scenarios, evaluating response consistency, average latency, and stability under multiple concurrent requests.

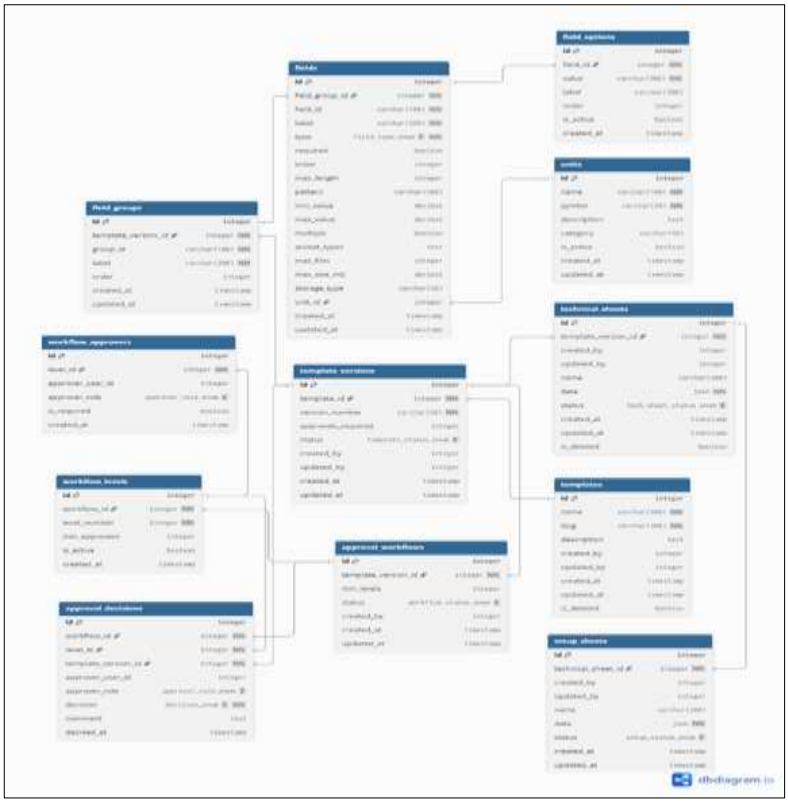

Figure 6: Multi-level approval workflow and derived setup form.
Source: Authors, (2026).

Table 3 below summarizes the main deliverables and improvements achieved in this development cycle.

Table 3: Improvement and delivery of the main activities of this sub-activity.

Delivery	Description	Benefit
Approval workflow	Multi-level flow with dynamic approvers	Document governance and traceability
Validation rules	Minimum number of approvers, specific positions/users	Reliability and security in the decision-making process
Auditing	Record of identity, position, decision, and date/time	Transparency and complete history
Setup sheet	Derived directly from the approved Technical Data Sheet	Traceable integration with machine configuration
Setup fields	Parameters, calibration, and operational checklists	Compliance and standardization in line preparation
REST integration	Endpoints for workflow and Setup Sheet	Standardized operability and secure consumption by external systems
Load testing	Tests with multiple approvers and stress scenarios	Stable and predictable performance
Duplicate prevention	Blocking of repeated approvals by the same agent	Integrity and fairness in the approval process

Source: Authors, (2026).

During the development cycle, critical points were identified and addressed, as they directly affected the system's consistency. Among the detected errors, the most notable was approval concurrency within the same level, which caused status inconsistencies when multiple approvers submitted decisions simultaneously. This issue was resolved through the adoption of transactional control with locks, ensuring the atomicity of operations. Another recurring error was the failure in linking the Setup Sheet to the Technical Sheet in cases of partial submission, which was corrected by enforcing mandatory referential integrity constraints, preventing setups from being created without a valid reference to the originating technical document. Duplicate approvals by the same user at different levels were also observed; this issue was corrected by implementing uniqueness validation per level, complemented by more robust audit trails. On the other hand, the successful aspects reinforced the solidity of the architecture. The workflow demonstrated high flexibility by allowing parameterization by roles and specific users, while maintaining adherence to business rules. The requirement for mandatory derivation of the Setup Sheet from an approved Technical Sheet ensured traceability between specification and factory execution. The APIs were standardized and submitted to integration tests, ensuring interoperability and consistency in external consumption. Furthermore, the complete audit trails—recording identity, role, decision, and timestamp—strengthened document governance. Finally, the endpoints maintained stable performance even under load scenarios, validating the system's scalability.

IV.2 HARDWARE AND BACKEND INTEGRATION

With the arrival and validation of the Raspberry Pi 5 and ESP32 hardware, the transition began from the code previously tested in simulation to the factory environment. This stage was carried out using an incremental integration approach, including bench tests and fine adjustments to communication protocols to ensure stability and adherence to real operating conditions. The first focus was on the ESP32 communication module, which was configured with firmware capable of supporting multiple communication channels, performing UART tests for interaction with sensors and actuators, as well as direct synchronization with the Raspberry Pi 5. The priority was to achieve low latency and deterministic response. To this end, a bottom-up methodology was adopted, in which lower-level routines were validated individually before assembling the main flow. Next, the Raspberry Pi 5 was integrated with the factory backend, receiving routines for collecting processed data from the ESP32 and sending it via REST API, with packet compression and exception handling. Dynamic authentication tokens were implemented in accordance with security guidelines, and load scenarios with multiple simultaneous connections were evaluated, simulating high-demand factory conditions. The integration followed Continuous Integration (CI) practices, with incremental builds and automated tests for each modification to drivers or communication routines.

Subsequently, synchronization tests were performed between the hardware and the factory system, validating consistency between the Raspberry Pi's local records and the data stored in the Horus database. Watchdogs were also implemented on the ESP32 to enable automatic reboot in case of communication failures, and peak-production tests were conducted with multiple meters connected. This phase followed principles of fault tolerance and minimal redundancy, supported by detailed logs for auditing and performance analysis. The results confirmed the robustness of the architecture, real-time traceability in Horus, and resilience against communication failures, preparing the solution for the next stage: the Production Control Module, focused on continuous data collection and metrics calculation such as productivity, downtime, losses, and rework. In parallel with the hardware integration, refinement of the template management module was carried out, focusing on code modularization, removal of redundancies, and performance optimization, ensuring greater structural clarity and maintainability. In terms of UX/UI, adjustments were applied to improve visual consistency and simplify navigation flows, reinforcing adherence to the standards established for the system.

Figure 7: Folders with refactored modules.
Source: Authors, (2026).

Critical bugs identified in template creation were corrected, including field validation failures, integration issues, and inconsistencies found in regression tests. The system's visual standardization was revised, reinforcing responsiveness for different devices. In this context, the Sidebar was redesigned with a scalable layout, optimized hierarchy, and more intuitive navigation, strengthening the visual identity and coherence of the frontend.

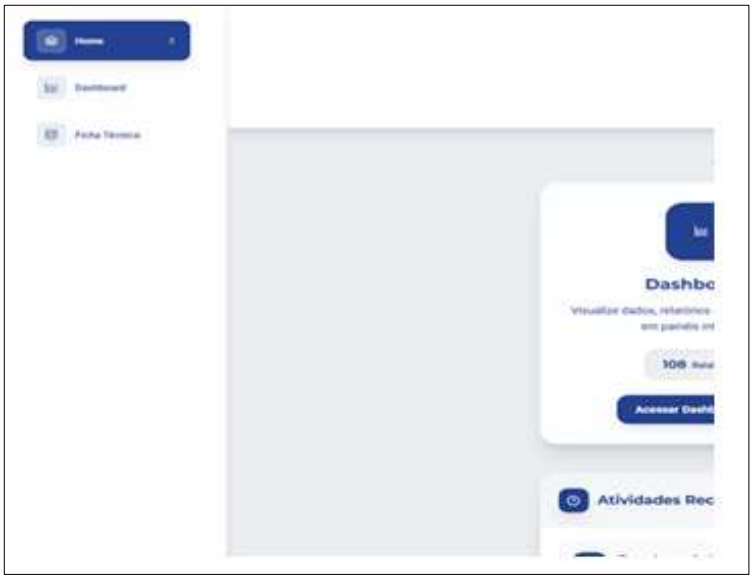

Figure 8: Sidebar.
Source: Authors, (2026).

The integration of the new functionalities into the backend was validated with revised API contracts and end-to-end tests. The DBeaver tool was extensively used to inspect data persistence, verify referential integrity, and confirm alignment between the user interface and the records actually stored in the database.

V. CONCLUSIONS

The execution of the project demonstrated significant progress in consolidating the Technical Data Sheets module, evidenced by the creation of a detailed technical diagram and a mind map that clearly represent the system's functional structure. These tools enabled the visualization of relationships between components and the flow of information, facilitating both the understanding of the module and the identification of potential improvements. In parallel, the functional mockups of the developed system's interfaces provided a solid foundation for validating the user experience, ensuring that the planned functionalities are aligned with operational needs and the manufacturing processes observed during technical visits. The research schedule was restructured according to the new team composition, ensuring optimized resource allocation and the achievement of established deadlines. Technical reports, both individual and consolidated, systematically documented the technical visits, presenting visual and descriptive evidence of the practices and mapped processes, which allowed the identification of critical integration points for the integrated system.

Furthermore, the maintenance of versioned repositories on GitHub ensured efficient control of the source code and associated documentation, promoting transparency and ease of tracking the development process. The initial architectural definitions, involving technologies such as FastAPI, Kafka, MariaDB, and ClickHouse, provided a robust foundation for scalable and efficient system development, ensuring interoperability and reliability in data processing. The detailed mapping of manufacturing processes and the identification of integration points with SIPE reinforce the importance of a structured, process-oriented approach, allowing the Technical Data Sheets module to effectively align with existing operations and support decision-making based on accurate and up-to-date information. In summary, the results obtained so far demonstrate consistent progress, technological integration, and adherence to best development practices, establishing a solid foundation for the next phases from the survey.
